The key theme of this new economic sociology is the analysis of economic phenomena in terms of social structure and culture, treating economic action as embedded in a wider context of social and cultural relationships. Although the formulation is similar to that of Parsons and Smelser, the newly reborn field emphasizes the empirical application of more recent sociological ideas such as social network and social capital and also intersects cultural sociology, another major field of sociological investigation. Very importantly, the field now includes a relatively large number of empirical investigators in contrast to the small number of earlier analysts. Hence a summary statement of the state of sociological research on economy and society is difficult to make in a very fluid and rapidly growing field. Swedberg (2003) sets out a rare effort in this direction and also has co edited a handbook (Smelser & Swedberg 2003). Chapters in the latter point to the way in which recent work has added rich empirical detail to the relationships between the economy and its social environments, for instance political and educational institutions.

A brief indication of the sort of theory and research characteristic of the new economic

sociology can be communicated by reference to investigations that emphasize social structural elements, especially those relating to the concepts of social network and social capital.

A social network is a population of actors – individual or collective – that are in some mode of connection with one another which mediates the form and content of their interaction. Actors may be dependent upon certain others for resources or they may trust certain others, among other types of connections. For instance, in application to an economy, one theory pertains to the argument that there are advantages to actors in certain positions within networks. A network may consist of a series of largely disconnected components except for certain relations that connect actors in distinct components. Such a network has "structural holes" – sectors with many absent relations. Actors whose relations form a bridge between otherwise disconnected components have certain competitive advantages in terms of information and control. It has been shown that they "enjoy higher rates of return on their investments because they know about, have a hand in, and exercise control over, more rewarding opportunities" (Burt 1992: 46). In another example of a social structural approach to economic phenomena, Baker (1984) analyzes stock options trading on the floor of a major securities exchange in the US, showing how price volatility is a function of network variables.

The economic concept of capital includes physical and financial resources employed in productive activities. Economists have extended this concept in referring to educational training as "human capital," consisting of resources in the form of learned skills and the like. Sociologists have made use of a still further extension of the concept in analyzing the benefits of "social capital," whereby social relationships function as resources that actors can employ to attain their ends. Like much else in social life, this particular form of capital is a byproduct of social relations formed for other reasons. For instance, among members of a certain occupation, a social club may be formed in order for the members to enjoy convivial activities, but at a later time, when some of the members become unemployed, the club may function as an informal employment service (Coleman 1990).

The extended concept of capital also plays a major role in the field theory of Pierre Bourdieu (1986), whose studies intersect economic and cultural sociology. A field may be defined as a competitive social space of positions characterized in terms of the total volume and relative composition of various forms of capital. While economic theory postulates consumers who make rational choices based on given preferences or tastes, field theory provides a conceptual basis for representing the heterogeneous social structural basis for such tastes, treating them as modes by which actors make distinctions (e.g., in the clothing or cars that they can afford to purchase) which in turn serve to distinguish them from other actors. In a somewhat similar mode in terms of investigating meanings and functions of economic phenomena from a wider perspective, Zelizer (1994) has emphasized that the social meaning of money extends beyond its function as a medium of exchange in the economy.

Comparing the new economic sociology to "the old" in the sense of the systems model of Parsons and Smelser, a major contrast is that Parsons and Smelser aimed to integrate sociological theory and economic theory by embedding economic concepts and mechanisms within a unified framework consisting of the general theory of action and an accompanying methodology of functional analysis. For instance, they attempt to "find a place" within the AGIL scheme for the factors of production set out by economic theorists. Labor, for instance, is a value commitment to work – with a variable cultural work ethic, following up Weber's ideas in this regard – that is acquired in the fiduciary system (in this instance in households) and enters the economy through an interchange process rooted in exchange processes regulated by an institution which, in market societies, is the employment contract. In a similar mode, but not always clearly or convincingly, it is argued that through interchange processes, capital enters the economy from the polity and organizing (entrepreneurial) activity enters it from the social integrative system. The fourth factor of production, traditionally "land" in economics, is somewhat vaguely treated in terms of facilities that are "givens" for the shorter term economic processes. Similarly, the various types of markets and other processes

(e.g., investment) treated in economic theory are "located" in terms of the AGIL scheme.

By contrast, the new economic sociology largely disavows any attempted integration of the two disciplines and, in fact, the research often is initiated in a polemical mode as opposing some assumptions made in economic theory. However, in both its old and its new form, the sociology of the economy is characterized by the application of sociological concepts and theories to analyze economic phenomena. In some instances, the concepts relate closely to some traditional economic concept such as capital. In other instances, the concepts have no linkage to traditional economic ideas. This is especially true of network concepts such as structural holes and bridges. In either case, the sociological analysis – whether in older forms or the new forms – tends to differ from economic analysis. The reason for this is that sociology, as a discipline, is concerned above all with patterns of social relations arising out of and shaping social interaction. It is this shared perspective that sociologists have employed in the analysis of the economy in relation to society.

education

Anna Strassmann Mueller

Changes in developed economies and societies stemming from the Industrial Revolution have shifted responsibilities for the education of young people from the family and community to schools. Schools are now a major institution, educating the vast majority of children and youth in the developed world and functioning as a primary engine of change in developing countries. Although education brings about changes in society as a whole as well as in individuals, schools are also influenced by larger social forces. Sociological theories address these central roles that schools play in society from differing perspectives.

The functionalist paradigm emphasizes the role that education plays for society. Émile Durkheim, one of the founders of sociology, was among the first educational researchers to focus on the function schools serve for the larger society. Durkheim (1961) argued that the main goal of education was to socialize individuals so that they share values with the larger society. Ensuring that all students received the same moral education allowed for a more integrated society with less social conflict about wrong behaviors or attitudes. A second important functionalist perspective on education developed in economics through research on human capital (Schultz 1961). The human capital perspective describes education as a set of investments that increase individuals' knowledge and skills, which in turn

improves national labor productivity and economic growth. Education then becomes an important tool for societies to increase the efficiency and size of their economy.

While the functionalist perspective emphasizes the role of education for society as a whole, the conflict paradigm focuses on divisions within society that education maintains or reinforces. Max Weber (2000) was one of the first to argue that education serves dual and potentially conflicting functions for society. First, schools can be an equalizing institution where individuals, regardless of their social status, can gain access to high status jobs through their own talent and hard work. Second, schools can reinforce existing status hierarchies by limiting opportunities to individuals from high status backgrounds. In other words, Weber recognized schools' potential to either facilitate or block social mobility. Weber's incorporation of the notion of social status into the function of schools in society was extremely influential in shaping sociological research on education. Randall Collins (1979), Samuel Bowles, Herbert Gintis, and others furthered Weber's ideas on status attainment by arguing that schools socialize individuals to accept their place in an unjust, capitalist society. This work shifted the emphasis found in human capital theory away from schools as providers of skills and training to schools as providers of hollow credentials that are rewarded in the labor market. Critically, these credentials do not represent higher levels of skills, but simply serve as status markers that employers use to sort workers into low and high prestige occupations.

Both historically and when comparing countries today, the structure of a country's educational system is closely linked to its economic and political history. Developed countries are generally characterized by a history of relatively steady economic growth, a stable political system, and freedom from the devastation of war. This common context enables developed countries to form a cohesive formal schooling system that serves all children until at least the age of 15 or 16. In recent decades, developed nations have incorporated the ideals of equality of educational opportunity and providing opportunities to children from disadvantaged backgrounds into their goals for educational policy.

Though all developed nations provide universal education and many are motivated by similar ideals, the structure of schooling can vary drastically from developed country to developed country (for an overview, see Brint 1998). In Japan, France, and Sweden, the school system is run by a central governmental ministry of education that ensures standardized curricula and funding. Other countries, such as Germany, Canada, and the US, are more decentralized and allow local or regional governments to maintain control over public education. Additionally, the school systems in these nations vary in how they structure opportunities to learn and earn credentials. In his classic article, Ralph Turner (1960) contrasted the English and US school systems, characterizing the former as a “sponsored” system, in which talent is identified in the early years and nurtured in a stratified system. The US system, on the other hand, is a “contest” system, consisting of a series of contests in which all students compete on a level playing field. Though “sponsored” and “contest” systems are “ideal types,” most developed nations’ school systems reflect aspects of sponsored or contest systems.

In the developing world, many countries have been independent from colonizing powers for approximately only 50 years and do not have the same history of political stability, economic security, and times of peace that privilege developed countries. These instabilities (along with problems related to poverty) affect the ability of developing countries to provide and prioritize universal education. In many developing countries, the school system is inherited in large part from former colonizers and is heavily shaped by the policies of the World Bank. The World Bank promotes a model of schooling that emphasizes primary schools, private spending, balances equity and efficiency, and discourages vocational education. Though the structure and experience World Bank policies provide can improve schooling priorities in developing nations, they sometimes do not recognize that factors unique to a particular country may require modifications. A central question concerning the role of education in developing nations concerns how important education systems are to economic growth. Much of the research on education in

developing nations examines this question and generally finds that having a disciplined and educated labor force is a positive and important step in economic development.

Though commonalities in the structure of schooling exist across countries in the developed and developing world, each country is generally unique in the development of its particular educational system. Systems of education not only reflect national values and attitudes, they also play a major role in shaping national culture and social status hierarchy. In the US, the idea of public schooling – or the common school – developed in the early nineteenth century as a response to political and economic shifts in American society (see Parkerson & Parkerson 2001 for a history). Prior to common schooling, the majority of Americans were educated by their families, and only children from wealthier families could afford for formal schooling. As the US moved away from a barter and trade economy toward markets where goods were exchanged for cash, white Protestant Americans from the middle and working classes recognized that the fragmented and informal system of schooling was no longer adequate preparation for their children to be competitive in the market driven economy. This realization led these Americans to demand that a quality primary education be made available to their children. The ideal of equality emphasized during the American Revolution meant that there was already growing political support among the Protestant political elite for the idea of public education for white children.

The end result of these forces was the development of the common school. Common schools had two main goals: first, to provide knowledge and skills necessary to being an active member of economic and social life; and second, to create Americans who value the same things – namely, patriotism, achievement, competition, and Protestant moral and religious values. Significantly, these goals were important both to individuals trying to make it in the new economic and social order and to the success of solidifying the young United States into a coherent nation. Religious diversity was not tolerated in the nascent nation, and Catholic immigrants were often seen as threats to the dominant Protestant way of life. Therefore, though common schools were open to all white

Americans, the emphasis on Protestant values (which went hand in hand with anti Catholic attitudes) alienated many Catholics. This religious tension eventually led Catholics to pursue alternative schooling and resulted in the development of Catholic private schools.

Though common schools provided more equitable access to education than the previous informal system, these schools still reflected the values of the ruling elite – white Anglo Saxon Protestants – in US society. In addition to appreciating Protestant values over those of other religions, educating white boys was generally seen as more important than educating white girls as white boys were more likely to benefit from their education upon entry into the formal labor market. Furthermore, African Americans, freed or enslaved, were almost categorically excluded from common schools in the early 1800s as the flawed “ideal of equality” applied only to white Americans.

Despite the development of the common school, elite white Protestant Americans were able to maintain educational superiority by opting out of the common school system. The elite private and boarding school system began before the American Revolution and flourished during the nineteenth century (at the same time that the common school system was expanding). Though the growing public education system diminished the percentage of secondary students in private schools, private schools maintained an exclusivity that appealed to elite parents eager to pass on status and advantage to their children. In *Preparing for Power: America's Elite Boarding Schools* (1985), authors Cookson and Persell explore the admissions process and the demographic characteristics of “the chosen ones,” America's most privileged students. Historically, these elite schools tended to have a homogeneous student body in terms of family background, religion, and race, and admission was based not on openly stated academic requirements but on a complicated balance of merit, family wealth, social standing, and an individual's ability to fit the school's ideal. Thus, the presentation of self as a person of status – someone with ambition, confidence, and poise – was just as important as academic capacities to gaining access to America's most elite secondary education. Though these private schools continue to promote an

elite social class identity, currently they also face pressure to diversify the racial composition of their student bodies.

While elite private schools have historically allowed privileged Americans to opt out of public schooling, religious schools have offered an important private alternative to non elite, and sometimes marginalized, Americans throughout the history of the US. Catholic schools were a part of Colonial America and are among some of the oldest educational institutions in the US. In contrast to elite private schools, religious schools had a moral purpose of teaching religious beliefs and producing religious leaders. Beginning in the 1800s, Catholic schools provided an alternative to the public school where children read the Protestant version of the Bible. Today, Catholic schools serve a more diverse student population in terms of race, social class, and religious beliefs. Catholic schools today are known for providing good opportunities to learn and prepare for college (Bryk et al. 1993). Critics suggest that Catholic schools select more promising students, an option not available to public schools.

Though research on elite and Catholic private schools suggests that access to a private versus public education affects students' academic opportunities, inequalities between schools within the public sector have long plagued the American educational system, with serious implications for children with no choice other than public schooling. As mentioned previously, the common school system generally excluded African American children until after the end of the Civil War and Reconstruction. Though the end of slavery meant that the common school system finally included African American children, they were generally educated in separate facilities (see Orfield & Eaton 1996 for a history). By 1896, the idea of “separate but equal” schools was officially sanctioned by the Supreme Court through its decision in *Plessy v. Ferguson*. Racially segregated schools became the norm across the US, though whether this segregation was by law or by practice varied by state and region. Equitable distribution of resources between racially segregated schools never existed; white schools received substantially more financial and academic support. “Separate but equal” schools were eventually declared inherently unequal in

the Supreme Court decision *Brown v. Board of Education of Topeka* (1954), and schools were ordered to desegregate “with all deliberate speed.”

Though *Brown* is perhaps one of the most widely celebrated Supreme Court decisions, schools in the US have failed to reflect the ideals of desegregation and educational equality put forth in the ruling. Early research in sociology of education recognized that stratification in educational attainment was related to students’ family background, such as race or ethnicity, rather than simply differences in achievement test scores (e.g., Coleman et al. 1966). These differences were social and had to do with the schools’ social context rather than factors that could be affected by redistribution of funding levels alone. Since the Coleman Report (1966) and its political consequences of busing that shocked the nation, educational researchers and policymakers have struggled to know how to provide equality of educational opportunity within a context of socioeconomic inequality.

Beginning around 1980, sociologists of education turned their attention to stratification systems at work *within* schools. Secondary schools tend to group students in courses or “tracks” (such as academic, general, or vocational), and through these groupings schools can either reinforce or disrupt the relationship between family background and attainment. Typically, the high school curriculum is organized into sequences of courses in which subject knowledge gained from one course prepares a student for the next course. Mobility between sequences is restricted and forms the foundation of a stratification system for adolescents. Furthermore, schools tend to provide more resources, such as higher quality instruction, to students in higher level courses, which can have serious consequences for low ability students (Hallinan 1994). The result is that students’ course taking patterns follow a trajectory or sequence of courses over the years of high school in which mobility between course sequences is unusual. This is especially true in mathematics, where mobility into the elite college preparatory classes is nearly impossible after the sequence has begun. Students’ placement in these sequences explains much of why family background is linked to students’ attainment and is strongly related to a variety of

outcomes that indicate students’ basic life chances.

Research on stratification within schools further confirmed the results of Coleman’s earlier analysis on equity in education – schools are more effective at educating students from privileged family backgrounds. Because schools have been idealized as a great equalizing force, understanding why family background is linked strongly to education became the next important goal of sociology of education.

Annette Lareau (1987), building on Pierre Bourdieu’s (1973) idea of cultural capital, offered one explanation of how parents transmit advantages to their children when she found that parents interacted with teachers and schools very differently depending on their social class backgrounds. In addition to conditioning how parents interact with the school, parents’ cultural capital also influences how they socialize their children. Lareau describes middle class parents’ childrearing strategies as “concerted cultivation” or active fostering of children’s growth through adult organized activities (e.g., soccer, music lessons) and through encouraging critical and original thinking. Working class and poor parents, on the other hand, support their children’s “natural growth” by providing the conditions necessary for their child’s development, but leaving structure of leisure activities to the children. These different styles have implications for students’ abilities to take advantage of opportunities in schools.

Coleman’s concept of social capital articulated another way that families transmit advantages to their children. In parenting, social capital refers to “the norms, the social networks, and the relationships between adults and children that are of value for the child’s growing up” and can exist within families and communities (Coleman 1987: 334). Social capital within families taps how close parents and children are and how closely parents are able to monitor their child’s development. For example, Coleman (1988) found that a higher percentage of children from single parent families (who have less social capital in the home) drop out during high school than children from intact families. Social capital in communities is also important, as Coleman et al. (1982) demonstrated: students in Catholic high schools were less likely to drop out compared to their peers

in other private and public schools, not because of school related differences (such as quality curriculum), but rather because of the close knit adult relationships surrounding Catholic schools. The cohesive Catholic community allowed adults to better transmit norms about staying in school to teenagers.

Though the principal manifest function of schools is undoubtedly to provide opportunities for learning, schools also serve as the primary location for social interaction with peers and for the development of adolescent cultures. Since Durkheim first emphasized schools as a socializing institution, sociologists have investigated how schools' adolescent cultures affect adolescents' priorities, goals, and behaviors. James Coleman's *The Adolescent Society* (1961) recognized the importance of "adolescent culture" in schools to the decisions, both academic and social, that adolescents make. Coleman stated that adolescents turn to each other for social rewards, not to adult communities; therefore, understanding the value systems of adolescent society is key to understanding what motivates students. Importantly, for some adolescents, the goals of formal schooling – achievement, engagement – are reflected in the adolescent culture; however, when students rebel against the formal goals of schooling, it can reinforce preexisting inequalities based on family background.

Fordham and Ogbu (1986) have examined how adolescents' oppositional culture to schooling develops and how it explains in part the links between family background and students' achievement. Given the history of racism in the US, Fordham and Ogbu argue that doing well in school has come to represent "acting white" to African American youth in an urban school. This may lead many African American students who are academically able to perform significantly below their capabilities. It also creates a tension for African American students who want to succeed academically; not only do they have to cope with the challenge of coursework, but they also have to deal with the burden of appearing to act white. More recently, this perspective has been challenged by researchers who argue that African American students actually hold educational values in high esteem and do not reject academic success.

Much of the sociological research on education has focused on equity – with good reason. Education has serious implications for adolescents' future lives. Individuals' academic credentials affect the jobs they are able to get and the incomes they earn. Individuals with a college degree earn higher wages than those with a high school degree who earn more than high school dropouts (Arum & Hout 2000). Educational attainment also has serious implications for health throughout the life course. More highly educated individuals experience better health (including self perceived health, morbidity, and mortality) than people with less education (Ross & Mirowsky 1999). Education also shapes the social relationships that individuals form. People tend to marry others with similar amounts of education. Taken together, these findings indicate that education plays a powerful role in individuals' lives. Though we don't fully understand *how* education affects these diverse aspects of the human experience, it is clear that education is an important social institution.

education, adult

David B. Bills

Perhaps because so much adult education takes place outside the boundaries of formal educational institutions, sociologists have devoted less scholarly attention to adult education than they have to most other kinds of schooling. There is little agreement on the boundaries of adult education and no clear consensus on a definition that specifies what is included and excluded. Even the terminology pertaining to adult education is inconsistent and shifting, as the range of terms used to refer to this broad and diverse category of education has included continuing, adult, further, recurrent, popular, second chance, educational extension, and life long learning (Kett 1994). One could add even more recent additions to this list of terms.

But while any definition of adult education is inevitably somewhat arbitrary, a few common features emerge. Perhaps the salient feature of adult education is that it is non compulsory or voluntary. Adult education typically involves educational reentry after one has left formal schooling to pursue work or family activities. It does not traditionally include full time enrollment in postsecondary degree or diploma programs although it often includes part time enrollment in such programs (Kim et al. 2004: v). Some analysts consider vocational education, worker training, and other clear forms of "human capital investment" as components of adult education, while others prefer to focus on education for leisure, self improvement, and personal development. Kett (1994) argued that adult education has more to do with its function of providing additional learning for those who have left the educational system than it does with age.

There is nothing in the United States that could be characterized as an "adult education system." The vast panorama of adult education programs and offerings in the US is an utterly non coordinated and decentralized "non system," ranging in quality from atrocious to excellent and in cost from free to prohibitive for most would be participants. The many professional associations and accreditation agencies with an

interest in adult education are at best loosely confederated and organized.

Because of the diversity of adult education, definitional uncertainties about its boundaries, and the lack of any national database on adult education, it is impossible to offer any definitive statistical portrait of its distribution. Still, a few kinds of adult education are especially prevalent. One of the most common is a huge infrastructure of providers of instruction to prepare high school non completers to take the General Educational Development, or GED, examination. The GED has been used for decades in the US to signify the equivalence of a high school degree. In the year 2000, about 860,000 people took the GED exam, with about 60 percent successfully passing it.

While statistics are less reliable, even larger numbers of people have participated in various kinds of adult literacy programs. These vary greatly in length, intensity, and pedagogical sophistication. Adult literacy programs are deeply rooted in American history, resurging particularly during waves of heavy immigration. While often presented as a means to alleviate educational and economic inequality, their actual impact on this, despite their other virtues, has been modest (Raudenbush & Kasim 1998).

A great deal of adult education is offered in response to the demand for instruction in avocational interests, hobbies, and personal growth. Unlike most compulsory education, much adult education is better characterized as consumption than as investment. That is, the goals of K 12 schooling are routinely stated in terms of the development of desired changes in young people's repertoires, preparing them to effectively assume adult roles as citizens, workers, and community members. In contrast, a large share of adult education is "consumed" for its own sake, for the personal satisfaction and edification that it offers. Sociological models of adult education that adopt the economic perspective of "education as investment" are often of limited value in explaining people's decisions to invest time and money in adult education from which they expect no economic returns.

Individuals pursue adult education from a wide variety of providers. Many providers are located in traditional educational institutions,

from K 12 settings to community colleges to four year colleges and universities. Other adult learning is situated in community organizations, business and industry, church groups, and libraries. Increasingly, vendors are providing adult education through various distance learning technologies, notably the World Wide Web and other asynchronous forms of instructional delivery.

Sociologists have had limited engagement with the mainstream adult education field and rarely draw on even the recognized classics of the adult education literature. Much of the adult education literature is quite normative, being rooted more in social movements of self improvement than in a systematic understanding of the sociology of adult education. Statistically and methodologically sound analyses and evaluations of virtually any aspect of adult education – participation, effectiveness, outcomes – are extremely rare.

The uncertainty about definitional boundaries creates a host of measurement and other methodological problems in the study of adult education. Even the inclusive definition offered by the National Center for Education Statistics (see Kim et al. 2004) is restricted to adult education activities in which an instructor is present. A wide variety of self paced, non certified, non formal learning activities that would clearly fall into any accepted categorization of learning (e.g., reading professional journals in one's field, or watching the History Channel) are often systematically excluded from consideration.

Adult education is a critical part of one of the most enduring social movements in American history, that of self betterment. Since the earliest days of the republic, adult Americans have pursued educational opportunities through such diverse venues as Chautauqua institutes, voluntary associations, libraries, reading groups, correspondence study, elder hostels, and church organizations (Kett 1994). The pursuit of adult education figures prominently in the American myth of the "self made man."

More recently, such impulses toward self improvement have given way to a more economically motivated agenda of "Lifelong Learning" or "the Learning Society." The rhetoric of Lifelong Learning is not as deeply institutionalized in the US as in many other

postindustrial nations, some of which have elevated the model of the Learning Society to the top of the economic development agenda. Advocates of the Learning Society believe that globalization and rapid technological change are increasingly rendering one's current stock of education obsolete. They add that policies to promote ongoing learning throughout the life course are needed to compete in the global marketplace. Even in the United States with its traditions of adult education for self betterment, most proposals to reform adult education eventually appeal to economic logic. Despite the cautions of many observers that the provision of skills is not sufficient in itself to meet the demands of changing markets (Crouch 1997), the engine driving adult education is changing quite inexorably from self improvement to social mobility.

There is no single data series that can document trends in adult education over more than a few years. Under any definition, however, participation in adult education has grown substantially over the past 30 years. Using the rather expansive definition adopted by the National Center for Education Statistics (NCES), in 2001 about 46 percent of American adults (about 92 million people) participated in some form of adult education. This was up from 40 percent in 1995. The most common form of adult education was work related, but personal development education was also very popular. In fact, fee based personal development education attracts more students to many community colleges than does tuition based coursework in degree programs. Less common but still very significant forms of adult education were English as a Second Language (ESL), basic skills education, vocational and technical degree programs, and apprenticeships.

Collectively, adult education adds a great deal to the nation's overall stock of formal schooling. Jacobs and Stoner Eby (1998) estimated that about 7 percent of the total educational attainment of recent American cohorts is the result of reentry education.

Individuals have very different opportunities to participate in adult education. For the most part, access to adult education is influenced by many of the same factors that influence access to other valued educational and socioeconomic outcomes. Whites participate at higher rates

than African Americans and Hispanics. Women participate at higher rates than do men, and have done so at least since the late 1970s. There is evidence, however, that the sorts of job training in which women participate tend to yield lower economic returns than the job training provided to men. There is little variation in participation rates for adults aged 16–50 (about 54 percent), but rates of participation in adult education drop sharply for those aged 51–65 (41 percent) and over age 65 (22 percent). More highly educated individuals are far more likely to participate in adult education than are those with less schooling (a finding that holds in many nations). Those in more privileged occupational and employment positions have greater likelihoods of participating in adult education than do those in less advantaged work situations, and those with higher household incomes are similarly advantaged (Kim et al. 2004).

Because much adult education is not based in formal school settings, the decision to pursue adult education is not strictly the same as the decision to return to school. Particularly for women, the ability to return to school hinges on a variety of marital and family factors, such as responsibilities for childcare and the amount of emotional and financial support received from one's partner. Most often, analysts focus on the "barriers" that stand between people and their ability to participate in adult education. There is as yet no widely accepted conceptual framework for understanding these barriers.

The growth in adult education is closely related to some important long term demographic trends. Foremost among these is the increasingly "disorderly" life course lived by many Americans. By "disorderly," demographers direct attention to the dissolution of the normative life course of linear and predictable sequences from one social role to another and its replacement with a life course regime in which people hold educational, employment, and family roles out of their traditional sequence and in many cases simultaneously. Thus, individuals are increasingly likely to structure their lives in ways that facilitate occasional or even frequent episodes of educational reentry.

Moreover, the aging of the population, in particular those born during the 1946–64 baby

boom in the United States, is resulting in a large "supply side" of potential participants in the adult education market. There are many more people in the typical "adult education" ages than ever before. Even though baby boomers evidently do not return to school at higher rates than earlier cohorts did, their sheer numbers have put enormous upward pressure on adult education. On the demand side, many American colleges and universities, to say nothing of community colleges, have expanded their adult education course offerings while redoubling their efforts to make education accessible to adults with work and family commitments. The adult education market is particularly open to adult education aspirants because of the relatively easy access to virtually any form of adult education in the US. Of course, as baby boomers are coming to be replaced by the much smaller 1965–82 birth cohort of "baby busters," the supply of potential adult learners available to colleges and universities will shrink quite precipitously. As Jacobs and Stoner Eby (1998) observed, in the near future the college population of the US will return to its traditional demographic composition of young adults.

education and economy

Richard K. Caputo

The relation between education and economy is interdependent and reciprocal. Education is a form of human capital, an intangible form of accumulated capital stock, which includes level and dispersion of education as well as those of applied and basic research. It has many measurable forms, including years of aggregate schooling, rates of enrollment, public education expenditures, and levels, types, and use of on the job training programs. Economic activity is understood as economic growth, usually measured as changes in the size or rate of gross or per capita gross domestic output, and determinant of how much improvement will occur in a society's standard of living. Unlike business cycles, which reflect short term (<10 years) aggregate fluctuations in output, incomes, and employment, economic growth is a long term concept, depending on past investments in physical capital like industrial plants and machinery, human capital, and the pace of technological innovation.

The major dimensions of education and economy include the causal directions and the levels of analysis for effects. The effects of education on economic growth are to be distinguished from effects of the economy on educational expansion. Microscopic research analyzes the effects of education on individual characteristics such as wages and occupational status. Macroscopic research focuses on the effects of education on aggregate output and productivity for national economies. Five theories guide related research: class reproduction, human capital, functional, institutional, and stratification. In addition, contemporary growth models are more likely to rely on total factor production, addressing the efficiency with

which factors of production are used and reflecting a broad range of economic and socio-cultural influences, rather than growth accounting, which is limited to a narrower range of economic factors of production.

Early reliance on human capital theory in economics and functional theory in sociology posited that education increased the productivity of national economies through increasing the productivity of individuals. Human capital and aggregate productivity studies assumed that more highly educated workers were more productive on the job, arguing that wages were the measure of worker productivity. It was questionable, however, whether wages should be used as a measure of marginal productivity, since this assumed a perfectly competitive labor market in equilibrium.

In regard to effects of the economy on education, earlier empirical studies challenged the functional theory view that as economies industrialize and jobs require greater literacy and technical skills, education expands in response. Secular mass schooling often preceded demand for high level industrial jobs in industrial and undeveloped countries. Early industrialization was also found to retard educational development. Early pressures to develop formal schooling were typically from political, religious, or cultural elites and focused on training state bureaucrats, military leaders, and religious cohorts, not on developing economic skills.

Class reproduction, human capital, functional, institutional, and stratification theories on the whole present clear though different images of education and the economy. The empirical evidence through the mid 1990s blurred lines separating them, many variables used were proxies for difficult to measure attributes, and the quality of data varied across studies.

Bleaney and Nishiyama (2002) examined three competing models of economic growth. All three study models had 26 explanatory measures in common, including the log of initial per capita GDP. No one model dominated the others, implying that an encompassing model with explanatory variables from all three fit the data better than any of the original models or any pair of them. In the final encompassing model passing a battery of tests for adequacy, human capital (that is, male schooling),

institutions, specialization in primary products, and terms of trade changes were all determinants of growth between 1965 and 1990.

Although inconsistencies across studies and complexities about relationships remain, contemporary research benefits from cross country, cross sectional panel data with a focus on the question, "Under what conditions does education contribute to economic growth and vice versa?" Barro (2001) has shown that economic growth is positively related to the starting level of average years of school attainment of adult males at the secondary and higher levels and has no relationship to primary education. Judson (1998) has shown that allocation matters: higher investment in universal primary education plays a positive role in economic growth, especially in poorer countries.

Kalaitzidakis et al. (2001) show a nonlinear relationship between education, measured as mean years of schooling, and economic growth, measured as per capita GDP growth between 1960 and 1990. They also report no relationship between education and economic growth *for high income/capital countries*, due in part to contrasting effects of male (positive) and female (negative) education.

Krueger and Kumar (2004) contend that higher rates of publicly subsidized investments in vocational education was one possible factor contributing to increased economic growth in Europe vis à vis that of the US in the 1960s and 1970s. As the rate of technological progress increased throughout the 1980s and 1990s, such subsidies contributed to the slower rate of economic growth than that of the US.

Bils and Klenow (2000) show that schooling accounted for less than one third of per capita GDP growth and that schooling responded to the anticipated rate of growth from income accompanying increases in GDP. They also note the importance of institutional factors such as better enforcement of property rights and greater openness in inducing faster GDP growth and higher school enrollments.

Galor and Tsiddson (2002) show that the evolutionary pattern of human capital distribution, income distribution, and economic growth were determined simultaneously by the interplay between a local home environment externality and a global technological externality. When the home environment externality was

the dominating factor, the distribution of human capital and the wage differential between skilled and unskilled labor became polarized. Inequality enabled members of more highly educated segments of society to overcome forces of a low, stable, steady state equilibrium and to increase investment in human capital. As such investment increases and “trickles down” to the less educated segments of society via technological progress in production, the return to skill improves, and investment in human capital becomes more beneficial to members of all segments of society.

Finally, correcting for the conceptual unsuitability of many indicators of institutional quality, both political and social, Glaeser et al. (2004) show that human capital investment between 1960 and 2000 was a robust predictor of economic growth independently of institutional development and that institutional improvement follows economic growth. Equally important, findings of this cross national study indicated that the key human capital externality was not technological, but political: courts and legislators replaced guns. These institutional improvements in turn brought about greater security of property and economic growth.

educational attainment

David B. Bills

Educational attainment refers to the highest level of formal education completed by the members of a population. Because national systems of education differ greatly from one another, the measurement of educational attainment is typically restricted to education completed in the country where the education was received (Siegel & Swanson 2004: 220), although researchers have developed various metrics to translate levels of completed schooling across countries (Kerckhoff & Dylan 1999). Educational attainment is sometimes recorded as the number of years of schooling that individuals have completed, but is more often measured as the highest grade or highest level completed. The distinction between years of schooling and highest level completed is particularly important in highly schooled and highly economically developed societies in which primary and secondary schooling are virtually universal. Moreover, in highly economically

developed societies distinctions at the upper levels of the educational distribution are of more social consequence than are distinctions expressed simply in years of schooling.

Educational attainment is a measure of the *stock* of education in a population (Duncan 1968). It is useful to distinguish educational attainment from various measures of the *flow* of education through a population. The most common measures of flow are school enrollment and educational progression. Educational attainment also differs from educational achievement, which pertains to various kinds of cognitive and analytic skills acquired in school, and literacy, a more judgmental measure of the distribution through a population of proficiency in reading and writing.

A difficulty in measuring educational attainment is that there is no fixed age at which individuals permanently sever their participation in formal schooling. The inclusion of individuals who have not yet completed their education in the calculation of the educational attainment of a population systematically underestimates the overall level of educational attainment. Because of this, the measurement of educational attainment must specify a lower age boundary in order to include only those who are most likely to have completed their education. Age 25 is a quite standard cut off for this purpose, but even this definition can become problematic as increasing shares of the population continue their education later in the life course and as educational re entry becomes more common.

The US Census Bureau began to measure educational attainment in the 1940 census by asking about the highest grade of schooling that the respondent had attended and completed. It maintained that practice through the 1980 census. Because this conceptualization of educational attainment failed to provide data on the degrees earned by respondents to the census (in particular, post secondary degrees), in 1990 the Bureau began to ask about the highest level of education completed. This change from years of education to levels of education had important implications for charting historical trends in the educational attainment of the population. Specifically, it is no longer possible to use census data to calculate the mean and the

median number of years of completed schooling in the population. Demographers generally regard this as an acceptable tradeoff for the greater precision and timeliness afforded by the new measurement procedure (Kominski & Siegel 1993).

The US Census Bureau publishes an annual report on the educational attainment of the population using data collected in the Current Population Survey. This administration of the CPS was once known as the Annual Demographic Survey, or more commonly the March Supplement. It is now entitled the Annual Social and Economic Supplement (ASEC).

The educational attainment of the American population has risen steadily since the mid nineteenth century. This upward trend was especially rapid in the twentieth century. The US attained virtually universal primary education before the end of the 1800s, near universal secondary education a half century later, and mass higher education not long after that (Walters 2000). The story is not simply one of uninterrupted growth in educational attainment. The trend line has shown some fluctuations, not all sociodemographic groups have participated equally in the growth of attainments, and there are recently signs of decelerating or even reversed growth. Still, the enormous growth of the educational attainment of the American population has been of unquestioned social, cultural, and political economic significance (Goldin 1998).

The US has historically been a world leader in the mass provision of opportunities for educational attainment, but the growth of educational attainment has been a worldwide phenomenon. This growth has often been rapid and dramatic. An important series of publications by Meyer and his colleagues have characterized the global expansion of formal education as "the world educational revolution" (Meyer et al. 1977).

Analysts of social stratification have regularly regarded educational attainment as pivotal to modern systems of social stratification. As conceptualized in Blau and Duncan's classic *The American Occupational Structure* (1967), opportunities for educational attainment are unequally allocated across several fundamental socioeconomic dimensions. Varying levels and

types of educational attainment are in turn crucial in allocating people into unequally rewarded positions in socioeconomic hierarchies.

Key to this simple model of social stratification is the distinction between ascription and achievement. Ascription (or ascribed status) refers to individual and aggregate level characteristics over which the individual has no control. Many of these have been hypothesized and empirically demonstrated to influence educational attainment. These include such factors as race, socioeconomic background, and sex. In contrast, achievement (or achieved status) includes those factors that are more under the control of the individual, such as effort, motivation, or ambition. These too have been shown to have significant impacts on educational attainment.

In the US, the relative importance of different ascribed characteristics has changed over time. For many years, girls and women received significantly less educational attainment than did boys and men. More recently, however, American females are receiving higher levels of educational attainment than are males at all but the very highest levels of the educational system. In many cases, such as many professional post secondary programs leading to remunerative careers, even these barriers are beginning to fall. The transformation of female educational disadvantage into female advantage is evident in many other countries as well.

The gap in educational attainment between white Americans and African Americans, which was once extremely large, has narrowed significantly. On some measures of educational attainment African Americans have even reached relative equality with the white population. Adducing many of the same social and historical factors that contributed to the decline in the educational gap between males and females, Gamoran (2001) anticipates that the racial gap in educational attainment too will continue to decline. At the same time, some Asian American groups have among the highest levels of educational attainment in the nation, while the gap in educational attainment between many Hispanic and Latino populations and the majority population has narrowed more slowly.

On the other hand, the role of socioeconomic status or class (including such indicators as parental education levels, neighborhood

poverty, parental occupational status, and family income) as a determinant of educational attainment has shown little sign of weakening over time and considerable evidence of persistence. The ability of researchers to understand the critical role of socioeconomic background as a determinant of educational attainment was greatly enhanced with the introduction and elaboration of the influential "transition model" of school continuation decisions developed by Mare (1980, 1995). This model drew attention to the continuing importance of social class at transitions from one level of the educational system to another, processes that were often overlooked under earlier linear conceptualizations of the determinants of educational attainment.

Not all of the factors that have been demonstrated to lead to variations in educational attainment are straightforward measures of ascription or achievement. Many researchers have assessed the role of cultural capital and social capital as important determinants of educational attainment (Coleman 1988). Cultural capital refers to culturally valued resources and dispositions that are held disproportionately by the more highly educated. Cultural capital need not reflect job skills or productive capacity in any significant way, but can nonetheless lead to enhanced life chances because of its association with the culture of privileged and elite classes. By social capital, analysts draw attention to how the placement of individuals in supportive social networks can provide educational advantages beyond those offered by an individual's own skills and talents.

While educational attainment is itself an unequally distributed and scarce social good, in a similar way the possession of educational credentials is a principal means by which status, prestige, and other aspects of life chances are distributed in modern societies. Higher levels of educational attainment are statistically associated with all manner of positive social outcomes. Relative to less educated individuals, more highly educated people have greater access to high paying and prestigious work with which they are more satisfied. They are generally in better health and display more healthy behaviors. Further, more educated people exhibit higher levels of community and civic participation. These findings should be

interpreted with care. In part, the benefits of educational attainment are due to the socializing effects of education itself, in part they are due to the greater access to economic resources facilitated by educational attainment, and in part they arise from selection effects into advanced levels of education.

These generalizations about the salutary benefits of educational attainment are true at the aggregate levels of states, regions, and nations, as well as the individual level (Buchmann & Hannum 2001). In comparison with less educated nations, more educated nations are more economically prosperous, healthier, and politically open. Once again, questions of cause and effect need to be carefully considered.

educational inequality

Yossi Shavit

In their classic study of stratification in the US, Blau and Duncan (1967) found that the effect of education on occupational attainment increased over time. They interpreted this to mean that America was becoming increasingly meritocratic. A meritocratic social system is one in which the attainment of desirable social rewards, such as good jobs, is determined by effort and ability rather than by inherited privilege. It is often assumed that the attainment of educational credentials requires both effort and ability and that education represents merit. However, educational attainment is also determined by social origin. An equally valid interpretation of Blau and Duncan's finding is that the intergenerational transmission of social privilege is increasingly mediated by education. The extent to which this is so is determined by the relative magnitude of two factors: the effects of social origin on educational attainment and the effect of education on occupational and economic attainments. Searching for a social system that is both meritocratic and egalitarian, researchers try to understand why there is a strong association between social origin and educational attainment and how to weaken it. This entry reviews the main determinants of educational attainment and of educational

inequality between social strata and between men and women. Sociologists attribute educational inequalities between strata to processes at work in families and the educational system.

FAMILY FACTORS

Ability, Encouragement, and Aspirations

The Wisconsin model is arguably the single most influential model of social stratification (Sewell et al. 1975). The model posits a chain of relationships between variables that affect educational and occupational attainment and begins by showing that there are substantial differences between social strata in students' scholastic ability. Next, it shows that both students' social origin and their ability affect their grades in school. The three groups of variables determine how much encouragement students receive from significant others (teachers, peers, and parents) regarding their future educational and occupational aspirations. Aspirations, in turn, affect students' ultimate educational and occupational attainments. However, the model explains only about 30 percent of the variance in educational attainment. This means that it explains a large part of the difference between people in educational attainment but also that most of the variance between them is due to other factors, such as luck, cultural differences between families, school differences, and more. The Wisconsin model has been replicated in many other countries.

Cultural Capital

Bourdieu (Bourdieu et al. 1977) has argued that school curricula reflect the codes and values of the dominant culture in society. He defined cultural capital as familiarity with these codes and values. The dominant culture is the culture of the privileged social strata. Children raised in these strata internalize the values of the dominant culture effortlessly and enjoy an advantage in the educational attainment process. In this way, the intergenerational transmission of cultural codes facilitates the reproduction of educational and social inequality between generations. These claims are cited often in studies of educational inequality, but

empirical data show that they overstate the extent to which cultural capital actually reproduces social inequality. Cultural capital is often measured by familiarity with highbrow cultural codes (the names of composers or painters) or by the frequency of participation in highbrow activities (visits to museums or classical concerts). Bourdieu's model expects to find rather strong correlations between these measures and school performance, but studies typically find weak ones. Recently, scholars like De Graaf et al. (2000) found that the main component of cultural capital that affects educational achievement is not the students' familiarity with highbrow culture or participation in it, but rather their exposure to books and reading at home. Children raised in affluent homes and whose parents are educated are more likely to benefit from the availability of books in the home and to do well in school. These findings are consistent with a large body of research showing that the home reading environment is important to the early acquisition of scholastic aptitude and reading and writing skills.

Family Size and Cohesion

There is a substantial body of research on the US and other developed countries showing that sibship (the number of one's brothers and sisters) is inversely related to children's cognitive ability and educational achievement. The resource dilution hypothesis suggests that children raised in small families benefit from a larger share, on average, of the families' resources, including parental attention which, in turn, enhances their cognitive development and educational attainment. The negative effect of family size is stronger when siblings are closely spaced because they draw on family resources simultaneously. The negative effects are weak when some siblings are old enough to contribute to the resource pool and can help in the development and education of younger ones (for a detailed exposition of this idea, see Zajonc & Markus 1975).

Studies on non western and some religious communities do not find a uniform negative effect of sibship size on achievements. For example, for Muslims living in Israel, students attending Catholic schools in the US, and

Orthodox American Jews the negative effect of sibship size on educational achievement is weak or even reversed. In these subpopulations, nuclear families are embedded in extended families or supportive communities whose assistance and resources mitigate the dilution effects of large sibships. Thus, whereas family size can be a liability in the educational attainment process, the social cohesion of extended families and communities is an important asset.

Social Capital in Families

Sociologists often refer to social cohesion of this kind as social capital, defined as the characteristics of one's social network (family, friends, etc.) that can facilitate the attainment of a goal (Coleman 1988). An important aspect of a family's social capital is family structure, namely whether or not both parents are present while the child is growing up. The educational achievements of children raised in two parent families are substantially higher than those of children raised in one parent families (McLanahan & Sandefur 1994). Research identifies three main reasons for this: first, single parent families, especially those headed by mothers, are economically disadvantaged; second, children raised by single parents receive less attention and guidance, on average, than those raised by two parents; and third, single parent families maintain a weaker social bond with the community and lack the social capital upon which other families can draw when in need.

Financial Resources

Children's educational attainment is also affected by their family's income because high income families can afford the direct and opportunity costs of education. The effects of family income on cognitive development and educational attainment are larger in the early ages (0–5) than in adolescence. Moreover, family income in childhood has a stronger effect on educational attainment at the secondary level than does contemporaneous family income (Duncan et al. 1998). This suggests that the effect of family income on educational attainment is mediated by developmental processes

rather than simply the ability to afford the costs of schooling. As Duncan and associates point out, preschool ability sets the stage for subsequent educational achievements, and children raised in poverty are less likely to develop the cognitive skills necessary for educational success.

And yet a recent study suggests that most research tends to underestimate the magnitude of the effect of financial resources on children's educational attainment. Conley (2001) compared the effects of current family income to the effect of the family's total wealth (including savings and home ownership) and found that the latter has a much stronger effect on American adolescents' likelihood to obtain a college education. Evidently, wealthy families can draw on their savings to pay for college expenses.

SYSTEMIC FACTORS

Most of the explained variance in students' educational achievements is due to individual and family characteristics of the kind discussed above. However, some variance is also explained by characteristics of the schools that students attend. Students benefit from attending small schools and from having a small student–teacher ratio in the classroom, as well as from attending schools that are attended by peers of privileged social origin. Two additional institutional characteristics of schools affect variance in educational achievement: curriculum organization and tracking, and the expansion of the educational system.

Organization of the Curriculum and Tracking

Fields of knowledge and school subjects are stratified by prestige. Although the hierarchy of subjects varies between societies, academic and scientific subjects usually enjoy higher prestige than utilitarian or nonscientific ones. Prestigious subjects are considered more difficult and deemed more suitable for able students who are likely to come from privileged families. The utilitarian and nonscientific subjects are offered to weaker students who often come from lower socioeconomic strata (Ayalon 1994). In most countries, success in prestigious subjects at the secondary school level is a prerequisite for

admission to selective colleges or universities. Therefore, curricular hierarchies play a role in the intergenerational reproduction of inequality of educational opportunity.

Most educational systems place students into distinct curricular tracks or streams. The most common distinction is between the academic tracks that teach the prestigious subjects and prepare students for higher education, and tracks that prepare them for immediate entry into the labor force. Track placement is determined largely by the students' prior achievements. But because student achievements are correlated with their socioeconomic origins, students from less privileged strata are more likely to attend non academic tracks; track placement, in turn, affects their subsequent educational attainment. Not surprisingly, academic track students are more likely to attend higher education and obtain lucrative jobs in the labor market. Thus, tracking transmits inequality between generations (Shavit 1990).

Expansion of Education

In recent decades, educational systems in most countries have expanded dramatically. In the 1950s and 1960s only about a third of children living in economically advanced countries completed upper secondary schools. This proportion has since increased sharply and now approaches 90 percent. Tertiary education in these countries expanded as well. In the 1960s higher education was attended by less than 20 percent of the relevant age group; by the 1990s attendance rate reached about 50 percent. Many policymakers believe that the expansion of education can reduce educational inequalities because expansion draws in adolescents of less privileged origin, raises their educational attainment, and reduces inequality between their education and that of the middle and upper classes. Scholars of social stratification are less optimistic. In the early 1980s, Mare (1981) developed a sophisticated model for analyzing educational stratification. The model views the educational attainment process as a sequence of transition points at which students and their families decide whether to continue to the next level or drop out. Their decisions are determined by variables representing the student

and family characteristics discussed above. Inequality of educational opportunity is measured as the effect of these variables on the odds of making the various transitions. The odds may decline at some transition points and increase or remain stable at others. Mare studied change in the stratification of education in the US during the first seven decades of the twentieth century. Although this was a period of dramatic educational expansion in America, the effects of social origin did not decline and even increased slightly. Replications of Mare's study in many countries, both industrialized and developing, produced similar results (Shavit & Blossfeld 1993). Several studies found exceptions to this pattern, but especially at lower educational levels where attendance rates of the privileged strata are approaching 100 percent. Any further expansion at these levels can only draw on the lower strata, among which attendance is not yet universal, and reduce inequality between strata in attendance rates.

Gender Gap in Education

Historically, when the rates of labor force participation by women were low, families preferred to invest resources in the education of their sons, which was viewed as an investment that would yield substantial income gains, rather than that of their daughters. Daughters were expected to function primarily in the private sphere: marry, bear children, and perform housework, activities not deemed to require an education above the very basic levels. The ensuing gender gap in education persisted for generations. Recently, this has changed dramatically. Women's educational levels have caught up and, in some countries, surpassed those of men (Bradley 2000). The equalization of gender differences in educational attainment is due to a pervasive change in the role of women in modern society. First, since the 1970s, there has been a global effort to promote norms of gender equality. Several international organizations, such as the United Nations, the World Health Organization, the World Bank, and the OECD, actively promote the status of women. Gender equality in education was identified as the primary mechanism by which women's status could be improved. Second, the expansion

of the public sector and the welfare state created demand for workers in service providing occupations. Third, the expanded provision of these services by the state played a double role: it relieved wives and mothers from some of their housework, and created jobs for them in the labor market. As a consequence, the labor force participation rates of women increased sharply.

While gender differences in access to higher education were eliminated and even reversed, differences between men and women in the type of institution and in fields of study remain. Women are still more likely than men to attend lower tier institutions such as two year or less prestigious colleges and are less likely to study the exact sciences and engineering. But these differences are also declining.

educational and occupational attainment

Juanita M. Firestone and Richard J. Harris

Both educational and occupational attainments are important (and related) aspects of prestige differences in the United States as well as throughout the more developed and developing countries. Prestige is used as a measure of social status and therefore is a part of the broader social stratification system. Social status is viewed as a subjective concept, based on individuals' perceptions about lifestyles. Most of us are aware of differences in lifestyles based on styles of clothing, types (and numbers) of automobiles, value and location of housing, and so on. The point is that differences in occupation

and education combine to produce differences in income, which then allow individuals and families to live a certain lifestyle. We then attach differences in social value to the different lifestyles; some are awarded high standing in society, while others are deemed to have little or no value. These judgments are played out within the contexts of gender, race/ethnicity, and class, and have been remarkably constant over time (at least since 1947 in the US) and across a wide variety of countries.

OCCUPATIONAL PRESTIGE

Most individuals place a lot of emphasis on a person's occupation when assessing prestige. For example, we make systematic judgments about a person's lifestyle based on whether we know they are a blue collar or a white collar worker. Sociologists often use prestige scores to rank occupations, which hypothetically could fall along a continuum from a low score of zero to a high score of 100. However, results for research generating occupational prestige scores indicate they rarely drop below 20 or above 80. Prestige scores, which are based on averages of individual scores, remain fairly stable over long periods of time and across different subgroups in the population. The lowest ranked occupations tend to be manual laborers (e.g., janitor, housepainter, garbage collector, housecleaner) or basic sales (supermarket cashier, furniture sales clerk, shoe/clothing sales clerk) or office (file clerk, telephone solicitor) positions. Medium prestige jobs include skilled manual (electrician, plumber, mechanic) or office (secretary, bookkeeper, bank teller, postal clerk) jobs. The highest prestige jobs are professional (judge, physician, professor, lawyer, registered nurse) or managerial (hospital administrator, general manager, accountant), which are typically ranked by level of expertise or responsibility. Importantly, there is a lot of within group variation as well, thus the prestige of neurosurgeons is much higher than that of general practitioners, although both fall in the highest prestige range. Interestingly, while specific types of occupations may vary, especially in developing countries (e.g., from a high score for chief of state to a low score for gatherer), the standard occupational prestige scale is

extremely highly correlated with prestige hierarchies of other countries, indicating similar prestige rankings cross nationally.

Gender and Occupational Prestige

In recent decades women's entry into the paid labor force has accelerated, especially among those with young children and babies. One important characteristic has been associated with the entry of larger percentages of women in the labor market – occupational segregation. Women have been segregated into a relatively small number of occupations, which are associated with stereotypes about feminine skills (e.g., secretaries, cashiers, hairdressers, nurses, elementary and kindergarten teachers). On the one hand, women's increasing labor force experience along with the decline in blue collar employment is creating a slow decline in occupational segregation. On the other hand, even when employed in higher prestige occupations, most women are concentrated in three fields: nursing, teaching, and social work. Thus, women's occupational profiles remain different from men's, and the average prestige scores for women's jobs within categories are lower than those for men. This is especially true in the technical/sales and skilled blue collar jobs. At the professional/executive level, the prestige scores are virtually identical, though there are still substantial differences in earnings.

These general patterns are consistent across different countries in spite of differences in the types of jobs available in developing compared to more developed countries. Cross culturally, stereotypes related to differences in job related skills between men and women remain strong. For example, students in various countries (both developing and more developed) identify managerial skills in stereotypical masculine terms. Furthermore, differences in career advancement of men and women are affected by the fact that differences in levels of career ambition vary according to national values. In many developing countries, career aspirations for women are optional at best and resisted strongly at worst. In the latter case, women are prevented by custom or policy from attaining the requisite skills to work in high prestige occupations.

Race and Occupational Prestige

Changes in race relations in the United States, along with anti discrimination legislation and equal opportunity and affirmative action programs, created dramatic changes in the occupational distribution of blacks over the years. For example, based on looking at the 10 highest and lowest ranked occupations in 1940, almost 80 percent of black workers were concentrated in the four lowest ranked categories, but by 1980 about 70 percent of black workers were in the upper six categories. In spite of these dramatic changes, blacks are still underrepresented at the top of the occupational hierarchy and overrepresented at the bottom, especially among service workers, which remained in 2000 the largest single black occupational category, as it had been in 1940. Recent occupational shifts (fewer blue collar jobs, growth of white collar jobs) have had a negative impact on black workers, thus in relative terms many young blacks have lost ground compared to whites because of higher unemployment and underemployment rates.

In the world context, racial differences in occupational prestige are often associated with the extent to which members of different races or ethnicities are perceived as outsiders with alien values. Thus "guest workers" or immigrants of different races and who exhibit other differences in cultural values (e.g., language, dress, religion) may be relegated to lower prestige jobs or to specific types of occupations (diamond cutters, sailors, traders). In both cases, members of races considered outside the typical citizenry are segregated occupationally based on stereotypes about their race; however, the latter groups are more likely to become integrated into a larger society.

Ethnicity and Occupational Prestige

Because of high birth rates and immigration rates, Hispanics as a group (including various subgroups, e.g., Mexican, Cuban, South/Central American, Puerto Rican) have become the largest minority group in the United States. As a result, Hispanics will become an increasing share of the future labor market. While the

various subgroups of Hispanics have different labor force characteristics (education level, experience, skills), one issue that may impact their position in the occupational hierarchy is English proficiency. This may be particularly true for recent immigrants, who may become underemployed or unemployed if they do not have the English proficiency to get and hold a professional or managerial position. The changes in the US occupational structure which positively impacted African Americans have had similar impacts on Hispanics. Thus, the percentage of Hispanics in higher prestige jobs has increased since 1980, although the largest percentage of Mexican origin workers are still concentrated among operators, fabricators, laborers, and lower level sales clerks. On average, the prestige of Hispanics in the US remains lower than that of white, non Hispanic workers.

As with different racial groups, intercultural encounters within countries can produce situations where individuals are stereotyped as incapable of working in higher prestige jobs. While it may be possible to learn superficial aspects of a different culture within a short period of time, it may be more difficult to absorb underlying values, especially if they are radically different from one's own culture. Thus, even foreigners who attempt to fit in to a new culture may be viewed with suspicion. One way of controlling suspicious individuals can be to limit their ability to climb the occupational ladder and achieve greater economic success.

EDUCATIONAL ATTAINMENT

The average education level of Americans is increasing, so that most adults in the US have a high school degree, and between 25 percent and 75 percent of individuals attend a college or university, depending on the economic background of their families. Thus, 25 percent even of individuals from lower socioeconomic circumstances attend at least a community college. In a general sense, everyone seems to understand that staying in school until you complete a degree pays off economically. With some exceptions, people with higher levels of education tend to have higher status jobs and earn more income. Sociological research indicates that

education does pay a dividend for all categories of workers. However, the less educated, those with fewer or outdated skills, and those with less experience may be losing ground with respect to wages. Research demonstrates considerable variation in wages within education levels (e.g., those with a high school degree, BA degree, or higher level degree) based on group memberships (e.g., gender, race, ethnicity). As with respect to occupational attainment, women and race/ethnic minorities tend to be on the lower end of statuses and wages within those groupings.

While a college education has a positive impact on individuals' prestige and earnings, access to college remains unequal based on the socioeconomic background of students. Graduation rates also vary based on group membership of students. In 2000, more than half of 18 to 24 year olds from families in the top income quartile completed college degrees, but only 1 percent of those from families in the bottom half of the income distribution completed degrees. The black-white difference in completing a college degree is smaller than in the past, but remains large.

Comparing educational attainment across different countries is a difficult task because of the heterogeneity of educational systems, particularly vocational and non academic training across various countries. Some researchers argue that it may not yet be possible to compare quantity of education (e.g., years, levels) across nations, but rather some system measuring quality of education would be preferable. One such process suggests assessing the differences in earnings or employment of educated workers that are attributable to the individuals' schooling. To accomplish this, a labor income based measure is created by weighting different segments of the workforce by the ratio of earnings at different levels of education. An alternative approach uses estimated rates of return to education rather than duration of schooling as weights in creating a comparative measure. The variations in available estimates for different countries highlight how such comparative measures can be sensitive to political assumptions about the social benefits of education, opportunity costs of missed wages, and other cultural values.

Gender and Educational Attainment

In recent decades the educational attainment of men and women has narrowed considerably. While the gap in college degrees between men and women has narrowed, the types of degrees earned vary by the sex of the individual. Men tend to earn degrees in fields associated with higher statuses and higher wages. In addition, educational attainment yields greater economic returns to males than to females. A part of this disparity is due to the occupational segregation discussed earlier. In the past, another part was due to women's intermittent labor force participation, when they were likely to move in and out of the labor force for family reasons (pregnancy, young children, husband's job moved elsewhere). Increasingly, maintaining a middle or upper middle class standard of living requires two incomes, and women's labor force participation is becoming more continuous over time.

In spite of a decreasing gap in male-female educational attainment, the gender gap in earnings remains larger than the race/ethnic gap. Some argue that at least a portion of the remaining gap among women of different race or ethnic groups results from minority women's greater likelihood of becoming single parent householders, being out of the labor force, living in low income neighborhoods, and facing various forms of discrimination. The gap between educational attainment of minority and white women leads to the continuing problem of double jeopardy. In sociology, double jeopardy refers to the compounding effects of being in two different minority groups (e.g., black and female or Hispanic and female).

Historically, Hispanic women have had significantly lower levels of education than non Hispanic women and lower than all groups of men. Early explanations of this difference focused on an idealized model of motherhood supposedly common among Hispanics that supported a patriarchal system that devalued female educational attainment in favor of becoming a wife and mother. Recent data suggest that increases in female headed households and marginal economic circumstances among many Hispanic groups have led to increasing awareness of the need to complete more years of education. As with other groups of women,

research indicates that Hispanic women do not receive the same returns for increasing levels of education. Language difficulties would likely compound these negative impacts.

Race and Educational Attainment

Sociological studies indicate that the economic penalty of race has declined since the 1960s – occupational mobility has increased, as has movement toward wage parity. These differences vary a lot based on the age of the individual. For example, among younger workers with college degrees, race disparities in occupational status and earnings have decreased considerably. A college degree moves black wages closer to parity with whites, although black incomes do not attain equality with whites. As noted earlier, however, access to education and completion rates for college degrees fluctuate across racial groups. Thus, to the extent that many blacks remain segregated from whites in inner cities and income disadvantaged areas, their access to the same educational and occupational opportunities as whites is limited.

Ethnicity and Educational Attainment

Past research has focused on differences in the ways Hispanics invest in higher education. Because of lower income and high poverty levels, many Hispanics attend community colleges or trade schools rather than attending universities or four year colleges. Because they often are also employed to support family needs, the opportunity costs associated with attending a university can be higher. Additionally, the increase in tuition costs and the lack of access to financial aid have impacted those from lower income families dramatically. In combination, these mean that Hispanics are more likely to delay a college education, drop out of college, or attend a community college, all of which can have a negative impact on educational and, as a result, occupational status.

CURRENT STATE OF RESEARCH

Changes in modern society have created opportunities for well educated professionals,

technicians, and managers. Alternatively, there have been important losses of well paid blue collar jobs because of the decline in manufacturing. Increases in the occupational service sector are associated with a polarization of the occupational status structure. On the one hand, opportunities for higher status jobs such as hospital administrators, medical technicians, accountants, hotel managers, and computer specialists have increased. On the other hand, there has been a commensurate increase in low status jobs such as fast food workers, janitors, and hospital orderlies. In addition, the distribution of individuals within occupational classifications is unequal, with women and race and ethnic minorities to a greater extent located in the lower status positions within classifications.

Along with this process, access to the college education needed to enter the high status occupations remains unequal. For example, the percentage of students enrolling in universities is much lower for race/ethnic minority groups and for individuals from the lowest income levels. Even among those who attend college, the background characteristics of students vary based on sex and race/ethnicity, and impact the type of degree attained. Thus, white males tend to receive degrees associated with higher status jobs (engineering, medical research), while women receive degrees associated with pink collar positions (human services, social work, elementary teaching) and race/ethnic minorities receive degrees associated with lower occupational status (general manager, office manager).

Cross nationally, changes include stronger focus on educating the populations of more developed countries. In the transition from rural to urban existence, education plays an increasing role for access to occupational positions. One interesting aspect of this process links directly both to the occupational structure of developing countries and to the occupational structure of more developed countries like the US. Outsourcing may mean an even stronger focus on education and professional skills in more developed countries, which could help stem the tide of highly educated and or skilled natives seeking to immigrate to places that pay better wages. Labeled by many as the “brain drain,” selective out migration has depleted the ranks of better educated individuals, especially in countries like India and Taiwan that are in

the process of becoming highly developed. Less developed countries still lag behind or may link education to sex, so that only boys are provided educational opportunities, or education may be linked to upholding traditional cultural values rather than creating an educated populace (e.g., Middle Eastern countries).

CONCLUSION

The occupational structures of the US and the more developed countries in the world have changed from one in which most workers were employed in predominantly goods producing jobs to one in which most are employed in service sector jobs. This change has produced a considerable amount of polarization with respect to occupational prestige, because it creates a demand both for professional jobs where high educational credentials are expected and for those that can be filled by individuals with limited educational credentials.

Educational status has increased along with this change in the occupational structure, although the changes have been non linear. The greatest gains in status in the US have gone to those with post high school degrees, especially those from prestigious institutions. Thus the absolute worth of some educational credentials may be devalued, creating a situation where individuals are underemployed given their educational attainment. For example, some argue that in the US at least, a bachelor's degree has the same value in today's labor market that a high school degree had ten years ago. Similarly, a master's degree today has the same value today as a bachelor's degree had ten years ago. In more developed countries, the greatest gains in status are associated with the skills that are utilized by multinational firms for outsourcing.

Changes in occupational and educational attainment are further impacted by gender, race/ethnicity, and class. Women, race/ethnic minorities, and those from lower income groups are more likely to be undereducated, have degrees from less prominent institutions, be employed in lower prestige occupations, or be underemployed relative to their educational credentials, contributing to increasing stratification within American society. In less developed countries, minority group status, whether

based on religion, sex, race, or ethnicity, still has the largest impacts on educational and occupational attainment.

effect sizes

Bruce Thompson

Sociologists historically have emphasized statistical significance testing as the *sine qua non* of empirical research. Statistical significance tests yield a $p_{\text{CALCULATED}}$ value that estimates "the probability (0 to 1.0) of the sample statistics, given the sample size, and assuming the sample was derived from a population in

which the null hypothesis (H_0) is exactly true" (Thompson 1996).

Effect sizes, on the other hand, are indices of practical significance that may be used either in place of, or as a complement to, statistical significance tests (Kirk 1996; Thompson 2006). Effect sizes quantify the extent to which sample results diverge from the expectations specified within the null hypothesis. Thus, if sample results exactly correspond to the null hypothesis (e.g., for the null hypothesis that the medians of three groups are equal, and the sample medians of the three groups are all 12.5), the effect size is zero. Effect sizes deviate further from zero as the sample results diverge increasingly from the null hypothesis (Thompson 2006a).

Across disciplines as diverse as economics, education, psychology, and the wildlife sciences, the frequency of published criticisms of this reliance has grown exponentially over the last few decades (Anderson et al. 2000). Indeed, some of these critics have argued that statistical significance tests should be banned from journals. As an example of the tenor of some of these views, Schmidt and Hunter (1997) can be cited as arguing that "statistical significance testing retards the growth of scientific knowledge; it never makes a positive contribution." Similarly, Rozeboom (1997) suggests that "null hypothesis significance testing is surely the most bone headedly misguided procedure ever institutionalized in the rote training of science students . . . It is a sociology of science wonderment that this statistical practice has remained so unresponsive to criticism."

During this same period, advocacy for the use of effect sizes as the basis for result interpretation has grown steadily. The 1994 *Publication Manual* of the American Psychological Association, used by more than 1,000 journals, first mentioned effect sizes and "encouraged" their use. The 2001 fifth edition of the *Manual* went further and described the failure to report effect sizes as a "defect." Because these admonitions are easily lost within the book length *Manual*, the editors of 24 journals have made effect size reporting an explicit manuscript requirement. Included are the flagship journals of two associations that are both received by more than 50,000 members. Indeed, as

Fidler (2002) recently observed: "Of the major American associations, only all the journals of the American Educational Research Association have remained silent on all these issues."

There are dozens of different effect size statistics (Kirk 1996). Common examples are Cohen's d , Glass's delta, η^2 , ω^2 , R^2 , adjusted R^2 .

Some effect sizes are in a standardized score metric (e.g., Cohen's d , Glass's delta). Other effect sizes are in a squared, variance accounted for metric (e.g., η^2 , R^2).

Some effect sizes are *not* corrected for the estimated influences of sampling error (e.g., η^2 , R^2). On the other hand, for some effect sizes adjustments are made for estimated sampling error influences (e.g., ω^2 , adjusted R^2). These types of estimates will differ less as (1) sample size is larger, (2) the number of measured variables is smaller, and (3) the true population effect size is larger. Effects are also attenuated by poor score reliability.

Because there are so many effect sizes, with more constantly under development, authors should be expected to note explicitly which effect size is being reported (Vacha Haase & Thompson 2004). Such reporting also facilitates the use of conversion formulas with which effect sizes can be converted into alternative effects (Thompson 2006b).

The correct use of effect sizes is not as widely understood as might be hoped (Thompson 2002). Many researchers tend to rely on Cohen's benchmarks for "small," "medium," and "large" effects as regards result typicality. However, as Thompson (2001) noted, "if people interpreted effect sizes [using fixed benchmarks] with the same rigidity that α [i.e., the probability of a Type I error] = .05 has been used in statistical testing, we would merely be being stupid in another metric." At least in relatively established areas of research, "there is no wisdom whatsoever in attempting to associate regions of the effect size metric with descriptive adjectives such as 'small,' 'moderate,' 'large,' and the like" (Glass et al. 1981).

Instead, effect sizes should be interpreted by *explicit, direct* comparisons of effects with those reported in the related prior literature. These comparisons, unlike statistical significance tests, inform judgments regarding result replicability.

- Recognition of abuse as a feature of older people's lives has been present in research and social policy for at least three decades. Mistreatment of elderly people has, however, had a much longer history. At worst, it has taken the form of outright persecution of those who, lacking resources of any kind, were thrown upon the mercy of their fellow citizens. At another level, mistreatment has been expressed through intergenerational tensions, for example during periods of economic recession as families struggle with the pressures arising from meeting the care needs of older as well as younger generations (Stearns 1986). At the same time, the meanings attached to, and the concerns expressed about, mistreatment of the old have varied from generation to generation. It is only very recently (in historical terms) that attempts have been made to translate a generalized concern about the suffering of the old into a more precisely defined concept of abuse. This transition has not been without difficulty, with complex issues raised about distinctions regarding the experience of abuse among different age groups, between various types of abuse, and the reasons for abusive behavior.
- In the UK, the first discussions about elder abuse occurred in the mid 1970s, although no systematic research on the topic was completed until the early 1990s. Thereafter, there was a significant growth of interest, with research reviews and surveys (Ogg & Bennett 1992), the development of pressure groups (notably Action on Elder Abuse), and guidelines designed to protect vulnerable adults (e.g., Department of Health 2002).
- Among researchers and practitioners there has been extensive debate about the precise nature of abuse and neglect, with a range of definitions circulating in the literature. Following the work of Wolf and Pillemer (1989), the main elements of elder abuse are generally agreed to comprise:
- *Physical abuse*: the infliction of physical harm or injury, including physical coercion, sexual molestation, and physical restraint.

elder abuse

Chris Phillipson

- *Psychological abuse*: the infliction of mental anguish.
- *Financial abuse*: the illegal or improper exploitation and/or use of funds and resources.
- *Active neglect*: the refusal or failure to undertake a caregiving obligation (*including* a conscious and intentional attempt to inflict physical or emotional distress).
- *Passive neglect*: the refusal or failure to fulfill a caretaking obligation (*excluding* a conscious and intentional attempt to inflict physical or emotional distress).

Glendenning (1997) concluded from his review that a number of uncertainties still surrounded definitions of elder abuse. These he identified as (1) the relationship between domestic and institutional abuse; (2) the issue of whether elder abuse can be clearly differentiated from the abuse of other adults; and (3) the relationship between neglect and other forms of abuse.

A limited number of studies have been carried out attempting to provide estimates of the prevalence (total number of cases) and incidence (new cases) of abuse and neglect. The first major prevalence study was the Boston study of Pillemer and Finkelhor (1988), which involved interviews with 2,000 older people and focused on three types of maltreatment: physical abuse, verbal aggression, and neglect. The study found that slightly more than 3 percent of the population aged 65 plus had been mistreated: 20 cases per 1,000 were physically mistreated; 11 per 1,000 were psychologically abused; and 4 per 1,000 were neglected. The authors estimate that if a national survey produced similar results, such numbers would represent almost 1 million people in the US.

A UK survey with a nationally representative sample conducted in 1992 by Ogg and Bennett (1992) reported on results from interviews with almost 600 people aged 65 and over, as well as 1,366 adult members of households in regular contact with a person of pensionable age. The study focused on older people's experience of physical, verbal, and financial abuse with family members and relatives. Approximately 5 percent of older people (60 plus) had experienced psychological (verbal) abuse, and 2 percent

reported physical or financial forms of abuse. Adults in contact with elderly people were asked whether they had recently found them selves "shouting at, insulting or speaking roughly to them or pushing, slapping, shoving or being rough with them in any other way." Responses indicated verbal abuse of older people running at 9 percent, but a lower rate of physical abuse (less than 1 percent).

The most detailed survey to date has been the American National Elder Abuse Incidence Study (NEIS) conducted in 1994–8, which focused on abuse and neglect of older people 60 years and over living in non institutionalized settings. The objective of the study was to collect reports of a random sample of cases of abuse and neglect occurring within a specified time period that could be weighted to represent annual estimates of *incidence* for the nation as a whole (Thomas 2000). Findings identified 450,000 older people experiencing abuse and/or neglect in domestic settings; taking account of self neglect increased the figure to 551,000. Of these, women were abused at a higher rate than men; the very elderly (80 plus) stood out as the most vulnerable age group; and perpetrators were most likely to be adult children and spouses.

In general, studies have found that risk of abuse appears to be higher for those older people living with someone and who have problems linked to mental or physical incapacity. Perpetrators are invariably presented as experiencing stress and/or social isolation. An under researched area concerns abuse and neglect of older people in residential care homes. McCreadie and Tinker (2003) cite research in 57 residential and nursing homes in the US which found that 10 percent of staff admitted to at least one act of physical abuse in the preceding year, with excessive restraint as the most frequently recorded form. Staff reported a very much higher rate of verbal abuse in comparison to physical abuse.

Attempts to define and map the extent of elder abuse indicate that it should not be viewed as a single, monolithic phenomenon, but that it takes a variety of forms in different settings and in different kinds of relationships. Victims and perpetrators exhibit a variety of characteristics depending on the nature of the

abuse. From a sociological perspective, elder abuse must be located across a number of levels, including familial, institutional, and societal. Research has tended to focus on the first of these, drawing on models of family violence. But institutional settings such as residential homes are also important and may generate different types of abuse and neglect. Finally, it is important to acknowledge the extent to which abusive situations are themselves socially created, through poverty, inadequate community care, and ageism within society. Informal care and family care in particular may be affected by inequality in later life. The tendency has been to focus on the influence of "family pathology" in creating certain types of abuse. But highlighting the role of individual families ignores wider issues about the labels attached to older people and the resources available to them to resist mistreatment. Attention to these broader issues is vital for a proper understanding of the range of factors influencing abuse and neglect in old age.

elder care

Norah Keating

Elder care is assistance provided to a senior because of that senior's chronic health problem or disability. Tasks include household work, indoor and outdoor home maintenance, banking and financial management, personal care, and care management (Keating et al. 1999). The term has been part of the gerontology lexicon for many years. Its origins lie in the description of the tasks provided by formal or paid caregivers (i.e., nurses or home support workers) to seniors with chronic illnesses such as dementia. More recently, the term has also been used to describe family members and friends who care for frail older adults. In contrast to formal caregivers, their care is called informal. Tasks done by these formal and informal caregivers are not unique and may be provided to younger adults as well. While adults over age 65 are considered seniors, in contemporary discussion elder care denotes assistance to those who are very old. In developed countries, onset of age related chronic illnesses is prevalent after age 75 and most people in residential (nursing home) settings are over age 80.

Formal and informal caregivers to frail seniors differ in a number of ways. Formal caregivers have an agency-client relationship based on an agreement to provide services, most often for pay. The services they provide in community settings are discrete, based on the mandate of the organization and time limited. In residential settings services are provided to support the health and daily living needs of frail older adults; in these settings employees are more likely to provide a variety of tasks. In contrast, family members and

friends provide care because of the personal history that exists between giver and recipient – one that is based on kinship, other affective ties, or a longstanding relationship. These care givers spend most time on household tasks and personal care that help keep seniors at home. If the senior is placed in residential care, their tasks shift toward care management, which includes monitoring and managing formal care and visiting (Keefe & Fancey 2000).

Kinship ties make family members more obliged to help; spouses and adult children are the most common family caregivers, though more distant kin such as nieces, nephews, and grandchildren also assist. About 20 percent of informal caregivers are friends and neighbors who are most likely to provide tasks other than personal care or to give high levels of assistance in the absence of kin (Wenger 1997).

Providing care to increasing proportions of frail seniors is one of the challenges of a world wide trend toward population aging. A contemporary approach to this challenge is reducing the amount of residential and formal care and shifting toward an emphasis on community based care with high levels of family friend involvement (Ward Griffin & Marshall 2003). This approach has been called sending care home. Care in the community is seen as more responsive to the needs of frail seniors because it is provided in familiar settings by people who know them best. Yet community care has costs to informal caregivers who provide the majority of this care and whose work is likely to be unpaid, invisible to others, and who may receive little respite from their caregiving duties. Countries are engaged in debates about the ideal mix of public/family friend elder care services and have found different solutions. For example, Scandinavian countries have higher levels of publicly funded elder care services than do countries in Southern Europe. In community settings in Canada, informal caregivers provide substantially more assistance to frail seniors than formal caregivers, often caring for more than 2 years with multiple caregiving responsibilities for seniors and others. Almost one quarter of frail seniors receive no care from either formal or informal sources.

The terms elder care, care giving, and informal care are controversial. Elder care is viewed

as a useful concept in fostering recognition of the support needed by frail older adults and raising awareness of the activities and commitments of their caregivers. Yet elder care also has been criticized as having connotations of decline, disease, and illness which have become associated with aging (Sims Gould 2005). Though this is not always understood, elder care is meant to denote a response to frailty in old age, not to old age itself. The term caregiving is broader in scope and is useful in distinguishing everyday exchanges of support from tasks provided in response to a chronic health problem. Caring families who are concerned about their older family members are not the same as caregiving families who do things for their older relative because of that person's chronic health problem and in order to help the person maintain their independence. Yet the word caregiving is criticized because it seems unidirectional, placing frail seniors as passive recipients of tasks rather than as members of social groups which evolve, have complex interactions and provide to, as well as receive from, others in the group (Guberman & Maheu 1999). The term informal caregiver was created to provide a clear contrast to those whose caring work was designated as formal. Because of the intensity and duration of care, the term family/friend care increasingly is used as an alternative to informal, which can denote involvement that is casual, intermittent, or periodic.

New directions in understanding elder care are addressing some of these controversies. These include considering how groups of family members and friends organize to provide care and focusing on caregiving as a career rather than a static situation.

Current knowledge of elder care is based primarily on studies of dyads of individual family friend caregivers and care recipients. The term primary caregiver comes from this tradition. A single caregiver, normally a family member, is identified as the main provider of services to the frail senior. This approach, while convenient, has led to a view that elder care is the domain of women and close kin.

Researchers have begun to analyze how groups of people with social or kin ties to older adults organize themselves to provide care.

Networks differ on a number of dimensions, including network size, age and employment status composition, and proximity to the frail senior, as well as proportions of kin and friends and women and men (Litwin & Landau 2000). Men are just as likely to be part of elder care networks as women, but they do different tasks such as home maintenance, while women are most likely to do household work and personal care. Some networks have substantial proportions of friends and distant kin, as well as close kin such as adult children. Half of frail seniors with family friend care networks receive formal care as well.

Increasingly, elder care is seen as an evolution of previous patterns of family interaction. Viewing caregiving as part of family solidarity and interaction over time shows how elder care emerges from families' history of relationships with one another. It provides a dynamic view of how caregiving changes in response to health or other transitions (Martin Matthews 2000) and of which family members and friends can sustain support as it evolves into more intensive elder care. This information is important in intervening to support family friend caregivers. Families with a history of difficult relationships may not do well in the intense task and intimacy requirements of elder care. Their relatives may be better served by receipt of care from formal services.

Elder care research is moving toward more qualitative studies to create deeper understandings of the experiences of caregivers and of the frail seniors for whom they care. Understanding their experiences is providing better conceptualizations of how social networks evolve into care networks and which frail seniors are likely to be without care. Further methodological development will help move elder care research from dyads to networks so that the sharing of care can be better understood. Rural researchers have begun to examine how communities might differ in creating supportive environments for older adults with chronic illness. This research also needs to include a time dimension to track changes in supportiveness of communities over the lifetime of adults who live there. Analyses of the interactions of family friend, formal, and community networks

are needed to have a more complete view of the contexts and sources of elder care.

elective affinity

J. I. (Hans) Bakker

The term elective affinity is currently associated with Weber's thesis concerning modern capitalism. A key aspect concerns the linkage, attraction, or inner "affinity" between "the Protestant Ethic/Protestant sects" and the "spirit" of modern capitalism. The idea of an affinity could be indicated by any two factors seeming to go together – to be "connected." Weber argues that there is an "inner affinity" (*innere Verwandtschaft*) between several things, especially between (1) a this worldly asceticism of sects (e.g., Quakers, Mennonites) and (2) the underlying "spirit" (*Geist*) of modern capitalism. Rather than hedonism, among Protestants there is an ascetic outlook, an estrangement from joy, as indicated by Benjamin Franklin's maxims.

The modifier "elective" is a vestige from Albertus Magnus, Scholasticism, Galileo, and the Latin of chemists like T. O. Bergman: *attractio electiva simplex* or *affinitas electiva*. The German term *Verwandtschaft* alone means "affinity," but the classical Latin phrase "elective affinity" had an impact on Goethe (Adler 1990). The term Elective Affinity (*Wahl verwandtschaft*) became a title for one of Goethe's romantic novels about marriage and "chemical" erotic attraction. Weber greatly admired Goethe and accepted an epistemology that stresses complexity rather than reductionism in the study of social action. Weber does not presuppose the same ontology as Goethe, but he used Goethe's word knowing his readers would understand the implicit referent. However, it gets lost in translation.

Many thinkers have been critical of Weber's thesis. Some critics have assumed that Weber's argument is a temporal, *causal* argument concerning the effects of an ethos on a material mode of production. Cohen (2002 29, 79–89) provides a thorough statement of the elective affinity argument in terms of "degree of similarity" and "rational effects," but concludes critically that "Weber's method of elective affinities can do nothing to sort out the causal ordering." The lack of possibility of a temporal causal argument is already emphasized in Weber's 1905 statement (Weber 2002a), published at the

same time as his famous methodological essay on "Objectivity." Weber was attempting to avoid positivistic causal argumentation of the sort characteristic of dialectical materialism. He was not attempting to replace a one sided materialist argument with an equally misleading one sided idealist argument. Since statistics had not yet been invented there was no universally agreed term to represent the notion of an "association" or "co relationship" between two factors or variables.

elementary theory

Pamela Emanuelson

Consistent with the classical theories of Marx, Weber, and Simmel, elementary theory is a multilevel theory of interaction in social relations. For example, elementary theory (hereafter ET) predicts power exercise, who benefits in

social relations such as exchange, coercion, and conflict. ET's actor level assumptions are (1) that actors pursue valued states called interests within social relations and (2) that an actor's interests can be inferred from the social relations and structures in which activity occurs. On a structural level, ET embeds social relations in social structures, which consist of two or more connected social relations. Social structures are in turn characterized by rules and restrictions, including but not limited to rules delimiting the maximum and minimum number of exchanges at a position and rules mandating the sequence of social interaction across a structure. ET makes predictions in light of the interrelations among relational and structural conditions and actor's interests.

Willer and Anderson (1981) demonstrated that ET predicts action in a diversity of social structures ranging from legal systems to political networks to several distinct community systems. Through an interactive process involving the relaxation of scope conditions, the discovery and conceptualization of new structural conditions, theory integration, and experimental testing, ET expanded beyond its original formulation in 1981 to predict action in increasingly complex structures. Major contributions made to the growth and development of ET include the discovery of new structural conditions (Patton & Willer 1990; Szmataka & Willer 1995; Corra & Willer 2002), the conceptualization of distinct network types (Markovsky et al. 1993; Lovaglia et al. 1995), and bridging between ET and status characteristics theory (Willer et al. 1997; Thye 2000). Recent growth in ET addresses the phenomenon of power at a distance (Willer 2003; Emanuelson & Willer 2003) and the effects of coalition formation on power exercise (Borch & Willer 2006). ET continues to grow with the goal of achieving a fully general theory of human behavior in relations and structures. To date, ET applies a modeling procedure, two principles, two laws, and seven structural conditions to predict action in relations embedded in structures.

MODELING PROCEDURE

ET uses network models to conceptualize relations in social structures. For instance, letters

Figure 1 Exchange relations.

such as A and B represent social actors. Paired signed arcs connecting social actors represent ing sanctions form social relations. The positive and negative signs at each end of the arcs represent the effect of transmitting or receiving. Signs at the receiving end of a sanction differentiate positive and negative sanctions. For instance, in Figure 1(a), the receipt of a positive sanction from A increases B's preference state but transmitting that positive sanction is costly and decreases A's preference state. Pairing negative and positive sanctions results in the three basic social relations, exchange (Fig. 1a), coercion (Fig. 1b), and conflict (Fig. 1c).

PRINCIPLES AND LAWS

Principle 1 defines ET's actor model. It asserts that *all social actors act to maximize their expected preference state alteration*. For instance, employees seek to maximize wages while employers seek to minimize wages. The first law is a payoff function. For employee j , Law 1 states that the payoff to j equals the value per unit times the quantity of money received plus the value per unit times the quantity of labor expended. Although Principle 1 accounts for employers' and employees' interests, determining the wage agreed upon requires a principle that applies to mixed motive relations.

In mixed motive relations both actors (1) prefer agreement to disagreement and (2) seek to increase their preference state at the other's expense. In the above example, when the payoffs to employer and employee are both positive, both benefit from continuing the relation, and the wage changes that increase the employers' benefit decrease the employees' benefit and conversely.

In this and other mixed motive relations, ET applies Law 2, resistance. An actor's resistance is the ratio of an actor's interests. The numerator represents the interest in receiving the best possible payoff while the denominator represents the interest in avoiding disagreement.

Assume that an employer breaks even when paying \$16/hour of work and assume further that dollar bills are not divisible. Then the maximum for an hour of work is \$15. If j , the employee, does not reach an agreement with the employer, j receives nothing. The employee's resistance takes into consideration the \$15 maximum benefit and the \$0 payoff at confrontation. The employer k 's resistance for both of his/her relations is determined in a like manner.

Principle 2 sets the resistance of two actors equal to each other. More specifically, Principle 2 states that *agreements occur at the point of equiresistance for undifferentiated actors in a full information system*.

STRUCTURAL CONDITIONS

ET asserts that structural conditions affect relations embedded in social structures. The theory (1) identifies seven structural conditions and (2) offers point predictions for the conditions' effects on outcomes in exchange relations. For exclusion, the strongest, most widely studied, and tested structural condition, three distinct network types have been identified: strong, equal, and weak power. The three are discussed below. Other structural conditions are four connection types, null, inclusion, inclusion null, and inclusion exclusion, and two variants, hierarchy/mobility (a variant of exclusion) and ordering (a variant of inclusion).

A typology identifying the number of an actor's connections and the maximum and minimum number of relations in which an actor can benefit generates types of connection. For the employer example, N_k is the number of potential employees k can reach, M_k is the maximum number of employee relations in which k can benefit, and Q_k is the minimum number of those relations in which k must reach agreement to benefit from any one.

An actor is exclusively connected if $N > M$. For example, imagine that employer k can

reach j_1 , j_2 , and j_3 all of whom need employment. Employer k , however, needs and wants only one new employee. Since $N_k = 3$ and $M_k = 1$, two potential employees will necessarily be excluded and the relations are exclusively connected at k . When the j s have no alternative employment, the structure is strong power. Networks containing exclusive connection can also be weak or equal power.

Strong power networks are networks with one or more high power positions that are never excluded and two or more low power positions at least one of which is always excluded. Low power positions are connected only to high power positions. In strong power networks, high power positions gain maximally at the expense of low power positions. In the above example, the j s compete to be hired by k until the one j is hired to work for \$1/hour while k profits maximally at \$15.

Equal power networks are networks in which all positions are identically connected. It follows that either no position is excluded or all face an equal probability of exclusion. Since positions are identical, none has a structural advantage over any other and payoffs are equal to all.

Weak power networks include all networks in which power is produced by exclusion that are not equal or strong. In weak power networks, positions have different likelihoods of being included in an exchange relation. An actor's likelihood of being included is calculated under the assumption that actors seek exchange equally with all other connected actors. As network size increases, the difficulty of calculating likelihood values increases; however, an applet program for calculating likelihood values is available on the faculty web page of David Willer at the University of South Carolina.

The resistance likelihood assumption asserts that the actor's evaluations of best possible payoff and confrontation payoff vary with the likelihood of being included (Lovaglia et al. 1995). When V is the total value in the relation, the confrontation payoff ranges between 0 and $V/2$ and the best possible payoff ranges between $V/2$ and V .

Compound networks are composed of "sub networks," at least one of which is strong power: they break between the high power position(s) and position(s) which are never

excluded. All breaks occur at suboptimal relations, but not all suboptimal relations are breaks. A relation is suboptimal when exchange in it reduces the number of exchanges that can occur in the network. To predict the distribution of benefit, the first step is to find and remove breaks. Once they are found, the resulting subnetworks are solved individually.

Hierarchy/mobility is not a connection type: it is a variant of exclusion. Hierarchy/mobility occurs when each step up in a bureaucratic organization decreases the number of offices, increases the salary and perquisites associated with each office, and promotion is competitive. Hierarchy/mobility's competitive mobility centralizes power to the top. Applying hierarchy/mobility, the effects of discriminatory practices on organizations are apparent. For instance, if an organization discriminates against promoting women, no woman will have an interest in competing. Therefore, the power of upper offices over those women decreases and may also decrease over men because of reduced competition.

An actor is inclusively connected if more than one exchange is necessary to benefit: $Q > 1$. For example, if employer k needs both j_1 for specialized task s_1 , and j_2 for specialized task s_2 to benefit, k is inclusively connected. Actor k 's minimum number of exchanges is $Q_k = 2 > 1$. Inclusive connection increases the costs of confrontation for the inclusively connected actor, thereby decreasing that actor's power.

In inclusively connected networks, power differences increase sequentially. Assume that k exchanges with j_1 and j_2 in that order. The consequence of disagreement in the first exchange is that k and j receive nothing. Hence, the k - j_1 exchange is at equipower. In the k - j_2 exchange, k will lose the investment made in the first exchange if agreement between k and j_2 is not reached. In contrast, j_2 has invested in nothing and has a confrontation payoff of zero. k is less powerful than j . When $Q > 2$, across exchanges, the inclusively connected actor's investments increase, as does the potential cost of not completing the next necessary exchange. Consequently, the last position to exchange with the inclusively connected position is the most powerful.

Ordering is not a connection type: it is a variant of inclusion. An actor connected by

ordering must complete $Q > 1$ exchanges in a specified sequence. For example, ordering advantages gatekeepers. A gatekeeper controls access to valued goods that he or she does not own. For example, suppose that employer k has a secretary that determines which j s k interviews. If the secretary is dishonest, he or she can demand fees for admittance to the valued interview. The power exercised by the secretary varies with the value of the interview to the interviewees.

By definition, an actor disadvantaged by ordering must complete exchanges in sequence; however, the incidence of power effects in the sequence is the reverse of the incidence found for inclusive connection. For ordering, the largest effect is in the first relation and decreases across exchanges until, in the last exchange, the power is equal. In the above example, the secretary is in the first relation and is powerful because he or she can block j 's valued outcome.

Whereas for exclusive connection N_k the number of k 's relations is greater than M_k , the largest number of exchanges from which k can benefit, for null connection $N_k = M_k$. Therefore, when k is null connected to all j s, k can complete all k 's exchange relations and benefits from each. Actors have identical estimations of maximum possible payoff and payoff at confrontation. All actors and exchanges are equal.

Inclusion null and inclusion exclusion are each a single connection type which mixes qualities of two other types. For inclusion null $N = M > Q > 1$ but for inclusion exclusion $N > M \geq Q > 1$. Imagine that employer k needs at least two ($Q_k = 2$) of three ($N_k = 3$) j s to complete a project. If k hires all three j s ($M_k = 3$), the project will be completed faster. Since $N_k = M_k = 3$ and $Q_k = 2 > 1$, k is inclusive null connected. Because k need not necessarily include all three j s, any inclusive advantage is eliminated and the three exchanges are equal power.

Now imagine that k needs at least three ($Q_k = 3$) of four ($N_k = 4$) j s to complete the project, and k can hire a maximum of only three j s ($M_k = 3$). Since $N_k = 4 > M_k = 3$ and $Q_k = 3 > 1$, k is inclusive exclusive connected. Because k must necessarily exclude one j , any inclusive advantage is eliminated and k benefits maximally in each exchange.

COERCIVE STRUCTURES

Positions in coercive relations are distinct; one is the coercee and the other the coercer. The coercee is under threat of receiving the negative sanction while the coercer can transmit the negative sanction or receive positive(s) from the coercee. The coercer's power is based on the effect on the coercee of the negative sanction; the larger that effect, the larger the flow of positives at agreement. Resistance predicts that flow in applications is not unlike its applications to exchange.

The asymmetry in the coercive relation produces power differently for coercee central and coercer central structures. For example, imagine that coercee j has an option of three coercers, ks . The j must choose a coercer, but once chosen, j cannot be coerced by any other ks . The ks will bid against each other until j pays the minimum possible for protection. In this coercee central structure, exclusion produces power like it does in exchange. Now imagine that k is connected to three js . The js are told that the j that does the least work will receive a negative sanction. In fact, this is a strong coercive structure in which the js compete to not be the least productive and k benefits maximally.

DIFFERENTIATED ACTORS IN EXCHANGE

Status value theory bridges between ET and status characteristics theory, a theory of status and influence, to make predictions in exchanges that include actors differentiated by status. Status value theory assumes that resources of high status actors are valued more highly than resources of low status actors. As a consequence, high status actors gain favorable outcomes. A recent advance in ET combines values quantifying status effects into resistance equations to make point predictions for exchange outcomes in networks with status differentiated actors.

Current research seeks to link legitimacy theory to ET. The goal is to determine whether legitimacy of coalitions in exchange networks affects actors' willingness to join. Coalitions are organizations of individuals that act as a single actor. Previous research has shown that

coalitions substantially improve payoffs to low power actors. At issue in research now being conducted is whether legitimacy stabilizes coalitions by resolving first and second order free riding and thus countervails power.

THE EFFECT OF RESOURCE MOVEMENT ON EXCHANGE

ET offers predictions for networks where resources move only between adjacent positions (discrete networks), and networks where resources move across a network (flow networks). The structures discussed above were all discrete networks. Nevertheless, the structural conditions discussed above also apply to flow networks. In a flow network, k sells X to j and j sells the X bought from k to h . Since only k starts out with X , and k is not connected to h , for h to receive X the sequence of exchange is determined: first k - j and then j - h . Therefore, ordering affects power in the first relation. Since $Q_j = 2$, j is disadvantaged by inclusion in the j - h relation. Whereas all flow networks contain ordering in first exchange and inclusion in the second, exclusion can mask their effects. For instance, if j was connected to two ks and j could buy X from only one, exclusion would mask the effect of ordering and j would pay the minimum price for X .

Predictions for flow networks take into consideration the structural conditions of exclusion, inclusion, and ordering, and the effect of sequence in reducing value available for negotiation in exchange relations across a flow network. As the resource X moves across the network, the total value of exchanges in the network is the difference between X 's initial and final value. In each exchange relation, some of that value is appropriated. For example, let h value X at \$16 and let resources be highly divisible. Suppose j pays k \$8 for X . Now the value available for negotiation has reduced from \$16 in the first exchange to \$8 in the second. Thus, the most j can make selling X to h is \$8 or the most h can profit is \$8.

CONCLUSION

ET is still growing. Initially, its applications were largely limited to micro level structures.

Now, research on coalitions and flow networks is applicable to complex meso and macro structures such as bureaucratic organizations and interorganizational networks. Furthermore, most work in ET uses experimentation with the aim of building strong theory. The rigorously tested and scope expansive theory is now useful for applications outside the laboratory. Lastly, much of the recent growth in ET has focused on networks of exchange relations. ET would benefit from new research aimed at examining coercive and conflict networks.

Elias, Norbert (1897–1990)

George Ritzer and J. Michael Ryan

Norbert Elias was born in Breslau, Germany in 1897. He was the son of a small manufacturer and was brought up in comfortable surroundings. After serving in the German Army during World War I, Elias returned home to study medicine and philosophy at the University of Breslau. It was his study of medicine that gave him a sense of the interconnections among the

various parts of the human body that would be so important to shaping his understanding of human interconnections – what he would term figurations. Elias received his PhD in 1924 and then went to Heidelberg, where he became very actively involved in sociology circles, most notably one headed by Marianne Weber. He also became friend and assistant to Karl Mannheim. This relationship led Elias to follow Mannheim as his official assistant to the University of Frankfurt in 1930.

After Hitler came to power in early 1933, Elias and many other Jewish scholars (including Mannheim) left Germany, first for Paris and later for London. Elias's most famous book, *The Civilizing Process*, was published in Germany in 1939. Unfortunately, there was no market in Germany for a book authored by a Jew and it also received little attention in other parts of the world. During the war and for nearly a decade after it ended Elias could not obtain secure employment and remained a marginal figure in British academic circles. In 1954, however, Elias began his career (at the age of 57) at the University of Leicester. He remained unpopular, however, among both faculty and students and during his time there none of his books were ever translated into English. However, during the 1950s and 1960s on the Continent, particularly in the Netherlands and Germany, Elias's work began to be discovered. It was during the 1970s that Elias's work began to receive both academic and public attention in Europe. This recognition is still growing today throughout the world. Elias died at the age of 93, living just long enough to bask in the early years of the much delayed recognition of his work.

FIGURATION

Elias proposed the concept of figuration as an alternative to thinking of the “individual” and “society” as different or antagonistic (Elias 1978). Figurations are not static, but instead are social processes. In fact, during the latter part of his career, Elias chose the label *process sociology* to describe his work (Mennell 1992: 252). Figurations involve the “interweaving” of people. They describe the relationships between people rather than describing a type

of structure which is external to or coercive over people. In other words, individuals are viewed as open and their relationships with one another compose figurations. Figurations are in a state of constant flux because of the changing nature of power, which is central to their understanding. They develop in largely unforeseeable ways.

The idea of a figuration is a broad one in that it can be used to apply to the micro and the macro, and to every social phenomenon in between. This image is best represented by Elias's notion of “chains of interdependence,” which constitute the real focus of his work.

CIVILIZATION

In addition to figurations and chains of interdependence, Elias's work is largely concerned with the “sociogenesis” of civilization, especially in the Occident (Bogner et al. 1992). In particular, Elias (1997) is interested in what he perceives to be the gradual changes that have occurred in the behavioral and psychological makeup of those living in the West. In his study of the history of manners, for example, Elias is concerned with the historical transformation of a wide array of rather mundane behaviors which have culminated in what we would now call civilized behavior. Some of the behaviors which most interest Elias include what embarrasses us, our increasing sensitivity, how we have grown increasingly observant of others, and our sharpened understanding of others.

Elias uses books (and other sources) on manners written between the thirteenth and nineteenth centuries to get at these changes. He concludes that our threshold of embarrassment has gradually advanced. For example, what people did at the dinner table in the thirteenth century – passing gas, for one – would cause great embarrassment to one in the nineteenth century (and twenty first century as well). Thus, that which is considered distasteful is over time increasingly likely to be “removed behind the scenes of social life” (Elias 1994a: 99). In another example, one thirteenth century poem warns, “A number of people gnaw on a bone and then put it back in the dish – this is a serious offense” and another volume states: “It is not decent to poke your fingers in to your

ears or eyes, as some people do, or to pick your nose while eating” (pp. 68, 71). The implication is that such behaviors were typical at that time and did not cause those who engaged in them much embarrassment. These texts provide admonitions against such behavior in an effort to “civilize” people. As time goes by, the knowledge that these things are not appropriate spreads throughout society and there is no longer a need to remind people that such behavior is inappropriate. Thus, a late sixteenth century document says: “Nothing is more improper than to lick your fingers, to touch the meats and put them into your mouth with your hand, to stir sauce with your fingers, or to dip bread into it with your fork and then suck it” (p. 79). Of course, there are some things (e.g., picking one’s nose) that are deemed more improper than others (e.g., licking one’s fingers), but by this time civilization has already progressed to the point where it is widely recognized that such behaviors are uncivilized. With certain behaviors safely behind the scenes, society then moves on to find other, less egregious behaviors that it defines as uncivilized.

POWER AND CIVILIZATION

In *Power and Civility* (1994b) Elias is concerned with changes in social constraint that are associated with the rise of self restraint, the real key to the civilizing process. The most important of these social constraints is the macrostructural phenomena of the lengthening of interdependency chains. This also contributes to the corresponding need for individuals to moderate their emotions by developing the “habit of connecting events in terms of chains of cause and effect” (p. 236). Thus, the ever increasing differentiation of social functions plays a central role in the process of civilization. In addition and in conjunction with this differentiation is the importance of “a total reorganization of the social fabric” (p. 231). This is how Elias describes the historical process of the emergence of increasingly stable central organs of society that monopolize the means of physical force and taxation. Central to this development is the emergence of a king with absolute status, as well as of a court society. Elias is especially interested in the case of France during the

reign of Louis XIV, although he points out that the courts of Europe all came to be closely linked. What Elias calls a “royal mechanism” is operating here in that kings are able to emerge in a specific figuration where competing functional groups are ambivalent (they are characterized by both mutual dependency as well as mutual hostility) and power is evenly distributed between them, thus prohibiting either a decisive conflict or a decisive compromise. As Elias puts it, “Not by chance, not whenever a strong ruling personality is born, but when a specific social structure provides the opportunity, does the central organ attain that optimal power which usually finds expression in strong autocracy” (p. 174). In other words, a king emerges only when the appropriate figuration is in place.

The king and his court were of particular importance to Elias because it was here that changes took place that would eventually affect the rest of society. The court noble was forced to be increasingly sensitive to others while simultaneously curbing his own emotions because, unlike the warrior, his dependency chains were relatively long. The noble was further restrained in that it was the king alone who was gaining increasing control over the means of violence. This monopoly of violence, in turn, is strongly related to the king’s ability to hold a monopoly over taxation, since it is taxes that allow the king to pay for the control of the means of violence (p. 208). The noble is further disadvantaged in that while taxes increase the king’s income, they reduce the nobility’s, further enhancing the power of the king (Elias 1983: 155). The nobles play an important role in the civilizing process because they carry the changes from the court to the rest of society. Further, changes in the West are eventually spread to other parts of the world. Thus, the rise of the king and his court and the shift in importance from warrior to courtier represent a key “spurt” in the civilizing process. This idea of a spurt is how Elias deals with social change – it is not an even, unilinear process, but rather one that stops, starts, and goes back and forth.

Despite the importance of the king, the nobles, and the court, the ultimate cause of the most decisive changes is related to the changes in the entire figuration of the time. In other words, the real importance of change is

found in the changing relationships between groups, as well as those between individuals in those groups. Further, this figuration ends up constraining both the king and the nobility, as there is a gradual movement toward a state. It is the private monopoly of the means of violence and of taxation (by the king) that sets the ground for a public monopoly of those same resources (by the state). The rise of the controlling agencies in society is linked to the rise of the controlling agencies within the individual. These two processes work in tandem to wield unprecedented power over individuals' ability to act on their emotions. That is not to say that individuals before this time were completely unrestrained and emotionally flamboyant, but rather that self control and moderation became increasingly important in constraining people's emotional lives. Elias recognizes that this increasing control is not entirely good. While life has become safer (fewer people act out violently), it has also grown less enjoyable. Unable to express their emotions directly, people turn to alternative outlets such as dreams and books to express themselves. Further, external struggles become increasingly internalized as (to use Freud's terms) battles between the id and the superego. Thus, a reduction in violence is accompanied by an increase in boredom and restlessness.

Longer dependency chains are thus ultimately associated with greater control of emotions and a simultaneous increasing sensitivity to others. This causes people's judgments about one another to become more finely nuanced and they are better able to control both themselves and others. With a reduction in the fear of violence and death, people turn their concerns to more subtle threats. This increasing sensitivity is a key contributor to the civilizing process and its continuation.

Another important aspect of the civilizing process is the socialization of the young to develop appropriate self restraint. This increase in self restraint, however, is also accompanied by problems, as "the civilizing of the human young is never a process entirely without pain; it always leaves scars" (Elias 1994b: 244).

elite culture

Adrian Franklin

Elite culture can be defined as those "high" cultural forms and institutions that were exclusive to, and a distinguishing characteristic of, modern social elites. It is a term that particularly references the cultural tastes of the established aristocracy, the commercial bourgeoisie, educated bureaucrats and political power brokers, and the professions in the eighteenth, nineteenth, and twentieth centuries. Over most of this period such groups dominated those who consumed and supported such cultural styles as opera, symphony orchestras, ballet and dance companies, the decorative arts, fine art, museums and galleries, and the literary end of live theater. While these forms all thrive in contemporary times, it is no longer clear that elite culture can be distinguished from popular culture in the way it was before the mid twentieth century (Blau 1986, 1989). While sociologists still identify the power and significance of social elites and their relatively closed cultural domains, their exclusive grip on elite culture has relaxed while at the same time they have become more *omnivorous* in their taste and now consume widely and freely from all styles, from the lowbrow to the highbrow. At the same time, new styles that blur elite and

popular cultural forms emerged from around the 1960s: the Beatles, for example, combined African American rhythm and blues with British working class "brass band," with western elite orchestral and strings, *and*, in places, with traditional Indian music. In turn, their audience base spanned the entire social spectrum. Artists such as Andy Warhol and Damian Hurst produced other such blurring or fusions and are credited with popularizing modern art.

According to Raymond Williams (1981: 97), the word *elite* does not emerge until the mid eighteenth century but was more commonly in use around the early nineteenth century. It was used to express social distinction by rank and Williams argues that its emergence can be attributed to a crisis over leadership. As he says: "there had been a breakdown in old ways of distinguishing those best fitted to govern or exercise influence by rank or heredity, and a failure to find new ways of distinguishing such persons by formal . . . election." Secondly, in response to socialist arguments about rules by class and class political conflict generally, it was widely argued that elites were more effective than classes (for example, by the Italian sociologists Pareto and Mosca). It is no accident therefore that this elitism, and the elite culture it produced, soon drew a cultural drawbridge up to distinguish itself from and cut out the "others." This is evident in Kant's "principle of pure taste," which identified absolute aesthetic value and valorized refinement, the attainment of virtuosity, and educated reflection over the popular, easygoing, immediate, simple, or traditional. But as Bourdieu argued, pure taste and its aesthetics were based on a *refusal* of the vulgar, simple, primitive, or popular and therefore constituted a *social* device or techniques of distinction. In the nineteenth century particularly, and long into the twentieth century, considerable energy was put into the creation of "high" cultural institutional development. At the same time, those low cultural forms which had hitherto been part of mainstream everyday culture were undermined and devalued as shallow and vulgar.

In the second half of the twentieth century, the possession of education (or what Bourdieu calls *cultural capital*) which distinguished the social elite became more commonplace through mass secondary education and the expansion

of the universities. Hitherto the social elite had been a relatively closed and circumscribed social group, sharing not only culture in common but also background, schooling, social networks, and experience. However, from the 1960s many from non elite backgrounds were being recruited into elite positions and making it in the culture industries and professions. It was this generation that reclaimed the cultural value and aesthetic depth of popular culture and placed it on an equal footing with elite culture. Meanwhile radio, television, and other media alongside new electronic technologies made elite culture more available to a wider audience and popular culture more popular with the elites. From the 1970s onwards, while it is still possible to identify elite culture, it has become more entwined in a broadening of popular, indeed globalized culture (DiMaggio 1997) and has now been identified in a new class formation, what Florida (2002) calls the *creative class*.

This is reflected in sociological surveys of consumer taste. Peterson and Kern (1996) looked at musical taste in the United States and found that highbrow consumers (those who mainly like opera and classical music) are increasingly consuming middlebrow (say, musicals) and "lowbrow" (country music, rock and pop). However, as with Bourdieu's pathbreaking book *Distinction*, a study of cultural taste in France, it is still possible to detect broad patterns of taste based on different combinations of cultural and economic capital and the habituses in which they combine. In Australia, an other survey modeled on Bourdieu's (Bennett et al. 1999) found the cultural elite still cultivated a taste for highbrow cultural forms. So, while two thirds of those with minimal education could identify only two classical composers from a list of ten music works, almost half of those with higher degrees knew eight or more. In broad terms, Bourdieu's distinction thesis was found to be true for Australia. However, an important caveat was that "the entire configuration of relations in our sample appears to have been skewed towards cultural forms which in Bourdieu's terms are 'popular,' devalued, or of diminished aesthetic value. Moreover, class judgments of taste seldom display a logic that is separate from the confounding effects of age and gender."

elites

Jaap Dronkers and Huibert Schijf

"History is a graveyard of aristocracies." With this phrase the Italian Vilfredo Pareto, who introduced the word elite in social sciences, formulated his idea of the decline and fall of elites, especially the political elite. For both him and Gaetano Mosca, the second founding father, the key concept was the circulation of elites (Bottomore 1993: 35). Many of these early writings on elites have a moral trademark. This can be seen in Machiavelli's *The Prince* (1513), where he gives a somewhat cynical but insightful analysis of the behavior of a ruler, but also provided instructions on how to act.

Theoreticians like Pareto and Mosca, but also the German Robert Michels (who formulated the famous "iron law of oligarchy" based on the inevitability of minority rule within the German Social Democratic Party), hold strong opinions on how elites should act and how their positions can be justified. The rightful behavior of elites is still, of course, fiercely debated in the public arena, but less so in modern social research on elites.

Today, the word elites is used in a very wide sense, for instance by speaking of a "sport elite." Nevertheless, in modern studies, elites are usually defined as the incumbents of top positions in both the public and private sector, like members of parliament or boards of executives. The focus is on the individual characteristics of these incumbents, the extent to which they are interconnected with each other, or the chance that people with certain characteristics are able to obtain such an elite position. However, the problem of sampling is transferred from individuals with high qualities to institutions (their influence in society is sometimes debated).

Information on elites (after all, public figures who draw much attention from the media) is easy to collect. Biographical summaries abound, both for the public and private sector, but publications like *Who's Who* are always a collection of persons where the criteria of inclusion of people, the rich and famous, very much depend on the bias of the editors and the information does not always have the quality required for thorough social research. However, many printed sources exist and are useful in situations where specialized surveys or interviews are difficult and certainly expensive (Moyser & Wagstaffe 1987; Bürklin et al. 1997).

By emphasizing the circulation of elites, Pareto and Mosca tend to underestimate the potential of elites to adapt to changing circumstances. Today, questions about openness or closeness of certain institutions and the chance that a particular person with certain characteristics will occupy an elite position are at the top of the agenda for sociological elite studies. Such investigations can be incorporated into the wider field of social stratification and mobility. Thus, the French sociologist Pierre Bourdieu emphasizes the process of *reproduction* of elites through scholarly and cultural capital and

spends much time in describing the French elite schools, les *Grandes Écoles*. A large study conducted by Bürklin et al. (1997) on members of the German elites in several public and private sectors tried to answer the question of whether elites from East Germany have been integrated into the local and national elites from West Germany.

Studies on elites can be summarized by means of two dichotomies. The first is directed to questions on *horizontal* and *vertical* integration. A classical study on horizontal integration of the American elite is C. Wright Mills's *The Power Elite* (1956). Mills wanted to show that the governmental, military, and business elites – all male, white, and Christian – are highly interconnected. The term *pantouflage* is used in France to describe the quite common shift of the French governing elites from the public to private sector and vice versa. In societies with cleavages along religious lines elites from each group are sometimes able to cooperate at the national level. On the borderline between studies of corporate networks based on linkages between corporations, created through multiple functions of some members of the boards of executives, and elite studies, is work by Windolf (2002). Vertical integration deals with the question how representative are incumbents with respect to the population as a whole. Usually, they are not representative and elites prefer contacts among their own kind than with people 'below'. Much debate on the trust of citizens in democratic institutions can be seen in the light of a steady decline of vertical integration.

The second dichotomy is between an *individualistic* and a *structural* approach. The first emphasizes the characteristics of individual persons, while the latter focuses on the links between these individuals and larger structures ranging from family connections to common membership in an institution, past or present. Many studies within the individualistic approach focus on parliamentary representatives (Best & Cotta 2000), other political figures, or civil servants (Page & Wright 1999). Families can be seen as a separate research unit, where both approaches are incorporated. Harbor barons or industrial families sometimes show a great ability to stay in top positions, creating an almost dynastic continuity. In contrast to the

accepted open and meritocratic character of modern societies, research shows that the ability to obtain an elite position in the Dutch nobility, an elite based on birth, has hardly declined during the twentieth century, although nobility is often seen as a relic from the past in Dutch public opinion (Schijf et al. 2004).

Very much in the tradition of research on social mobility, the German sociologist Hartman (2002) looked at the social background of engineers, lawyers, and economists who finished their high school education in 1955, 1965, 1975, and 1985. He then examined who was able to reach an elite position later in life. His conclusion is that the openness of the German educational system has increased, but that this is not true for the chance of obtaining an elite position, which still depends on an appropriate high social background. This use of longitudinal data seems to be promising for elite research in the future, because this research focus on the chances of obtaining such an elite position for a large group of persons and therefore highlights the openness or closedness of a society as a whole.

During the twentieth century many members of local elites became members of national elites. Today, one can see rapid development of a global economy, increasing popularity of international business schools, and the availability of large scale international communication. Nevertheless, although rather scarce, research shows (e.g., Hartman 1999) that so far there are few indications of the rise of an international business elite. In the boards of executives in countries like France, Germany, Great Britain, and the US, the overwhelmingly majority of members of these boards have the same nationality as the countries where these corporations are located. The only exceptions are foreign subsidiaries. Many executives had educational careers in their country of birth. This might change in the future, but it is very likely that top managers will follow a mainly local career instead of a global one. With the development of the European Union and its institutions, there might be an international bureaucratic elite in the making, but that is still not certain.

Other research topics on elites are less developed. For instance, little knowledge is available about the lifestyle of the elites or the neighborhoods they live in. The study by Pinçon and

Pinçon Charlot (1989) on elite quarters in Paris offers an inspiring example of such research. The present research on elites also shows much emphasis on formal characteristics of incumbents. Far less information is available on how elites operate in (in)formal settings, or how the horizontal connections really work.

Evidence of much modern research shows that countries where no dramatic changes have taken place show a remarkable stability in their elites. Of course, the circulation of political elites often happens due to regular elections as part of the democratic process, but other groups or families turn out to be able to maintain elite positions over several generations by adapting to new circumstances.

Ellis, Havelock (1859–1939)

Jeffrey Weeks

Havelock Ellis, editor, critic, essayist, and pioneer sexologist, was born on February 2, 1859 in Croydon, Surrey. His father was a sea captain and rarely at home, so Ellis's mother was the dominant influence in his early life. She was an ardent evangelical Christian who had experienced a conversion at the age of 17, but Ellis early on slipped away from the more rigid aspects of her faith. He was provided with a basic education in private schools in south London, but his main education derived from wide reading. The crucial formative influence was his stay in Australia for four years from the age of 16.

Here, in the outback, in almost total isolation, he began to experience conflicts in his awakening sexual life and in his spiritual outlook. Born in the year of the first publication of Charles Darwin's *On the Origin of Species*, Ellis was a child of a new scientific optimism, unattracted to a religious world outlook which he saw as dying, but repelled by the absorption of science into a chilly utilitarianism. It was in this state of mind that he reread a book by James Hinton, a writer on political, social, religious, and sexual matters, entitled *Life in Nature* (1862). The book sparked a spiritual transformation. In particular, for the young Ellis, the belief that sexual freedom could bring in a new age of happiness helped direct him towards the scientific study of sex. To prepare him for this, he resolved to train as a doctor, and returned to London in April 1879 ready to face his new life.

His actual work as a doctor was spasmodic. During his training and in the years that followed his real preoccupation was with his literary and scientific studies. The London of the 1880s was a focus of intense intellectual and political ferment, and Ellis immersed himself in this new culture. Through his involvement in various progressive groupings he met many of the radical luminaries of the time. He began editing and writing, publishing essays on religion, philosophy, travel, and politics. However, Ellis was never a political activist. Even as a

well known writer in later life, giving his formal support to campaigns for sex reform, eugenics, abortion, and voluntary euthanasia, he was extremely reluctant to become involved in public controversy. It was in private involvements, through a vast daily correspondence, and by his voluminous writings that he exercised his influence. Even in his publications, his manner was often indirect, preferring, as he put it, to express the shocking things in a quiet, matter of course way, sugar coating the pill. Yet both his private life and his public writings had the potentiality to shock his contemporaries.

It was in these early years of incessant intellectual activity that Ellis began the two most important emotional involvements of his early life. The first was with the South African feminist author Olive Schreiner, already famous for her novel *The Story of an African Farm* (1883) when they met early in 1884. It is not clear whether their relationship was conventionally consummated. Ellis himself appears not to have been strongly drawn to heterosexual intercourse, and had a lifelong interest in urolagnia, a delight in seeing women urinate. The sexual ardor, certainly on Schreiner's part, appears to have soon cooled, though the emotional intensity remained. It survived Schreiner's return to South Africa in 1889, continuing until her death via an almost daily correspondence and occasional meetings.

Ellis's relationship with the woman who was to become his wife, Edith Mary Oldham Lees, began the year after Schreiner's departure, and was strengthened by a common interest in the work of Hinton. She too was a passionate woman, who, despite an intense mutual involvement with Ellis (he was to devote almost half of his autobiography to their relationship), pursued an independent life as a lecturer and writer. By Victorian standards the partnership was highly unconventional. Edith's emotional and sexual passions were primarily lesbian, and both she and Ellis were to have a series of close emotional involvements with other women, certainly sexual in Edith's case, more ambiguously erotic in Ellis's case.

By the early 1890s Ellis was ready to embark on what he regarded as his crowning achievement, *Studies in the Psychology of Sex* (1897–1910, with a seventh, supplementary,

volume in 1928). The series began with *Sexual Inversion*, the first serious study of homosexuality published in Britain. It was conceived as a collaboration with the poet and critic John Addington Symonds, himself homosexual, and anxious to promote a more tolerant climate towards homosexuality. He completed the book after Symonds's death in 1893, the first printing appearing in German, then in English in 1897 under their joint names. Ellis now became embroiled in an unfortunate series of events. First of all, Ellis was forced by Symonds's family to withdraw his co author's name from the book. The aftermath of the trials of Oscar Wilde was not the best time to publish a major text on homosexuality that might sully another aesthete's reputation. Then Ellis found himself caught in the web of a dubious publisher, and a subsequent trial of the secretary of the sexually progressive Legitimation League, George Bedborough, for selling the book. In the 1898 trial, which did not directly involve Ellis, the book was labeled a "certain lewd, wicked, bawdy, scandalous libel" and subsequently withdrawn from sale. Ellis was confirmed in his caution about getting involved in public controversy. More crucially, he determined thereafter that the *Studies* should be published in the US; no complete edition has ever appeared in Britain.

Despite this unfortunate beginning, the *Studies* were to prove enormously influential. The first volume set the tone. By collating all the available evidence, historical, anthropological, social, and scientific, the aim was to demonstrate that homosexuality (or inversion, his preferred term) was not a product of peculiar national vices or periods of social decay, but a common and recurrent part of human sexuality, a quirk of nature, a congenital anomaly. In line with what was then considered advanced thinking, his conviction of the biological origins of human behavior was to color much of his thought. First, he sought to establish the natural basis of human sexuality in all its forms; nothing that was based in nature could be seen as inherently wrong. But secondly, he attempted to reconcile these variations to what he regarded as the supreme biological origin and function of sex, the man wooing a woman for the purpose of reproduction. Though an advanced advocate of a woman's right to sexual fulfillment, his view of an essential female

passivity in sexual matters subsequently attracted sharp criticism, particularly as it appeared to subordinate female sexuality to male. His biological determinism was to lead him to give support throughout his life to eugenics, the planned breeding of the best, and to differentiate him from his great contemporary, Sigmund Freud. Yet despite his biological preoccupations, Ellis was no empirical scientist. His method was that of the naturalist, collecting facts from a vast variety of sources and presenting them in an ordered, but essentially descriptive fashion. As a result, he never established a scientific school. But for his progressive contemporaries he seemed a prophet of a more humane attitude to sex. Through the *Studies*, probably more read about than read, he became internationally famous as a sexologist, and a magnet for other would-be reformers.

On completing the sixth volume of the *Studies* Ellis wrote: "The work that I was born to do is done." In fact, many years of productive writing, and growing fame, lay ahead. He continued writing on sexual matters, including a textbook, *The Psychology of Sex* (1933). His various other interests were reflected in a number of collections of essays; and the publication of *The Dance of Life* (1923) for the first time made him a bestselling author. From the 1920s he also contributed short articles to American newspapers and journals, which did little for his intellectual reputation, but contributed significantly to his finances.

Edith Lees had died in 1916, after some years of growing ill health. In the last months she had secured a legal separation from Ellis, but her death left him emotionally bereft. His emotional life was not, however, over. From 1918 he shared his life with an acquaintance of Edith's, Françoise Lafitte Cyon, also known as Delisle (1886–1974), separated wife of a Russian journalist, and mother of two boys. As with Edith, for many years, Ellis retained his own home, and each of them continued to cultivate strong relationships outside their partnership. But in the last years they lived together. These final years were shadowed by ill health, as well as continuing poverty. He died on July 8, 1939.

Havelock Ellis has been described as one of the great "modernizers" of sex. Certainly, he was to become an inspiration to many liberal

reformers of the 1950s and 1960s. In retrospect, however, perhaps his major contribution was not as a scientist or theorist, or even great reformer, but as an outstanding example of a pioneer in writing about sex and sexuality in a calm and dispassionate way. He put sexuality into words that helped shape the erotic climate of the twentieth century.

emergent norm theory

Mikaila Mariel Lemonik Arthur

Emergent norm theory hypothesizes that non traditional behavior (such as that associated with collective action) develops in crowds as a result of the emergence of new behavioral norms in response to a precipitating crisis. For proponents of emergent norm theory, collective action includes all types of social behavior in which the conventional norms stop functioning as guides to social action, and instead people collectively overturn or go beyond the normal institutional practices and frameworks of society (Turner & Killian 1987) and therefore new conventions must form as part of the collective action. The basic suppositions of emergent norm theory are that collective action is rational, that collective action is a response to a precipitating event, and that new norms of behavior appropriate to the collective action situation emerge through group processes without prior coordination and planning.

First proposed by Turner and Killian in 1972, emergent norm theory has grown out of two main traditions. The LeBonian tradition of thinking of crowds as normless entities and collective action as irrational behavior led Turner and Killian to think about how norms are instituted in crowds. Second, symbolic interactionism and small group analysis contributed a model of norms as developing through interaction.

Emergent norm theory suggests that crowds come together because a crisis occurs that forces people to abandon prior conceptions of appropriate behavior and to find new ways of acting. When a crowd forms, there is no particular norm governing crowd behavior and no leader exists. But the crowd focuses in on those who act in a distinctive manner, and this distinction is taken on as the new norm for crowd behavior. As this new norm begins to be institutionalized within the crowd, pressures for conformity and against deviance within the crowd develop, and discontent is silenced. This silencing of alternative views contributes to the illusion of unanimity within the crowd.

The norms that develop within crowds are not strict rules for behavior. Rather, they are more like overarching frameworks for behavior that set limits on what is appropriate (Turner & Killian 1987: 9–11). These norms develop through either emergent or preexisting social relationships. Turner and Killian suggest that anything which facilitates communication among crowd participants facilitates the emergence of norms, and they call this process “milling.” In addition, though the emergent norm theory perspective does, as noted above, contest the notion that crowd behavior is particularly irrational, it suggests that many crowd participants are suggestible and that this suggestibility contributes to the spread of emergent norms.

There are two main avenues of criticism that have faced emergent norm theory. The first, proposed by Reicher (1987), suggests that when crowds come together, they bring norms with them. Therefore, new norms do not have to emerge. These norms are different depending on the group making up the crowd – for instance, an urban mob will exhibit different norms than a group of suburban teenagers at a rock concert. These differences reflect the

different ways that crowds behave, but are norms nonetheless.

The second line of criticism suggests all social behavior results in the renegotiation of social norms, and second, that the creativity in norm creation and behavior that has come to be seen as “norm emergence” emerges not from interaction but rather through long term rational planning processes or through reliance on small changes to established repertoires. Couch (1968), while writing before the development of emergent norm theory, is often cited to support this criticism. An additional area of criticism suggested by some researchers is that there are significant methodological difficulties in tracing the emergence of a norm in a crowd setting.

While emergent norm theory was originally applied to a variety of forms of collective behavior, it is most commonly relied on to help understand the behavior of large groups, or crowds. In particular, emergent norm theory has gained a strong foothold in disaster research, as it is used to understand the behavior of groups who experience a precipitating crisis (a disaster) and then are forced to find new ways to respond that will help to ensure the safety and survival of as many people as possible. Tierney (2002), for instance, has used emergent norm theory to help understand the civilian initiated evacuation of the World Trade Center on September 11, 2001. Other researchers, such as Johnson (1987), have suggested that emergent norm theory can explain not just orderly civilian initiated evacuation but also the aggressive and selfish behavior sometimes seen in mass panics. Johnson believes that in certain situations, the breakdown of social order leads to these types of behavior as rational responses to the new social circumstances.

Emerson, Richard M. (1925–82)

Karen S. Cook

Richard Marc Emerson, a primary architect of social exchange theory and power dependence theory, received his PhD from the University of Minnesota in 1955 where his primary advisors were Don Martindale (sociological theory) and Stanley Schachter (psychology). He attended graduate school after serving during World War II in the elite 10th Army Mountain Division upon completing college at the University of Utah, where he majored in sociology and minored in philosophy. His first academic appointment was at the University of Cincinnati. He joined the faculty in 1955 and received tenure in 1957. While at Cincinnati he wrote a number of important papers and participated in research projects related to family relations (as a senior research associate in psychiatry) and in leadership training, a popular field of study post World War II. He was recruited to the Department of Sociology at the University of

Washington in 1965, where he served on the faculty until his premature death in 1982 at the peak of his academic career.

Richard Emerson is best known for his work on social power. In the early 1960s he published two highly significant papers, “Power–Dependence Relations” (1962) and “Power–Dependence Relations: Two Experiments” (1964), that changed the way social scientists subsequently viewed social power. Both are now citation classics. The 1962 article is one of only 30 that have received over 500 citations since being published in the *American Sociological Review*. The primary significance of this work is that it changed the way power was typically defined in sociology and political science. In Emerson’s theoretical framework, power is viewed as a function of a social relation rather than as an attribute of a particular person, group, or collectivity. This conceptualization is the basis of what is known as *power dependence theory*. The key insight in this formulation was that power was determined by the dependence of one party on another for resources or services of value. Dependence is a function of: (1) the *value* of that service or resource and (2) its *availability* from alternative sources. Emerson later used this conception of power in his analysis of social exchange relations. Thus the power of actor A over actor B in a two party exchange relation specified as $Ax:By$ (where A and B are actors and x and y are resources of value) increases as a function of the value of y to A and decreases proportional to the degree of availability of y to A from other sources. The more dependent B is on A, the more power A has over B in the $Ax:By$ exchange relation. The postulate that power is based on dependence is the central proposition in Emerson’s theoretical formulation: $P_{ab} = D_{ba}$.

Emerson developed his exchange theory in two papers written in 1967 and circulated widely in unpublished form before they finally appeared in 1972. In these papers he laid out a micro foundation for social exchange (Part I) based on behavioral psychology similar to the basis of the exchange formulation developed in 1961 by George Homans. In Part II Emerson developed a theory of social exchange networks building upon his dyadic exchange formulation.

The extension of exchange theory from dyads to networks laid the foundation for much of the subsequent theoretical and empirical development of exchange theory in sociology in the three decades after the publication of these seminal papers. An important feature of this work was its focus on network positional determinants of power.

Networks, according to Emerson, were sets of connected exchange relations. They could be simple or complex networks that represented actors linked by ties of exchange. The nature of the exchange connections depended upon whether or not the exchange relations involved cooperative social exchange (positive connections) or competitive access to alternative resources (negative connections). If exchange in one network relation enhanced exchange in another, the two exchange relations were positively connected at a node (actor). If exchange in one network relation reduced the likelihood of exchange in another relation, the two relations were defined as negatively connected (or as alternative exchange relations). More complex variants of the nature of connections and the determinants of positional power were subsequently developed by Markovsky et al. (1988), Willer, and their collaborators who developed not only an alternative method of representing network connections, but also different methods for calculating the locus of power in a network (e.g., using the graph theoretic index of power or *GPI* and its modifications). Experimental research supports the idea that the link between power and centrality in a network is dependent upon the nature of the exchange connections involved, among other factors (Cook & Emerson 1978; Cook et al. 1983; Yamagishi et al. 1988).

To analyze change in networks, Emerson proposed that power balancing mechanisms often came into play to alter the distribution of power in a network of exchange relations. For example, coalitions could form among power disadvantaged actors in a network and such collective action could result in a redistribution of power if the disadvantaged actors could act collectively to alter the terms of trade to their advantage. Emerson referred to this form of structural change as network consolidation. A different form of change involved network

extension. In this case power disadvantaged actors could seek alternative exchange partners to reduce their dependence upon a particular powerful actor by gaining access to resources from others. These were two of the main forms of structural change posed by Emerson as potentially “power balancing” forces within exchange networks. Two other mechanisms of “power balancing” focused on changes within the dyadic exchange relation, not the network. These mechanisms included “status giving” or an effort to enhance the value of the resources offered to the one in power in the exchange relation, and “withdrawal,” which entailed terminating the relationship, a more drastic means of reducing dependence.

While the focus of much of the work on social exchange has been on the determinants of power in dyadic exchange relations and in exchange networks, other features of social exchange relations have also been examined, including social cohesion, relational satisfaction, fairness or distributive justice, commitment between exchange partners, especially under uncertainty, and trust. Even though some of these topics were included in Emerson’s original theoretical formulation, they were not empirically investigated very extensively in the laboratory until after his death, with the exception of the study of commitment, which was included in an early experimental study by Cook and Emerson (1978; see also Cook & Emerson 1984). Linda Molm and Edward Lawler are two of the investigators in the past decade who have studied relational cohesion, trust, and commitment experimentally. Lawler’s focus has been on affect and relational commitment. Molm has focused on comparing different forms of exchange, such as negotiated and reciprocal exchange, and their differences not only in terms of the use of power, but also in the levels of cohesion, relationship satisfaction, and trust that develop between the partners.

Emerson’s fieldwork on power and authority relations in Pakistan is less well known than his theoretical work on exchange and his collaborative laboratory studies of exchange networks with Cook, Yamagishi, and others. He published several papers before his death on the effects of the British system of authority and rule on the small villages and principalities

of Pakistan and India. These articles relied more on historical data and observations that Emerson collected while in the field in Pakistan and India, where he spent time on several sabbaticals as well as on various mountaineering expeditions. In fact, some of his laboratory studies of power were representations of his interest in the factors that resulted in the centralization or decentralization of power in various village structures. Although he is best known in the current era for his laboratory work on exchange theory and power in exchange networks in collaboration with his colleagues at the University of Washington, he is also known there for his love of mountains and his interest in the anthropology of the remote mountain villages he often visited during his career as a sociologist.

Apart from his love of academia, Emerson had considered becoming a sculptor before entering graduate school and was an excellent photographer. He was also a serious mountaineer, having grown up surrounded by snow-capped mountains in Utah. While in the Northwest he climbed mountains for much of his life and was a member of the first expedition on Mount Everest to make a successful ascent up the West Ridge (in 1963). The National Science Foundation funded his involvement in the expedition as part of a research project that he had initiated on reactions to performance feedback under conditions of high stress. The mountain climbers were required to keep diaries during the ascent to record their reactions to various performance feedback studies that Emerson was conducting during the climb. Just before his assassination, President Kennedy decorated Richard Emerson with the Hubbard Medal on behalf of the National Geographic Society for this research. Two of Emerson's climbing partners on this adventure suffered serious injury from frostbite and one of the porters died on the climb. During his life Emerson returned a number of times to the mountains of Pakistan, often with a new research idea in mind.

emic/etic

Michael Agar

“Emic” and “etic” have become shorthand terms, especially in anthropology, for an “insider” versus an “outsider” view of a particular social world. For example, an outsider view of an economic exchange might hold that the seller’s goal was to maximize profit. An insider view from people actually involved in the exchange might show that profit was only one of many concerns. Kinship ties, a long relationship history, previous social favors, earlier non cash trades, a desire to curry favor – such social threads in a relationship might result in an exchange that, to an outsider, would look “irrational,” while to an insider it would make perfect sense.

The distinction between emic and etic, insider and outsider, originated in the linguistics of the 1950s, most famously in the work of Kenneth Pike (1967). Linguists of that era were primarily concerned with learning and describing unwritten languages in field settings. As part of this larger task, they had to master the phonology, or sound system. As a means to this end, they created a notational system that allowed them to describe all possible sounds that the human organism can produce. This notational system was called phonetics, and that term later became abbreviated to etic.

Phonetics offered a classification of sounds that humans could produce, given the physiological possibilities of the articulatory system. Training tapes, much like a foreign language

course, taught the budding linguist how to hear sounds that his own language had trained him not to hear. For example, if one raises the tongue so that the two sides touch the alveolar ridges while allowing air to pass through the middle, one is producing what a phonetician would call a “lateral fricative.” While the sound is unfamiliar to most English speakers, it is critical for a speaker of Navajo.

The fact that a lateral fricative would sound strange to an English speaker is why the concept of “phonemic” was invented. The speakers of a particular language, like English or Navajo, will not perceive all the sounds described by phonetics. Instead, they will hear only a subset. As they acquire language as children, speakers learn to hear some sounds and ignore others. The sounds that speakers of a particular language hear as significant, the units of sound that make a difference for them, are the “phonemes” of that language. “Phonemic,” as we will see, was shortened to “emic.”

Here is an example. In English, say the word “pin” and the word “spin” with a hand held in front of the mouth. After the “p” in “pin” a puff of air will be felt on the hand. After the “p” in “spin” little or no air will be felt. A linguist doing phonetics would say the first “p” is aspirated while the second “p” is not. This difference makes no difference to a native speaker of English. One could say “pin” without aspiration or “spin” with it, and though it might sound unusual, the different pronunciations would still be heard as the same words. Aspiration, in English, is not phonemic. In other languages, such as Hindi, it is. “Pin” with aspiration and “pin” without it would signal two different words.

Here is another example. In Kannarese, a language of South India, a “d” can be alveolar or retroflex. Say “d” with the tip of the tongue along the alveolar ridge just behind the teeth. Now say “d” with the tongue rolled back, the tip tapping the back of the ridge as it moves forward to articulate the “d” sound. That is retroflex. In Kannarese, there are two words that an English speaker would spell “nadi” and hear as the same. One – with the alveolar “d” – means “river.” The other, with the retroflex “d,” means – loosely translated – an impolite “get out of here.”

The field linguist began by first writing things down using phonetic notation. Then, using methodologies that are beyond the scope of this entry to describe, the linguist would analyze the phonetic transcription of the language to determine which differences made a difference for native speakers and which did not. The linguist would then develop a phonemic notation to symbolize those differences.

What about the phonetic variations? To return to the earlier English example, a linguist would note that aspiration after a "p," or any other "stop," is *not* phonemic for English speakers. Instead, the linguist would posit a rule that aspiration occurs after a stop that begins a word which is then followed immediately by a vowel, a word like "pin." This kind of phonemic rule lets the linguist use the single symbol "p" for both aspirated and unaspirated versions. The rule works for other stops in English as well, sounds like "b," "t," "d," "k," and "g." Now, instead of writing a full phonetic transcription, the linguist can shift to a less cumbersome phonemic transcription that reflects the psychological significance of sounds to local speakers.

Now consider the earlier example from South India, the alveolar and the retroflex "d." Since these two "d's" do make a difference to speakers of Kannarese, a linguist has to represent that difference in the phonemic transcript. He can't just use the single symbol "d." Fortunately, the original phonetic notation with which the linguist began his work provides a way to write this difference down, usually with a dot under the "d" for the alveolar version and a wedge under the "d" for the retroflex.

In the 1960s, anthropology borrowed and shortened the linguist's distinction between phonetic and phonemic and began talking about "etic" and "emic." But the abbreviated concepts were applied to ethnography as a whole, not just to language. Just as in the case of phonetics, an etic approach meant an ethnographer described and explained events with a language external to the social world in which those events occurred. And like phonetics, the etic language of description might be rooted in human biology, as in Edward T. Hall's studies of "proxemics," his shorthand term for the use of social space (Hall 1959). Measures of physical distance or bodily motion served as the etic framework. Other etic

approaches drew on "outsider" languages from social theory, exemplified by Marvin Harris's writings of the time (for a recent version of his arguments for etic ethnography which began in the 1960s, see Harris 1998). He advocated an etic framework grounded in his commitment to neo Marxian theory.

Halls's proxemics, as the name suggests, was also emic, since his ultimate goal was to describe how different groups had different interpretations of social space. For example, one group might expect two people to stand closer than another group would during an informal conversation between strangers. Where such emic differences existed, a person from the former group would read the other as "cold," while a person from the second group would read the first person as "pushy."

The concept of emic ethnography flourished with the growth of cognitive anthropology (D'Andrade 1995), an approach that concerned itself with what was then called psychological reality. Their "phonetics" were assumed universals of human cognition, for example, taxonomy. Their "phonemics" were the way particular taxonomies of plants and animals were filled in by different peoples living in different parts of the world. Many other kinds of emic studies were done as well, involving local concepts and their organization, to reveal the variety of ways that people organized their experience, their emic, using their universal human capacity to do so, the etic.

Unfortunately, because of acrimonious debates between "materialist" or etic and "symbolic" or emic approaches to anthropology during the era, "etic" and "emic" turned into labels for competing kinds of ethnographic descriptions. This was a fundamental error, since neither the original linguistic concepts nor their development in cognitive anthropology had defined an "either/or" use of the terms. The shift to etic/emic as a partition of the ethnographic space rather than a process by which it was explored introduced distortion into the use of the terms that continues to this day. The question should not be, does one do emic or etic ethnography? The question should be, how does one tack back and forth between human universals and the particular shape that a social world takes at the time an ethnographer encounters it?

The emic/etic distinction appeared about half a century ago. With the many changes in the world and in our theories about it since then, the emic/etic distinction looks more complicated than it used to. It is worth considering a few examples here to foreshadow the future of the concepts, as well as to reflect on their past.

Phonetic/phonemic endows the linguist with the privileged position in language description. She is the one who defines the universals that limit what the local differences might be. She controls the methods that will make that determination, and she declares what the phonemic is and when it is done. With work in socio linguistics that began with Labov in the 1960s (Labov 1966), we learned that sound differences that were not “phonemic” according to the old 1950s approach in fact signaled important social meanings that convey a speaker’s and listener’s sense of identity and situation. Phonetic was more important than the original distinction allowed.

This problem of authority becomes even more striking when phonetic/phonemic in linguistics shifts to etic/emic in ethnography. What is the etic for humanity in general and who decides? What is the universal set of beliefs, values, or rules for behavior that cover all possible configurations that are human across regions and through history? And on what grounds would a researcher claim to know what they are whereas the subjects of his research could not? Recent anthropological debate centers on just this bias in an academic field that traditionally considered itself “culture free.” Those who privilege themselves to define the etic, one could argue, are just another kind of emic.

Say an encounter between an outsider and an insider is an encounter between two kinds of emic, not between an etic and an emic. In this formulation, the encounter is cast in a more egalitarian light. Two different meaning systems, two different emics, try to make sense out of each other, rather than an outsider with prior knowledge of universal human universals figuring out the locally relevant system that draws on that universal scheme. But what about the etic? Don’t universals play a necessary role in bridging local differences? They have to, or else no bridge would be possible. In our poststructural, postcolonial era, though, we see that the etic has also become more

complicated. There are no clear lines between “insider” and “outsider” in today’s world. In our transnational times we can expect that any two people who share a local social world will to some extent have different interpretations of that same world. The fact that they share activities will not imply a perfectly overlapping emic perspective. On the other hand, any two people from anywhere in the world will to some extent share interpretations of some phenomena, as soon as they meet, without any prior contact. They will partially overlap in emics, even though they have never had anything to do with each other directly.

With all these complications, what are we to make of the emic/etic distinction in contemporary research? It still has value as a general alert, a caution that what X says about what Y is doing or thinking probably doesn’t correspond to what Y would say, certainly not perfectly, sometimes off by several orders of magnitude. This fairly simple – and usually accurate – principle is worth contemplating for its breadth of application, its explanatory power, and its call for uses of the distinction in public policy. It is also worth contemplating why this simple principle is so seldom attended to.

A second enduring use of the emic/etic distinction returns us to its linguistic roots in the 1950s. One useful definition of ethnography is making sense out of human differences in terms of human similarities. Recall the early use of the phonetic/phonemic distinction as a tool to help a field linguist achieve exactly that goal. Phonetics laid out the human territory; phonemics described its particular shape among a particular group at a particular point in time.

Any ethnography is a mix of human universals and local histories. Without the universals, comprehension across differences would not be possible. Without the local histories, the universals would mislead when it came to understanding a different world. Here, etic and emic signal a still undeveloped strain of social research, one that celebrates the richness of particular human moments while at the same time integrating the various universal theories of the human situation that they bring to life. Long ago, Robert Redfield, engaged in a post World War II review of anthropology sponsored by the Social Science Research Council,

said that good ethnography was like good literature. It gave a "glimpse of the eternal in the ephemeral" (Redfield 1948). Etic and emic are ways, in ethnographic jargon, to continue the spirit of the wise writing of that ancestor. Etic and emic are both part of any human understanding, not distinct varieties of it.

emotion: cultural aspects

Jack Barbalet

The relationship between emotions and culture has been discussed ever since there was interest in what it means to be human, and since then that relationship has been contrastingly characterized as either inimical or reconcilable. Culture can be understood as the defining values, meanings, and thoughts of a local, national, or supranational community. When emotions are conceived in terms of psychological feelings and physical sensations, then they appear inimical to culture. This is because such a perspective suggests the involuntary nature and disorganizing consequence of emotions. The opposition between cognition as reason and

emotion, implicit in this representation, is classically defended in Plato's critique of dramatic poetry in the *Republic*, for instance. Plato's supposition that emotion is pleasure or pain dissociated from thought or knowledge was corrected, however, by Aristotle's more comprehensive appreciation of emotion as not merely physical but also cognitive, in which culture and emotions are reconciled.

In his treatment of anger, for instance, in *Rhetoric*, Aristotle agrees that emotion has a biological component, the physical sensation of pain, and also a complex cognitive component, including perception of an undeserved slight, and an intention, desire for revenge. Thus Aristotle distinguishes between emotions in terms of both the different physical sensations associated with them and their different cognitive or cultural elements: hatred and anger are different not just in their physical sensations, but also in the way in which each emotion conceives its object, as when Aristotle says that anger has an individual as its object whereas hatred applies to classes such as thieves or informers. Similarly, fear and shame are distinguished not just physically but cognitively, as expectation respectively of imminent harm or disgrace. There is something else, then, that should be noticed in this account, even though Aristotle does not make it explicit; namely, that imagination is important in the experience of emotion. Thus culture is unavoidable in emotion through a number of routes. The situation that provokes an emotion, as opposed to the physical or biological structure that supports it, is broadly cultural, and so is the intention it promotes; finally, thought itself or imagination may lead to emotional experience.

The different conceptions of the relation between emotion and culture found in Plato and Aristotle stand as models for all subsequent statements. Relevant changes in accounts of emotions since classical Athens have included improvement in understanding the physical structures and processes underlying emotions, but also a difficulty in maintaining the methodological reach of Aristotle's approach to the cultural dimensions of emotions. In the Middle Ages, for instance, because the only emotional commitment approved by the Church was love of Christ, emotions were seen as ardent,

vehement, and overpowering, as passions, a term unavoidably also associated with Christ's suffering. Any emotion apart from Christian devotion was thus regarded as subversive of religious faith and correspondingly condemned as irrational. By the sixteenth and seventeenth centuries, probably through the emergent significance of market exchanges and diplomacy in which it was necessary to form a view of the intentions of others, an operational interest in emotions loosened from theological prejudice and emphasizing their expressive and rhetorical significance became the subject of numerous publications in France, Spain, and England. This trend was consummated in the eighteenth century discussion of moral sentiments, in which "moral" meant not merely ethical but especially social and cultural analysis, and "sentiments" implied the cognitive, even intellectual, content of emotions and feelings. From the nineteenth century, however, treatment of emotion focused on its physical basis at the expense of its ideational components, a development encouraged by enormous strides in anatomical, physiological, and neurological sciences. This trend was reinforced by subsequent psychological experimentation that treated only those emotions amenable to laboratory investigation – visceral, reactive, and of short duration – and thus reinforced the partial and limited idea that emotions disrupted thought and were therefore inimical to culture.

By the 1980s the cultural dimensions of emotions were again given their due. In some quarters this meant a focus on the cognitive elements of emotion to the exclusion of any thing else. This arose through a number of factors but was legitimated intellectually by broad recognition of the significance of what psychologists call the cognitive appraisal process, namely, that the type and intensity of an emotion elicited by an event depend on the subject's interpretation and evaluation of perception of its circumstance and environment. Psychologists recognized that this process is extremely complex involving both inordinately rapid and automatic central nervous system processes as well as more controlled and conscious activities, sociologically described as "interpretation and definition of the situation." The neurological revolution in emotions research came from focus on the first aspect of

this process and the constructionist theory of emotions from the second.

The majority of sociologists and anthropologists and large numbers of psychologists and philosophers who have written on emotions over the last 25 years believe that emotions are constructed by cultural factors. The constructionist position holds that emotional experiences depend on cultural cues and interpretations, and therefore that linguistic practices, values, norms, and currents of belief constitute the substance of experience of emotions (McCarthy 1994). Biological and even social structural factors are irrelevant for this approach. A corollary of constructionism is that persons can voluntarily determine the emotions they experience, that the cultural construction of emotions entails emotions management. The constructionist approach has enlivened discussion of emotions and drawn attention to the ways in which emotions are differentially experienced across societal divisions and through historical time. The object of any emotion will be influenced by prevailing meanings and values, as will the way emotions are expressed; thus what is feared and how people show fear, indeed how they may experience fear, will necessarily vary from culture to culture. The strength of this perspective is demonstrated by the fact that emotions attract cultural labels or names. In this way emotions become integrated into the broader conceptual repertoire of a culture and prevailing implicit cultural values and beliefs are infused into the meaning of named emotions (Russell 1991). Thus the notorious difficulty of translating emotion words from one language to another.

But by treating emotions exclusively as strategic evaluations derived from local meaning systems, the constructionist approach is arguably itself captive of cultural preferences. It is important to remember that emotions that escape cultural tagging are not thereby without individual and social consequence. Indeed, there is much evidence that socially important emotions are experienced below the threshold of conscious awareness and cannot be fully accounted for in only cultural terms (Scheff 1990). If culture shapes or constructs emotions, what is it that is shaped or constructed?

In a neglected but important discussion, Agnes Heller (1979) argues that cultural

adaptation of innate emotions involves elaboration of cognitive situational feelings that regulate them. These affective interpretations of emotions achieve their regulatory capacity by virtue of being secondary modifications of physically based affects or emotions, such as fear, that are provoked by events and expressive of them. Thus it is necessary to describe the cause of fear, for instance, in physical (endocrine/neurological) or social structural (insufficiency of power) terms, while the object of fear – what persons are afraid of – must largely be defined culturally. From this perspective the cognitive dimensions of emotions are not treated at the expense of their physical and social structural elements, but together with them. The real significance of this position, found in writers such as Norbert Elias (2000) and Émile Durkheim, is that it permits exploration of an aspect of the relationship between emotions and culture ignored by the constructionist approach, namely, the contribution emotions make to cultural experiences and components.

In *The Division of Labor in Society* (1893), Durkheim includes emotions within the category of collective conscience, the latter standing for a determinative cultural formation. In *The Elementary Forms of Religious Life* (1912), his treatment of cultural institutions refers to the sustaining importance of emotional effervescence. Ritual settings, argues Durkheim, provide a framework within which emotional experiences are formed, and the affective dimensions of the emotions and their directing energy give life to cultural practices and institutions. In particular, attention to common cultural objects, coordination of actions and symbolic gestures, and diffusion of orientation and practice through a society are all achieved as a result of emotional focus and contagion. Unlike constructionist arguments, Durkheim's discussion regards emotions as irreducible foundational forces of cognitive and cultural phenomena.

There are a number of ways in which emotions support and shape culture. Randall Collins (1990: 27), for instance, has suggestively claimed that values "are cognitions infused with emotion." This is an insightful corrective to the position found in sociology through the influence of Max Weber's approach, for instance, namely, that values and cognitions

operate through exclusion of emotions. Indeed, Adam Smith's pioneering cultural sociology, *The Theory of Moral Sentiments* (1759), shows how self judgment and judgment of the conduct of others are based in emotional appraisals, and how such emotions interact with what he calls custom and fashion. More recently and from a quite different perspective, Jonathan Turner (2000) demonstrates that emotions underlie not only attunement of interpersonal responses and social sanctioning, but also moral coding and the evaluations of social resources. On a more macrosociological level, it is useful to consider the composition of broad cultural temper in terms of underlying emotional patterns. Suggestive statements of the relevant processes are in papers by Joseph Bensman and Arthur Vidich (1962), and Joseph de Rivera (1992).

In their discussion of the differential impact, both positive and negative, on opportunities for income through movements in the business cycle, Bensman and Vidich indicate the sources of emotionally informed outlooks of distinct economically defined groups that impact on the broader societal culture, as when descending real income gives rise to status defensiveness and resentment of others. In a similar fashion, Rivera shows how political developments impact on the cultural ambience of whole societies through what he calls emotional climates. These studies point to the economic and political sources of the aggregation of collective emotional patterns from individual level emotions arising out of structured situations. The emotional climates that are identified in this process function as both orienting patterns of culture, which influence individual appraisals, and collective outcomes of individual emotional experiences.

The role of emotions in the construction of culture points not only to the composition of emotion but also significantly to its function. Emotions alert individuals to changes in and elements of their environment that are of concern to them, provide focus to situations in which these things are integral, and facilitate appropriate strategies to normalize these situations. That is, emotions both define the situations of persons and indicate what their interests are or intentions might be within them. It is a short step from this statement of the

function of emotion to one concerning the emotional contribution to culture. It was mentioned above that cultural regulation of emotion occurs through elaboration of cognitive situational feelings. It is likely that this process can be understood as emotional reaction to emotional experience, and that much cultural variation can be understood in this way. Jealousy, for example, is a widespread if not universal emotion. But in "traditional" or "Mediterranean" societies people are proud of their jealousy, whereas in "modern" or "western" societies people may be ashamed of it. Even the apparent absence of certain emotions from particular cultures can be explained in this way, as with Simmel's "blasé feeling," the emotional antidote to self regarding emotions under conditions of metropolitan life.

This discussion encourages reconsideration of the process of cultural appraisal or definition of the situation, which constructionists typically explain through application of "feeling rules." But artifacts such as feeling rules, following Bourdieu, might better be understood as outcomes rather than determinants of practices. That insult of Untouchables leads to acquiescence rather than anger may be explained through cognitive appraisal implicit in Hindu religious belief, in which gratitude results from receiving caste deserts. But such cultural explanations fail to account for the sustained coercion by higher caste persons in maintaining Untouchable subservience, or the mass conversions of Untouchables to Islam or Christianity when opportunity permits. Alternatively, constraints of social inferiority provide a sufficient structural antecedent precondition to account for Untouchable emotional experience of apathy and hopelessness, emotions that contribute to Untouchable culture. In this account, social structural relations elicit emotional reactions that then contribute to cultural experience (Kemper 1978; Barbalet 1998).

Not all social relations generative of emotional experience are current or past; they may also be imagined. Imagined relations are central to future oriented emotions, such as fear, anxiety, and hope, but also vicarious emotions in which persons at some level and in some manner imagine themselves to be others. This latter form is especially important for an

understanding of cultural experiences led by entertainment and advertising industries that pervade, indeed dominate, the present (Illouz 2003). As the rapid communication and electronic projection of images stimulating vicarious emotions are characteristic of modern commercial culture, so the significance of emotions for the support of cultural experience is to that degree reinforced.

emotion: social psychological aspects

Leslie Wasson

People may perceive emotion as residing in the individual and composing some portion of personal subjective experience. However, certain common patterns of emotional experience exist. We have shared social definitions of emotions, which are generally recognized and which can be evoked or referenced in socially appropriate situations. These emotion norms then become incorporated into the definition of the situation. While psychology and psychiatry have investigated emotions as internal to the individual, sociology has only recently contributed a social, interactionist analysis of emotion, or affect, to scholarly discourse.

The sociological approach to the study of emotion rests on a two stage theory of emotion. The first stage is an internal state of biological arousal, and the second is a reflexive process using situational cues to interpret or identify which emotion is an appropriate response in that situation (Rosenberg 1990). There may also be a process of negotiation with others as to the emotional definition of the situation.

One of the most fundamental issues in the sociology of emotions is the tension between universality and variability in the experience and expression of emotions, particularly the emotions of shame or embarrassment, since these are so evocative of sympathy or empathy from situated others. Data from cross cultural research imply that the type of community or social structure is a determining factor in the variability of emotional experience and expression. Yet, when we behold expressions of certain emotions from other societies, such as the grief of the Iranians at the death of Ayatollah Khomeini, we have little difficulty recognizing the emotions they represent (Flaherty 1991). Universality, then, may be found in the subjective experience and expression of these emotions, and variability is found in the situations in which these emotions are negotiated as appropriate responses.

The sociology of emotions claims adherents from two different theoretical orientations:

positivists and constructionists. Extreme positivists would assert that there are affective roles which are coercive or deterministic in their effect on people's behavior and emotions, and that these emotions are somehow "hardwired," or biologically inherent in the human species. From this standpoint, the individual would presumably feel only those emotions that were appropriate to the operative role. While not denying the existence and influence of affective roles and conventions, the constructionist paradigm states that these affective roles are manipulated and negotiated situationally by the individual through interaction with other participants. Under the constructionist paradigm, an individual might or might not feel appropriately in a given situation, but may in fact be giving a sufficiently convincing portrayal of the emotional conventions for the interaction to proceed as negotiated (Goffman 1959). These two positions define the extremes of a theoretical continuum. Presumably, many sociologists would employ some combination of the two positions, such as the social psychological approach discussed below, which focuses on structural influences on individual experiences of emotion.

In keeping with this distinction between determinism and constructionism, the sociology of emotions literature demonstrates many other analytical and theoretical differences common to much of sociology as a whole. The most important theoretical or analytical differences are as follows: cognition vs. emotion, structure vs. interaction, biology vs. socialization or political economy (e.g., gender), the social control of emotions vs. emotional forms of social control, and physiology vs. phenomenology (Kemper 1990). Similarly, the chief methodological debates center on questions of quantitative vs. qualitative methods of analysis, and prediction vs. description. Although there are significant areas of overlap, one convenient way to characterize the field of sociology of emotions is to examine it in terms of symbolic interactionist approaches and social psychological approaches.

Traditional sociological examinations of the self (Mead (1962 [1934]); Goffman 1959) have generally left open the question of emotion. Emotion has often been mentioned in passing, relegated to the discipline of psychology, or

carefully skirted in treatises on motivation or motive. Social psychological research on emotions had until recently focused extensively on the use and recognition of physiological cues connected to emotional states, primarily under experimental conditions.

There are some notable exceptions, however. In 1962, Schachter and Singer undertook an experiment to test the source of emotional definitions of the situation. Their participants were injected with substances that stimulated states of physiological arousal for which there were no affective cues in the situation. Subjects were then provided with cognitive cues toward one or another emotion. After controlling for the influences of the experimental setting, Schachter and Singer concluded that, although physiological arousal is necessary to emotion, it is not sufficient. Cognitive or, in symbolic interactionist terms, situational cues or definitions indicated the appropriate emotion label for the participants.

Affective arousal can be ambiguous, but so can situations. Certainly, something is happening physiologically that we are interpreting as the presence or occurrence of emotion. However, the same physiological sensations may be defined as any one (or more) of a variety of emotions, or, in some cases, as symptoms of illness. Affective roles do exist and are passed along through socialization. However, the implementation of all or part of these affective roles is subject to a good deal of interpretation and negotiation. While the affective convention is the unquestioned default for many situations, the endless variation of human interactions (and their sometimes unanticipated consequences) creates environments in which improvisation may be the most successful interaction strategy for the individual.

Gross and Stone (1964) wrote a pioneering article on the emotion of embarrassment, in which they proposed a theoretical justification for the treatment of embarrassment (and, by association, emotions in general) as a social phenomenon. Gross and Stone contributed two key ideas to the study of embarrassment. First, they commented on the social nature of embarrassment, and pointed out that certain situations are more prone to the effects of embarrassment than others (i.e., situations requiring "continuous and coordinated role performance" [1964:

116]). Second, they pointed out that certain situated identities are more precarious than others, and are therefore more prone to embarrassment, such as the identity of adolescents. Early work by Goffman (1959) also indicated that emotions could be described as forms of situated interaction.

Research in the sociology of emotions has, to some extent, left out the feeling actor, whether as researcher or as participant. It may leave unexamined the tension between reflecting and feeling described by Mills and Kleinman (1988). Mills and Kleinman suggest that reflexivity (or cognition) and emotionality are not two ends of the same continuum, but rather two entirely different processes. This approach suggests one possible resolution of the cognition versus emotion debate.

Randall Collins (1990) argues that emotions are the third element of a core theory of society, along with structure and cognition. Emotions, for Collins, make up a "moral order" in society, without which social solidarity would not be possible. Emotions then become a medium of exchange, in which emotional energy is the coin. Collins's model is unusual in that he portrays the positive emotions as being of high emotional energy, and the negative emotions are perceived as low emotional energy. Emotional interaction is a manifestation of structural needs in this model, and, in a sense, the needs of this market structure predict individuals' emotional states.

Hochschild (1979) proposes a conceptualization of emotion which resembles that of Collins (1990), but which provides greater autonomy for the subjective individual. Her model links structure and interaction via ideology to explain ways in which structure influences or limits emotion. She proposes a gender strategy of emotion management (as well as a class or ethnic strategy) to explain differences in expressivity between men and women. Hochschild contends that the public ideology of emotion (the situational emotion norm) becomes the private (or at least the appearance of the private) experience. Gordon (1990) provides a treatment of structural effects on emotion resembling that of Hochschild (1979). However, his mechanism for the influence of structure and culture on emotional states is language rather than ideology. His "open system" model has four

components: bodily sensations, expressive gestures and actions, a social situation or relationship, and emotional culture.

Kemper (1990) provides a more interactionally based, if also more deterministic, picture of emotions in social relations by calling for a systematic codification of situational conditions that predict emotions. Kemper compares these systematic rules to the laws of motion or physics. However, his formulation cannot account for the deviance phenomena or for the frequent occurrence of mixed emotions and ambivalence.

Theories of socialization have postulated the existence of learned patterns of emotional experience (Schott 1979). Through internalization of emotion norms in early socialization, individuals learn what emotions are appropriate to types of situations, and are therefore equipped to manage situated emotional identities. At minimum, an examination of emotional socialization and the uses of emotions in social control provides some idea of the contents of the emotional and interactional resources carried by individuals from one encounter to another. At about age 1 year 6 months, a child shows tenderness or affection toward significant others. However, it is not until the age of 5 or 6 that the child recognizes the selfhood of themselves and others. This development of the "looking glass self" (Cooley 1902) allows the growing social actor to experience sympathy or empathy, which Shott considers a prerequisite for the adoption of the "role taking" emotions of pride, shame, or envy.

A figurative or virtual audience, which Mead (1962 [1934]) might have identified as the "generalized other," serves an internal regulative function similar to that provided by the literal social audience. Feeling rules and the consequent emotion work are the media through which the self learns to control his or her own behavior and feelings. This conforms to Schott's (1979) assertion that emotional social control becomes articulated in adult society as emotional self control. This is not the social control of emotions, but rather the attribution of an emotional social control from within the individual.

The development of a sociology of emotions has led to the formulation of several conceptual

models and middle range theories. In the intellectual dialogue surrounding the formulation of these constructs, theoretical, epistemological, and methodological issues have arisen. Theoretical issues in the sociology of emotions include the familiar debate between positivists and constructionists, and structural or cultural versus interactional causal arguments. Epistemological questions regarding the relative functions of cognition versus emotion are still being debated, and questions of objective emotional symbols versus subjective emotion and introspection have been posed by emotions researchers.

Contemporary research on emotions in the symbolic interactionist tradition is alive and well. A sample of recent publications might include: Lois (2001) on emotions in a volunteer search and rescue group, Lundgren (2004) on social feedback and self appraisals, and Sharpe (2005) on the emotional labor exercised by adventure guides.

Sociologists who posit a predictive, interactionally based model for emotion, called affect control theory, include David Heise and Lynn Smith Lovin (Smith Lovin & Heise 1988). An essential component of affect control theory is the belief that there are set patterns of emotional response that are situationally specific, and therefore predictable. Affect control theorists program a computer to model human affective responses based on situational inputs. If the researcher enters the proper contextual elements, supposedly the computer can predict the affective state of participants in the situation. This is a fairly structural model of emotionality. Affect control theory is concerned with prediction rather than description, and with objective emotional responses to situational contexts rather than the subjective experience of particular emotions.

Some researchers in the social psychology of emotion utilize quantitative or structural methods and models to measure the correlations between particular emotions and situational conditions or social arrangements (Robinson et al. 2004). Their research findings have implications at the micro level for the transformation of emotions in social group or organizational contexts, and at the macro level for the recognition of the influence of larger social characteristics and institutions on emotion.

Other examples of contemporary researchers using a social psychological framework might include Lawler (2001) on using an affect theory to explain social exchange, or Van Kleef et al. (2004) on the interpersonal effects of emotions in negotiations.

FUTURE DIRECTIONS

Some research on socialization supports the assertion that emotion rules and conventions are learned by novice social actors as part of the socializing process. Through interaction with caregivers, and later with peers, "the child gradually constructs a conception of the whole emotion with its components" (Gordon 1990: 159). Emotional socialization reflects the social position of the individual in the social structure as well as the prevailing emotional culture norms. However, less empirical research has been forthcoming on the mechanics of acquiring emotion norms or feeling rules.

Research on emotions is beginning to occur in disciplines besides sociology. In history, for example, one might read Strange (2002) on death, grief, and mourning among the working class at the turn of the twentieth century. In philosophy one might read Nichols (2002) on the role of emotion in cultural evolution, or in the theory literature Reed (2004) on emotions in revolutions.

Empirical research that explores the relationships among emotions, identities, socialization, and social control is needed to ground theoretical constructions about emotional social control. Research should explore not only the specific mechanisms through which emotional social control is exercised, but also the conditions under which these control efforts vary. This intersection of self and society, in which the internal characteristics of the individual come to replicate and reinforce the external structures of society, is an essential connection between micro and macrosociology.

emotion work

Jackie Eller and Renata Alexandre

INTELLECTUAL AND SOCIAL CONTEXT

Emotion, hence emotion work, has been considered in the work of many early sociologists, such as Durkheim, Simmel, and Weber (see Barbalet 2002; Turner 2006), but it was not until Hochschild's work in the 1970s and 1980s that a sociology of emotions was taken seriously. Although today's researchers do not always agree with Hochschild on a precise definition of emotions, or how best to study them, there is general agreement that emotions are socially defined, made meaningful within socio-historical situations, and critical to any analysis of social interaction.

Drawing on the symbolic interactionist perspective and the rich heritage of Mills and Goffman, Hochschild (2003) states that an emotion has a signal function that communicates information telling us where we stand in

relation to the situation, to social expectations, to ourselves, and to other actors. Furthermore, emotions are managed (emotion work) through situationally and culturally relevant feeling rules so that ideally each encounter with others receives its expected and appropriate amount of feeling. Emotion work, according to Hochschild, is the management of one's emotions in private contexts, in contrast to emotional labor which is the management of feeling in public contexts. Context gives meaning to the *exchange value* of emotional labor (managing self and others' emotions as an aspect of one's labor power; commercialization of feeling in the marketplace) and the *use value* of emotion work, but both refer to the evocation, transformation, or suppression of one's feeling through surface and deep acting. Surface acting is purposeful management of behavioral expression so that one appears to feel the emotion called for in a given situation. Deep acting, on the other hand, refers to one's efforts to construct the genuine emotion that underlies the expected behavioral expression.

Of particular interest in Hochschild's examinations of emotion work and emotional labor have been gendered expectations within organizations and the costs of emotional inauthenticity, noting that women have historically shouldered the burden of emotion work in the household and in the workforce, specifically within the service industry. Her work helped to make visible this invisible labor done inordinately by women, as well as to stimulate studies of emotional labor of Wal-Mart greeters, midwives, paralegals, and academics, among others.

CHANGES OVER TIME

A great deal of research on emotions has been conducted over the past 30 years clearly indicating their significance in understanding social interaction and organizations. Research has also reiterated the importance of status, specifically gender, on emotional expectations and management. The major change though, has been in the agreement that emotion management (the more likely used synonymous term for emotion work) occurs within many work and work-unrelated contexts beyond the household and service industry and that it is a complex process

of managing self and others (e.g., Thoits 1996). Somewhat in contrast to Hochschild's work, the study of the sociology of emotion in the last couple of decades also tends to interpret cultural norms as being less influential on human behavior and attaches more authority to human agency with regard to emotion work.

CURRENT AND FUTURE EMPHASES

Drawing on such approaches as affect control theory, which "posits that sentiments about role identities, behaviors, settings, and individual attributes and emotions interrelate through three dimensions of affect" (Lively & Heise 2004: 1110), social constructionism, power and structural theories, and the deviance literature in addition to Hochschild's theory, current research on emotion work can be organized into four general, often overlapping, categories: (1) a particular identity, emotion (e.g., guilt, shame, remorse, anger, jealousy, envy, ambivalence, or anxiety) and its management in given situations (e.g., in the context of being ill or in response to the illness of others, as an aspect of terrorism, tragedy, or personal failure); (2) gender, emotions and emotion management, particularly within the context of feminist analyses (on gender and emotion, see Simon & Nath 2004); (3) emotion management within widely varying organizations (e.g., prisons, legal profession, among paramedics and firefighters, medical arenas, academia, service organizations, and commercial leisure) and social movement activism (e.g., women's rights, environment, animal rights, among hate groups, and in recruitment efforts); and (4) negative and deviant emotions (emotions or emotional expressions perceived as threatening to social order either for their connection to criminal behaviors or their inappropriateness to the social context). The management of remorse, for example, has been examined in the context of trials and jury deliberations.

As emotion work is first and foremost an interactive process, the majority of research is qualitative in nature, including participant observation, ethnographic, narrative, in depth interviewing, or focus groups. However, there is a significant body of research based in affect control theory which draws on mathematical

models to predict emotions called forth in particular situations and hence an examination of the likelihood and extent of emotion work (Heise 2002; Smith Lovin 1995). In fact, Lively and Heise (2004) use survey data to analyze the integration of emotion management and affect control theories which has led to broader micro and macrosociological understandings of emotion in social interaction.

An interesting business application of social science emotions research is found in the work place. Businesses/employers understand that they can gain in sales, repeat customers, and work place relations by facilitating effective emotion management among employees. In fact, this ability to effectively monitor, understand, use, and change one's own and others' emotional expressions is commonly referred to as one's emotion intelligence.

In his "Lifetime Achievement Award Acceptance Statement" (Emotions Section of the American Sociological Association) (2003), Kemper envisioned that the future study of emotions and emotion work would reflect the pervasiveness of emotions in social life, examining them in all institutional sectors of society and in large and small groups. His vision is apparently becoming a reality.

emotions and economy

Jocelyn Pixley

Emotions and economy, according to orthodoxy, are as far apart as passions from rationality. Some classical sociologists removed emotion categories from modernity; for others, emotions are significant (Durkheim and Simmel), uniform “residues,” sentiments (Pareto), or ambiguously traditional (Weber). Economics, with honorable exceptions (like Adam Smith), associates emotions with irrationality. Economy is the home of instrumental rational action. This distinction is completely inconsistent with uncertainty.

Social action oriented to future economic provision or gain must be launched by emotions, often below cognitive awareness. Dull compulsion may involve low levels of emotional energy, whereas emotions are heightened by choices which depend – tenuously – on future outcomes of relationships. Rationality and, preferably, reason can play a role in decisions, but only by accepting the future as inaccessible. In practice, this is hard to do (Pixley 2004). Uncertainties – possibly greatest in monetary economies – are here not trivial but “matter”: there may be vulnerabilities to losses, broken promises, or threatening prospects of a damaged reputation from mistakes or default. In face of perceived and unperceived, unimaginable futures, a range of emotions is involved in this largely internal process (i.e., endogenous, not just exogenous, as neoclassical theory concedes, at least). Specific anticipatory emotions disregard, play down, or help suppress the future’s unknowability, and so provoke decisions and action. Gullibility, distrust, trust,

caution, and fear are the main emotions in forming expectations. Such practices are colloquially called consulting gut feelings, soothsaying, intuition, or, more grandly, prognostications.

With the later outcomes or unexpected events come equally uncontrollable emotions, immediately and then retrospectively cast. All are just as diverse and unpredictable. Expected outcomes may lead to smugness, *entscheidungs-freudig* (joy in decision making), arrogance, or vice versa: grim confirmation, even despair. Unexpected outcomes give shock and anger, or relief, whereas the unintended events (a backfire) may provoke shame or *schadenfreude*.

Emotion categories are theoretically included in economy by a number of contemporary sociologists (e.g., Collins, Kemper, and Barbalet) and economists (e.g., Heilbroner, Hirschman, and potentially Minsky), but excluded from both ends of the ideological spectrum (Pixley 1999). Orthodox economic theories of “markets,” even of “firms,” assume rational actors can make predictions, while Soviet theories of command economies assumed that planning overcomes uncertainty. In practice, command economies removed choice and devolved anxiety, fear, or fatalism onto workers and, basically, whole populations. But “in theory,” trust and trepidation play no role in decisions: in neoclassical theory, failures occur mainly from *the intrusion* of emotions – as would a “virus” or psychological “disability” – and their complete irrationality. Few sociologists have any faith in probability theory or fervent conviction in planning. In fact, both types of positivism deny choice and the unknowability of the future. Yet sociologists are not usually well versed in Keynesian notions of expectations, or how these “govern” economic action. In the Keynesian view, because decision makers do not know the future, they act on “imagination and hope” (Shackle 1972).

Typical emotions are diverse, then, and depend on the prevailing economic and cultural arrangements (Luhmann). Emotions also vary by status, class, other social positions (resentment, humiliation), and further vary by phases in the business cycle (Barbalet; Collins). Orthodox economics, however, reduces human motivation to a universal and *timeless* emotion, namely, greed, cast at the macro level of an aggregate of individuals. Its watered down

version – “interest” – is said to be rational, not emotional like greed or avarice. “Interest” comprises orthodoxy’s hope for theoretically predictable models. But events are not predictable, *nor is greed* (Pixley 2002): outcomes of its pursuit are unknowable and even identifying what future interests “will be” is fraught. In contrast to economics, sociological perspectives include a whole range of likely emotions induced by various factors. Individuals, in aggregate, sharing a common social experience (rural labor for survival, or modern unemployment) may share similar emotions. Luhmann distinguishes premodern emotions – of faith in, or resignation to, fortune and fate – from modern, strategic emotions of trust for gain. Other sociologists focus on group emotions arising out of interactions between members. Durkheimian ideas about the emotional power of ritual processes which foster collective symbols, and the way effervescence in group life can spread contagiously, have been taken up by economic historians. Contagions, “manias,” or panics may cause an emotional “climate” – a depression, irrational exuberance, or animal spirits. Unsurprisingly, this is seen as invariably dysfunctional. In contrast, emotion research shows that impersonal organizations *require and elicit specific emotions*, some cognitively managed and others below the threshold of awareness.

When the term “economy” is reduced to a machine like entity or sole aim like “maximizing utility or profits under scarcity” – “constrained maximization” – or action directed to “means of survival,” it is difficult to identify relevant emotions. Aristotle’s distinction between householding – *oikonomia* – and *chrematistics* is useful to make comparisons and to direct research on emotions to the various ways of “studying up” and “studying down.” Expectations in the first, *oikonomia*, may entail emotions of caution, prudence, and trepidation, because householding is long term management for increasing value and conserving resources for the members of the household and their future generations. The second, *chrematistics* – manipulation of property and wealth for short term returns to the owner – presupposes a continual future orientation with all its anticipatory emotions like distrust and hope.

Modern households have “expectations” somewhere between these cautious and relentless

future gazing poles. Engaged in both market and non market economic activities, households are only marginal economic decision makers in either householding or manipulative terms (*oikonomia* or *chrematistics*), being so dependent on broader social relations. Households form expectations that depend on crucial decisions in corporate and bureaucratic domains, and must cope with intended, unintended, and unexpected consequences of decisions imposed top down.

Constant short term manipulation of wealth or cautious long term conservation are both beyond the effective capacity of modern households in aggregate. It is true that a rise or fall in consumption patterns, in “climates” of depression, confidence, or exuberance, can easily effect great change, but modern households are positioned by the money economy. Thus Simmel sees cynicism and the blasé attitude not only as typical emotional and defensive responses to the market, but also as the emotional sources for modern rationality. Even so, present and future orientations provoke different levels of emotional intensity. The unknowable future can be “unbearable” at the economic peak, but plays a reduced role in domestic and much paid labor (i.e., *oikonomia*), with their focus on immediate tasks and skills. Service sector, creative, professional, productive, and unpaid caring tasks are absorbing and present oriented, often with low level economic emotions: pride in a job well done (or self blame) and generally vague confidence in large scale organizations (like banks) or anxiety about future life chances of family members.

Confidence is a matter of lack of choice: if misfortune occurs (e.g., from a corporate collapse), blame is cast elsewhere at the actors making decisions to trust the unknowable future. If paid labor requires cut throat competition, trust and fearlessness may be required from above: this often induces recklessness and necessary scapegoats after the fallout. These are corporate policy issues. Emotions also vary according to historical memory of economic events across all economic and political spheres, and how the household sector is positioned by states, corporations, and markets (short term manipulation) and social movements’ impact on states (long term conservation policies “from below”).

In democratic welfare states where many households are mutual or social property owners, through state pensions, public housing and health, anxiety may be reduced by the “freedom from fear” of joblessness or homelessness. Under privatized arrangements, households are positioned – indirectly – as individually “responsible” property owners through banks, real estate markets, and investment fund firms. Individuals may be enthusiastic speculators from a contagion of optimism fostered by the investment firms dealing in stock and property markets. Others may experience anger, cynicism, or fear when let down by their confidence or loyalty in banks and corporations. Lack of confidence in economic institutions varies among countries. The principle of “buyer beware” implies a distrust that is ineffectual for lone individuals if consumer regulations are weak. Confidence in the safety of products for sale may hold under more regulated regimes (usually brought about by social movement protest).

These emotions connected with economy may seem starkly different from Weber’s line that affective emotional action is opposed to goal directed rational action. Yet Weber’s analysis of passionately held values to guide rational action, the modern loss of brotherliness, and his famous attribution of extreme anxiety to Puritans facing the uncertainty of everlasting damnation all suggest his ambivalence toward emotions. Whether the rise of capitalism depended, unintendedly, on an anticipatory emotion focused on predestination, today, corporate and financial attempts to control the future are routine.

Modern large scale organizations are highly future oriented and relentlessly engaged in short term decisions (the “iron cage”). The more competitive the situation, the more actors tend to rely on trust and distrust. Inside the mighty investment firms, emotions and their physiological symptoms – sweaty palms, rapid pulse – are fairly well documented. Fearlessness and arrogance are standard operating procedures to cope with daily uncertainty and to avoid the future abyss altogether (the latter point also argued by the late Robert Heilbroner). Traders who learn fear are often sacked because it takes time to unlearn fear. This intensity of the preoccupation with the future

is emotion generating. It is extremely hard to *accept* the inaccessible future if one is constantly dealing in it. This may explain the attractions of orthodox rational choice and rational expectations – in providing business with a sense of certainty – owing to their theoretical inability to conceptualize present and future. Likewise, futurists (from Toffler to Bell) offer their comforting technological determinism, and so too, at worst, do financial “gurus.” Yet temptations to gain and use “insider” knowledge are ubiquitous. It is the illegal recourse to a “sure thing” (and “unfair” in breaking stock exchange, or horse racing, rules of spreading “risk”) which emphasizes the unknowability of the future. Also, why insure if the future is “certain”? Herein lies the ambiguity between prudence, speculation, and gambling: life insurance started with gambling on “lives,” but needed legislation so as not to “hasten deaths.”

The business and financial world is preoccupied by the future – indeed, “overwhelmed by numbers” – with endless forecasts and inquiries into the “state” of individuals’ current feelings (business and consumer confidence surveys). However, economists conduct little research on the emotions essential to future gazing. In contrast, contemporary sociology has developed an impressive literature on trust and risk. This includes warnings about collapsing the future into the present, on the unavoidable and often highly rational emotions like trust, the institutions of impersonal trust, and the reflexivity of risk society. But the focus tends to be on risk, not the “radical uncertainty” argued by Keynesians (money being radically uncertain).

Economists mostly see emotions as irrational sources of error (and, save for “interest,” unpredictable), whatever their disputes about uncertainty. Pareto lies somewhere midway between marginalist economics and sociology. His conservative conclusions about emotions dictating all social action are partially behind today’s elitist assumptions about the “masses” or “mom and dad investors” suffering from irrational exuberance or panics. In this view, emotions apparently do not afflict rational or “smart” financiers. Pareto is more ambivalent. Rational actions *mainly* arise from “interest,” whereas non rational or “non logical” actions originate in sentiments or “residues” which are

ideologically justified in “derivations,” most notably or coldly by elites. Although these extra rational or irrational elements of human nature lead to “errors,” there are positive aspects to non logical rituals. In Pareto’s view, relatively changeless sentiments are best manipulated by “elites” (Meisel 1965; Finer 1966).

Although Pareto qualifies the economic view of rationality, his conservatism influenced managerial theories (Burnham) about rational decision making being an exclusive “property” of elites. But the modern economy faces *radical uncertainty* with frequent outcomes – quite frankly – of gross corporate errors. The future cannot be controlled by unknowable future “interests” or calculated by probabilistic risk. Risk is the only future for neoclassical approaches, rational choice theory, and behaviorists (apart from external “shocks” or allegedly neutral “technical change”). Neoclassical economics argues predictions are possible, and denounces emotion per se as an irrational interference at the level of its microeconomic models. Behavioral economists take another line on risk, and use emotions as another *deus ex machina* to explain unexpected events, such as “irrational exuberance” and crashes. For behaviorists, “people” fail because they lack mathematical skills or forget basic skills – in fact, often blinded by their models of a risk free future. This makes them all “overconfident,” leading to mistakes in calculating probability, not because no one knows the future.

The distinction between risk and uncertainty was set out clearly by Frank Knight (see Pixley 2004: 35). Risk must comprise a set of known chances to be measurable. Anything that is unmeasurable is a true uncertainty: this was taken up by Keynes and Hayek, later by Minsky. Keynesians, institutionalists, and chaos theorists insist on radical uncertainty, not a future of mere risk. The weather is “only moderately uncertain” compared to the unpredictability of finance (Keynes 1937: 24). Probability can only be assessed “objectively” by comparing invariant factors, such as two dice and a table. Subjective probability is about imagining completely incompatible and unknowable futures which cannot be weighed or compared: extrapolation is frequently pointless.

Economic and financial forecasting is usually published with a *ceteris paribus* escape clause;

however, “other things” rarely remain equal because forecasting is about past, recorded trends of discrete factors, not endlessly surprising “new” endogenous events, nor policy changes, external events, and their unimaginable combinations. Forecasts tend to “cluster” due to forecasters’ competitive fear of being alone and wrong. These are reputation issues which matter inordinately in economic action, yet reputations are always retrospective: a reputation is built on lack of contrary evidence, whereas a potential default or mistake can only be imagined.

In addition, during the last 30 years, money has been treated as a commodity capable of infinite trading, but money involves claims and credits, a social relation itself (Ingham 2004). This commodification of promises and privatization of social or mutual security into “securities” has heightened the emotions of distrust and gullibility. Such a climate of oscillating emotions – anxiety, hope, anger, and fear – is due to the excessive impact of financial trading and demands for shareholder value on the “non financial” sector (itself heavily trading in securities and debt these days). It explains, more starkly, how cynicism and the blasé attitude are recreated once trust is broken.

A major unresolved research issue in emotions and economy is the extent to which trust is *only* an emotion or is completely strategic: this is a huge debate (e.g., Cook; Swedberg). Another is about how to characterize impersonal, interorganizational relations as emotional. Emotions create physiological symptoms in individuals. Faceless organizations cannot be said to “feel” any more than they “think” or have a “conscience.” One debate is over how emotions are institutionalized in specific organizations. A more controversial dispute is how interorganizational relationships are emotionally structured. For example, the organizations in the business of impersonal trust, like credit rating agencies and accountancy firms, are required to *access the future*. They are paid to predict what amount of capital will be needed in the future or how creditworthy a firm or country will be. All other sectors rely on these predictions and some collapse when inevitable failures occur. Reputations for trustworthiness are lost, credibility disappears under claims and counterclaims about which organization is to blame. Huge global banks were “bedazzled”

by the arrogance of long term capital management in 1998, said the chair of the US Federal Reserve, a disaster which apparently brought the entire financial "system" to near collapse (until its bailout). Methodologically, it is difficult to account for endogenous emotions like "bedazzlement" among "organizations," if they can only be "felt" by the office bearers of those entities: competition plays a part, but also the virtuosity of *entscheidungsdfreudig*, as Neil Smelser alluded to, in passing, years ago.

This question of credibility is not tautological (i.e., credibility means "believability") if one includes social processes of attribution (Mieg 2001). Meso level struggles over attributions are continuous, as evident in lawsuits and public relations campaigns. Private and public institutional reputations can be subject to impression management for only so long. The point at which such "confidence games" start to resemble "con games" is unpredictable, but these processes ("rituals" even?) are ubiquitous, as evident in the way that struggles over attributions of success, failure, and blame are reported daily in the business news.

Many post war Keynesian policymakers hoped to *reduce emotions* from economy with demand management and global control over money. They hoped to provide stability by trying to give certainty to the convention that the future will validate present decisions. For sociological emotions research, emotions are not irrational, needless intrusions into economy, nor extraneous and dysfunctional interferences with economic action. In this conception emotions are unavoidable, although cautious emotions (required SOPs) would provide more stability than corporate demands for fearlessness. Past data – rational calculations, extrapolated under the convention that the past continues into the future – combine with retrospective emotions about outcomes of previous decisions (and outcomes of attribution struggles). These retrospective feelings and extrapolations create an imagined future, while a projected hope, trust, or distrust motivates decisions and *moves* a boardroom to act today: after the event, these emotions can rapidly turn into their contraries: shame, anger, disappointment, or relief; smugness for "prescience" and foolish arrogance.

Contemporary debates on emotions and economy have been revived by renewed sociological

analysis of emotions in general: one future direction that needs developing is research on emotions at "global" interorganizational levels. Another is the problem of trust in face of the unbearable future.

emotions and social movements

Guobin Yang

Emotions are spontaneous, self induced, or externally produced self feelings. Examples include positive feelings of love, loyalty, pride, joy, and enthusiasm and negative feelings of hatred, sympathy, fear, anger, sorrow, sadness, jealousy, shame, and dejection. Emotions are both embodied and take symbolic forms. A sense of anger or joy has tell tale somatic signs; often, it finds symbolic expression in voice, gestures, words, and tones, not to mention literary and artistic forms.

Emotions have a distinct social character. They often occur in social situations and arise out of social interactions. A society has its emotion culture, which sets social rules and norms for the appropriate kinds of emotions on specific occasions and for the legitimate ways of publicly expressing emotions. The emotion culture of a society embodies and expresses the values of that society. If a feeling of indignation is directed at an act of injustice, it is because society condemns injustices. Emotion culture therefore resembles a habitus, an embodied cultural and social milieu that shapes feeling and action. Practical action activates emotion culture and is guided by it.

Emotions condition and accompany collective action and social movements. Their absence or presence, as well as the types and intensity of emotions present, underpin every phase of a social movement from emergence to

decline. Preexisting social networks of friends and neighbors are crucial for mobilization – they are networks of trust and loyalty. Events of social injustice may provoke moral shocks, indignation, and anger and thus move citizens to action. Once initial mobilization starts, the emotional dynamics of collective action become complex and fluid. Both movement activists and their opponents perform emotion work in order to shape the outcomes of the movement. Activists strive to build emotional solidarity and a sense of collective identity. Opponents typically attempt to sow fear as a deterrent to collective action. When this happens, movement participants mobilize “encouragement mechanisms” (Goodwin & Pfaff 2001) such as communal gatherings to manage fear.

These “encouragement mechanisms” are among many possible practices used by movement activists to reduce negative emotions and create positive emotional energy. Activists’ emotion work varies depending on whether it is directed at themselves, at the public, or at opponents. The most common practice is rituals. Rituals encompass a wide range of patterned and ceremonial activities such as anniversary celebrations and public parades. As Émile Durkheim long ago understood, rituals create emotional effervescence and revitalize the ritual group. In social movements, rituals are used to build internal solidarity, to move the bystanders and the general public, and to shame opponents. In repressive political environments, activists may appropriate official rituals for mobilization purposes.

Rituals have symbolic components – singing, dancing, and the like. Yet not all symbolic forms are ritualistic. The symbolic expression of emotions in collective action is analytically a distinct practice. To build pride and enthusiasm among participants, to win sympathy from the public, and to arouse anger at the opponents, movement activists tell stories, sing songs, play music, compose poems, chant slogans, and dress up in colorful costumes. These symbolic expressions can be serious or playful. A spirit of play is a familiar part of social movements. Jokes, humor, and parody can undermine the seriousness of power in forceful ways.

Emotions not only influence various phases of a movement, they are also the very stakes of struggle. Structures of power and inequality

shape what emotions are appropriate to what social groups. For example, in bureaucratic institutions, anger is the privilege of the superiors, not the subordinates. The dominant emotion culture in contemporary society is emotion management. As Arlie Russell Hochschild (1983) shows, this culture forces individuals to manage how they feel – to stir up or suppress a feeling as the occasion requires. Such management serves instrumental rational purposes at the expense of emotional fulfillment. Emotion management is thus a culture of instrumental control over emotions. It has a built in mechanism against collective action. To free collective action of this cultural constraint, social movements, at least in their more radical moments, operate outside, not within, the dominant emotional codes. They seek to subvert existing feeling rules and mobilize counteremotions. In this way, emotions become the stakes of struggle.

Emotions long took a back seat in modern sociology. They were either ignored or conceptualized as the opposite of rational and purposive action. This was so even in the study of collective action and social movements. Before the 1960s, emotions were used to explain away crowd behavior. The standard theory was that crowd behavior was irrational and pathological, and so were the emotions that drove it. In the 1970s, many students of social movements rejected this line of thinking and its associated categories. They abandoned the concept of crowd behavior and talked instead about collective action and social movements. A resource mobilization theory based on rational actor assumptions was developed. Studies exemplary of this new thinking postulate that individuals' inclination to join social movements depends on the material and organizational resources available to them. Emotions disappear from this picture.

These two theoretical orientations were shaped by the social conditions in which they were born. In post World War II Europe and the United States, material prosperity, a cozy family life, and law and order were the concerns of the day. Thus when sociologists rejected crowd behavior on the basis of its irrationality and pathology, they were responding to the moods of the times. The new thinking that rejected theories of crowd behavior and gave rise

to resource mobilization models of social movements similarly reflected the social conditions. The tumultuous days of student protests had just gone by. The new generation of intellectuals had first hand experiences in the protest activities. Not surprisingly, these scholars affirmed social movements as rational, democratic political struggles. In their endeavor to rationalize social movements, however, they went to another extreme and dropped emotions from their theoretical models.

Emotions reentered the study of social movements in the late 1980s. By then, cultural analysis and the sociology of emotions had gained influence. These new intellectual trends reflected renewed attention to the centrality of meaning and human agency in sociological explanation. Among others, the works of Norman Denzin, Randall Collins, Theodore Kemper, and Arlie Hochschild significantly advanced the understanding of the social nature of emotions, opening the way for a new wave of sociological studies of emotions and movements. Since then, many articles have appeared. *Passionate Politics* (2001), a volume of articles based on a conference held in 1999, marked the first major collective endeavor made by sociologists to bring emotions back to the study of social movements. In 2002, the international journal *Mobilization* published a special issue on emotions and social movements. Another edited volume, *Emotions and Social Movements*, was published in 2005.

While the growing literature on emotions and movements is diverse in theoretical and methodological approaches, there are two distinct trends. First, there are many efforts to bring emotional dynamics into the explanation of all aspects of collective action and social movements. Emotions are considered to affect recruitment processes, movement emergence, the internal dynamics of a movement, as well as movement demise. The most exciting current research on this topic is in this area. Second, there is an attempt to incorporate emotions into existing categories of social movement theory, including organization, identity, framing, repertoires, and political opportunity structures. There is a growing understanding, for example, that studies of collective identity prioritize the cognitive dimension of identity at the expense of its emotional dimension.

These two lines of research have greatly enriched the understanding of collective action and social movements. But many challenges remain for students of emotions and movements (Polletta & Amenta 2001). One is methodological. One reason for the neglect of emotions in the study of social movements and sociology more broadly has to do with the fact that emotions, despite somatic signs, are not directly observable. The texture of emotional events consists of fleeting and ephemeral details such as gestures, voices, and smiles, yet these details do not often leave concrete records. Of course, many movements have left behind narratives of various kinds, and so far these have provided a main source of data analysis. But these narratives cannot fully capture the fluid dynamics of emotions. A possible corrective is to rely more on ethnography and visual sociology.

Secondly, in attempting to incorporate emotions into the study of social movements, many analysts tacitly or explicitly treat emotions in an instrumental manner. As Craig Calhoun (2001) cautions, some scholars have simply considered emotions as just another thing for movement organizers to manage or another resource to use against the opponents. In effect, then, emotions are turned into another kind of rational preference. Such an approach falls into the same trap as theories devoid of emotional components. This tendency is rooted in the dichotomizing of mind/body and reason/emotion that fundamentally structures modern western thinking. "Putting emotions in their place," as Calhoun puts it, is to study emotions in such a way as to transcend, not reproduce, this pervasive dualism.

To meet this challenge, one research agenda is to conduct more studies of collective action and social movements in non western societies. As anthropologists (Lutz 1988) have shown, these societies have different emotion cultures. Emotions may thus have very different meanings and expressions. Do interests have the same kind of influence on collective action as in modern western societies? Is it possible to separate emotions from interests? How do emotions structure social action in such cultures? Exploring these questions will help to uncover ways of transcending the reason/emotion dualism still prevalent in current research. Another

research agenda is to study how social movements are not only suffused with emotions, but also aim to transform emotion cultures. Are there influential movements that target or change emotion cultures? What are their characteristics? How do they compare with other movements in their trajectories? Addressing these questions will contribute to the understanding of both the constraints of the dominant culture of instrumental rationality in contemporary society and the possibilities of emotional emancipation.

empire

Lloyd Cox

In its broadest transhistorical sense empire refers to a large scale, multi ethnic political unit (usually with a state at its core) that directly or indirectly rules over, and therefore encompasses, smaller political units that were previously independent. Hence, empire always involves relations of domination and subordination between core and peripheral areas and their populations, which are most often established by conquest and maintained, in the last instance, by the exercise or threat of force. Nevertheless, empire may fall short of direct colonial rule and instead be implemented through informal mechanisms of political control based on indigenous elites and indirect methods of cultural domination and economic exploitation. These formal and informal practices of empire, and the ideologies that justify them, constitute *imperialism*. Both terms have their etymological roots in the Latin *imperium*.

In ancient Rome, the meaning of *imperium* was originally restricted to the authority of

Roman magistrates to act in the name of Rome and its citizens, at home (*imperium domi*) and abroad (*imperium militiae*). With the territorial expansion of Roman rule around the time of Julius Caesar and Augustus, the term came to connote authority abstracted from any particular bearer of that authority; the distinction between *imperium domi* and *militiae* progressively collapsed; and the term took on an explicitly territorial dimension. Rome and the territories over which it ruled were now considered to form a single *Imperium Romanum* (Armitage 1998: xv–xvi). This *imperium* was in principle limitless, embodying a universalist ethos that distinguishes it from modern empires premised on the particularist and territorially circumscribed claims of national states. It also defined itself as coterminous with “civilization,” labeling all those outside its parameters as barbarians and therefore legitimate targets of conquest – a Manichean distinction borrowed from the Greeks, but one that is overtly or covertly a feature of all empires.

The existence of empire in antiquity was not, of course, limited to the Romans. The ancient Egyptians, Assyrians, Babylonians, and Greeks all built significant empires, as did the Macedonians, Persians, Incas, and Chinese. In fact, the unification of the latter under the Ch'in and Han dynasties in the two centuries BCE eventually realized an imperial dominion that rivaled if not exceeded that of Rome, both in terms of geographical extent and technological dynamism. The ocean going exploits of the Chinese eunuch Admiral Cheng Ho in the early 1400s even held out the possibility of a Chinese alternative to European modernity and global expansion, albeit one that was, for reasons that were bound up with China's domestic political economy, ultimately not realized.

If for the moment we leave aside the empires of Christian Europe, the other great premodern empire is represented by the expansion of Islam out of the Arabian peninsular from the seventh century CE, followed by its various off shoots in the second millennium (principally the Mogul and Ottoman empires). During the course of this thousand year expansion, what had initially been an empire was politically fragmented. From the early centuries of the second millennium it is therefore more appropriate to speak

of Islam as a *civilization* encompassing several empires, rather than as an empire in its own right. What lent it a degree of coherence was the written Arabic language and the capacity of shared Islamic religious values to impose a pattern of family resemblance on the institutions of otherwise diverse localities. By the end of the eighteenth century, Islam and its last great imperial vestige – the Ottoman Empire – was coming under increased pressure from European imperial powers, which had begun their inexorable global expansion from the late fifteenth century.

EUROPEAN EMPIRES OLD AND NEW

The establishment of modern European empires can be roughly divided into three periods. The first runs from the late fifteenth to the middle of the seventeenth century, and is marked by Portuguese and Spanish expansion and then decline. The Iberian invasion of the Americas was sealed with the ideological and legal imprimatur of the Roman Catholic Church, which legitimized the invasion in terms of the salvation of the Godless. The subjugation of the indigenous populations, and their forced induction into slavery and other forms of coerced labor, laid the foundation for the massive export of silver and gold bullion back to Europe from the 1530s. This not only helped to maintain the power of Iberian and Austrian monarchs, under the auspices of the Habsburg Empire and Holy Roman Emperor, it also oiled the wheels of European commerce and contributed resources to future maritime exploration, conquest, war, and empire building. It also, however, elicited multiple challenges to Spanish/Habsburg power, instantiating the historical tendency for empires to beget resistance to their further expansion.

The second period runs from approximately the middle of the seventeenth to the middle of the nineteenth century, and was initiated by successful challenges to Spanish/Habsburg hegemony by Holland, Britain, and France, and by their own establishment of maritime empires. Along with the expansion of the African slave trade, this period of European empire building is marked out by two key attributes that distinguish it from the previous

imperial periods. On the one hand, a new conception of sovereignty was institutionalized in Western and Northern Europe, which recast the relationship between political power, territory, and property. In this new conception, sovereignty was idealized as the absolute and indivisible condition of states, whose rule was uniformly exercised over a clearly defined, bordered territory into which other states could not legitimately intervene. Political space became increasingly nationalized and decoupled from church and dynasty, which prefigured the formation of empires conceived in national terms. On the other hand, this was the period in which the great national trading companies (the French India Company, the Dutch and English East India Companies, and many more) and the associated doctrine of mercantilism became key factors in the extension of European imperial dominance across much of the world. These companies secured special trading rights and military protection in return for the revenues and territorial influence that they extended to their respective states, which was expressed in accelerating commercial and military rivalries. In many ways, the national trading companies represented the thin end of the colonialist's wedge, as they were often the forerunners to direct colonial rule.

The third and final period of European Empire begins in the second half of the nineteenth century and is not concluded until wide spread decolonization in the decades following World War II. The decades between 1870 and 1914 represent the zenith of European imperialism, with the vast majority of the planet's surface being ruled directly or indirectly by Europeans or their descendants. This period was characterized by several widely acknowledged defining features. First, colonial annexation became the rule rather than the exception, though it was exercised rather differently depending on the colonial power. British rule, for example, was typically more indirect (frequently deploying modified indigenous structures of power to secure its dominance) than say French rule, which was more centralized and assimilationist. Second, the imperialism of this period was coupled with a virulent nationalism that embodied the pseudo scientific language of racial superiority. The hierarchy engendering realities of European empires

required an explanation and legitimization, for which theories of racial superiority and survival of the fittest were perfectly suited. The coincidence of political, military, and economic inequalities with differences of phenotype offered a seemingly self-evident reason and justification for the continued domination of non-whites by whites. Third, it was a period of intensifying militarism and inter-imperialist rivalries between the great powers. The acquisition of colonial territories both contributed to and was a gauge of a state's status as a great power. This helps explain why European states were so keen to acquire colonial territories, even in some circumstances where the economic benefits of doing so were marginal or even negative. Finally, the last decades of the nineteenth century were ones where the character of capitalism underwent important changes, which many contemporaries of the period argued had profound implications for the trajectory of empires and imperialism.

THEORIES OF EMPIRE AND IMPERIALISM

In the *Communist Manifesto* (1847) Marx and Engels had famously provided a thumbnail sketch of the globalizing logic of capitalism. It is principally the needs of a constantly expanding market for its products which, they suggest, "chases the bourgeoisie over the whole surface of the globe," with cheap commodities being "the heavy artillery with which it batters down all of the Chinese walls." They were ambivalent in their normative judgments about this process, with early articles on India and China arguing for the historically progressive role of capitalism imposed from the outside (notwithstanding the brutal means by which this was accomplished), while articles on Ireland suggested that colonial rule could just as likely retard as promote economic development. Such ambivalence was mirrored in the views of later liberal and socialist commentators, as capitalism matured beyond its free market, competitive forms that were the backdrop to Marx's theorizing.

The most important early twentieth century liberal analysis of empire and imperialism is that of John Hobson (1938). His argument is

basically that monopoly capitalism, unlike its competitive predecessor, entails a tendency to over savings and therefore under consumption. Depressed domestic demand in turn depresses opportunities for profitable investment at home, which drives capital export and overseas investment. These investments, plus possibilities for future investment, must be protected from the predatory capitalists of other national states. This creates economic and political pressures for the formal annexation of colonies and thus intensified imperialist rivalries and militarism. He was adamant that a small group of financiers were the main culprits driving government policy in this imperialistic direction.

In subsequent critiques of Hobson and those who followed his lead, it has been pointed out that his "financiers" were not nearly as homogeneous in their interests as he assumed, and nor were they the exclusive or even main beneficiaries of imperialism. Moreover, the alleged link between under consumption and capital export is tenuous. As many commentators have suggested, capital may be exported not because opportunities for profitable investment do not exist at home, but because the rate of return on investment is simply greater abroad. And nor do such investments depend upon colonial annexations. The US and Argentina, for instance, were key destinations for British investment in the late nineteenth century, while many of its colonial possessions proved to be of little value in terms of investment or trade.

Despite the weaknesses, Hobson had a significant influence on early twentieth century debates on empire, not least those within the socialist movement. Traces of Hobson's ideas can be found in the substantial treatises on imperialism by Luxemburg, Hilferding, and Bukharin, as well as in the more synoptic work by Lenin. While the former works are more weighty in their intellectual contributions, it is Lenin's *Imperialism* that has had the most enduring historical legacy, as it was canonized by orthodox Marxists, becoming the standard against which other theories and praxis were piously judged.

Lenin defined imperialism as the "highest" stage of capitalism, characterized by five main features: (1) the concentration and centralization of capital into great monopolistic trusts

and cartels; (2) the progressive merging of banking and industrial capital into "finance capital"; (3) the centrality of capital export as opposed to commodity export; (4) the emergence of international capitalist monopolies that share the world among themselves; (5) the completion of the territorial division of the planet among the capitalist powers. Like Hobson, Lenin placed particular emphasis on the third of these features, with capital export being necessitated because capitalism becomes "overripe" in some advanced countries, with a "superabundance" of capital outstripping opportunities for profitable investment at home. The competitive quest for spheres of profitable investment in the capitalist periphery would, he argued, ultimately lead to militarism and war.

Lenin's *Imperialism*, and implicitly all of those theories largely based on it, has been criticized on empirical and theoretical grounds. Empirically, the merging of industrial and banking capital has not proven to be the inexorable trend that Lenin expected, and nor has capital export been mainly from more to less economically developed parts of the world. In Lenin's time, and even more so today, the predominant trend has been for the bulk of foreign direct investment to occur within and between the advanced capitalist states – those that are, in Lenin's terms, overripe and exhibiting a superabundance of capital. Theoretically, Lenin has also been taken to task for failing to specify adequately the causal relationship between his five key characteristics of imperialism, and between them and the broader tendency he identifies toward militarism and war. In addition, his work has been criticized for defining imperialism as a *stage* of capitalism. This unduly narrows the compass of the term imperialism. A strict application of Lenin's criteria would place many clear cut examples of empire outside of his definition, including the Soviet, Nazi, and Japanese empires established between the wars.

In the quarter century following World War II, the almost universal process of decolonization marked the denouement of formal European empires. It did not, however, engender the expected fruits of modernity in many of the new states or end foreign involvement in their politics and economies. On the contrary, political independence frequently concealed

continued economic and political subjugation which, from the 1960s, inspired new generations of radical theories focused on "neo imperialism" or "neocolonialism" – basically the idea that postcolonial societies, while formally independent, were in substance still politically and economically dominated by a few wealthy imperialist states and multinational corporations based in those states.

André Gunder Frank's theory of the "development of underdevelopment," Arghiri Emmanuel and Samir Amin's analysis of unequal exchange, and Immanuel Wallerstein's world systems theory were hugely influential in this new generation of thinking about imperialism. Following the theoretical leads of radical theorists Paul Baran and Paul Sweezy, and in Wallerstein's case that of the *Annales* school of French historiography, these theories shared the view that a lack of development in the "third world" was not an original condition, but one that was the product of the 500 year expansion of European powers and the capitalist world market. Simplified greatly, the argument was that this history had divided the world into mutually conditioning metropolitan/core or satellite/peripheral areas, with the former systematically retarding development in the latter by expropriating its economic surplus and imposing relations of dependency through unequal terms of trade. Such positions have been criticized for homogenizing diversity with all embracing labels such as core and periphery (and, for Wallerstein, semiperiphery), and for failing to account for dramatic economic advances in peripheral states such as South Korea, Taiwan, Mexico, and Brazil. They have also been disparaged for their economism and disregard of culture.

Intellectual currents that emerged in the 1980s sought to remedy this neglect of culture. Edward Said's *Orientalism* (1978) prompted a plethora of new studies emphasizing how discursive practices constitute the colonized "other" in ways that help to reproduce relations of domination. While not ignoring economic subordination, Said's primary focus was on Orientalism as "a political vision of reality whose structure promoted a binary opposition between the familiar (Europe, the West, 'us') and the strange (the Orient, the east, 'them')." Through a close textual analysis of novels,

travelogues, colonial records, and other cultural artifacts, Said demonstrates how European self image is itself a construction of Orientalism, essentially derived from the counterposing of a rational, progressive, and civilized “us” to an irrational, inert, and barbaric “them.” Such insights had been anticipated by an earlier generation of intellectuals and activists in the colonized world, such as Frantz Fanon and Aimé Césaire, who had drawn attention to colonialism’s objectifying, dehumanizing, and stereotyping of the colonized subject. Where Said went beyond them was in his treatment of the mutually constitutive relations between knowledge and power, and in his use of literary materials to illustrate and substantiate these relations.

Said’s Orientalism thesis, and the numerous contributions that follow his lead, often brought under the label of postcolonial studies, has generated much controversy, and not just from those whom Said would label as Orientalists. Many have pointed out that Said presents Orientalism’s binary oppositions as relatively static categories, which underplay the extent to which they have been a site of continual contestation and change. Others have taken Said to task for homogenizing the West, and thereby falling into the very ways of thinking that he is seeking to challenge. Finally, Said, and postcolonial theorists more generally, has been criticized for over inflating the importance of literature and discourse, at the expense of the material and institutional factors upon which all empires stand or fall.

In the 1990s, discussion of empire and imperialism was overshadowed by the new conceptual innovations centered on globalization, globalism, and globality. Much of this literature questioned the contemporary applicability of concepts such as imperialism, arguing that the maturation of multilateral institutions, international law, and global cultural flows rendered them anachronistic. A recurring motif is the erosion of state capacities in the face of accelerated cross border flows of information, capital, and people, which is said to decenter political power on the world stage. In this view, empire is a phenomenon of the past, not of the present or future.

More recently, however, new theories of empire have proliferated, largely in response to the foreign policy stance adopted by the US

since the events of September 11, 2001. This has re raised debate about the nature of empires and the factors contributing to their decline, such as imperial over stretch. A major contribution is Hardt and Negri’s *Empire* (2000), which has enjoyed widespread popularity and publicity. Its main thesis is that sovereignty has been rescaled upwards from the national to the global level, thereby constituting empire as a deterritorialized global entity. In this view, empire is transnational rather than American. Many subsequent analyses have rejected this deterritorialized, non national vision of empire, instead arguing that the global projection of US power and its readiness to undertake unilateral and preemptive military action is evidence of the existence of, or aspirations to acquire, an empire (Mann 2003; Johnson 2004). Others agree that the US is an empire, but argue that it is a liberal empire that may well be beneficial for those populations that are subject to US rule (Ferguson 2004). The continued US occupation of Iraq, and its military involvement in many other regions of the world, promises to sustain this renewed interest in empire and imperialism, whatever our normative judgments about its costs and benefits might be.

empiricism

Charles McCormick

The term empiricism refers to both a philosophical approach toward understanding the world and the principles and methods that ground modern scientific practices. The philosophy of empiricism, which was first stated by Aristotle and other classical philosophers, came to fruition in the writings of Enlightenment era scholars including David Hume and John Locke. A key philosophical question at the time was whether knowledge should be generated based on experience, as the empiricists argued, or on a combination of intellect and intuition, as proposed by rationalists such as René Descartes. An increased acceptance of the empirical approach to understanding the world fostered the growth both of modern science and the Industrial Revolution.

Empiricist philosophy has become codified as modern principles of scientific inquiry which include the formulation of verifiable hypotheses that are tested through unbiased and repeatable experiments. While physical sciences allow for precise measurement of phenomena of interest, this is more difficult in the social sciences for several reasons, including the “observer effect,” where people who are aware they are under scientific observation may change their behaviors to conform with or thwart researcher expectations, and the fact that the effects of social pressures cannot be measured directly. The founders of sociology, including Émile Durkheim and Max Weber, helped create an empirical approach to studying society when they addressed these issues.

Durkheim helped found the scientific approach to the study of society with his publication *Rules of Sociological Method* in 1895, which explains that sociology rests on the observation and measurement of the effects of social forces on people through measurable phenomena such as crime and suicide rates. The hermeneutic approach to sociology provides an alternative approach toward understanding the effects of society on human behavior, by using methods such as interviews, textual analysis, and self observation to understand social phenomena. Max Weber is considered a foundational researcher in this approach primarily as a result of his study *The Protestant Ethic*, which argued that the Protestant belief system provided a strong foundation for the growth of capitalism.

The scientific approach to sociology popularized by Durkheim and the hermeneutic approach roughly correspond to the modern quantitative and qualitative approaches to sociology. Within each of these camps there is a further division over the role that social theory should play in driving social research.

Researchers who support the deductive or “theory driven” approach argue that studies should focus on testing existing social theories, while supporters of the inductive or “data driven” approach argue that researchers should approach social phenomena with few preconceived notions and then allow their theories and research questions to evolve over the course of their research.

Perhaps the best way to understand the difference between the inductive and deductive approaches is to consider two very different studies that attempted to explain the causes of minor crimes.

In *Fixing Broken Windows: Restoring Order and Reducing Crime in Our Communities* (1998), criminologists George Kelling and Katherine Coles used the deductive approach to test the “broken windows” theory of crime. Kelling and Coles gathered evidence on the enforcement of minor crimes such as aggressive panhandling and found that lack of enforcement of these crimes sends a sign to criminals that additional crimes will be tolerated, in turn suggesting that police and community groups should focus much of their attention on prevention and rapid punishment for minor or

“nuisance” crimes, rather than on higher profile detective work, and on “community building,” which helps convince the landlord of a property, for example, that a broken window is worth fixing. In accord with the deductive approach, Kelling and Coles’s research was tested and refined in a large scale longitudinal study in Chicago which found that collective efficacy, or “social cohesion among neighbors and their willingness to intervene on behalf of the common good,” is at least as important as the enforcement of minor crimes emphasized in most municipal reforms in preventing crime.

The inductive approach to researching crime was taken by sociologist Jack Katz in his book *Seductions of Crime* (1990). Katz approached the problem of crime with few preconceived notions about whether poverty, a lack of education, or other factors drive crime and his inductive approach yielded surprising and controversial results. After talking with shoplifters and analyzing detailed narratives of situations that precipitated murders and other crimes, Katz finds that the immediate emotions associated with committing the criminal act are a fundamental driver behind many crimes. In the case of murder, Katz explains that murder rarely provides economic benefits to perpetrators and that murders are generally committed by otherwise sane individuals. The primary driver of most murders, Katz argues, is the murderer’s feeling of righteous indignation which is used to justify his act as in defense of “the Good.” For example, when an individual repeatedly refused to move a car that was blocking another man’s driveway, even at gun point, the property owner shot and killed him. As in this case, Katz found that murderers are often attempting to defend moral goods that most people support, such as property rights or self respect, but using unjustifiable means to do so. Similarly, he found that minor crimes such as shoplifting are driven by “sneaky thrills” as much as by economic need, again providing evidence that the “criminal mind” is driven by normal human emotions rather than by psychological pathology or cold blooded economic calculations.

Both inductive and deductive studies are important building blocks of the social sciences. Inductive approaches often generate theories

which can be tested with deductive methods, and deductive theories can form a framework for inductive studies. For example, researchers have used more formal methods to test whether the “seductions of crime” are major drivers behind crime (Phillips & Smith 2004), and researchers have used broken windows theory as a starting point for an inductive study of *how* and *why* minor crimes act as a signal that more and more serious crimes will be tolerated (Sampson & Raudenbush 2004). This integration of inductive and deductive approaches is important because it helps to resolve some of the limitations of social science that only emphasize one approach.

employment status changes

Richard Layte

The three decades that followed the end of World War II are often referred to by social scientists as the “Golden Age of Capitalism” in Europe and North America. This period of relative peace was marked by rising living stan

dards and high levels of employment within societies where the "traditional" family structure still held sway. In this environment, individual employment status changes were fairly few – into a job or career following education and retirement sometime around age 60, with women moving out into full time motherhood at the birth of their first child. This "Golden Age" began to unravel in the 1970s as wide spread changes in attitudes changed behaviors and high oil prices increased inflation and constrained growth. By the early 1980s, the labor markets of western industrial nations were very different from earlier decades, with high levels of structural unemployment and an increasing "feminization" of the labor force as women sought to combine marriage and childbirth with a job or career. In this new environment, simple models of a homogeneous "life cycle" were replaced by more complex and dynamic understandings based on the "life course," where uncertainty and instability were the norm and individuals experienced multiple employment status changes across their life.

This interest in the role of structural change was accompanied by a growing awareness among social scientists that there were winners and losers in this more fluid environment, and that social class processes and educational qualifications were essential for understanding the problems some individuals had in entering the labor market initially and avoiding unemployment once in the labor force. Social behavior occurs within a context, however, and this was increasingly recognized as European integration and particularly European Commission funding for comparative research focused attention on the role that varying educational systems, labor market institutions, and legal regulation had on the pattern of employment status change. The role which labor market structure, education, and social class processes and institutional context play in the increasingly complex patterns of employment status change is discussed below. The focus is on the processes associated with entry into the labor market and the role of flexible working practices in increasing employment status volatility across the life course.

The transition from education to work is one of the central changes in a person's life

and research suggests that its impact can last a lifetime (Korpi et al. 2003). The transition from education to work has changed considerably across most countries in the last three decades. Unemployment among young people increased sharply in the 1980s, with the consequence that young people stayed in education longer and gained higher level qualifications. The transition itself also became more protracted, with young people taking longer to make the transition and more likely to experience spells of unemployment, particularly those with lower educational qualifications, from manual social classes, or from ethnic minorities. From a microsociological or microeconomic perspective, the transition into the labor market is a "matching process" within which young people balance their present and future returns with continued education and training and employers attempt to recruit those individuals who are most productive and least costly to train. This matching process will be reflected in the stratification of outcomes for individuals. Higher levels of education, skills, and productivity will be of vital importance, but these are also structured by the social class background of the individual, their sex, and their ethnicity (Shavit & Müller 1998). However, this micro level understanding also needs to be placed within the structural context of the prevailing economic environment and the impact of differential education and labor market systems. In some countries (notably the US, Ireland, and Southern Europe), the education system is oriented toward providing general qualifications with little concern for the relevance of these qualifications for employers. In this sense, qualifications are general "signals" of the individuals' possible productivity. Other countries (Germany, Austria) have extensive vocational training systems featuring large scale apprenticeship schemes, with training in the work place as well as in the classroom. The latter have been shown to provide a much smoother entry for young people into the labor market, which avoids spells of unemployment and entrapment in poorly paid insecure work. Poor outcomes for young people have also been associated with "rigid" labor market regulation in terms of the employment protection for those already in the labor force (Bernardi

et al. 2000). Changing economic structures in industrialized countries after the mid 1970s led to increasing levels of unemployment and worklife turbulence for those in employment, with redundancy reaching far into the previously stable middle classes, although unemployment was still more concentrated among the manual classes and unskilled. Across Europe, many states responded to higher levels of unemployment with deregulation, or "reregulation," of the labor market to allow greater use of "fixed term" or short term contracts and part time working in an attempt to stimulate employment. This led to a surge in these types of contracts across many countries and to a substantial growth in the numbers of women working (Gallie et al. 1998). The question for researchers was whether fixed term contracts and part time hours were a "bridge" to better employment, or rather a "trap" locking people into jobs with poor prospects, conditions, and security. Research (Layte et al. 2000) has shown that previous unemployment spells are a major determinant of future unemployment and of downward occupational mobility, but research on the impact of fixed term contracts is mixed. Although research suggests that fixed term contracts are more likely to lead to unemployment, they can also act as a stepping stone to a more permanent contract, although evidence for both is mixed. Part time work has also been shown to be complex in its impact, with employment conditions and prospects dependent more on the type of job and contract rather than on the number of hours worked per se (Gallie et al. 1998). In conclusion, it is clear that the last three decades have seen an increase in volatility in employment status changes, with an increased risk of unemployment both for those entering the labor market and for those already working. However, these risks are not evenly spread and sociological research has detailed the influence of individual and social characteristics such as social class and the role of national educational and labor market systems.

en

Hirochika Nakamaki

En is originally a Buddhist concept for indicating causal relations, but it is also a term that is used regularly in Japanese social life. It has also proved to be a very convenient term in academic analysis. In Buddhist terms, *en* is used as a common idiom to refer to an individual's destiny from a previous reincarnation. *En*, however, refers to an indirect causal relationship rather than a direct causal relationship. In Buddhist usage, the concept of *kechi en* refers to relations with a particular Bodhisattva (Enlightenment Being). In Esoteric Buddhism, the *kechi en kanjou* is a rite based on *kechi en*. Here, in a secret ritual, the disciple throws flowers onto the top of a Mandala, and establishes a relation or tie with the Bodhisattva hit by them. *En* days are specially designated days said to have a special connection with the Bodhisattvas. Kannon day is the 18th day of the month, Jizou is the 24th, and Fudou is the 28th. On these days, a visit to a temple is said

to be a particularly pious act that brings substantial rewards.

The concept of *en* became separated from stricter Buddhist usage, and came to be used as a term to refer to general social and personal relations. *En gumi*, to make a connection, is a common term to indicate marriage, and *en dooi*, a “distancing of relations,” refers to a state where a potential marriage is considered impossible. Good *en* refers to a happy married life, and one particular form of bad *en* is “rotten relations” between a husband and wife, where one cannot separate even if one tries, what is recently termed co dependency. To have *en* indicates a positive prospect for the construction of human relations, whereas to lack *en* implies a resignation, a lack of probability for the building of a successful relationship. These are all commonly heard expressions in daily life.

En came to be used as a new term in academic analysis, and is found in use in the media and general society. *Chi en* and *ketsu en* are good examples. In the former, the term indicates local social relations, the latter refers to relations of kith and kin. Also, compound terms that utilize the word *en*, such as “kin groups” and “residential groups” or “local society,” are connected to references to society and group. The terms “local relations” and “kinship relations” refer to exceptionally restrictive social relations, what Chizuko Ueno has referred to as “non optional relations,” or ascriptive relations. Examples of such kin *en* (*ketsu en*) have continued since the times of hunting, fishing, and gathering societies. It is thought that local *en* (*chi en*) have become stronger since agriculture developed. In sociology and social anthropology, there is a huge body of knowledge about kin relations such as family, and consanguineous and affinal kinship relations. Moreover, within the East Asian civilizations sharing the Chinese writing style, there is a special quality in the application of the term *en* to newer types of human relations. To give two examples, the corporate or company relations of Japan (*sha en*), and the academic relations (*hagyeon*) of the Republic of Korea.

When Europe entered the modern era, ties of locality and kinship came to be replaced by new forms of social relations, and concepts such as *gesellschaft* and association were provided by

scholars. In Japan, on the other hand, the cultural anthropologist Toshinao Yoneyama proposed the concept of “associational ties” (*kessha en* or *sha en*) in the early 1960s. He reworked the concept of “association” (*sha en*) to provide a more inclusive meaning than that then being used by journalists (*kaisha en* or corporate association), in order to emphasize the function by which companies were associated with each other in corporate social networks. It was worked out specifically as a relational concept, an equilateral accompaniment to associations based on kin and locality, and also intended to emphasize the remarkable increase in the importance of these relations that accompanied industrialization and urbanization. As a background note to this work, during the post war period, one in which continuously high levels of socioeconomic growth were achieved, social groups based on company/corporate association came to stand in equal importance to associations of kinship and locality. The very concept of corporate associations (*sha en*) is itself a product of that period, the background of which was the substantial levels of corporate development that occurred. Naturally, the roots of corporate associations can be found in the various forms of ascriptive and associative units of sociopolitical organization dating from the Edo period (1600–1868). Another primary factor contributing to the development of corporate association is the fact that, compared to China and Korea, Japan has always had a relatively weak principle of paternal succession. As pointed out by the anthropologist Tadao Umesao, the origins of corporate association as a social unit are to be located first and foremost in the Japanese household, characterized by a strong paternal authority (*ie*). It was that particularly Japanese legal fiction known as the parent–child (*oya ko*) relationship that led the way from the household unit to the modern form of corporate association. The latter, born in this manner, is without a doubt the most important development in social relations in modern Japanese society. Yoneyama has emphasized that the so called License/Qualifications Society (*shikaku shakai*) is the result of these developments.

Technically speaking, since corporate associations are voluntary forms in terms of association and withdrawal, the term itself refers to a

second order social unit. Nonetheless, looking at the typical form of associations found in Japanese corporations until the bursting of the bubble economy in the early 1990s, the difficulty of resigning from a company once employed was such that these forms must be seen as having a highly restrictive quality. In this connection, the sociologist Chizuko Ueno has proposed the concept of optional associations, or associations of choice (*sentaku en*) as a residual category to kin, locality, and company associations. Born as an effort to better conceptualize new forms of human relations in urbanizing societies, such forms are free in association and withdrawal, and so lacking in the restrictive qualities of other forms. Examples of such social groups include the audiences at concerts, and so called “e friends,” persons whose social networks are mediated by electronic media such as the Internet. Further examples include hobby associations such as poetry or bird watching circles. Ueno has paid particular attention to urban women, especially socially isolated housewives. In opposition to the ways in which their husbands were immersed in their corporate social networks, these women found it necessary to construct a whole new variety of social groups based on voluntary association, such as those centered on their childrens’ education, their hobbies, and so on. Teruko Yoshitake has also christened such forms as “women’s associations” (*jo en*). In fact, there is even such a women’s group based on the joint ownership of grave plots. These optional associations, however, have little restrictive power, and so tend to be unstable in nature. Nonetheless, as Ueno has pointed out, as we face a rapidly aging society, we have reached a period where such optional forms of association are increasingly in demand, to replace associations of kinship, locality, and corporation.

In Japan there have been a number of terms coined using the root term *en* to define different forms of association, besides company associations, optional associations, and women’s associations. Yasuyuki Kurita and Tadashi Inoue have defined “information associations” (*jouhou en*), and Teruhiko Mochizuki has defined “value associations” (*chi en*) and “knowledge associations” (*chi en*). At the same time, the historian Yoshihiko Amino has discovered material regarding the use of the term

association (*en*) in medieval documents. He has reinterpreted the term *mu en* (literally, no relations), a term seeming to imply a lack of social associations or relations. He argues that this term does not in fact refer to a lack of social relations, but rather to the social situation of people removed from restrictive social relations based on fixed residence, as implied in the term *u en*, that is, “to have” social relations. Moreover, Amino has pointed out that the *mu en* form of association is itself seen as the associational basis of urban social relations.

The term *en* has proven so useful for expressing particular forms of social association that it has even appeared in texts translated into Japanese. As an example, Francis Hsu’s term “kin tract” has been translated into Japanese as “*en tract*.” Furthermore, based on Hsu’s term, Tsuneo Ayabe has provided a definition of club associations as a contractual type of association (*yaku en*).

In this current era, characterized by social trends such as global population flows, nomadic lifestyles, aging societies, and so called “gender free” marriages, we are seeing the attenuation of the restrictive nature of older forms of association based in kinship, locality, and company associations. At the same time, we are groping for new kinds of association that will entrust social bonds in the future. One phenomenon spurring on such developments is the spread of information technologies. A major focus of attention in coming years will certainly be the “virtual *en*” found in IT networks.

encoding/decoding

James Procter

The terms encoding and decoding are key words within a theory of communication first developed by Stuart Hall (1973). This paper challenges the established, empirical theories of mass communications research, which assume media messages are relatively transparent and stable. Hall uses the terms encoding and decoding to demonstrate that the media message is neither transparent nor dependent on the competence of individual receivers/viewers, but is in fact *systematically* distorted by the entire communication process.

In particular, Hall argues there is a lack of fit between the two sides in the communicative exchange between the moment of "encoding," when the message is translated into the aural visual signs of televisual discourse, and the moment of "decoding," when the viewer translates the encoded message. Hall notes that the visual nature of televisual discourse means we tend to overlook the mediated nature of media imagery, which appears to be a transparent reflection rather than a systematic construction of the world around us. Hall's sense that televisual discourse creates a communicative boundary that distorts media messages is informed by structuralist theory. Just as structuralism argues that language and sign systems do not reflect, but structure and construct, the real, so Hall argues that the visual discourse of television translates reality into two dimensional planes, and therefore is not to be confused with the referent it signifies. As he famously put it: "The dog in the film can bark but it cannot bite!"

Hall goes on to employ the structuralist distinction between denotation (a sign's literal meanings) and connotation (a sign's associated meanings) in order to pursue the competing meanings generated by the same media message. If at the denotative level there is a general agreement about the meaning of a sign – "the photo image of a sweater *is* (denotes) an object worn" – at the connotative level, meaning is contingent and can change depending on the context in which it appears and is read. Within the discourse of the fashion industry, Hall

suggests, the sweater may connote *haute couture* style of dress." However, located within the discourses of contemporary (1970s) romance, it may connote "long autumn walk in the woods" (Hall 1973: 12–13). It is at the level of connotation that the sign acquires its ideological significance, a significance that is capable of changing depending upon the context in which it is used. Hall is particularly interested in the "polysemic values" of the televisual sign within this context. An apparently innocent item such as a sweater acquires different, potentially conflicting meanings and ideological values depending on the context in which it is encoded and decoded.

Hall's account ultimately differs from an orthodox structuralist reading in that it is not simply interested in language and discourse as a closed, formal or ahistorical system, but with the "social relations" of the communicative process at any given moment. Adopting Marx's theory of commodity production, Hall likens encoding to "production" and decoding to "consumption." When an item is depicted on the news, it does not appear as a raw unreconstructed event; it is discursively produced, or encoded in terms of what Hall calls the "institutional structures of broadcasting." These might include such things as conducting interviews with authority figures, specialists, and eyewitnesses, researching news archives, obtaining relevant photographs and film clips, and so on. While these institutional processes help to secure or determine meaning in significant ways, creating what Hall calls "dominant" or "preferred" meanings, there is no intrinsic meaning embedded within televisual discourse. For the encoded message to generate meaning it must first be decoded by the viewer. It is only at this moment that the television message acquires "social use or political effectivity."

Hall regards decoding as the most significant and the most overlooked aspect of the communication process. Where mass communications theory suggested the viewer plays a passive role in the construction of meaning, Hall regards audiences as active consumers. If audiences were once regarded as an undifferentiated "mass," Hall is keen to distinguish between different positions taken up by audiences. In order to do this he develops three hypothetical

categories first posited by Frank Parkin in *Class Inequality and Social Order* (1971): the dominant hegemonic position, the negotiated position, and the oppositional position.

Viewers that decode a particular media message in terms of the preferred meanings of the dominant social order might be said to occupy the dominant hegemonic position. For example, a viewer watches a report on the "War on Terror" led by President George Bush following 9/11 and concurs that, yes indeed, something must be done to stop global terrorism. The negotiated position refers to viewers who adopt a more contradictory response to the media message, and whose acceptance of the preferred or dominant meaning is conditional. For example, a viewer watches the same report on the "War on Terror," accepts the need for action, but questions the treatment of prisoners at Guantanamo Bay on humanitarian grounds. The oppositional position refers to that of the viewer who recognizes but rejects the dominant meanings of the media message. For example, a viewer who watches the "War on Terror" report, but reads it in oppositional terms as a war to secure US hegemony. As Hall views it, these three positions are not static or discrete, but constitute an overlapping continuum across which viewers move. Nor are these positions individual, personal, and self-conscious responses to particular media messages. Rather, they refer to ideological and therefore largely unconscious positions taken up by certain social groups, communities, and constituencies relating to class, gender, ethnicity, and so on.

Hall's paper became particularly influential in the 1980s and early 1990s, when it prompted fresh research within cultural studies into the neglected issue of audiences. One of the most influential research projects to develop Hall's encoding/decoding model was conducted by David Morley in *The "Nationwide" Audience* (1980). *Nationwide* was a popular early evening light news program broadcast by the BBC until 1983. Morley applied the three hypothetical positions associated with dominant, negotiated, and oppositional readings to actual audience responses to *Nationwide*. Morley, who grouped his audiences in terms of occupation, class, and so on, found that reading positions did reflect the ideological values of these different social

groups to an extent, but concluded that these positions were in no way reducible to social categories such as class.

endogamy

Nazli Kibria

"Endogamy" refers to in-group marriage, or a pattern of marriage in which the partners have a shared group affiliation. Its conceptual counterpoint is exogamy, or a pattern of marriage in which the partners are different in their group affiliation. For scholars of race and ethnic relations, the significance of endogamy stems from its relationship to group boundaries and the processes by which they are maintained, transgressed, and negotiated. Indeed, endogamy is

generally understood to be among the most important social mechanisms in the formation and re formation of racial and ethnic groups.

Endogamy is increasingly recognized to be a complex and emergent social process. Underlying this recognition are theoretical developments in the study of ethnic identity, which is increasingly seen as multiple and fluid rather than singular and stable in character. This conceptualization also suggests that definitions of endogamy will also shift, depending on what particular aspect of identity is under consideration as well as the historical circumstances and meanings that surround it. As, for example, in the case of a marriage in which the partners are different in their ethnic affiliation but similar in their religion, a marriage that is endogamous in one respect may not be so along another dimension. Furthermore, there is a sense in which marriage itself, regardless of whether it initially involves persons who are similar or different in a particular way, may work to create endogamy or at least make exogamy invisible. As highlighted by situations in which one spouse undergoes conversion into the religious affiliation of the other spouse, marriage may result in the incorporation of the "outsider" into the group in question.

Even with these considerations, it would be fair to say that endogamy, defined as a marriage pattern that preserves the primary group distinctions prevalent within a society, has been and continues to be a widespread norm. In pre modern societies, endogamy was largely ensured by prevalent structural conditions, in particular the limited degree of social and geographical mobility available to and experienced by most persons. In addition, marriages were understood not as matters of individual negotiations of romantic love but as practical contracts that were closely intertwined with the authority and interests of the larger kin group (Giddens 1992). These conditions too were encouraging of in group marriage in the sense that in pre industrial societies the endogamy of members was generally advantageous to the kin group, allowing it to consolidate and to expand its local networks and resources.

In late modern societies, endogamy continues to be the norm, particularly with respect to the boundaries of social class and race. This

is certainly the case in the contemporary United States. In some parts of America, interracial marriage remained illegal until the 1960s. To day, however, it is maintained not by laws but by other dynamics, most importantly perhaps by the presence and power of informally segregated social networks in the organization of people's lives. Writing of the contemporary US, Whyte (1990) observes that "dating and mating" almost invariably take place within rather than across race and class based networks. However, while racial endogamy continues to be the norm in the US, it is also the case that it has declined over time. In 1960, 99.6 percent of all marriages were racially endogamous, in comparison to 94.6 percent in 2000. As noted by Nagel (2003), rates of racial exogamy are highest among Native Americans (67 percent), followed by Asians (26.3 percent), Hispanics (26.1 percent), blacks (10.9 percent), and whites (6.1 percent).

The rise in racial exogamy has generated a growing body of literature on its implications, particularly for the "mixed race" children who emerge from these unions. Scholars writing about interracial marriages in the 1930s and 1940s were overwhelmingly pessimistic about the fate of the children, emphasizing their identity confusion and lack of acceptance by others (Song 2003). Much of the contemporary literature has a very different tone, emphasizing the positive aspects of a mixed heritage. Instead of choosing the affiliation of one parent over another, "mixed race" persons are increasingly inclined to acknowledge and to maintain their diverse heritage, thereby challenging the singular conception of racial identity that has been prevalent in the US (Root 1992). This is so even among those who have one black parent, and who thus face the deeply rooted US "one drop rule" whereby any black ancestry results in one's automatic assignment by others to the category of black. It was in part due to the efforts of "mixed race" persons that the US Census underwent an important policy shift in 2000. Respondents are now allowed to check off as many race affiliations as they wish instead of being limited to a single one.

endogenous development

Kosaku Yoshino

Endogenous development was presented as an alternative perspective on development that reconsidered modernization theory, which had until the 1960s been the dominant analytical paradigm of social change, especially in American sociology. From the late 1960s throughout the 1970s, criticisms were directed against modernization theory on the grounds that modernization was a West centric model and that as such it would not necessarily lead to industrial growth and fair distribution of social benefits in non western settings.

The notion of "endogenous development" originates in two sources. One is a report entitled "What Now: Another Development," produced by the Dag Hammarskjöld Foundation. It was presented to the Seventh Special Session of the United Nations General Assembly in 1975. The Assembly met in the midst of a deep crisis in development and international economic relations, with problems being brought to the fore in areas such as food, energy, population, the environment, and economic and monetary matters. The central elements of this alternative mode of development, according to the report, are that it is (1) "geared to the satisfaction of needs, beginning with the eradication of poverty"; (2) "endogenous and self reliant, that is, relying on the strength of

the societies which undertake it"; and (3) "in harmony with the environment." It was proposed that an endogenous and self reliant development stems "from the inner core of each society," relies on "the creativity of the men and women who constitute" a human group, becomes "richer through exchange between them and with other groups," and entails "the autonomous definition of development styles and of life styles." Thus, the notion of endogenous development is not narrowly that of economic development per se, but deals also with cultural and social development (Dag Hammarskjöld Foundation 1975).

The other original contribution came from a Japanese sociologist, Kazuko Tsurumi. She first used the term "endogenous development" in 1976. As someone who studied under the supervision of Marion Levy, Jr. and as a long time student of the indigenous scholarship of Kunio Yanagita, a founding father of Japan's folklore studies, Tsurumi was in a good position to critically examine western theories of social change and modernization in light of non western experiences. In an attempt to construct an alternative model of development to modernization, she emphasized the value of "endogeneity" of development on the following grounds.

First, modernization theory as formulated in Europe and culminated in the United States in the 1960s identified early developers such as England, the US, and France as endogenous developers who pioneered the model of modern society. By contrast, latecomers to modernization such as Japan, China, and other Asian, African, and Latin American countries are exogenous developers or model receivers. Endogenous refers to something internal that is generated from within a system, as opposed to exogenous, which means something generated from outside. The early developers created models of modernization out of their own traditions, whereas all latecomers borrow models from the early developers. This, of course, causes tensions between exogenous models of technology, science, and social organization and the indigenous patterns of technology, social structure, and values.

Second, from the point of view of the non western world, Tsurumi emphasized the

development of the non material life. Through "spiritual awakening" and "intellectual creativity," people can become active agents of social change. This theme was explored at the United Nations University's Asian Regional Symposium on "Intellectual Creativity in Endogenous Culture" at Kyoto in 1978 (Abdel Malek & Pandeya 1981). In offering some concrete examples of such development, Tsurumi drew attention to the revival of the idea of symbiosis of nature and people in the movement to regenerate the pollution devastated area of Minamata in Japan, the conscious use of traditional social structure to avoid or mitigate the more negative aspects of industrialization and urbanization in the Jiangsu Province of China, and the Buddhism based self help movement in Thailand and Sri Lanka.

Tsurumi summarizes the essential elements of endogenous development as follows. The goal of endogenous development, first and foremost, is for all humans and their groups to meet basic needs in food, clothing, shelter, and medical care as well as to create conditions in which individuals can fully utilize their potentialities. This goal is common to all human beings, but paths to it follow diverse processes of social change. To achieve this goal, individuals and groups in each region must autonomously create social visions and ways forward to the goal by adapting to their own ecological systems and basing development programs on their own cultural heritage and traditions. With this as a starting point, foreign knowledge, technology, and institutions can be more effectively and harmoniously adopted to aid the development process. She argues that "the expansion of endogenous development on a global scale would mean the achievement of multilinear development. We can then exchange models with one another regardless of whether the models are those of early comers or latecomers" (Tsurumi 1989).

Modernization theory was constructed using a society (a nation state) as the basic unit. In turn, dependency theory, formulated as a critical response to modernization theory, focused on relations between center and periphery. As such, dependency theory, too, presupposes a nation state and its subsystems as its basic units of analysis. By contrast, the theory of

endogenous development identifies a region as its analytical unit. Here, region is not the same as a subsystem of a nation state but an entity that quite often crosses boundaries between nation states. In formulating the concept of region, Tsurumi relies on Tamanoi (1979), who defines "regionalism" as "a pursuit of administrative autonomy and economic self reliance as well as cultural independence by the residents of a region, who hold a sense of attachment to their regional community on the basis of its climatic and ecological characteristics."

The notion of endogenous development began to be employed extensively in the late 1970s by organizations, including the United Nations and UNESCO, as well as by individual researchers in various countries and regions. It was an attempt to explore an alternative route to development in a world faced with dangerous and seemingly intractable global problems, such as disruption of ecosystems, poverty, and famine.

Engels, Friedrich (1820–95)

Clifford L. Staples

Without Karl Marx, of course, few people today would know the name of Friedrich Engels; but without Engels we might have heard much less from Karl Marx.

Engels was born into a wealthy, devout, Protestant family in the industrial town of Barmen (now Wuppertal) in the Rhineland region of what is now Germany. The industrialist father wished his eldest son to follow in his footsteps, and so in 1838, before he could even finish high school, Engels was sent to clerk for a business in Bremen. But his lack of higher education did not prevent Engels from tackling difficult philosophical issues. In Bremen, free from the fundamentalism of his Pietist parents and teachers, he became a voracious reader of literature, philosophy, history, and science. Critically, neither his privileged family background nor his own eventual success as a capitalist prevented him from devoting his life to destroying capitalism. He also had a natural talent with languages – a skill he would put to good use in his later years as an international political figure and organizer.

It didn't take much to be a political radical under the Prussian monarchy in the 1830s, and so Engels published his early anti-Pietist and democratic views under the pen name of Friedrich Oswald. He was soon drawn, however, to the more intellectually challenging work of the "Young Hegelians," a cluster of Hegel's followers. In 1841, at the age of 21, Engels moved to Berlin and volunteered for the military. Doing so allowed him to satisfy his required military service while attending university lectures, writing articles and pamphlets, and meeting with the Young Hegelians. While Engels would retain a keen interest in military science and strategy throughout his life, he seems to have had plenty of energy, as well, for books and bars and in causing as much trouble for the authorities as possible.

The Young Hegelians wanted to apply Hegel's philosophy of dialectical change, development, and progress to church, state, and

society: a radical turnabout that was most unwelcome by the establishment. But there were disagreements among the young radicals and many of them, while expressing anti-establishment views, remained committed to Hegel's idealism – an idealism that others (Ludwig Feuerbach, Karl Marx, and Friedrich Engels among them) found untenable.

While Engels was in Berlin, Ludwig Feuerbach published *The Essence of Christianity*, a book that, for some, pointed the way out of the confines of the Hegelian system and urged a reconsideration of materialism. And while Engels as well as Marx would reject the somewhat crude materialism of Feuerbach, Engels some years later described Feuerbach's view as an "intermediate link between Hegelian philosophy and our own conception."

In 1842, after completing his military service, Engels traveled to Cologne, where he met with Karl Marx and Moses Hess, both of whom were editors at the *Rheinische Zeitung*, which Engels had written. Hess saw England as the country most likely to produce his hoped-for communist revolution. As it happened, Engels's father had significant financial interests in a large textile factory in Manchester, and so Engels, now a communist himself, went for two years to Manchester to work in the factory as a clerk. In addition to directly observing conditions in the factory, he also met trade unionists, socialists, and other radicals, and based on fieldwork in the neighborhoods of Manchester, wrote articles about social and economic conditions for Marx's *Deutsch-Französische Jahrbücher*. He also began a critical study of the works of English political economists. In 1845 he would publish a book entitled *The Condition of the Working Class in England, 1844* based on his fieldwork in Manchester, and his work on the English political economists would point Marx toward the material for *Capital*.

On his way home to Barmen, Engels made a brief stop in Paris and again met with Marx. As Engels later wrote: "When I visited Marx in Paris in the summer of 1844 we found ourselves in complete agreement on questions of theory and our collaboration began at that time." In the next two years Engels would marry Mary Burns – a working-class Irish woman – with whom he would live until her

death in 1867 (after which he lived with her sister), and he and Marx would collaborate on several manuscripts, including *The Holy Family* and *The German Ideology* in which they would make some attempt to flesh out their philosophical and political positions and distinguish themselves from a number of rivals. This writing – or theory – was done, of course, in the interest of furthering the radical political practice to which both were committed. And it was out of this collaboration, and at the request of the London based League of the Just, that perhaps the world's most famous political pamphlet, *The Communist Manifesto*, was written.

In 1848 the rebellions in France spread to Germany, and Marx and Engels quickly took up the fight against the Prussian monarchy by moving to Cologne and taking over editorship of the *Neue Rheinische Zeitung* newspaper. But afraid of the growing strength of the workers, the German bourgeoisie sided with the aristocracy and moved to crush the workers. Marx was soon deported, but Engels took an active part in the uprising, serving as an aid to a commander fighting against the Prussians. As defeat neared, Engels escaped to Switzerland, and from there made his way to London.

With the defeat of the 1848 rebellion, Marx and Engels concluded that the near term prospects for revolution were unlikely and so turned their attention to scholarly and organizing work that they hoped would prove useful when the revolutionary moment reappeared. Marx began his work on political economy in the British Library while Engels once again took up the position of clerk, and eventually partner, in his father's Manchester factory. For the next 20 years Engels lived and worked in Manchester, providing both for himself and for the Marx family living in London.

While Marx worked on *Contribution to the Critique of Political Economy*, published in 1859, and the first volume of *Capital*, in 1867, Engels would clerk by day and by night keep up an almost daily correspondence with Marx, ghost write many of the articles that Marx had agreed to write for the *New York Daily Tribune*, and continue with his own wide ranging studies in natural sciences, history, and military science. A man of boundless energy and optimism, Engels also managed to find time for a lively social life.

In 1870 Engels sold his share of the Manchester factory, moved to London, and joined Marx on the General Council of the International Workingmen's Association – the First International – which had been founded in 1864. Now retired, he took over the burden of the organization's correspondence, freeing Marx for his more scholarly work.

Of particular concern to Engels and Marx at this time was the emergence of the German Social Democratic Party in 1875, a move they supported, though not unconditionally, as Marx wrote in the *Critique of the Gotha Program*. For his part, Engels wrote a series of articles defending Marx and himself against the attacks from within the Social Democratic Party by the followers of Eugen Dühring. Later, these articles were collected together into a book known as the *Anti Dühring*, selected chapters of which were then excerpted and published in a widely read pamphlet entitled *Socialism: Utopian and Scientific*. In 1881 the German Social Democratic Party dropped the Gotha program and adopted a Marxist program largely because of the influence of the *Anti Dühring*.

After Marx's death in 1883 Engels devoted the rest of his life to Marx and Marxism, largely at the expense of his own work. Although he did manage to publish *The Origins of the Family, Private Property, and the State* in 1884, his *Dialectics of Nature* was published in 1925, long after his death. His first priority was to see to it that the remaining volumes of *Capital* were published – no simple task given the disorganized state in which Marx left his papers. Volume 2 was published in 1885 and Volume 3 appeared in 1894. His second priority was leading the international socialist movement, which he did by continuing his worldwide correspondence, writing articles for and advising the leaders of the Second International, and meeting with visiting intellectuals and revolutionaries, such as Georgi Plekhanov, one of Russia's first Marxists. Engels also managed to visit the US for two months in 1888, and in 1893 addressed the final session of the Congress of the Second International in Zurich. Vigorous until the end, Engels died of throat cancer in 1895.

Much of what Engels had to say to sociologists is learned via the study of his more famous

collaborator, Karl Marx. But, as is evident from the multiple ways in which Engels supported Marx during, and even after, Marx's life, without Engels Marx might never have become the legendary figure we know today. This is why we continue to recognize Engels's contribution to Marxist sociology.

But Engels is and should continue to be appreciated on his own. As capitalism spreads to all corners of the globe, the conditions of the English working class in 1844 are today being reproduced in the conditions of the Chinese, Mexican, and Malaysian working classes. Thus, Engels's *The Conditions of the English Working Class in England, 1844* could continue to be studied and analyzed by fieldworkers as one approach to critical ethnography. Beginning in the 1970s, feminist anthropologists and sociologists read Engels's *The Origin of the Family, Private Property, and the State* as they sought to understand women's subordination and oppression across cultures and over time. To this date, Engels's book is often included on lists of key works in feminist theory, though of course his claim that women were the first oppressed class continues to be critiqued and debated. Finally, many sociologists have come to believe that the discipline should be more attentive to and focused on the needs of the public rather than the needs of elites, and it is difficult to think of anyone who might better fit the description of a "public sociologist" than Friedrich Engels. We should, therefore, continue to study his life as well as his work – with and without Karl Marx.

enterprise

Alberto Martinelli

The sociological analysis of the enterprise focuses on the relationships between enterprises and their social environment (Martinelli & Smelser 1990), with specific regard to two major topics: the study of organizational models and social systems of production and the study of the context of entrepreneurship.

Since the 1970s the productive model based on mass production and Fordist/Taylorist work organization in the large corporation have undergone crisis and transformation. As a consequence, a new economic sociology has arisen, which centers on the origins and developments of new organizational models of production based on flexibility. These changes at the micro level of the enterprise's organization were accompanied with parallel changes at the macro level of the relationships between state and market, as Fordism in the work place was often related to a government's Keynesian policies.

The Fordist/Taylorist model was the dominant model of enterprise organization in the twentieth century and reached its peak in the two decades after World War II. Its key distinctive elements were mass production, vertical integration, the use of a low skilled labor force, and the fragmented organization of working tasks. This model of enterprise organization had been analyzed in the earliest studies of economic sociology (like those of Sombart and Weber), but it became the main object of sociological industrial research in the course of the twentieth century, although the timing and speed of its diffusion varied in the different capitalist countries. Typical examples of this kind of research are the work of Kerr et al. (1960) on the organization of

American enterprises, the studies of the French school of *Sociologie du travail* on the consequences of technological change, and Dore's (1973) comparative research on British and Japanese enterprises.

In the last decades of the twentieth century the internal structure of the enterprise organization underwent major changes, first of all in the decline of mass standardized production in favor of flexible specialization, customized production, and diversified quality mass production. The main factors accounting for this change – a true “second industrial divide” (Piore & Sabel 1984) – were the growing demand for more diversified and higher quality products by better informed and more demanding consumers in the mass markets of developed countries; and the spread of the new information and communication technologies that allow just in time production and better quality controls. These changes fostered a diversification of productive models and a reframing of the firm's relationships with the social context. In the light of these changes a new economic sociology has developed, which focuses on the analysis of “social systems of production.” These systems include the internal structure of the enterprise, industrial relations, training systems, relationships with competitors, suppliers, and distributors, the structure of capital markets, the nature of state interventions, and the conception of social justice (Hollingsworth & Boyer 1997). Analyses of these systems explore the links between the various institutional forms of the enterprise and its social environment using concepts like social networks, trust, social capital, cultural values, and norms.

In the new phase of industrial organization we witness multiple and diversified productive models affecting both large and small enterprises. The most interesting organizational developments studied by sociologists concern the large enterprises as networks and industrial districts. The need to reduce the separation between the design and the making of products – which was typical of Fordism – meant that large enterprises changed both the internal organization of labor in the direction of just in time production and greater cooperation with workers, and the external networks of cooperation with specialized suppliers all along

the supply chain. As far as small firms are concerned, sociological research has focused on industrial districts, which grow where either one or both the following contextual factors are present: traditions of good craftsmanship and strong community ties (as in areas of northern and central Italy) and first quality higher education and research institutions (as in areas like Silicon Valley, Boston Route 128, Baden Wurtemberg, and the Fukuoka region). Critical elements in the success of industrial districts are such intangible assets as trust and capacity to cooperate, which are in turn rooted in strong local identities.

Enterprise as networks and districts of small and medium size firms are not, however, the only forms taken by flexible specialization. The other side of flexibility is the informal economy or, more specifically, the hidden economy. The informal economy includes, besides the production of illegal goods and services with illegal means (criminal economy), and the production of goods and service for self consumption without the intermediation of money (family or communitarian economy), the production of legal goods and services by illegal means (hidden economy). The hidden economy develops wherever greater flexibility and competitiveness are sought by violating fiscal and labor laws and disregarding standards of both environmental sustainability and social responsibility. The enterprises of the hidden economy are influenced by their cultural and institutional context: areas of the hidden economy are, for instance, well entrenched in immigrant communities of major American and European cities. Actually, all the new flexible forms of productive organization are more embedded in their social contexts than those predominant in the Taylorist/Fordist phase.

The other major sociological contribution to the study of the enterprise is the analysis of the context of entrepreneurship. Sociologists have contributed significantly to the study of entrepreneurship, critically integrating economic theory. Most economists, with notable exceptions like Schumpeter and Kirzner, seem to think that entrepreneurial activities will emerge more or less spontaneously, whenever economic conditions are favorable, as an instance of rational profit maximization. Context is either ignored or taken into account, disregarding its

social and cultural complexity and the variety of different historical settings, and there is no appreciation of the interaction between actor and context.

Most sociologists consider entrepreneurship as a much more problematic phenomenon, deeply embedded in societies and cultures; they focus on the influence of, and the mutual interplay among, non economic factors such as cultural norms and beliefs, class and ethnic relations and collective action, state intervention and control, organizational structures, bounded solidarity and trust, deviant behavior and marginality status, social approval of economic activity, business ethics, and motivations for achievement. A key concept in the sociological analysis of entrepreneurship is that of double embeddedness (Kloosterman et al. 1999), which highlights the two major ways in which the context of entrepreneurship can be analyzed: first, as the politico institutional environment of market capitalism, such as types of markets (of factors of production and of goods and services), and types of laws (fiscal, labor, anti trust) and institutions of governance; second, as the social and cultural background of entrepreneurs, such as cultural attitudes favoring technological innovation and risk taking and networks of social relations and social capital.

The study of the institutional context of entrepreneurship is a longstanding tradition of research, from the Harvard Center for Entrepreneurial History to recent studies on institutional coordinating mixes and on the varieties of capitalism. Entrepreneurship is basically defined by technological innovation in a competitive market. However, both technology and competition require an extensive social organization. Successful entrepreneurs are those who succeed in establishing stable relationships with their internal and external stakeholders (i.e., persons or groups who claim rights or interests in a corporation and its activities, past, present, or future – not only shareholders but also workers, suppliers, customers, and local communities). The ability to establish these relationships is itself dependent on the production of stable societal institutions such as governments and laws. Contrary to the view that firms are efficient wealth producers while

governments are intrusive and inefficient, the sociological analysis of entrepreneurship shows that the establishment of a stable and reliable legal and political environment through government legislation and policies (patents, anti monopolistic laws, consumers' protection laws, public spending to sustain aggregate demand, support for exporting firms, etc.) is required for entrepreneurial activities to develop and endure.

There is no single appropriate institutional environment for entrepreneurial development that can pretend to universal validity. Different varieties of capitalism exist and evolve through time, as do different modes of corporate control (Fligstein 1990). But the institutional context of entrepreneurship is not limited to the interplay between markets, firms, and governments. Studies on the institutional varieties of capitalism have shown how more complex institutional mixes of markets, states, hierarchical organizations, communities, clans and networks, and associations coordinate and regulate business activities (Crouch & Streeck 1997). Each of these coordinating mechanisms has its own logic – its own organizational structure, its own rules of exchange, its own procedures for enforcing compliance both individually and collectively; each can be evaluated in terms of efficiency, effectiveness in delivering private and collective goods, and capability to meet the claims and expectations of various stakeholders of the firm.

This richness of institutional contexts has not diminished because of globalization. Contrary to a widespread belief, globalization does not induce homogenization toward a single model, but stimulates a variety of institutional responses, which are rooted in the specific cultural codes and social relations of different countries and regions.

Sociological research on entrepreneurship has also focused on the other side of double embeddedness: the social and cultural background of entrepreneurs. The question of the contextual conditions which produce entrepreneurs has been traditionally addressed in terms of deviance and marginality. Acting in a hostile social milieu, where prevailing attitudes are against innovation, and being excluded from political power, marginal entrepreneurs

concentrate on business, but, being outside the dominant value system, they are subjected to lesser sanctions for their deviant behavior. More recent works on ethnic communities (Portes 1995) and women show that factors like racism, sexism, and credentialism render people "outsiders" through processes of exclusionary closure; such outsiders often form "feeder groups" from which new entrepreneurs emerge.

Weber's comparative analysis of religious ethics and economic action in the origin of capitalism provides the basis for studies stressing cultural context variables. Neo Weberian research focuses on the degree to which the forces of rationalization responsible for dislodging individuals from their embeddedness in nature, religion, and tradition continue to shape economic growth and social modernization (Berger 1991). Economic growth develops from the bottom up, not from the top down: ordinary individuals, competing with each other to achieve a variety of goals – including economic profit and self advancement – in their everyday activities, practices, habits, and ideas, create the basis for other distinctly modern institutions to emerge that may mediate between them and distant, large scale structures of society.

The most convincing contributions to the study of the context of entrepreneurship are those integrating various approaches and selecting the most appropriate mix for the analysis of specific empirical questions and historical realities, as in the case of research on ethnic entrepreneurship (Waldinger et al. 1990). All these studies work out models which try to combine a plurality of variables in order to understand the relation between the entrepreneur and the context in which he or she is embedded: social networks, selective migration trends, settlement patterns, structure of markets, access to ownership, residential patterns, group culture and aspiration levels, immigration, and labor market policies.

enterprise unions

Ross Mouer

The enterprise union (*kigyobetsu kumiai*) has been the dominant form of union organization in post war Japan. When the interest in Japan's economic prowess suddenly surfaced in the 1970s, the *kigyobetsu kumiai* was singled out as one of the three features constituting the Japanese model of industrial relations. Possibly the least understood of the three, the enterprise union was often confused with the company union and an approach to employee relations

whereby the union is coopted by management to foster and to maintain a compliant labor force subservient to the needs of management (Galenson & Odaka 1976). The Japanese have a term (with a negative connotation) for this kind of unionism – the *goyo kumiai*, literally, a union at his majesty's (i.e., management's) service. The debate on the nature of the enterprise union in Japan brought to the general discussion of unions a more subtle delineation between different types of union organization (e.g., as in Kawanishi 1992).

Kigyobetsu kumiai refers to a form of union organization which restricts union membership to regular employees at a given enterprise. "Regular employees" are those employed on a permanent long term basis. In larger firms these employees have access to career paths within the firm's internal labor market(s). Two or more enterprise unions may exist at the same enterprise. Generally, "the enterprise" is a designated place of business, and each firm, company, or corporation may have multiple places of business. Accordingly, a manufacturing firm with five factories might have one (or more) independent enterprise union at each factory. It is common for ideologically aligned unions at different enterprises operated by the same firm to join together in a firm wide federation (known as a *kigyoren*). Such a federation may recast itself as an enterprise union with the union organization at each enterprise (e.g., factory) having branch status (as a *shibu*). Enterprise unions may affiliate with an industrial federation either directly or through a firm level federation. It should be noted that several forms of union organization exist in Japan at the enterprise level.

The labor movement in post war Japan has been characterized by ideological fissures, with a good proportion of firms in the 1960s embracing the branch of a left wing, politically active industrial union (known within the firm as a "number one union") and an economically oriented conservative enterprise union (known as a "number two union") (see Fujita 1968). Number one unions were in many cases affiliated with a left wing national center known as "Sohyo" (General Council of Trade Unions of Japan) via an industrial federation or directly as a branch of an industrial union; the number two unions were affiliated with a national peak

organization known as "Domei" (Japanese Confederation of Labor) through their industrial federation (see Fig. 1).

In many firms the antagonistic competition between these two types of enterprise unions produced an interesting dynamic in many firms and, more generally, within the economy as a whole. Sohyo (founded as a national center in 1949), its industrial unions (and federations), and the number one unions tended to focus more on workers' rights, social justice, and other issues related to the autonomy of workers on the shop floor. Domei (founded as a national center in 1964), its industrial federations, and the number two unions tended to focus more on ways to cooperate with management to improve productivity and, ultimately, the remuneration which could be paid to employees. Although each approach had its own rationale, during Japan's first four post war decades many workers entertained a dual consciousness which was open to both emphases. Management at many firms responded by adopting a middle of the road approach which combined, for example, the egalitarian demands for an age based wage system with elements that rewarded performance and other characteristics more tightly linked to improving efficiency. However, the merger of the two major national centers at the end of the 1980s to form Rengo (Japan Union Confederation) diminished the significance of this form of "latent functional specialization" which resulted from the way Japanese workers organized themselves.

The pros and cons of the *kigyobetsu kumiai* were vigorously debated during the 1970s and 1980s, owing in part to the relevance attached to it as part of the Japanese model (e.g., Shirai 1983). Among the positives, various observers have pointed to the ability of the enterprise union to understand the financial realities of a particular firm and the various individuated needs of its employees within the context of a dynamic labor market. To the extent that those needs revolved around employment security and higher incomes, the union was seen to be in a superior position when it came to tailoring an overall package of demands which would be predicated on the firm's economic health as the basis for achieving the long term employment security and income related goals of its

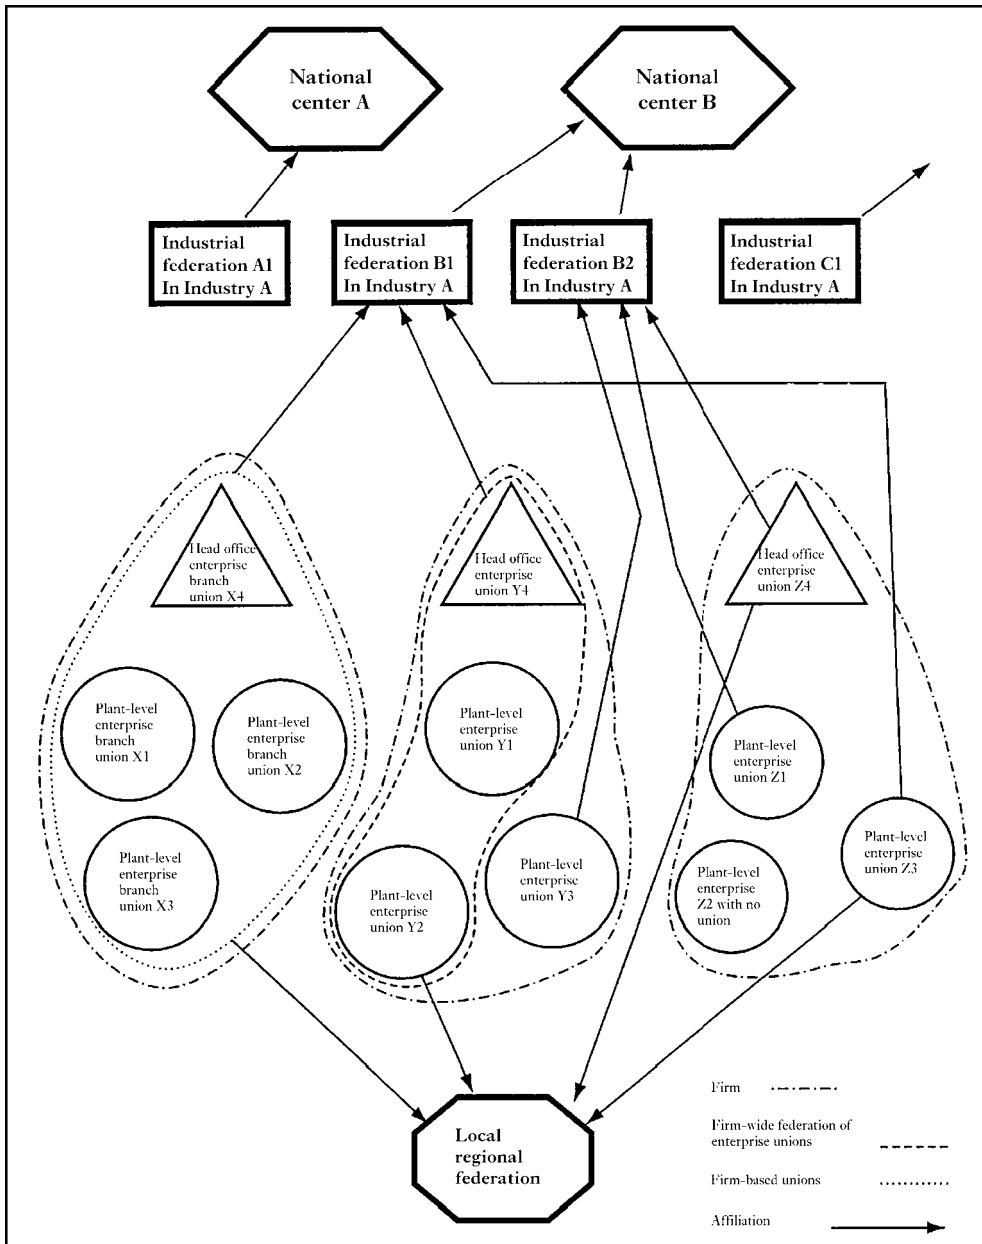

Figure 1 Enterprise unions.

members. It was argued that leaders of the enterprise union were as “insiders” better positioned than “outsiders” from an industrial union (1) to obtain relevant information from management in their firms and (2) to understand the decision making/negotiation strategy

of their own firm. This in turn would result in a greater likelihood that concessions would be won. In return for a conciliatory approach, it was argued, a firm would later reimburse its labor force as the economy continued to expand. Some would see in this arrangement a

tradeoff between wage restraint and the maintenance of the other two components of the model mentioned above – especially the guarantees of long term employment.

There was in this approach, however, a feeling among some critics that firms were “buying off” union leaders and their membership. Critics of the *kigyobetsu kumiai* have maintained that too much closeness between labor and management resulted in labor and management postponing many of the hard decisions that needed to be made to establish sustainable rates of change in the enterprise. Recognizing the ability of union leaders to discipline the labor force in a responsible manner, some critics have focused on how enterprise unions have functioned like adjunct personnel departments facilitating management programs that intensified workloads or even implemented redundancy packages and other measures designed to rationalize further the way firms are run. Performing this kind of personnel management function for management, such critics would argue, many enterprise unions ended up sacrificing the interests of their members. The enterprise union has also been criticized for keeping union assets and resources in a segregated state, and for relying on locally generated leadership which is often more committed to resuming roles on the firm’s management team than to training as professional leaders for the union movement. In this regard, the tendency for effective union leaders to be promoted back onto the management team has been noted.

These concerns have focused attention on the ability of enterprise unions to negotiate successfully with management to achieve long term and short term outcomes in the interests of their members. Another set of concerns has revolved around the elitist characteristics of the enterprise union as an organization reserved for the privileged regular (male) employees in Japan’s largest firms. Here critics have noted the tendency of the enterprise union to ingrain among its members a fairly strong consciousness that they are the aristocracy of labor. Over time, it has been argued, members of many enterprise unions came to believe that their own interests were well served by tiered subcontracting, an arrangement from which they benefited when the working conditions for

employees doing the same work in smaller subcontracting firms were inferior to their own. In this sense, then, the enterprise union has been predicated on the assumption that fairly extensive internal labor markets would ensure the future well being of union members, and has been extremely effective in representing the interests of the workers it represents. From this perspective, however, the most lasting criticism might be that enterprise unions have tended not to be concerned with non members – those casually employed by the firm, those who are no longer employed by the firm (as a result of voluntary and involuntary separation), and those in the firm’s tiered pyramid of subcontractors. It is not surprising, therefore, that the enterprise union has been prevalent mostly in Japan’s large firms.

A final debate concerns to what extent enterprise unionism accounts for the decline in the unionization rate in Japan from about 35 percent in 1975 to just over 20 percent in 2000. However, declining rates seem to be rather universal, and aspects of this phenomenon have been noted overseas (e.g., concerning globalization and changing industrial structures). Already in the 1990s moves were made to form new types of special interest unions (e.g., for women employees or for line supervisors – *kacho* – or for part time workers) or more general unions (which could embrace unemployed workers). The immediate challenge in Japan will be for the union movement to somehow embrace both the non regular employee and the 60 percent of the labor force still employed in Japan’s smaller firms that employ fewer than 100 persons. For the enterprise union, the organization of those in the first group may be possible in large firms, but efforts of such unions are likely to run against the diseconomies of (small) scale when it comes to doing so in Japan’s smaller establishments. However, as the first group becomes more diverse, there, too, the difficulties faced by the enterprise unions in trying to differentiate their appeal may be insurmountable.

For some time the enterprise union has been seen as the most uniquely Japanese component of the Japanese industrial relations model (the other two components being long term employment and seniority wages). Its prevalence was explained largely in cultural terms.

However, as an appreciation of how it functions in structural terms, the merits of enterprise bargaining have been recognized abroad to the extent that it was introduced (without the enterprise union) to Australia in the late 1980s and early 1990s to remove the complexity which comes from management (and union negotiators) having to deal with a large number of industrial unions, and the complex array of industrial awards that often resulted from having multiple unions involved across an array of jurisdictions.

environment, sociology of the

Riley E. Dunlap

Environmental problems attract sociological attention because they are fundamentally social problems: they result from human social behavior, they are viewed as problematic because of their impact on humans (as well as other species), and their solution requires societal effort. It is therefore not surprising that sociologists

have shown growing interest in environmental issues in recent decades and that environmental sociology has become a recognized field. Yet, sustained sociological investigation of environmental problems did not come easily.

To establish a new discipline, the founders of sociology emphasized its unique focus on the explanation of social behavior by *social* as opposed to biological and physical phenomena. The Durkheimian emphasis on explaining social phenomena only in terms of "social facts" created an anti reductionism taboo that delegitimated use of biological and geographical factors in sociological analyses. It was important for sociology to move beyond, for example, explanations of racial and cultural differences in terms of genetics and climate, respectively. In the process, however, sociology adopted an implicit sociocultural determinism that provided infertile ground for sociological analyses of environmental problems. In mainstream sociology, "the environment" came to refer to the social context of the entity (group, community, institution, etc.) being examined, and the physical environment was seen as little more than the stage on which social behavior was enacted (Dunlap & Catton 1979).

Consequently, when environmental issues burst upon the scene in the 1970s in North America and shortly thereafter in Europe and the rest of the world, sociologists were not among the vanguard studying them. And when sociologists did focus on environmental issues, they typically analyzed the social processes involved in "constructing" environmental conditions as problems. There were numerous studies of the roles played by environmental activists, the media, scientists, and policymakers (including Green parties) in placing environmental problems onto the public agenda, as well as of the public's perceptions of such problems. Sophisticated models of the social construction of environmental problems gradually evolved (Hannigan 1995).

The onset of energy shortages and wide spread discussion of the "limits to growth" in the 1970s led a few sociologists to question the popular notion that modern societies had overcome resource constraints (Catton 1980). Likewise, continuous discoveries of serious pollution (from local toxic contamination to acid rain) and increasing incidences of resource

degradation (from strip mining to deforestation) led others to accept the reality of environmental deterioration and to investigate its social causes and consequences (Schnaiberg 1980). This generated an interest in societal–environmental relations (and at least an implicit rejection of anti reductionism), which some sociologists saw as representing the arrival of an “environmental sociology” (Dunlap & Catton 1979).

The constructivist and realist approaches to the sociological investigation of environmental problems have both continued to evolve. Although an intensive debate occurred between their proponents over the past decade, both traditions remain strong, with the realist camp predominating in North America and the constructivist being strong in Europe.

Sociological work on environmental issues continues to reflect the inherent social dimensions of environmental problems, encompassing investigations of the causes of environmental problems, the societal impacts of such problems, and strategies and prospects for ameliorating these problems. These realist oriented approaches are complemented by constructivist analyses not only of how conditions come to be defined as problems, but also of controversies over the causes and impacts as well as the very existence of environmental problems.

CONSTRUCTIVIST AND REALIST APPROACHES

Building upon such basic observations as levels of airborne particulates being ignored in one era and/or locale but seen as “pollution” later on or in other places, a rich body of sociological literature clarifies how various environmental conditions become defined as “problems”; the frequently contested nature of such problems; and the implications of competing interpretations of the sources, impacts, and solutions of the problems. Originally relying heavily on perspectives from social problems and the sociology of science (Yearley 1991), over time such analyses have drawn on social movement theory, discourse analysis, cultural sociology, and postmodern theorizing.

Numerous studies of claims, claims makers, and claims making activities have yielded

valuable insights into the social processes necessary for gaining widespread acceptance of conditions – ranging from local toxic wastes to global environmental change – as “problematic.” Originally the emphasis was on environmental activists as key claims makers, but the importance of scientists has drawn increasing attention. The vital role of the media both in publicizing and in interpreting claims has also received attention. Such analyses have demonstrated that environmental problems do not simply emerge from objective conditions, but that their recognition is contingent upon issue entrepreneurs being successful in overcoming a series of barriers and gaining widespread societal acceptance of their definition of the situation (Hannigan 1995).

Besides clarifying how various conditions come to be accepted as environmental problems, constructivist analyses have shed light on the importance of how the problems are defined. For example, the notion of “*global* environmental change” conveys an image of global contributions to climate change, deforestation, and biodiversity loss, and thus shared responsibility for dealing with them – thereby masking crucial differences between the contributions and capabilities of rich and poor nations.

Early environmental problems like air and water pollution were readily perceptible, but newer problems such as toxic wastes, ozone depletion, and climate change depend on scientific measurements and interpretation for their discovery, analysis, and possible amelioration. The resulting heavy dependence of environmental advocates on scientists has received scrutiny from sociologists. Analysts such as Yearley (2005) have emphasized that the environmental movement’s heavy reliance on science is a mixed blessing for several reasons: (1) demands for scientific proof can be used to stall action, particularly by unsympathetic politicians; (2) the probabilistic and tentative nature of scientific evidence falls short of the definitive answers laypeople and policymakers seek; and (3) reliance on scientific claims makes environmentalists vulnerable to counterclaims issued by “skeptical scientists” supported by industry.

Attention to discourse has allowed other analysts to provide insight into the importance of how environmental problems and policies are

“framed” by different interests. In addition to the above noted implications of framing macro level issues such as climate change and loss of biodiversity as “global” problems, sociologists have noted how dominant conceptions of sustainable development fostered by powerful institutions such as the World Bank reflect a “green neoliberal” ideology that serves the interests of wealthy nations and western capital (Goldman 2005). On the other hand, attention has also been given to how an “environmental justice” frame has been created to represent the interests of minority and working class communities exposed to disproportionate levels of environmental hazards, illustrating that the underprivileged can also benefit from strategic framing.

Constructivist work demonstrates that environmental problems do not simply emerge from changes in objective conditions, that scientific evidence is seldom sufficient for establishing conditions as problematic, and that the framing of problems is consequential. These are major insights, and represent a quintessential sociological contribution that, for example, helps environmental activists and scientists understand why their claims frequently fail to produce the desired effect while still allowing constructivists to avoid charges of environmental reductionism or determinism.

In the 1990s some constructivists followed postmodern fads and “deconstructed” not only environmental problems and controversies, but also “the environment” (or, more typically, “nature”) itself. Proclamations that “there is no singular ‘nature’ as such, only a diversity of contested natures” (Macnaghten & Urry 1998: 1) were not uncommon. This provoked a reaction from environmental sociologists of a realist bent, who argued that while one can deconstruct the concept of nature, an obvious human (and culturally bound) construction, this hardly challenges the existence of the global ecosystem and by implication various manifestations of ecosystem change construed as “problems.”

Representatives of the realist camp such as Ted Benton, Peter Dickens, Raymond Murphy, and Riley Dunlap argued that a strong constructivist approach that ignores the likely validity of competing environmental claims slips into relativism, has the potential of

undermining environmental scientists and playing into the hands of their opponents, precludes meaningful examination of societal–environmental relations seen as fundamental to environmental sociology, and at least implicitly resurrects the disciplinary tradition of treating the biophysical environment as insignificant (Benton 2001).

In response, many constructivists replied that they were not denying the “reality” of environmental problems, as their postmodern rhetoric sometimes suggested, but were simply problematizing environmental claims and knowledge. In eschewing relativism in favor of “mild” or “contextual” constructivism, most constructivists have moved toward common ground with their realist colleagues. The latter, in turn, have moved toward a “critical realist” perspective that, although firmly grounded on acceptance of a reality independent of human understanding, recognizes that scientific (and other) knowledge is imperfect and evolving (Carolan 2005). The result is that the “realist–constructivist wars” of the 1990s are subsiding and the sociology of environmental issues (increasingly grounded in ontological realism and epistemological relativism) is a more intellectually vital area as a result of housing both approaches.

While seldom problematizing environmental knowledge, environmental sociologists in the realist camp often go to pains to examine the validity of measures of environmental problems such as deforestation (Rudel & Roper 1997). The defining feature of their work is use of empirical indicators of environmental conditions – from local air pollution to national CO₂ emissions – in their analyses. Such work is often quantitative, and bears on each of the three aspects of environmental problems noted above – their causes, social impacts, and potential solutions.

CAUSES OF ENVIRONMENTAL DEGRADATION

A central focus of environmental sociology, particularly in the US, has been to explain why environmental degradation seems endemic to modern industrial societies, and thereby provide sociological insight into the causes of

environmental problems. Early work often critiqued natural scientists' monocausal explanations, emphasizing factors such as population growth, technological developments, or overconsumption. Frequently coming from a neo Marxist or political economy perspective, sociologists called attention to the roles of capitalism and its supporting governmental structure ("the state") in creating environmental degradation.

Arguably the most influential analysis was offered by Schnaiberg (1980), who provided a cogent critique of Paul Ehrlich's emphasis on population growth, Barry Commoner's emphasis on technological developments, and the widespread emphasis on materialistic consumers as the key sources of environmental degradation. Schnaiberg's "treadmill of production" model offered a sophisticated alternative that stresses the inherent need of market based firms to grow, the accompanying pressure to replace costly labor with advanced technologies, and the inevitable increase in resource use and pollution that results. He further clarified how a powerful coalition of capital, state, and labor develops in support of continued growth, making it difficult if not impossible for environmental advocates to halt the resulting "treadmill."

A number of other environmental sociologists working from a Marxist tradition, most notably Ted Benton and Peter Dickens in the UK and James O'Connor and John Bellamy Foster in the US, have offered alternative insights into why capitalism produces environmental degradation, but the treadmill argument has thus far garnered more attention.

Despite the appeal of Schnaiberg's treadmill model, it has proven difficult to test empirically on a macro level, and has been used primarily to explain the lack of success of local recycling programs and environmental campaigns. In an era of economic globalization, the treadmill model needs to be integrated with global level perspectives such as world systems theory in order to provide the theoretical leverage necessary for adequately examining the relationship between the globalization of capital and environmental degradation. In addition, recent sociological attention to the importance of consumption raises questions about Schnaiberg's dismissal of consumers' contributions to

environmental degradation (Yearley 2005). And finally, proponents of "ecological modernization" have challenged the fundamental premise that capitalism inevitably produces environmental degradation.

Ironically, given the dismissal by Schnaiberg and many other sociologists of the perspectives of Ehrlich and Commoner, a recent alternative to the treadmill draws explicitly from the "IPAT equation" (holding that environmental impact is a function of population, technology, and affluence) that evolved from debates between the two ecologists. Rooted in the human ecology tradition espoused by some early environmental sociologists (Benton 2001: 5–6), the "STIRPAT" (or "Stochastic Impacts by Regression on Population, Affluence, and Technology") model developed by Dietz, Rosa, and York offers a way of testing the relative impacts of various driving forces on environmental degradation (York et al. 2003). Early results, which will no doubt provoke further studies, suggest that population is more important than most sociologists believe, resurrecting the neo Malthusian perspective of Catton (1980).

In between the neo Marxist and human ecology perspectives lie a host of efforts to explain the sources of environmental degradation, exemplified by Rudel and Roper's (1997) sophisticated analyses of the origins of tropical deforestation. The past decade has witnessed a flood of empirical, comparative studies – often taking the nation state as their unit of analysis – that investigate the relationship between a range of factors (demographic, technological, economic, political, etc.) and various indicators of environmental degradation ranging from deforestation to CO₂ emissions to ecological footprints (e.g., York et al. 2003).

IMPACTS OF ENVIRONMENTAL DEGRADATION AND RESOURCE SHORTAGES

Sociologists have devoted less attention to the social impacts of environmental degradation, perhaps due to lingering fears of environmental determinism. The earliest focused not on environmental degradation but on the impacts of the 1970s energy shortages. While diverse impacts,

from regional migration to purchasing behavior, were investigated, equity impacts were the primary focus. Studies documented that both the shortages and policies for dealing with them (e.g., higher prices and taxes) tended to be regressive, with lower socioeconomic strata bearing a disproportionate cost.

Inequities have been a persistent concern in environmental sociology and attention next shifted to the distribution of environmental hazards such as air pollution and waste sites. A consistent finding from US studies is that lower socioeconomic strata are disproportionately exposed to environmental hazards, and the same is true for racial/ethnic minorities. While there has been debate over the relative importance of income and race in generating inequitable exposure, many analysts argue that the evidence suggests a pattern of "environmental racism" (Brulle & Pellow 2006).

The environmental justice theme is increasingly extended to the international level, as numerous studies find that the lower strata (and sometimes ethnic minorities) in poor nations also suffer disproportionately from environmental degradation. More generally, sociologists have documented unequal ecological exchanges among nations, with rich countries importing poor country's natural resources at bargain prices while shipping their own wastes (sometimes directly, but often by relocating dirty industries) to those same countries. These findings of consistent inequalities in exposure to the burdens of environmental degradation are at odds with Beck's model of the "risk society," which posits that exposure is becoming a universally shared experience.

Studies of communities that have been subjected to toxic contamination or other serious environmental hazards are also common, and often bridge the realist-constructivist divide. While some document the debilitating community impacts stemming from obvious contamination, many focus on the controversies that arise when allegations of contamination are countered by denials. Communities subjected to a "technological disaster" such as toxic contamination tend to experience severe conflict between parties holding competing views of its seriousness. This results in a "corrosive" community that stands in stark contrast to the "therapeutic" community that typically

develops in response to a "natural disaster" such as an earthquake, hurricane, or flood (Freudenburg 1997).

SOLUTIONS TO ENVIRONMENTAL POLICIES

Sociological contributions to environmental protection policies have largely occurred via policy evaluations. Sociologists commonly question the efficacy of information campaigns to stimulate pro environmental behaviors among consumers, emphasizing, for example, that providing community wide collection of recyclables along with garbage collection is more effective than encouraging people to use recycling centers. In a similar vein, research has highlighted the degree to which energy consumption is embedded in sociotechnical systems over which consumers have little control, and that promoting energy efficient construction standards may be more effective than appealing for household conservation. Studies highlighting the structural constraints on consumer behavior have enabled sociologists to offer valuable input into assessments of environmental policies (Dietz & Stern 2002).

Some environmental sociologists in Northern Europe have engaged more fully with environmental policy by attempting to explain what they see as a pattern of significant progress in environmental protection in their nations. Reversing the field's traditional focus on explaining environmental degradation, proponents of "ecological modernization" argue that a core task of environmental sociology is to explain environmental progress (Buttel 2003). Their evolving theoretical efforts have emphasized the importance of technological innovations, new patterns of cooperation between industry and government, and the gradual growth of an "ecological rationality" that offsets the traditional dominance of economic criteria in decision making. More generally, advocates of ecological modernization have argued that economic growth and environmental protection are compatible, and that capitalism can lead to environmental improvement rather than degradation (Mol & Sonnenfeld 2000).

Ecological modernization has encountered heavy criticism, particularly from American

scholars who have questioned the adequacy of its standard methodology (case studies of particular industries or governmental entities), its focus on institutional change rather than improvements in environmental quality, and its generalizability beyond Northern Europe. Most fundamentally, trends toward ecological modernization such as improvements in the eco efficiency of industries have not been adequate to offset economic and population growth, with the result that the "ecological footprint" of most nations and certainly the entire world continues to grow at an unsustainable rate.

Although ecological modernization has been found deficient by a growing number of critics, and certainly lacks face validity given downward trends in most indicators of global ecological health, it may offer insights into how and why particular industries and governmental entities (such as US corporations and communities that voluntarily develop CO₂ emission reduction programs) become more environmentally responsible.

Debates such as those between constructionists and realists, neo Marxians and neo Malthusians, and proponents of ecological modernization and their critics reflect the intellectual vitality of environmental sociology, and resolution of these debates via empirical tests and theoretical syntheses promises to move the field forward. Add in the fact that strong environmental sociology organizations exist in many nations, as well as within the International Sociological Association, and that the subject matter of the field (environmental problems) shows no sign of disappearing, and it seems safe to assume that sociological study of environmental issues has a promising future.

environment and urbanization

Richard York and Eugene A. Rosa

The rapid urbanization of the world's population (accompanied by the rise of megacities) and the profound growth in the scale of impacts on the natural environment were two dominant trends of the twentieth century. Today over 3 billion people, nearly one half the human population, live in urban areas (United Nations 2004). Humans have altered the composition of the atmosphere, contributing to global climate change, have changed land cover over a large proportion of the earth's surface, and have contributed to a dramatic rise in the rate of species extinction.

All signs point to a continuance of these trends in the twenty first century. More than half the world's population will live in urban areas before 2010 and nearly two thirds will be urban residents by 2030 (United Nations 2004). It appears that environmental impacts will likely follow a similar pattern of growth. The parallelism of these trends points to the importance of assessing the connection between urbanization and environmental degradation. The causes and consequences of urbanization are highly complex as they are embedded in other global processes, such as modernization, population growth, trade liberalization, migration, and the expansion of global capitalism. Global environmental change is similarly embedded in a complex of transformative processes.

Nevertheless, urbanization plays a dominant role in the mounting global pressures on ecosystems. It is largely responsible for greenhouse gas accumulations, upper atmospheric ozone depletion, land degradation, and the destruction of coastal zones. There are broad reciprocal dynamics between urbanization and environmental change and the consequences for ecosystems and human capital.

ENVIRONMENTAL DEGRADATION AS A DRIVER OF URBANIZATION

Natural increase accounts for 60 percent of urban growth while migration, particularly

rural-urban migration, accounts for the remaining – substantial – 40 percent (United Nations 2004). There is a reciprocal, reinforcing dynamic between migration from rural to urban areas and environmental degradation. The rapid rise in global urbanization accounts for one side of the environmental degradation dynamic. Around the world, human concentrations pressure nature's capital and services primarily in rural areas with natural resources, contributing to the degradation of rural environments (deforestation, soil erosion, and desertification) and undermining the livelihoods of many people, particularly the rural poor in developing countries. This rural degradation has often served to limit the ability of rural peoples to maintain their way of life and, therefore, has served as a major push factor in rural to urban migration. Indeed, Shandra et al. (2003) found substantial empirical support that rural environmental degradation is a major driving force behind urbanization in developing countries. There is little doubt that part of the reason for rural environmental degradation can be traced to the activities of rural populations themselves – such as forest clearing for subsistence agriculture. But, increasingly, rural environmental degradation is driven in large part by non local forces. Hence, urbanization drives environmental degradation in rural areas, which, in turn, drives rural-urban migration, resulting in further urbanization and further degradation.

URBANIZATION AS A DRIVER OF ENVIRONMENTAL DEGRADATION

Urbanization introduces direct internal and external environmental impacts. For example, cities account for 80 percent of all CO₂ emissions and 75 percent of industrial wood use (Hinrichsen et al. 2001). The immediate and direct environmental consequences of urban development, such as congestion, concentrated pollution, and paved over natural habitats, are obvious to everyone, particularly to the urban population itself. Temperatures tend to be higher in city centers than in surrounding areas and nighttime cooling is less, due to the large heat trapping structures and treeless concrete jungles of cities. These concrete jungles affect

“heat retention, runoff, and pollution, resulting in urban heat islands” (Karl & Trenberth 2003: 1720) that impact public health. Furthermore, the environmental consequences of urbanization stretch well beyond their urban point source, contributing to regional and even global pollution. The pollution problems of urbanization are orders of magnitude larger for megacities (generally defined as those with populations over 10 million, like Mexico City), of which there are now 17 according to the United Nations.

Urbanization is responsible not only for direct impacts, but also for diffuse ones. However, the consequences of urbanization for the environment are complex. On the one hand, all else being equal (e.g., total population, economic production, level of industrialization), urban populations have a lower impact on the environment than rural populations because concentration in urban areas allows for more efficient use of space and transportation. For example, per capita energy use for climate control (heating and cooling) is typically much lower in urban areas due to the preponderance of multifamily housing with their common walls, floors, and ceilings (Darmstadter et al. 1977). On the other hand, despite these direct internal benefits, the most important environmental consequence of urbanization is the effect it has on the structure of regional, national, and global economies, production systems, and political structures.

Historically, economic, cultural, social, and military power has concentrated in cities, which have controlled social systems over large areas. In fact, over the past five millennia the world system has been dominated by a handful of cities exerting dramatic influence over global production (Chew 2001). As noted above, the environmental consequences of urbanization, therefore, are not restricted to the immediate environs of the city. In fact, the most severe impacts of urbanization may be felt at great distances from cities themselves, where resources are extracted for consumption in urban areas. For example, Chew (2001) documents the environmental consequences, such as deforestation, driven by the demand of ancient cities for natural resources. A more recent example documents how the growth of Chicago in the nineteenth century was in large part responsible

for the rapacious extraction of natural resources from the American West (Cronon 1991). Cities require massive quantities of resources for their construction and maintenance, and, therefore, shape land areas much larger than themselves to provide for their material appetites. For example, the highly urbanized Netherlands consumes resources from a total surface area equivalent to 15 times larger than itself (McMichael 2000: 1122).

Urbanization leads to changes in the culture and lifestyle of the population, including expanding the consumption of resource intensive goods – with clear consequences for the global environment. For example, urbanization, at least in the modern world, generally increases the per capita consumption of meat, which is particularly resource intensive to produce. The modern city is also intimately associated with the rise of the automobile. For example, Riley (2002) argues that urbanization may lead to the acquisition of cars not only by urban residents (due to their affluence and car friendly urban infrastructure), but also by rural residents seeking access to urban amenities. Private car ownership, which is increasing at a spectacular rate, totals more than 750 million vehicles worldwide (McMichael 2000).

Urbanization impacts lifestyle and human capital in indirect ways, too. It increases the demand for centrally generated commercial energy (as opposed to the individual use of traditional fuels, such as biomass), resulting in the accelerated combustion of fossil fuels in power plants. An unavoidable consequence of fossil fuel burning in power plants and in transportation is the production of greenhouse gases, such as CO₂, and a whole host of air pollutants such as particulate matter, ozone, carbon monoxide, sulfur dioxide, and nitrogen oxides. Virtually all of these pollutants have adverse effects on public health, a key component of human capital, and the World Health Organization (WHO 2002) estimates that worldwide air pollution is responsible for 3 million deaths annually.

The most serious consequence of urbanization for the natural environment may be the changes it introduces in the quality of human interaction with nature. Building upon a foundation laid by Marx, Foster (2000) argues that urbanization, in large part driven by capitalism,

generates a “metabolic rift” between town and country – between changing forms of social organization and the environment. The primary factor generating such a rift is the separation of people from the land when they become concentrated in urban centers.

The separation of people from the land leads to two reinforcing dislocations. First, organic matter (e.g., agricultural and human waste) that can provide nutrients to biological systems (a potential ecological benefit) is separated from where it can be recycled into the rural soil and becomes concentrated in urban areas. Second, due to the separation between the sites of agricultural production (rural areas) and the sites of consumption (urban areas), a potential ecological benefit (nutrient rich organic matter) is transformed into an ecological cost (a waste problem). Instead of fertilizing the soil, as it would if it were not concentrated in urban areas, this “waste” must be disposed of, which leads to second order demands on resources and attendant ecological disruptions, due to, for example, the energy and land needed for sewage treatment plants and landfills.

Note that the metabolic rift thesis does not necessarily suggest that urban residents have a higher per capita impact on the environment than rural residents. Rather, it argues that the process of urbanization affects the structure of national production and consumption systems, resulting in an upward spiral of environmental degradation. In a sense, the urbanization process can “urbanize” the countryside too, so that rural residents may in fact adopt lifestyles similar to urban residents (e.g., rural residents may consume non local products and landfill “waste” that could be recycled into the soil).

Counter to the claims that urbanization leads to a metabolic rift, some scholars of modernism argue that urbanization, by contributing to the development of the structures of modernity, serves to *reduce* environmental degradation (Ehrhardt Martinez 1998). This body of work comes out of either the “ecological modernization” perspective in sociology or the “environmental Kuznets curve” perspective in economics. Ecological modernization theorists argue that the structures of modernity contribute to the development of ecologically rational institutions, policies, and technologies that help to curtail environmental degradation

(Ehrhardt Martinez 1998). Likewise, environmental Kuznets curve (named after economist Simon Kuznets) theorists propose an inverted U shaped relationship between economic development and environmental degradation, where environmental impacts increase in the early stages of development, but level off and then decline as societies modernize (Grossman & Krueger 1995).

Although the work of Ehrhardt Martinez (1998) has demonstrated that national deforestation tends to follow a Kuznets curve relative to urbanization, other work (York et al. 2003b) suggests that this finding, considering the full effect of urbanization, and modernization more generally, on the environment, is spurious. Since, particularly in the contemporary era of globalization, the resources a nation consumes do not necessarily come from within its own borders, environmental degradation in a particular nation may not be tied to the consumption of that nation, but, rather, to the consumption of other nations linked to global markets. Cross national research on the “ecological footprint,” a measure of the amount of land area needed to support the resource consumption and waste emissions of nations that takes into account imports and exports, suggests that urbanization, as well as other indicators of modernization, tend to increase, not decrease, pressure on the environment (York et al. 2003b). Furthermore, urbanization also tends to drive up national CO₂ and methane emissions, the principal greenhouse gases (York et al. 2003a). In fact, urbanization appears to have a greater effect on methane emissions than does economic growth (York et al. 2003a). Taken together, these results suggest that continuing urbanization represents a serious threat to the environment and new patterns of urbanization may exacerbate that threat even further. For example, the growing suburban sprawl taking place in many developed countries, particularly the United States, represents a severe threat to the environment, since it devours land and is strongly associated with motorization.

Of course, not all types of urban development are the same, and the hope for the twenty first century is that the worst effects of urbanization can be avoided or mitigated. The current challenge around the globe, then, is threefold. First, it appears important that

“overurbanization” be curtailed. This will require a greater understanding of the factors that drive urbanization in the first place, and the identification of socially acceptable options for limiting unnecessary urban development. Second, less environmentally destructive forms of urban development need to be devised since it is clear that, for the foreseeable future, many urban areas around the world will experience rapid growth. Third, empowering those in rural areas by addressing social, political, and economic inequalities around the world may help curtail the unsustainable exploitation of the rural periphery by the urban core.

environmental criminology

Jacqueline L. Schneider

Environmental criminology is a generic phrase that encompasses a number of different approaches aimed at reducing the occurrence of criminal events by examining the physicality in which the crimes occur. Rooted in human and social ecology, environmental criminology studies crime, criminality, and victimization as they relate to place, space, and their interaction (Bottoms & Wiles 2002). Specifically, environmental criminology explores how criminal opportunities are generated given the nature of the existing setting (see Felson & Clarke 1998). The aim is to identify ways to manipulate attributes of space in order to reduce opportunities to commit crime at various points in time.

Crime has four determinants: law, offenders, targets, and places (Brantingham & Brantingham 1991). Classical criminology addresses legal aspects of criminal activity, while the positivists have traditionally focused on offenders.

The pioneering work of Jacobs (1961) and Newman (1972) brought targets and places into focus, thus redressing the balance between the four determinants. It is the emphasis on targets and place that sets environmental criminology apart from other more traditional criminological schools of thought such as classical criminology and positivism. For example, rather than seeking to understand why offenders commit crime, preventive measures are designed after analyzing the ways in which the environment generates crime opportunities. In other words, crime can be designed out of an area once patterns of crime events are identified. The behavior of the offender in terms of where and how crime is committed becomes more important to the environmental criminologist than the motivation behind the behavior.

According to the Brantinghams (1991), locations, characteristics of locations, and movement paths that allow the intersection of victims and offenders, along with the perceptions of crime locations, fall under the auspices of environmental criminology. According to Cohen and Felson (1979), patterns of interaction and activities of daily life are not random; rather, patterns of interaction across time and place are routine, thus bringing routine activity theory to light. Since the organization of our routine activities pertaining to time and space is predictable, explanations of crime patterns can be identified and preventive measures designed. Eck and Weisburd (1995) expand our understanding of crime events by combining rational choice theory (Cornish & Clarke 1987) with routine activity theory in order to explain the distribution of crime events.

Several themes run through the environmental criminological philosophy: (1) activities are routine; (2) location is chosen by a structured search and decision making process by participants; (3) crime generators and attractors exist; and (4) measurement issues pertaining to spatial reliability need exploring (see Bottoms & Wiles 2002). Target and place are studied at three basic levels: macro is the highest level of spatial aggregation and focuses on the distribution between countries, states, or cities; the intermediate or meso level of analysis examines subarea distributions of targets, offenders, populations, and routine activities; and

micro level analysis studies specific crime sites, focusing on building types, landscaping, lighting, or other physical interventions.

Environmental criminology, while underutilized, has slowly gained in prominence since the 1970s. Crime mapping, a tool used by environmental criminologists, has raised the profile of crime pattern analysis and has helped identify areas where crime is occurring. This technology, however, has also become useful in predicting where crime events are most likely to occur (see Bower et al. 2004; Ratcliffe 2004).

environmental movements

Christopher Rootes

Environmental movements are networks of informal interactions that may include, as well as individuals and groups who have no organizational affiliation, organizations of varying degrees of formality (including even political parties, especially Green parties) that are engaged in collective action motivated by shared identity or concern about environmental issues. Such networks are generally loose and uninstitutionalized, but their forms of action and their degree of integration vary. However, environmental movements are not identical to organizations or episodes of protest. It is only when organizations (and other, usually less formally organized actors) are networked and engaged in collective action, whether or not it involves protest, that an environmental movement exists (Diani 1995: 5; Rootes 2004a).

Such linkages are not always readily visible. Where environmental movements are well established, the balance of their actions is likely to have shifted from highly visible protest to less visible lobbying and even “constructive engagement” with governments and corporations. Just as the collective action of the movement may become less visible, so too, where environmentalism has become most entrenched, there are many “subterranean” linkages among groups and organizations, and the full range of movement activities is less and less adequately represented in mass media.

The methodological implications of this are that no one strategy is likely to yield anything approaching a complete picture. Although studies of protest events (Rootes 2003) may represent the most visible face of the movement and escape the constraints of organizational studies that necessarily omit the less organized part of the movement, they are unlikely to give an adequate account of the less public – or simply less publicized – activities of the movement, including a great deal that happens locally and beyond the focus of mass media. Careful ethnographies of both national organizations and

local campaigns are thus a necessary complement to event based studies.

FORMATION OF THE MODERN ENVIRONMENTAL MOVEMENT

Although concern about the environment has a long history, modern environmental movements date from the late 1960s. The increasingly obvious effects of accelerating industrialization and exploitation of natural resources provided growing audiences for the alarms of conservationists and preservationists. It was, however, the radical critique of capitalist industrialism and representative democracy associated with the New Left and the counter culture that created the public space for the development of new social movements, as well as furnishing their tactical repertoire. Especially in the US, environmentalism benefited from being a relatively consensual issue in a period of intense political polarization, but concern about the environment soon gave rise to new and more radical environmental movement organizations (EMOs) that embraced nonviolent direct action, and rapidly spread to Western Europe. Thus, Friends of the Earth (FoE) and Greenpeace arose in response to the apparent timidity of conservationist EMOs such as the Sierra Club. The internationalism of these EMOs, as well as their skilful exploitation of mass media to put pressure on governments and corporate decision makers, struck a chord, and these were the fastest growing EMOs during the 1980s.

Their rise encouraged innovation in the tactics, and especially the agenda, of older conservation organizations, and by the end of the 1980s networking among older and newer organizations and joint campaigns were increasingly common. Indeed, the history of environmentalism on both sides of the Atlantic has been one of successive waves of critique, innovation, and incorporation, and radical ecologist groupings and the environmental justice movement (EJM) have in turn grown out of dissatisfaction with increasingly institutionalized reform environmentalism.

Many organizations formed in earlier waves of environmental concern have, to varying degrees, adapted to accommodate subsequent

concerns and developments in ecological consciousness. In the US, despite observers' doubts that established, "wilderness obsessed" EMOs are capable of accommodating the concerns of the EJM, especially since 2000, the Sierra Club and Greenpeace have taken the environmental justice agenda seriously. In Western Europe the environmental justice frame has been increasingly adopted, especially by FoE, while established EMOs such as the World Wide Fund for Nature (WWF) and the national bird protection societies have developed a more inclusive ecological perspective and have broadened the range of their campaigns to include issues of habitat and the welfare of human populations (Rootes 2005). The rhetoric of conflict and critique may give a misleading impression of divisions within environmental movements whose existence can be demonstrated by the persistence, despite such differences, of network links of varying degrees of strength and intensity (Dalton 1994).

VALUES AND SOCIAL BASES OF ENVIRONMENTAL ACTIVISM

The rise of values and attitudes favorable to environmentalism is frequently explained in terms of "post materialism" (Inglehart 1977). According to this thesis, post material values prioritizing aesthetic, intellectual, and self actualization needs are gradually supplanting materialist values that place a higher priority on economic and security needs, chiefly because new, younger generations raised in relative affluence and security are replacing older generations who had, during their formative years, more often experienced economic privation and the insecurities of war. The rise of environmentalism was counted among the consequences of this "culture shift," but post materialism may not be as good a predictor of environmentalism as has been supposed because it embraces both post materialist aesthetic and principled concerns with environmental protection *and* essentially materialist concerns with safety and security. Even global environmental concern, often portrayed as unproblematically post materialist, might be represented as a materialist concern.

Post materialism is relatively weakly correlated with support for environmentalism because concerns for the environment are held both by highly educated "post materialist" ecologists, who are not so much fearful for their own security as concerned about global environmental problems whose effects are relatively remote, as well as people, usually less well educated, who are more exercised by fear of the threats that pollution poses to their own immediate material security. Post materialism is a better predictor of environmental *activism* than of environmental concern because activism, unlike concern, is highly correlated with higher education, which is itself an antecedent of most forms of political activism.

Most research on the social backgrounds of environmental activists and the members of national EMOs has concluded that they are disproportionately highly educated and employed in the teaching, creative, welfare, or caring professions and, especially, the offspring of the highly educated (Rootes 1995). As a result, environmentalism has sometimes been interpreted as the self interested politics of a "new class" of traffickers in culture and symbols, opposed or indifferent to the interests of those whose labor involves the manipulation of material things. However, environmental activists are not exclusively drawn from such backgrounds, and approval of EMOs and environmental activism, as well as pro environment attitudes, are widespread among most segments of society.

Grassroots environmental movements involve a broader cross section of society than do the major national EMOs, in part because locally unwanted land uses are more often imposed upon the poor. Women play more prominent roles in grassroots mobilizations than in national EMOs, reflecting women's greater attachment to and confidence in acting in the local community than in the wider public sphere, and the fact that the barriers to entry to the local political sphere are lower than in national politics. Grassroots environmental activism is thus an important means of social learning about environmental issues, a school for participation generally, an entry point for new activists and new issues, a source of revitalization of the environmental movement, and a

means by which it may be made more socially representative.

VALUES AND FORMS OF ACTION

Theorists have distinguished among conservationism, environmentalism, and ecologism, but it is unusual for such clear philosophical distinctions to be precisely mirrored in divisions among movement organizations, their members and supporters. Organizational formalizations of ideological division are more likely in the formal political sphere, where membership tends to be exclusive, than in the movement milieu, where organizations are more fluid, overlapping memberships are common, and where the flexibility of the network structure is better able to accommodate differences without their becoming overtly conflictual.

The discursive frames adopted by environmentalists have consequences for the ways in which they campaign and the forms of organization they adopt (Brulle 2000). Yet, as Dalton (1994) discovered, whether European EMOs had been originally committed to conservationism or ecologism made surprisingly little difference to their choices of strategies, tactics, and styles of action. The apparent convergence within the broad environmental movement sector was not simply a matter of the progressive institutionalization and incorporation of more radical organizations such as FoE and Greenpeace; just as FoE and Greenpeace learned the etiquette necessary to smooth dealings with the powerful, so traditional conservationist organizations became less conflict averse in their tactics and more skilled in the use of mass media. Although EMOs' values do influence their strategy and tactics, greater effects are attributable to "political opportunity structures" – the pattern of opportunities and constraints inherent in the structures of the national political systems within which those organizations operate.

Even where they embrace direct action, environmental movements are almost wholly nonviolent, but movement cultures do not exist in a social and political vacuum. Violent environmental protests in Italy and Spain were carry overs from other, wider political ructions

– in Italy, the tail end of the political violence of the 1970s and 1980s, and in Spain, the temporary association of militant Basque nationalism with environmentalist struggles. Similarly, confrontational environmental protest in Britain in the 1990s rode the wave of more general confrontational protest that rose with the campaign against the poll tax (Rootes 2003). National political cultures explain less than political conjunctures.

INSTITUTIONALIZATION AND ITS DISCONTENTS

Conventionally, it has generally been assumed that "success" for a social movement means its institutionalization, usually as a political party. However, Eyerman and Jamison (1991) argue that a movement exists only in the relatively brief liminal period when a new, autonomous public space is created. Thus, from their perspective, the identity of the environmental movement dissolves as its organization fragments and its "movement intellectuals" become established in universities, industrial organizations, law and journalism, professionalized campaigning organizations such as Greenpeace, and political parties, including Green parties. For Eyerman and Jamison, movements are by definition transient, and the institutionalization of the environmental movement is a contradiction in terms.

Recent history suggests that environmental movements may have squared the circle. Whether measured by size, income, degree of formality of organizations, number and professionalization of employees, or frequency and kind of interaction with established institutional actors, EMOs in most industrialized countries have, since the late 1980s, become relatively institutionalized. Yet such institutionalization has not simply entailed the deradicalization of the movement or a loss of shared identity.

Some have worried that institutionalization has turned EMOs into "protest businesses" (Jordan & Maloney 1997) or a "public interest lobby" (Diani & Donati 1999) increasingly incapable of mobilizing supporters for action. Yet, in Germany, a substantially institutionalized

movement coexisted in the 1990s with the revival of highly confrontational, at times violent, anti nuclear protest, and established EMOs gave assistance to local anti nuclear groups (Rucht & Roose 2003). In Britain, during the 1990s, EMOs grew in numbers and size as well as access and influence, but reported environmental protest also increased and became more rather than less confrontational (Rootes 2003).

The rise of new, more radical groupings such as Earth First! can be traced in part to dissatisfaction with the apparent timidity of more established EMOs, but shared identity among environmental campaigners survived even as their tactical repertoires varied. Even the radical "disorganizations" most committed to direct action were connected by networks of advice and support to more established organizations. The sense of identity among the constituent parts of the British environmental movement did not dissolve as a result of the institutionalization of its more established organizations and the reactions against it, but instead grew as groups came to practice a division of labors and to realize the advantages of cooperation.

The European experience shows that it is possible for an environmental movement to retain many of the characteristics of an emergent movement while taking advantage of the opportunities presented by institutionalization, and that institutionalization is no barrier to the mobilization of protest. While some writers have referred to the "self limiting radicalism" of Green parties, it is the "self limiting institutionalization" of environmental movements that is the more striking and that has more profound implications for sociological theory. Their survival and their resistance to the deradicalizing effects of institutionalization has distinguished environmental movements from the other "new social movements." Because pressing environmental problems are part of the chronic condition of an industrialized world, western environmental movements, although by no means universally anti capitalist, are recurrently influenced by the critical analyses of their radically anti capitalist constituents, as campaigns against genetically modified organisms and neoliberal globalization have shown.

BEYOND THE NATIONAL

The character of environmental movements varies from one country to another according to material differences in their environments. Thus, in the US, Canada, Australasia, and the Nordic countries, wilderness issues have often been more salient than pollution issues. In Western Europe, where the physical environment is more obviously a human product, the concern to protect landscapes is more readily combined with concerns about the consequences of environmental degradation for people.

In the most recently industrialized parts of Southern Europe and in the countries of Central and Eastern Europe ravaged by rapid industrialization under communism, environmental concern is more often a matter of personal complaint than of global environmental consciousness. As a result, despite occasionally intense local campaigns, EMOs are relatively weak. Environmental movements were credited with a major role in the popular mobilizations against communist regimes, but their subsequent weakness suggests that green was often protective camouflage for anti regime activists who subsequently turned to mainstream political roles, or that the political and economic urgencies of post transition states have sidelined environmental concerns.

Especially in the less industrialized countries of the global South, environmental issues are bound up with struggles surrounding the distribution of social, economic, and political power and resources, and mobilizations rarely take the form of environmental movements. The lack of safeguards for democratic political activity or possibilities of judicial redress of grievances, and the underdevelopment of civil society, present severe impediments, and success for their campaigns often depends upon the support of Northern environmental or human rights organizations.

It is not, however, only in the global South that environmental struggles bundle claims for environmental protection with demands for social and economic justice, and often for substantive democracy as well. Thus, in Britain, EMOs have increasingly been prominent participants in a variety of humanitarian and

anti war campaigns. In the US, environmental demands have, especially in and since the 1990s, been conjoined with the critique of class and especially racial inequalities. Distrustful of the alleged elitism of established EMOs, the environmental justice movement took the form of a loose network of local campaign groups (Schlosberg 1999).

A preference for deliberately informal networks rather than formal organization is characteristic of recent waves of environmental activism on both sides of the Atlantic, but the relationship of local environmental protests to environmental movements is problematic. Most local protests are NIMBY in origin and, although some undergo a convincing transformation into universalist campaigns that reach out to and link up with others and with the environmental movement generally, others remain particularistic and do not centrally involve even the local branches of established EMOs. Only exceptionally do local campaign groups grow into more general EMOs, but they may nevertheless serve as sources of innovation and renewal within national environmental movements, by "discovering" new environmental issues, initiating new generations of activists, and devising new tactics.

National and local political cultures and material differences affect the forms, development, and outcomes of environmental movements, as do differences among political opportunity structures. National EMOs are dependent for their resources and legitimacy upon national publics, and their dynamics and trajectories are shaped by locally and nationally idiosyncratic events and institutions. Consequently, the concertation of transnational environmental activism is difficult. Even within the best developed supranational polity – the European Union – EMOs remain primarily national in their networks, collective action repertoires, and thematic concerns, despite the EU's importance as the principal locus of environmental policymaking (Rootes 2004b).

The absence of a developed global polity presents even greater obstacles to the formation of a global environmental movement. Although international agreements and agencies encourage the development of transnational environmental NGOs, the latter are not mass participatory organizations and, outside the

North, rarely have deep roots in civil society. The consequent lack of democratic accountability is unlikely to be merely temporary. However, if the prospects for an effective and genuinely democratic global environmental movement appear limited today, better and cheaper means of communication promise to erode distance just as increasing access to higher education gives more people the skills and resources necessary to operate transnationally. The example of Earth Action International, and the increasingly effective internationalization of FoE International, may be straws in the wind.

Since the 1980s the study of environmental movements has increasingly moved beyond local and national case studies (which have nevertheless proliferated) and toward systematic comparative studies. Since the mid 1990s these have come increasingly to revolve around the issues raised by the prospect of a transnational movement addressing global environmental issues. It is here that the practical challenges and the need for sociological work are greatest.

epidemiology

Hung En Sung

Epidemiology is the study of the distribution of disease as well as its determinants and consequences in human populations (Bhopal 2002). It uses statistical methods to answer questions on how much disease there is, what specific factors put individuals at risk, and how severe disease outcomes are in patient populations, in order to inform public health policymaking. The term disease encompasses not only physical or mental illnesses but also behavioral patterns with negative health consequences, such as substance abuse or violence.

The measurement of disease occurrence begins with the estimation of incidence and prevalence. Disease incidence is the number of new cases in a population within a specific period of time. First ever incidence picks up only first ever onsets; in contrast, episode incidence records all onsets of disease events, including those of recurrent episodes. Cumulative incidence expresses the risk of contracting a disease as the proportion of the population who would experience the onset over a specific time period.

Prevalence is the number of people in a population with a specific disease. Point prevalence counts all diseased individuals at a point in time, whereas period prevalence records those with the disease during a stated time period. Cumulative prevalence includes all those with the disease during their lives or between two specific time points. The nature of the disease itself determines the appropriate choice of measure. For example, for single episode conditions with a clearly defined onset such as chickenpox, first ever and cumulative incidence rates are most useful, but for recurrent conditions with ill defined onsets such as allergy, period and cumulative prevalence rates are most often analyzed.

Population epidemiology attempts to unravel causal mechanisms of disease with a view to prevention. Since most diseases are determined by multiple genetic and environmental factors, exposures to single risk factors are usually neither sufficient nor necessary causes of a disease. Consequently, efforts are devoted to

quantify the level of increased risk when exposed to a particular risk factor. Risk is normally measured as either a ratio of the prevalence of disease in two populations or the ratio of the odds of exposure to a particular risk factor between two groups. Clinical epidemiology, in turn, aims at the identification of disease outcomes with the goal of controlling the damage done to patients.

The successful application of epidemiological methods to the study of social maladies (e.g., divorce, homicide, drug addiction, etc.) and the emergence of social epidemiology using sociological constructs (e.g., social inequalities, racial discrimination, sexism, residential segregation, etc.) in the analysis of disease herald an even closer collaboration between epidemiologists and sociologists in the coming years (Berkman & Kawachi 2000).

epistemology

Thomas A. Schwandt

The Greek words for knowledge and explanation are *episteme* and *logos*, respectively. Epistemology is the study of the nature (theory) of knowledge and justification. Epistemology is the kind of philosophy (or the primary role assigned to philosophy) valued in the scientific view of the world. In such a world, significant emphasis is placed on providing evidence for our claims to know, and philosophy has the task

of examining the logic and methods involved in questions of *how* we know and what gives knowledge the property of being valid. The phrase “after epistemology” or “overcoming epistemology” often heard in philosophical circles is, in part, a reaction to restricting philosophy to epistemological concerns, to matters of “knowing about knowing.” The tradition of Continental philosophy (hermeneutics, existentialism, critical theory, phenomenology, etc.) that inspires much thinking in the social sciences today, expands the concern with knowing to “knowing about being and doing.” In other words its concerns are not strictly epistemological, but also metaphysical and aesthetic.

Debates between the two great classical modern philosophies of rationalism and empiricism that developed in the seventeenth and eighteenth centuries form the backdrop for understanding the emergence of social science methodologies. Empiricist epistemology (Locke, Hume, Berkeley) argued that knowledge is derived from sense experience; genuine, legitimate knowledge consists of beliefs that can be justified by observation. Rationalist epistemology (Descartes, Spinoza) held that reason is the sure path to knowledge. Rationalists may claim that sense experiences are an effect of external causes; that a priori ideas (concepts, theories, etc.) provide a structure for making sense of experience; and/or that reason provides a kind of certainty that the senses cannot provide. Kant’s philosophy is recognized for (among other things) its grand synthesis and reconciliation of the key insights of these two theories of knowledge.

Empiricism as an epistemology continues to occupy a central place in thinking about methodology, particularly in Anglo American traditions. It is one of the cornerstones of the naturalistic interpretation of the social sciences – the view that the explanatory and predictive methods of the natural sciences, as well as the aim of developing a theory of the way the natural world works, ought to be extended to the social (human or moral) sciences. Empiricism today in the social sciences most often appears within a mix of ideas drawn from positivism, logical positivism, behaviorism, representationism, meaning realism, and operationalism, such that it is probably more proper to speak of empiricist epistemology as an orientation or

disposition toward investigation of social (and behavioral) phenomena. Key components of this disposition include placing primary emphasis on a set of epistemic (cognitive) virtues thought to comprise scientific rationality (e.g., objectivity, value neutrality, critical reliance on method), objectifying that which one studies (i.e., treating it as an object that stands independent of the inquirer), distinguishing meaning from significance (meaning inheres in texts and social action and is discoverable; grasping that meaning is not to be confused with judging its significance for any person at any particular place and time); and deep skepticism of the scientific status of interpretation and understanding. What is widely recognized as the “interpretive turn” in the social sciences arises from, in part, a strong critique of this nexus of beliefs within which the epistemology of empiricism occupies a central place.

Rationalist and empiricist epistemologies are foundationalist; that is, they hold that any claim labeled as “knowledge” must rest on a secure (i.e., permanent, indisputable) foundation. The rationalist locates this foundation in reason; the empiricist, in sense experience. While acknowledging that reason and experience are important in understanding the nature of knowledge, much contemporary epistemology is nonfoundationalist – it rejects the view that knowledge must be erected on an absolutely secure foundation. Nonfoundationalists argue there simply are no such things as secure foundations; hence, our knowledge is always conjectural and subject to revision. This distinction between foundationalist and nonfoundationalist epistemologies is one way of marking the difference between philosophies of positivism and postpositivism. The former believe in the possibility (and necessity) of unassailable ground for any claim to knowledge; the latter abandon this idea. However, postpositivism does not discard the idea that knowledge is built up from (relatively) neutral observations of the “way things are.” It simply acknowledges that, at any given time, our understanding of the way things are might be mistaken. Postpositivists are thus fallibilists with respect to knowledge – the presumption is that current knowledge is correct given the best available procedures, evidence, and arguments, yet current understandings can be revised in light of new criticism or evidence. In Popperian

and other critical rationalist postpositivist philosophies, empirical data continue to serve as a very important basis or underpinning of knowledge, but evidence (empirical data) is never considered to be forever beyond dispute, and subsequently knowledge claims based on data should never be considered beyond the possibility of revision.

Some postpositivist epistemologies significantly depart from empiricist thinking in this regard while accepting the general idea of fallible knowledge. Philosophical hermeneutics, critical theory, pragmatism, and some versions of feminist epistemology argue that knowledge is never something created out of neutral empirical data; rather, it is actively constructed – hence, knowledge claims are always interpretations that are culturally and historically contingent, reflective of certain interests, and infused with moral and political values. Of course, efforts to know always have at their disposal something to work with (i.e., material events, actions, texts, people, and so on). But what we make of the meanings of what is to be known is always constructed in some significant way. These epistemologies reject the notion that a subject (inquirer) can remain disengaged from the object of understanding, as well as the idea that a subject’s knowledge is a straightforward representation of “what is out there.” Distinctions among these constructionist epistemologies relate, in part, to how they interpret the consequences of the fact that all knowledge is constructed in and out of interaction between human beings and their world.

Some constructionist epistemologies endorse a pragmatic and practical rationality and look to dialogue, argumentation, and practical reason in an Aristotelian sense as the ways in which knowledge is created in social practices. They accept that knowledge is by definition uncertain and that the best we can do is make a stand on the basis of (admittedly fallible) human judgment that requires the use of both reason and evidence. We make this stand in light of contingent, practical circumstances. In other words there is no ultimate test for what constitutes adequate and legitimate knowledge independent of the demands of a given situation. We are always deciding what is appropriate and effective action and knowledge given the moral practical situation in which we find ourselves.

So, for example, one could never give an unconditional and unqualified answer to the question, "What would it mean to intervene effectively in this situation?" absent a full grasp of the situation in question. This response abandons epistemology with a capital "E" – the search for the foundations or essences of knowledge – but retains the idea of epistemology with a lower case "e" – reflection of various kinds about what it means to know in given circumstances. Operating in this way, these constructionist epistemologies are relatively continuous with the Enlightenment belief in the emancipatory power of reason.

Other constructionist epistemologies are, at the very least, a good deal less hopeful about the power of reason (and dialogue, argument, etc.) and, at worst, seek to rupture the connection with this Enlightenment notion. These epistemologies promote radical skepticism or epistemological nihilism. They hold that plural constructions of meaning, diverse perspectives, the absence of certainty and foundations, shifting identities of subjects, and the like all add up to either a radical undecidability of all claims to know, or that what constitutes knowledge is inextricably connected to analytics of interest/power. These epistemologies (if they can be called this) are dedicated to demonstrating disensus and disruption in supposed understanding, and constantly aiming to unsettle any claim to know.

essentialism and constructionism

Ken Plummer

The debate over constructionism and essentialism is a longstanding philosophical argument, from Plato and Aristotle to contemporary debates over deconstruction in literary theory. Broadly and simply, essentialism suggests that qualities are inherent in objects of study, with little reference to contexts, ambiguities, and relativities. It is a "belief in the real, true essence of things" (Fuss 1989: xi). By contrast, constructionism (and its allied concept deconstruction, as put forward by Derrida) suggests qualities are always bound up with historically produced, contextually bound meanings or discourses. They are always open to change and never fixed. Many terms are allied antinomies such as absolutism and relativism, realism and interpretivism, and holism and methodological individualism. Other terms, such as humanism, can be used by either camp.

These ideas came to be applied to the field of sexuality during the late 1960s and 1970s and for two decades it was the primary debate in the newer groups studying sexuality. Drawing initially from the work of symbolic interactionists (Blumer's *Symbolic Interactionism*, 1969; Gagnon and Simon's *Sexual Conduct*, 1973), the highly influential work of Peter Berger and Thomas Luckmann's *The Social Construction of Reality* (1967), of feminism, and of the later Foucault (in *The History of Sexuality: Volume 1*, 1977), the core idea emerged that

human sexuality was socially constructed. This meant that, for example, homosexuality was also socially constructed: it had a history, and was produced in different ways at different times. There was no uniform type of homosexual; it was a multiple experience that was constantly open to change. By contrast, essentialists clung to the idea that sexuality was a fixed and powerful biological drive and that the homosexual was a clear kind of being (often defined by biology). Conflicts over these positions became widespread, culminating in two international conferences in Amsterdam – one headed by the essentialists, the other by the constructionists (Van Nierkerk & Van Der Meer 1989).

Essentialist theories of sexual identities suggest that an inner sense of self unfolds through biological or psychic processes, and the task is to uncover the “true” meaning of who one is sexually. A classic reading of Freud would suggest that although one is born of “polymorphous perversity” and potential bisexuality, that is channeled into a relatively stable and repressed sexual and gender identity through the resolution of the Oedipal complex. Through inner struggles with feelings towards the mother and father, children assemble a (largely unconscious) libidinal structure which helps to define then as male and female, homosexual and heterosexual.

Constructionist theories of sexual identities are concerned with locating oneself within a framework of sexual categorizations. Most commonly, identities are seen as heterosexual, homosexual, bisexual. But there are many others, such as sado masochistic, sex worker, pedophile, or person with AIDS (PWA). Such terms, once invented, can be seen to characterize a person. But many of these are new; they are historically produced. Thus, Ned Katz in *The Invention of Heterosexuality* (1995) suggests that the idea of the heterosexual was not invented until the late nineteenth century, and that indeed the identity of homosexual was invented prior to this. This was also a period of clear sexual polarization – identities of being sexual were divided into a clear binary system that did not exist before (as Thomas Laqueur suggests in his *Making Sex*, 1990).

VARIATIONS AND PUZZLES

Several problems have been identified with this debate. The first suggests that the debate tends to erect a false dualism or binary tension, in which each term actually comes to depend on the other. Without essentialism, constructionism would not make sense (Fuss 1989). Secondly, it is suggested that the debate is frequently drawn too starkly and sharply and that there are in fact “different degrees of social construction,” ranging from those who more modestly suggest historical and cultural variability of meanings to those who suggest “there is no essential . . . sexual impulse” (Vance 1989). Thirdly, it has been suggested that ideas of constructionism when taken in their simplest form create ways of thinking that are almost commonplace. And finally, the political implications of the debates are unclear. Constructionists can be radical and conservative; and so can essentialists. Spivak (1984–5) suggest that strategic essentialism champions essentialism even if it is not fully believed in because it is needed in the fighting of conflicts, intellectual arguments, and political battles. It can be a useful shorthand.

This debate has been one of the most prominent in sexual theory in the latter part of the twentieth century and has at least had the virtue of making researchers more aware of the shifting social meanings of sex and the sexual cultures that are linked to them.

ethic of care

Joya Misra

During the 1980s, a number of feminist scholars developed the concept of an ethic of care, which posited an approach to morality focused around caring. This approach drew upon many earlier currents of thought, which argued women's morality centers around nurturing/mothering, cooperation, and maintaining relationships. Sara Ruddick (1980, 1989) espoused an ethics focused around "maternal thinking" (attentive love and trust), which she argued could be used to transform private relations of love and caring into public discussions of peace. Nel Noddings (1984) similarly suggested that an ethic of caring could help create moral people, criticizing dominant ethical approaches as problematically placing "principles above persons." These works valorize the assumed ethical values of "women," and have been criticized for their essentialist tendencies.

During the same period, Carol Gilligan (1977, 1982), in her groundbreaking research on moral development, coined the term "ethic of care," which she compared to an "ethic of justice" to describe two modes of gendered moral reasoning. Gilligan argued that while an ethic of justice primarily reflects fairness and abstract, individual rights, an ethic of care centers around specific contextual circumstances and responsibility in relationships (Lister 1997). According to Gilligan, men are more likely to draw upon an ethic of justice, while women express both ethics, in part because women are more likely to view themselves as connected to others relationally. Gilligan's work has been tremendously influential. However, it has also been roundly criticized for an implied gender essentialism, though Gilligan herself rejects any notion of absolute gender differences (Larrabee 1993; Tronto 1993). Scholars such as Linda Nicholson and Carol

Stack also effectively critique Gilligan's lack of focus on historical context and the potential differences in moral reasoning among women, by class, race/ethnicity, age, and so on. (Larrabee 1993). Yet, Patricia Hill Collins (1990), while critical of Gilligan's formulation, draws from the ideology of an ethic of care in discussing black feminist approaches, linking caring to political activism.

For more recent theorists, an ethic of care must be separated from essentialist notions of "women's morality," which places women on the outside of political and cultural institutions, and excludes many women from its definition. In doing so, recent scholarship emphasizes the importance of bringing the ethic of care into the public sphere, or politicizing care (Larrabee 1993; McLaughlin 1997). Joan Tronto (1993) argues for shifting from a "feminine" to a feminist care ethic by placing care within its political context, and in doing so, recognizing how care is central to existing structures of inequality and power in society. An ethic of care requires attentiveness to the need for care, taking responsibility for care, providing competent care, and responsiveness from the care receiver. The central moral question for an ethic of care then revolves around how we can best meet our care responsibilities, taking account of the needs of both caregivers and care receivers (Tronto 1993). Yet, in order to improve the status of care and caregivers and the quality of care, we must understand care as a political idea, and recognize how social, political, and cultural institutions shape care and could be reformulated to support care more effectively. Tronto (1993) suggests that an ethic of care requires dedication to both valuing care and reshaping institutions to reflect the importance of care. An ethic of care is then not simply an abstract principle, but an ethic that forces us to consider inequalities inherent at both local and global levels.

Recent scholarship emphasizes the importance of viewing the ethic of care as related to and interdependent with an ethic of justice based on rights. For these scholars, an ethic of care is a necessary but not sufficient element to create a moral and just society. As Ruth Lister (1997: 115) argues, both an ethic of care and an ethic of justice are enriched in combination; indeed, an ethic of care without an ethic of

justice could “perpetuate the exploitative gendering of care relationships.” These works also emphasize the importance of placing an ethic of caring within its political context, and recognizing its potential role in activism and social change.

ethics, business

Martin Kornberger and Carl Rhodes

The concept of ethics has a long history in western philosophy. Usually, ethics is understood as reflecting on and recommending concepts of right and wrong behavior. Following this

definition, business ethics is the reflection on the ethical behavior of business organizations.

Much discussion of business ethics focuses on the ethical consequences of the pursuit of economic interests by business. On the one hand, some argue “good ethics is good business,” suggesting that the pursuit of economic interests within law-given restrictions will automatically lead to ethical behavior. On the other hand, more critical ethicists argue the pursuit of economic self-interest by firms is fundamentally opposed to ethical conduct. In their perspective, financial profit and moral principles cannot be aligned. Such considerations engender considerable debate both within organizations and in the public sphere more generally. The practical implications of this in contemporary times is that organizations are more and more under pressure to rethink the ethical consequences of their behavior and readjust their actions accordingly (for a business example, see Royal Dutch/Shell Group 1998).

The young but rapidly growing body of academic literature reflects the importance of business ethics. Although ethics have their antecedents both in ancient philosophy and religion, business ethics is an emerging discipline. Further, while a consideration of the ethics of business can be traced to the seminal work of Adam Smith (1863), the explicit development of business ethics as a field of research and study is much more recent. The first *Journal of Business Ethics* was founded in 1981, quickly followed by others such as *Business and Professional Ethics Journal*, *Journal of Business and Professional Ethics*, and *Business Ethics Quarterly*. The breadth of research areas within business ethics includes ethics and trust, ethics, management and leadership, ethics and organizational reward systems, ethics and organizational culture, ethics and empowerment, ethics and organizational power, interpersonal relationships and ethics, corporate social responsibility, corporate sustainability, ethics and financial investment, and ethical decision making.

NORMATIVE AND DESCRIPTIVE ETHICS

For some, business ethics is conceived of as a *normative* ethics in that it seeks to establish

means of judging whether business practices are right or wrong. This can be done both to assist managers in dealing with moral dilemmas and to enable past actions to be judged as to their ethicality. Business ethics is also an applied ethics because it seeks to use such normative models in order to investigate the ethicality of the nature and consequences of particular events or practices in business. In this normative approach, business ethics in practice is generally understood as being related to the rules and/or cultural norms that govern, or should govern, organizational conduct. In organizations this commonly means that managing ethics is done through formalized codes of conduct that should govern everyday actions and decisions. Indeed, it is reported that 78 percent of the US top 1000 companies have a code of conducts (Nijhof et al. 2003). This approach is also used in theories of business ethics which develop normative models for passing ethical judgment on business practices (Gatewood & Carroll 1991) or propose the development of ethical rules for organizations (Beyer & Nino 1999).

The study of business ethics has also been pursued as a *descriptive* exercise because it uses scientific analysis to describe the actual behavior of organizations and their members. This descriptive approach would not seek normative guidelines that ought to be applied in practice, but rather monitor and describe what actually happens. The key question in both approaches is whether ethics are *relative* to history and tradition (e.g., given that bribery might be an established part of one country's business culture, it would be considered unethical in other countries) or whether is a set of *absolute* norms that are valid any time, anywhere in the world (e.g., men and women should be treated equally regardless of religious belief). These differentiators are contested in the face of key issues in business ethics such as corruption, manipulative advertising, whistle blowing, the environmental impact of business, customer rights, workplace harassment, and equal opportunities for women and minorities. Business ethics is also concerned with the ethical treatment of employees, echoing longstanding concern over the possibilities of worker exploitation in the capitalist labor process. Conversely, there have also been controversies over rising levels of

remuneration for chief executives and other top level managers.

RELATIONSHIP BETWEEN ETHICS AND BUSINESS

A key issue that has been addressed and debated within business ethics is the possible relationship between ethicality and business activity in general. One approach suggests that ethics and business can and should be aligned in order to create competitive advantage (Raiborn & Payne 1996). The core argument is that ethics does not contradict the driving forces behind business organization and that there is no conflict of interest between profits and principles. As an example, Francis and Armstrong (2003) argue an ethically informed risk management strategy increases commercial outcomes, prevents fraud, and lifts corporate reputation. This reflects a more general position that an organization's ethical commitment is aligned with its self interest. Such a perspective dates back to Adam Smith's argument that maximizing personal advantage will lead through the mechanism of self interested actors competing in the market to a maximum of collectively beneficial outcomes. In sum, this suggests that "good ethics is good business" and that profits and principles are mutually inclusive. Another example of this is the practice of "strategic philanthropy" (Porter & Kramer 2002), where organizations choose to make charitable and philanthropic donations in order to strengthen their competitive position by, for example, developing the business environment in the markets where they operate or enhancing their public image. Similarly, it has been argued that an increased focus on ethics by organizations can lead to an increase in organizational commitment and hence productivity (Cullen et al. 2003). According to this approach, good management will be by definition both a har binger of profits and ethical outcomes.

More critical approaches to business ethics question the convenience of the arguments outlined above and are skeptical about the possibility of profit seeking organizations being ethical. This approach criticizes the core assumptions that provide the cornerstones of classic

management and organization theory by suggesting that moral principles are of higher priority than profits (Quinn and Jones 1995). Here, ethics are seen as confronting business rationality because each abides by different and contradictory values. At an extreme, this approach asks whether business ethics is possible in a (capitalist) system driven by the pursuit of profits (Jones 2003). This suggests that the reason for labeling strategic behavior as ethical, or for developing ethical rules, is seen as calculative by nature and thus ethically dubious. Further, even when ethical rules are developed, this may be done not with a concern for the ethicality of organizational action, but rather for external consumption (Kjønstad & Willmott 1995) by shareholders, customers, governments, and other stakeholders. The argument is that the very idea of business ethics is an oxymoron.

ORGANIZATIONAL AND INDIVIDUAL RESPONSIBILITY

Another key issue for understanding business ethics is a consideration of the relationship between the ethical responsibility of individuals and that of the organization as a whole. For some, ethics resides very much with the individual human being (manager or employee) who has to defend ethical values and make ethical choices, often in spite of their organization. This also suggests that unethical organizational behavior results from the individual actions of "bad apples" who are either amoral or guided by immoral principles. Such an individualization of ethics suggests that it is particular people who are ultimately responsible for ethical behavior and that the organizational requirement is for an "empowering ethics" which supports moral learning and development instead of restricting ethics through codes (Kjønstad & Willmott 1995). Business ethics thus emerges when people are "morally assertive" and use their personal ethics to mediate corporate priorities (Watson 2003). In short, this suggests that ethics is a moral task of managers who are personally "in charge" of ethics. In relation to ethical rule systems in organizations, such a view has been used to argue that because rules reduce individual margins of

freedom they provide a form of discipline that can prevent people from acting ethically in order to transform organizations (Ibarra Colada 2002: 178). In this scenario, the organization (and its rules) is a powerful, restricting machine, against or within which the ethical individual can/should act ethically. From this perspective, an organization is an ethically questionable entity whose ethicality can only be tempered by individuals who act in relation to the rules that constitute organizations through behavior guided by a personal ethics (ten Bos 1997).

In contrast, others have argued that organizational systems can provide the basis for ethics in a way that transcends individual action alone. Such an approach can be traced to Weber's seminal work on bureaucracy in the early twentieth century. In contemporary times this has emerged from a critique of changes to organizations that have seen them move away from bureaucratic forms of organizing. This suggests that organizational changes favoring flexibility, enterprise, and short termism wither away trust, loyalty, and mutual commitment in organizations (Sennett 1998). Thus, organizations can and should be organized such that they pursue a communal ethics. This opposes an individualistic ethics which stresses autonomy, moral responsibility, and freedom towards one of mutual obligation and respect for standards. From this perspective, it is argued that it is precisely formal organization that makes ethics possible by training managers in technical expertise, and through a clearly defined hierarchy that describes everybody's responsibility, duty, and rights, through the understanding of the office as "vocation," detached from personal privileges, passions, and emotions (du Guy 2000).

Given the growing impact of business organizations on the lives of individuals, global politics, and the environment, a consideration of business ethics is critical to responsible forms of business. As corporate disasters such as Enron, the rise of NGOs such as Greenpeace, and the success of "ethical" businesses such as the Body Shop show, business ethics will be one of the key future challenges for businesses. Thus, managing ethics will be just as important as managing finance, production, or distribution.

ethics, fieldwork

Jane Zeni

Ethics in social sciences fieldwork draws on the perspectives of philosophy, law, and psychology to guide decision making by researchers and policymakers. Ethics can be defined as "the study of right and wrong; of the moral choices people make and the way in which they seek to justify them" (Thompson 1999: 1). Consciously or otherwise, field researchers make ethical decisions whenever they gather, interpret, or present their data. There is a growing consensus that ethical practice in fieldwork cannot simply be guided by the rules that govern biomedical or psychological research in laboratory settings.

These rules are based on the Nuremberg Code (1949), which established the principle of "informed consent," and the Declaration of Helsinki (1964), which mandated the protection of human participants in biomedical research. Institutional Review Board (IRB) and Research Ethics Committee (REC) reviews have their roots in such notorious abuses as the experiments by Nazi physicians on concentration camp prisoners. In the United States, the Tuskegee syphilis study recruited indigent black men for research they believed would include treatment; instead, researchers documented their illness and eventual deaths for 40 years, even after the discovery of penicillin offered a cure.

Since 1974, all research conducted in US colleges and universities that receive federal funding must be approved by an IRB; in Australia and increasingly in the UK, the REC plays a similar role. This process has now been adapted by many schools and public agencies. The protection of human participants has expanded to research across the social sciences,

in qualitative as well as experimental modes. An IRB review typically starts with a set of yes/no questions:

- Is this research designed to study normal educational practices conducted in an established educational setting?
- Does the research use survey procedures, interviews, educational tests, or observation of public behavior? (Subquestions ask if participants will remain anonymous, and if not, whether they will be at risk.)
- Does the research involve collection or study of existing data, documents, or other records? (Anonymity is encouraged except in public records.)

The prospective researcher next explains the purpose and methods of the study and attaches the consent documents to show that research participants will be clearly informed before they agree to participate. Research using data from vulnerable and underage participants must undergo a more extensive review.

An IRB also mandates training in research ethics. Many US universities have adopted a free web based course from the National Institutes of Health (NIH) that guides novice researchers through the principles underlying ethical review with a set of cases and dilemmas (www.nihtraining.com/crtpub_508/index.html). While these reforms are significant, the ethical reviews pose problems for qualitative researchers in the social sciences.

As the use of NIH training suggests, the model is quantitative experimental and survey research. Cases are drawn from biomedical and psychological studies. If “research ethics” in qualitative fieldwork is identified with IRB/REC principles, some important risks may be misconstrued. Two such principles – “informed consent” and “anonymity” – can illustrate the dilemma.

Informed consent has been considered the core of ethical review. However, at the start of most qualitative studies even the researcher cannot fully predict the course of the inquiry. Trying to cover all possibilities, the researcher may prepare a document in legal language that is meaningless or frightening to the uninformed. One solution is to negotiate informed consent in stages. A teacher might launch a

classroom study with a newsletter asking parents for a simple consent to participate. During the months of data gathering and interpretation, the teacher researcher would communicate openly with participants. Later, if the work will be published, certain parents would be asked for explicit consent to share their child’s data (Clayton Research Review Team 2001). People need to know the kind of text or presentation, the audience(s) who will have access, and the context in which their words, names, or pseudonyms will appear.

Anonymity to protect the privacy of research participants is generally recommended for research in all genres. However, anonymity may offer little protection in fieldwork involving literate and knowing participants. For example, if a sociologist conducts a small scale qualitative study of dating practices among university students, the published report may lead to lively speculation on campus. Similarly, if a vivid case study appears under a teacher author’s name, the students may be recognized from the lunch room to the school board. Any social researcher should realize that publication may touch the “subjects” of a study – whether or not they are named.

Ethical dangers in fieldwork usually arise, not in the methods or process of research, but in its later dissemination. The findings may place individuals at risk of professional embarrassment, personal reprisals, or loss of reputation. On the other hand, participants who have worked collaboratively with the author may want credit for their intellectual contributions rather than anonymity. Choosing the most ethical approach to informed consent, anonymity, or intellectual property rights requires thinking through the local situation as well as the global principles of the ethical review.

Ethical guidelines specific to field researchers doing qualitative studies have been developed inductively through analysis of a growing body of cases. A useful way to organize this body of material is to examine the researcher and the researched – how each is constructed, their roles in the study, and the relationships between them. Studies can be arranged on a continuum from traditional “outsider” (researcher enters the field as a stranger) to complete “insider” (researcher has an established role – educator, social worker, community organizer – within

the field being studied). Moving along the continuum will foreground certain ethical issues while resolving others.

At one end of the continuum are "outsider" studies in which a scholar, typically from a university or research institution, examines a community that is both unfamiliar and distinct from the communities where the scholar normally resides. If the researcher maintains the outsider stance, revealing little of his or her own subjectivity, then the ethical decisions and dangers seem clear cut: present the facts, avoid bias, do no harm. Smith (1990) describes three notorious cases from the 1960s and the 1970s in which social researchers assumed roles that gave them access to observe gay sex, terrorist plots, and apocalyptic religion. Today's IRBs, however, forbid deception in field studies unless the researcher has evidence of proportionate benefits and a plan for honest and prompt debriefing.

Since the 1980s, discussions of ethics in fieldwork have increasingly advocated knowing interaction between the researcher and the researched. According to the principles of "participant observation," rooted in the social sciences rather than in medicine (Glaser & Strauss 1967; McCall & Simmons 1969), a researcher enters the field from somewhere outside, but strives to understand the perspective of the insider. The researcher is ethically obliged to present his or her role and purpose to participants; the researcher is also obliged to represent the participants respectfully in published findings.

Recent scholars are moving further along the continuum, away from the ideal of the neutral observer. The anthropologist constructs an authorial "signature," a sense of "being there" (Geertz 1988) to become for the reader a trustworthy narrator of this story. This increasing self representation in fieldwork has generated two ethical arguments. According to one, the author should "bracket" whatever personal experience or bias might distort the picture; according to the other, the author should claim that insider position as the source of credibility. The former view, associated with phenomenology, has been criticized for an underlying post positivism (Guba 1990: 20–3). The latter, called standpoint theory, is associated with feminism and critical social theory. Standpoint

theorists propose that researchers who resemble the participants in race, class, gender, ethnicity, sexual orientation, disability, or other dimensions of culture are best positioned to understand their experience. Researchers from marginalized groups are "outsiders within," having access to the perspectives of the majority culture as well (Banks 1998; Collins 1998). Critics, however, warn that standpoint theory makes the self, and one's own roles and communities, the only legitimate field of study.

Researchers from a dominant culture are also exploring these issues. They hope to offer trustworthy insights by analyzing their own lenses as well as the experiences of the Other. By shedding the mask of cultural invisibility, perhaps any researcher can gain a double perspective that minimizes distortions (Kirsch 1999). "Covenantal ethics" (Smith 1990) aptly names such relationships of mutual respect and caring.

If traditional scholarly "outsiders" represent one end of a continuum, then the opposite end is represented by researchers who are themselves "insiders," full participants with roles to play that did not originate with the study. This is the action research stance (also called "practitioner research" or "teacher research" in the field of education). An action researcher does not struggle with the challenges of entering the field, and the risk of deception is small. Yet new ethical questions emerge. Mitchell (2004) warns of the tension between the researcher role and the teacher role, and the risk that students will be exploited. Maclean and Mohr (1999), however, argue that the professional role and commitment to students, co workers, and community members must always take priority over the data; they define ethics among colleagues as "respect for each other's professionalism" (p. 129).

Practitioners doing action research or collaborative studies should especially beware of relying on the traditional approaches to informed consent and anonymity. Reputations can be at risk if the findings include "bad news." Should a researcher protect certain participants by composite portraits rather than traditional interviews? Should some fieldnotes remain unpublished if the point can be supported by data that will not embarrass participants? Such ethical questions can be answered

only at the level of specific studies in specific field settings.

One new field setting is not a physical place, and it disrupts such categories as “being there,” “interviewing,” and “participant observation.” Social research in electronic communities is burgeoning, along with new ethical dilemmas for researchers. Privacy is difficult to protect when numerous, perhaps unknown “others” participate in a listserv or blog. Consent forms present new challenges, and electronic signatures may or may not be accepted by an IRB. Following an action research model, a researcher might send an electronic newsletter explaining the study, inviting questions, and promising to omit any data from people who opt out. Later, if there is to be a publication quoting certain participants, a paper consent letter would be sent by regular mail. Mann and Stewart (2000) suggest that since the “online world” lacks the network of laws and traditions that regulate most social behavior, it gains an aura of transgression.

Field researchers must accept that no perspective can be free of ethical dilemmas. Instead, a research dialogue should bring together insiders and outsiders. Such approaches include “constructivist inquiry” (Denzin & Lincoln 2000) or the “deliberative democratic view” (House & Howe 1999). The ethical mandate is inclusion, representing the perspectives of multiple others as well as the self. As Fred Erickson quipped, “Neither the insider nor the outsider is gifted with immaculate perception” (in Cochran Smith & Lytle 1993: ix).

Turning from the researcher to the researched, Sharon Lee (2001) proposes a parallel continuum: subject, informant, participant, collaborator. The traditional term, “human subjects,” falls at one end, isolating the researched from any contamination by the researcher, and stripping the context where the research happens. Currently, the preferred federal language is “human participants,” implying some level of involvement rather than passive consent. Going further, van den Berg (2001) refers to the “inhabitants of the research,” suggesting context as well as collaborative relationships. Reflecting on this continuum, Eikeland (2006) rejects the “condescending ethics” of protecting research subjects, arguing that the standard for fieldwork is the “community of inquirers and interpreters.”

Nevertheless, respect for participants calls for the acknowledgment that most research communities have a fixed time period and predictable end. Seeing an interviewer as a friend and sharing personal life stories is an abuse of trust if that “friend” will disappear to write up a case study (Kirsch 1999: 30). The “therapeutic assumption” or the “educative assumption” may lead participants to see a doctor’s main goal as healing and a teacher’s main goal as student learning. They may consent to a study whose goal is to benefit, not themselves, but some wider population in the future.

Fieldwork usually takes place amid asymmetrical power relations. Most researchers “study down” (portraying the experiences of people with less social or institutional power, from families in poverty to college students) rather than “study up” (portraying the experiences of corporate executives or elites). Ethical field studies must treat a participant holding less power with the respect that participants holding more power would demand. Issues of ownership and intellectual property rights are now being discussed in English departments, where composition studies include samples of student writing, and in social sciences, where oral histories are recorded (Anderson 1998).

Collaborative research introduces another set of power issues. When a university professor or doctoral candidate engages in research with a community leader, teacher, or others in the field, the research may benefit one party disproportionately; university careers require publication, while the others do not. One party may also incur more risk than another; in the classic Smith and Geoffrey study (1968), the professor used his real name and the teacher, “Geoffrey,” chose a pseudonym.

The “voice” of the report is rarely discussed as an ethical decision. While scholarly dialect can facilitate conversations among researchers, it can also exclude others from those conversations. A fieldworker should report at least some findings in language comprehensible to the stakeholders. To convey the variety of perspectives, some researchers create multigenre and multivoiced texts that honor the participants’ right to co interpretation (or counterinterpretation). For example, van den Berg (2001) redefines “accountability” as the researcher’s

ethical and political responsibility to people in the research scene. Participants are invited to review a draft, and their responses may be woven into the final report or appended as an alternative view. Gloria Ladson Billings (1994), in her ethnographic portraits of urban teachers, also portrays herself in three voices: as scholar, as teacher, and as child recalling her own school experiences. Such texts call attention to them selves as constructions. Some readers find them powerful and convincing, literary as well as scholarly; others may question how the portrait was shaped by the writer.

As these examples suggest, an ethical review of fieldwork should be more (not less) complex than what is typically recommended for laboratory experiments. Instead of yes/no questions, the researcher can adopt an inquiry stance, returning to examine ethical issues at several points in the process. Mason (1996: 29) suggests "a practical approach to ethics which involves asking yourself difficult questions – and pushing yourself hard to answer them."

To supplement the ethical review questions cited above, field researchers have proposed alternative lists (Sunstein 1996; Zeni 1998, 2001; Bishop 1999):

- What question am I exploring? Why?
- To whom am I professionally accountable?
- Which participants do I have some power over? Which have some power over me?
- Whose views of reality am I representing?
- Am I trying to interpret the experience of those who differ from me in culture (race, gender, class, etc.)?
- How have I prepared myself to understand the "other"?
- Is this my story, my informants' story, or a story that fits someone else's theory?
- What would happen if I shifted point of view to tell this story?
- Should my report include the voices of others, especially when their views differ from mine?

Such "difficult questions" can move ethical decisions beyond the legalistic into the personal, the relational, the covenantal. Dialogue among insiders and outsiders can help to nurture an ethical practice of fieldwork.

ethics, research

J. I. (Hans) Bakker

It has always been important to recognize the rights of research subjects as individuals and as members of various kinds of groups or collectivities. Ethnic minorities and racial groups, for example, should not be treated any differently.

They should be given the same respect as any other subgroup. That has not always been the case in the past. That was brought home particularly as a result of atrocities during World War II. “Ethics review . . . emerged from the aftermath of the horrors of the Second World War, when Nazi sponsored medical experiments furthered macabre social aims” (Hoonard 2002: 3). The Nuremberg Code was an important step. The UN’s Universal Declaration of Human Rights is another. However, beyond the more obvious concern with extreme violations, the precise philosophical articulation of ethics can vary according to whether the ethicist holds to some kind of theologically based or secular perspective.

There has been very little consideration of the context in which discussions of ethics occurs; societal “frames” and sets of such frames are often unstated assumptions which do not have conceptual or operational definitions outside of very specific times and places (Scheff 2005). Generally, humanist, neo-Kantian, pragmatist, or other secular ethical systems are most common (Canti 2004). The principle of the separation of church and state makes it difficult to adopt religiously based notions of the sacredness of the individual, but Kant’s secular version, emphasizing respect for individual human dignity and autonomy, results in a similar awareness of the importance of not violating human dignity. While the philosophical questions concerning ethics are not frequently asked, there nevertheless are implied ethical standards that can be traced to ancient Greek and Enlightenment ethical viewpoints. For example, the ethics proposed by Descartes are quite different from Aristotelian ethics (Kahn 2005), but much current thinking goes back to Aquinas and Aristotle rather than Cartesian Enlightenment themes. Yet such issues are rarely discussed. A commonsense version of respect for human dignity and civil liberties is usually in the forefront. The general notion of utility is also frequently mentioned, with beneficence outweighing any possible harm. Mention of Aristotle’s non-utilitarian notions of justice and equity (Smith 2001) would be considered out of place. The concept of ethics that is applied is not universal, but specific to a “modern” historical and societal context. That became apparent in the case of a sociological

study of casual sex in public places (Humphries 1970). In the US, practical interpretations have been largely based on a form of pragmatist philosophy that does not attempt to interfere with research that could be considered reasonable, but also does not try to impose too many rules. Denzin and Lincoln (2003) take a somewhat critical view of some of the assumptions underpinning current notions of "interpretation" and their well known book has had a significant impact among qualitative researchers. Denzin (2003: 486–9) projects greater interest in research guided by "postpositivist, constructivist, critical theory, and poststructural sensibilities." Ethical guidelines which operate now do not directly confront such postmodern approaches at a philosophical level, hence "ethics" is mostly regarded from a strictly "modernist" perspective.

While there has not been much discussion concerning philosophical underpinnings, there has been great concern expressed with regard to practical application. It is clear to all that there should be some ethical guidelines. Nevertheless, many researchers have felt inhibited by specific aspects of the protocols. The question of written versus verbal consent is deemed to be of great practical importance by many researchers. It may be difficult, for example, to obtain candid opinions from individuals or members of communities if the researcher has first to obtain written consent. Similarly, certain forms of experimental research may be considered too likely to interfere with respect for privacy or respect for autonomy. Institutional concerns are not necessarily deeply rooted in philosophical ethics. Instead, there is a desire to conform to the letter of the law. It is common practice to have a lawyer on an ethics board since the legal implications of violation of ethics are frequently a cause for concern among administrators. The importance of research ethics in the social sciences has been emphasized a great deal more as a result of legislation in the US which has created Investigative Review Boards (IRBs) that are ultimately the responsibility of the Office for Human Research Protection (OHRP). US federal guidelines for the protection of human "subjects" or participants have been interpreted in different ways by various actors (Levine 2001). According to the "Common Rule" (Section 46.101

[b]), certain categories of research may be exempt, but individual researchers are not free to exempt themselves. Key components which members of an IRB committee may consider for IRB approval involve (1) informed (written) consent, (2) confidentiality, (3) anonymity, (4) permission to drop out of the study at any time, (5) feedback to research participants, and (6) further steps in the approval process should the research be varied in any way. The data must be stored in a secure environment and is supposed to be destroyed after the study has been completed. Complete anonymity is often difficult to accomplish. Any deviation from any of those principles may result in lack of approval. Permission must be secured in writing. However, it is not always possible to secure informed consent in written form. Hence, for fieldwork in a developing country, a researcher may be granted permission to obtain only verbal consent, as per Section 46.117(c) of the regulations (AAA 2004). Information collected in everyday situations cannot be used retrospectively, since ethical approval was not obtained in advance. Then, too, there may be studies which require some degree of ruse. Obviously, it is not possible to obtain written informed consent from research participants who are not actually being informed about the true intent of the study. In psychological research, however, it is frequently necessary to keep the actual goal secret in order to obtain spontaneous responses. When interviewing mentally challenged individuals it is not always clear what guidelines should prevail (Flynn 1986).

Discussions of practical aspects of the IRB/REB model in the US and Canada have led to critiques of managerial aspects of the status quo and those practical concerns have in turn led to a rekindled interest in some of the broader methodological questions. The IRB model has been criticized for being basically a "biomedical" approach to research (WMA 2002), sometimes involving physically invasive procedures and frequently based on the application of a strict version of the "hypothetico deductive method" as the key part of the scientific method (Nagel 1961). That deductive approach has not been easy to translate into ethnographic fieldwork and other forms of qualitative sociological research. Many qualitative researchers take a

“grounded theory” approach and do not begin their research with hypotheses drawn from the existing literature. Hence, it is difficult to decide in advance what research instruments will be used. At the same time, “there is no logical reason to believe that qualitative analyses cannot be used to test deductive theory” (Lucas 2003).

Recent approaches which stress the way in which different models of science lead to different kinds of considerations concerning “values and objectivity” (Lacey 2005) are frequently left out of consideration. For example, a phenomenological approach to sociology (Barber 2004) can involve “ethnomethodological” research (Garfinkel 1972). In attempting to study nuances of expectations in everyday situations it would be deeply disturbing to announce ahead of time what is happening. The study of a “breach” in normal expectations requires that participants not be informed before the fact. Moreover, the research may not even be inductive. It may be exploratory research which involves a certain amount of guesswork, or “abduction.” Such studies might at one time have been dealt with in an expedited manner by one or two individuals, but they now often require approval by a full committee. In reaching a decision the members of the committee may not all be equally well informed about all relevant questions pertaining to the theory being investigated, since they cannot all have expert knowledge on all social science theories. There may be a bias for or against experimental research as opposed to research in naturally occurring settings.

Certain categories of research do not require ethical approval from IRBs. For example, survey questionnaires which are distributed by an organization for the purposes of administrative change are not considered true research requiring ethical approval. Moreover, certain aspects of research are not subject to IRB approval. For example, the IRB is not concerned with the methodological approach of the research and does not offer advice concerning research design, use of statistical tests, and other such details of implementation. The primary concern is with research participants. Indeed, the move away from using the word “subjects” is probably indicative of the greater awareness of the importance of ethics, an awareness prompted by certain extreme cases of abuse.

Instances where research participants were administered drugs such as LSD without their knowledge or consent and earlier cases where subjects were given sexually transmitted diseases (Jones 1993) are grievous examples. Of course, much social science research is relatively harmless, or would appear to be so on the surface (Hoonard 2002). An undergraduate or graduate research project involving a survey questionnaire does not necessarily constitute a great risk to participants. Nevertheless, all research has to be vetted by IRBs in the US. In Canada a similar approach is maintained by Research Ethics Boards (REBs), with similar concerns. The REBs were established in accord with a statement issued by the three major funding councils. The so called “Tri Council Policy Statement” of September 17, 1998 has had a major impact on the regulation of funded research proposals in Canada. The type of research being conducted can influence the way in which ethical guidelines are interpreted. The normative framework can also be influenced by the source of funding. Generally, there is less concern with ethical considerations in non funded, social science student research that is not invasive and more attention paid to detail in heavily funded biomedical research that is heavily invasive (e.g., administration of drugs or carrying out of surgical procedures). Similarly, minors and “incompetent” adults may be regarded as having greater risk even if the research is perceived as being balanced by significant long term benefits.

Confidentiality involves the data only being used for the explicit purposes for which permission had been granted and further consent prior to disclosure to third parties. Recontacting participants in order to obtain consent for secondary use of data requires further IRB (REB) approval. Whenever a human being is vulnerable it is highly likely that ethical approval should not be granted, especially if it is clear that their compromised position makes such persons manipulable. It can be argued that the principle of distributive justice requires that the burdens and benefits of all forms of research should be distributed among all sectors of the population.

Aunger (2004) argues forcefully that in ethnographic research a high degree of reflexivity is necessary. For example, informants may

learn new information between one interview and the next. His comments can be applied to the ways in which all applications of research ethics procedures may sometimes disturb the way in which a subject is presented and understood. It is not just a matter of the skill level of the researcher; it is a systemic problem related to research design. The most extreme criticism comes from some postmodern ethnographers who deny the "objectification" that goes with "essentialist" notions of the self and therefore conclude that certain ethical guidelines do not easily fit in with their nuanced objectives (Angrosino & Mays de Pérez 2003; Taylor 2003). A pragmatic balance between methodological and practical concerns continues to be an elusive goal and the enormous variety of types of research undertaken make straightforward generalizations highly problematic and sometimes contested.

ethnic cleansing

Dusko Sekulic

The term ethnic cleansing refers to various policies of forcibly removing people of another ethnic group. At the more general level it can

be understood as the expulsion of any “undesirable” population from a given territory not only due to its ethnicity but also as a result of its religion, or for political, ideological, or strategic considerations, or a combination of these characteristics.

The term entered the international vocabulary in connection with the Yugoslav wars. It comes from the Serbian/Croatian phrase *etničko čišćenje*, whose literal translation is ethnic cleaning. In the Yugoslav media it started to be used in the early 1980s in relation to the alleged Kosovar Albanian policy of creating ethnically homogeneous territory in Kosovo by the expulsion of the Serbian population. The term itself was probably taken from the vocabulary of the former JNA (Yugoslav People's Army), which spoke of cleansing the territory (*čiscenje terena*) of enemies to take control of a conquered area. In the wars of Yugoslav succession, ethnic cleansing was a strategy used widely by all sides, starting with the expulsion of Croats from the areas in Croatia inhabited by Serbs. The main goal of these actions was to alter the demographic structure of the territory by getting rid of the unwanted ethnic groups.

The origin and the extended usage of the term ethnic cleansing in the public discourse of the 1990s could create the impression that it describes a historically new phenomenon. In reality it was only an invention of a new term to describe an age old practice. It was carried out widely with or without significant coercion or as part of murderous genocidal campaigns. Ethnic cleansing could be used as a component of state policies, sometimes even based on international treaties, or as a consequence of spontaneous outbursts motivated by prejudice, hatred, and/or revenge. It was employed by empires, small communities, dictatorial and democratic regimes, and in all historical periods. Mann (1999) puts ethnic cleansing on a continuum together with assimilation and genocide. The targeted population for cleansing could be a religious minority, an ethnic group, or simply political ideological opponents. The political and historical context of cleansing can also be strategic, with the goal of removing the population that presents a potential threat.

Historical evidence reveals numerous examples of the practice. Some historical accounts

indicate, for example, that Assyrian rulers made a state policy of forced resettlement of their conquered lands and the replacement of the population by settlers from another region (Bell Fialkoff 1999). In the Middle Ages cleansing was mainly applied against religious minorities. Anthony Marx (2003) argues that religious intolerance – specifically, the exclusion of religious minorities from the nascent state – provided the glue that bonded the remaining population together.

The rise of modern nationalism and the nation state created a new framework for such cleansing activities. It is inherent in the modern project of nationalism that “We the people” generates a sense of the alien “other.” And because the sovereignty of the modern nation state is territorial, the “other” may be physically excluded from the territory of the people.

There are endless examples of cleansing, exchanges, or exoduses of populations accompanying the creation of modern nation states. Exchanges of populations between Greece, Bulgaria, and Turkey were sanctioned by international treaties (the 1913 Convention of Adrianople and the peace treaty between Bulgaria and Turkey). The partition of India, the creation of the state of Israel, the division of Cyprus, and the successor states of the former Yugoslavia are just a few examples.

One of the biggest ethnic cleansings, culminating in extermination, was the Nazi campaign against the Jews. The Holocaust combined elements of deportation, expulsion, population transfer, massacre, and genocide. Some other examples of very similar practices in modern times are the holocaust of Armenians and the massacres of Tutsis by Hutus known as the Rwandan genocide.

Stalin's regime cleansed ethnic groups because of strategic considerations and also perceived internal political enemies on a grandiose scale. The expulsion of Poles from Belorussia and the Ukraine (1932–6) to Kazakhstan, the deportations of Poles, Lithuanians, Latvians, and Estonians from areas occupied by the Soviet Union in the 1930s, the mass deportations and exile of the Chechens, Ingush, Volga Germans, Balkars, Kalmyks, and Crimean Tatars in 1943–4, all fall into the first category.

The second type of cleansing was directed toward different types of class enemies – kulaks,

alleged enemy spies, and collaborators. In Asia, the Chinese and Cambodian communists accepted bloodlines as a way of identifying class enemies. The Khmer Rouge took this approach a step further into something that Mann (1999) calls "classicide" as an analogy to genocide. It killed about half the number of Cambodians with a bourgeois background.

In analyzing the transformation of empires into nation states, Brubaker (1995) states that the occurrence of migrations and different forms of ethnic cleansing depended on the extent to which disintegration was accompanied by war or other types of violence, on the established nature of the potential target for cleansing, on the anticipated and actual policies of the successor states toward the minorities, on the availability and quality of resettlement opportunities, and on "voice" as an alternative to "exit." There is nothing preordained about its occurrence. It happens under conditions that can be understood, explained, and predicted.

ethnic enclaves

Jan Lin

The ethnic enclave is a subeconomy that offers protected access to labor and markets, informal sources of credit, and business information for immigrant businesses and workers. Ethnic enclaves offer entrepreneurial opportunities and earnings for immigrant owners and managers through the exploitation of immigrant labor in poor working conditions. They are phenomena that advance our understanding of the changing experience of immigration and social mobility in America. The enclaves of Asian and Latino immigrants emerging since the 1960s are comparable to the enclaves of Jewish and Italian immigrants at the turn of the twentieth century. They present a route for economic and social mobility by promoting positive returns on human capital for immigrants in the labor market. During the decades of immigrant restriction, ethnic enclaves were shunned in the US as economic and spatial barriers to the successful assimilation and upward mobility of immigrants to American life. Since the 1960s, however, ethnic enclaves have been increasingly seen as agents for economic and social mobility. Ethnic enclaves are proliferating in both the cities and suburbs of contemporary immigration gateway cities such as New York, Miami, Houston, and Los Angeles. They constitute and convey the process of globalization as nodes of trade and transaction in flows of ethnic labor, capital, commodities, and cultural products across trading regions. There are costs as well as benefits that come with the insertion of ethnic enclaves into the complex social dynamics of contemporary global cities.

Pathbreaking research in the early 1980s on the concept of the enclave economy initially focused on the contrast between the Cuban enclave and the black economy of Miami (Wilson & Portes 1980; Wilson & Martin 1982). This research methodology utilized input-output multiplier matrices. The Cuban owned firms of the Miami area were found to comprise a dynamic subeconomy of construction, manufacturing, retail and wholesale trade, and banking firms that recirculated and multiplied income through interindustry and

consumption linkages. The economy of black neighborhoods, by contrast, was impoverished and capital scarce, with income constantly leaking out of the community through branch manufacturing plants and chain stores owned by whites and large corporations. The enclave economy was conceptualized as an alternate subeconomy from the segmented mainstream economy, which was split into an upper tier of jobs with good mobility ladders, and a lower tier of dead end jobs in which minorities and the economic underclass predominated. Investment capital was commonly raised in ethnic enclaves through devices such as kinship networks and rotating credit associations. These ethnic enclaves offered a protected sector for immigrants newly arrived without English language skills, good education, or official papers.

The study of the enclave economy was extended to a number of Latin American and Asian enclaves and comparisons made with earlier European immigrants (Portes & Manning 1986). In her research on New York's Chinese enclave, Min Zhou (1992) drew a distinction between an "export sector" that derived earnings from outside the enclave, and a "protected sector" that derived from earnings from sales to co ethnics. The dynamism of the ethnic enclave economy is based in large part upon the multiplier effect, by which export earnings are spent and recirculated among co ethnic enterprises throughout the remainder of the protected sector. For example, garment manufacturing can be viewed as an export sector that multiplies enclave income through forward and backward linkages with co ethnic suppliers and buyers, as well as consumption linkages with other co ethnic enterprises such as restaurants and markets. On the other hand, ethnic restaurants and other retail businesses comprise characteristics of both an export and protected sector. The concept of an "export sector" is clearer in theory than in practice, comment John Logan et al. (1994). They concluded that ethnic enclave economies are best typified by co ethnicity of owners and workers, spatial concentration, and sectoral specialization. Evidence of sectoral specialization can be found in measuring overconcentration of ethnic enterprises or labor in particular industries as compared with the general population. A greater

degree of sectoral specialization indicates a more successful ethnic enclave.

A segment of the research utilized a "returns on human capital" research methodology, which determined that positive returns accrued to employers at the expense of workers. This research found that ethnic enterprises undertook a kind of ethnic self exploitation by which immigrant employers profited from their ability to exploit co ethnic workers in a "sweatshop" sector under poor working conditions and poor labor rights. There was some debate regarding whether the enclave should be defined by place of work, place of residence, or industry sector (Sanders & Nee 1987). "Sweatshop" is a label for an enterprise that exploits workers with poor wages and benefits, bad working conditions, and low occupational security. Some researchers found evidence of significant gender differences in labor market outcomes. Positive returns for men were to some degree derived from negative returns to women as subordinate workers (Zhou & Logan 1989). The surplus value generated through ethnic solidarity in the enclave economy was derived effectively through worker exploitation by socioeconomic class and gender. The disparity in short run benefits is followed by positive aggregate benefits in the long run.

Contemporary Asian and Latin American immigrants have succeeded the European immigrants of the turn of the twentieth century, in the urban industrial districts and residential neighborhoods of many US cities. Their appearance has helped revive many commercial, warehousing, and manufacturing districts that had been declining since the 1950s, as a result of suburbanization, the outmovement of industry, and the "runaway shop" to the developing world. The new ethnic enclaves are not just an illustration of immigrant succession, they are an outgrowth of neoliberal economic and free trade policies since the 1960s, which promoted the mobility of labor and capital between the US and its trading partners. The Hart Cellar Immigration Act of 1965 removed restrictive quotas and restrictions on immigrant flows, as well as introducing banking deregulation to encourage capital outflow and inflow, and policies oriented to encouraging the import and export of goods (Sassen 1988). The new gateways of globalization include cities

such as New York, Washington, DC, Miami, Atlanta, Houston, Los Angeles, and San Francisco. The growth of ethnic enclaves in the Frostbelt as well as the Sunbelt leads us to a revision of our understanding of post industrial urban transition, through which the dynamism of globalization and immigration can be seen as superseding the decline associated with deindustrialization.

Ethnic enclaves are not just a factor in the insertion of immigrants into the American economy. They are nodes in the flow of immigrant labor, capital, and culture between the US and the emerging economies and trading regions of Asia, Latin America, and the Caribbean. The sweatshops of the immigrant garment industry are connected with trends of global sourcing in manufacturing. The banks of the ethnic enclave are crucial institutions in mediating transnational capital flows, whether they are inflows such as investments for overseas investors or outflows such as remittances for immigrant labor. New Asian and Latino immigrants have succeeded the earlier generation of Italian and Jewish immigrants in the traditional central city "urban village," but many enclaves are appearing in suburban locations, with ethnic signage proliferating in strip malls and commercial arterials. The ethnic suburb, or "ethnoburb," has become a common feature of life in some American cities. The ethnoburb is a symbol not only of immigrant success, but also of intergroup conflict in the global city.

The insertion of ethnic enclaves into the social and economic dynamics of the post industrial cities has been in some areas a vociferously conflicted and contested process. In some cases such as the Cuban enclave of Miami and the Chinese enclave of Monterey Park, California, in the 1980s, the proliferation of ethnic businesses and signage led to the growth of nativist and xenophobic reactionary local social movements, and support for English only language ordinances. In Monterey Park, the link between the ethnic enclave and rapid commercial development also sparked a growth control movement among local homeowners and politicians (Horton et al. 1987; Li 1999). Some immigrant entrepreneurs focus on certain occupational niches as economic and social "middleman minority" between dominant white

groups and poor minorities. Chinese, Korean, and Indian immigrants commonly operate small business groceries, liquor stores, and motels. They fulfill a function undesired by white elites. They act as a social buffer between the dominant and oppressed groups of a society, and in situations of crisis may bear the brunt of underclass anger, as seen in the black/Korean violence that followed the Rodney King disturbances of 1992 in Los Angeles (Min 1996).

For most of US history until the 1960s, ethnic identity and customs were generally suppressed in cities through projects of urban settlement and social reform work that sought to assimilate immigrants to the English language and American values. Chicago was the seminal expression of the modern industrial city in the early twentieth century, the paradigm of the "human ecology" school of urban sociology. The ethnic ghetto was stigmatized as a place of vice, crime, moral corruption, and public health hazards. This was a time of immigrant restriction and Americanization campaigns. Chicago School sociologists such as Robert Park codified the view that immigrant colonies such as the Jewish "ghetto," Little Italy, and Greek Town, which occupied the "zone in transition" surrounding the central business district, would eventually dissipate with the eventual upward mobility of working class immigrants into the suburbs and their cultural assimilation into the middle class. Douglas Massey (1985) later articulated this phenomenon as the "spatial assimilation" thesis. Upward social mobility into better jobs and social status was linked with spatial mobility into better homes and neighborhoods. Ethnic enclaves were seen to create social immobility and spatial entrapment.

The human ecology school held the prevailing view of the social reformers in the early twentieth century that ethnic enclaves were dysfunctional slums that harbored social pathologies and blight (Ward 1989). During this period of urban growth, city managers and the federal government actively began bulldozing ethnic enclaves under slum clearance policies of the interwar period and urban renewal in the post war period, to make room for expressway arterials, middle class housing, expansion of the central business district, and

government buildings. Chinatowns, Little Italies, and Mexican neighborhoods were viewed as obstacles to modernization and cultural assimilation. Herbert Gans, in the seminal study *The Urban Villagers* (1962), decried the officials and policymakers who designated the Italian American West End neighborhood as a slum and led to its demolition to make way for middle class housing. In Los Angeles during the same period, a celebrated Mexican American community was razed to make way for the construction of Dodger Stadium. Since the 1960s, however, city managers and planners have increasingly come to see ethnic enclaves as tools rather than as obstacles to growth. The preservation of ethnic places and neighborhoods is of growing utility in efforts to promote globalization in metropolitan economies through the construction of world trade centers, convention centers, and urban tourism.

The growing emergence and persistence of ethnic enclaves has changed the meaning of ethnicity and American identity. Ethnicity in contemporary America is becoming less of an ascribed experience that preserves ancestral traditions, and more of an achieved experience where these traditions may be created and enacted for outside consumers as much as co ethnic participants. Ethnic enclaves are increasingly producing for the export sector of American consumers as well as the protected sector of immigrant consumers. At the turn of the last century, when ethnic minorities were suppressed by doctrines of manifest destiny and assimilation, the sustaining of ethnic food ways and folkways protected bonds of communal social capital and spiritual meaning. In the current era of the multicultural and global city, ethnicity is increasingly tolerated, celebrated, and transacted. Ethnicity has been activated and affirmed by consumers of such culinary trends as Japanese sushi, Chinese dim sum, and Spanish tapas. Ethnicity has also been appropriated and branded by transnational fast food franchises such as Taco Bell. As ethnicity becomes increasingly transacted in the era of global consumer capitalism, the original intention, authenticity, and ownership of local ethnic culture can come under threat.

In the current era of economic and cultural change, ethnic enclaves constitute and

convey global processes in US immigration gateway cities. Opportunities have arisen for ethnic entrepreneurs to profit from a growing American interest in consuming and experiencing ethnic foods, music, theater, arts, fashion, museums, and festivals. The Civil Rights Movement also resulted in legal and political protections for racial and ethnic minorities, dampening the power of assimilation rhetoric and promoting the sustaining of ethnic cultural heritage and a politics of cultural pluralism. Trends of economic globalization have led to widespread outsourcing of manufacturing employment to offshore locations, stimulating growth of post industrial activities onshore in a range of industries involving the production of culture for consumption. The cultural endowments of urban regions, like the mineral or agricultural resources of their hinterlands, have become important components in their repertoire of economic activities. The competition among cities for prosperity in the global economy has promoted strategies of urban "branding" for entertainment and tourism, to help boost cities suffering economic decline. The "branding" process is promoted through corporate trademarking of office buildings, sports stadiums, concerts, and festivals. Urban redevelopment in the new "symbolic economy" involves the use of devices such as museums, theaters, restaurants, and local cultural districts (Zukin 1995). The growth of the ethnic cultural economy involves the mobilizing of the "creative capital" of a new talented and credentialed class of workers including artists, curators, designers, and chefs, who are qualified in the production and distribution of creative goods. The creative economy has an innovative edge in the area of high technology and a cosmopolitan edge since it prospers in areas of cultural diversity and tolerance (Florida 2002). In the new creative economy of cities, economic innovation links with a pattern of urbanity that draws talented individuals and traders from the hinterlands and other trading regions to create value in products based on taste, fashionability, and design.

A host of social conflicts and contradictions affecting ethnic producers of culture as well as white consumers accompany these trends. Many ethnic enterprises such as restaurants

provide opportunities for a “front region” staff of owners, gourmet chefs, and waiters while exploiting a “back region” staff of dishwashers and kitchen assistants (Zukin 1995). Immigrant restaurants may exploit the back region staff with poor wages and working conditions. For the manual workers in the back region of the restaurant, the enclave economy offers certain economic opportunities, but their chances for upward social mobility are as limited as for those who toil in the low wage service sector in such enterprises as cleaning, security, and fast food restaurants. The best advantages of the ethnic restaurant sector accrue to the front region staff, whose profitability depends upon their ability to effectively mobilize their ethnic creative capital.

The marketing of ethnicity carries a host of positive as well as pernicious implications. The consumption experience of “eating the Other” is problematic insofar as it permits white Americans to assume a positive association with the culture of subaltern racial/ethnic minorities while camouflaging ongoing social inequality and white privilege. The growth of an ethnic “creative class” is a stimulus to urban redevelopment through a cultural affairs strategy that promotes the gentrification of inner city neighborhoods and the displacement of low income residents. Issues of cultural authenticity and ownership come to the fore as ethnic neighborhoods are preserved and marketed like theme parks in American cities. As it becomes increasingly acceptable for ethnic foods and cultures to be consumed and transacted, some forms may become aesthetically incorporated into the repertoire of tastes and “cultural capital” associated with the elite social classes in America. Increasing the aesthetic appeal of a cuisine increases its chances for marketability. Some ethnic groups, such as Puerto Ricans, have faced more challenges than groups such as Cubans or Japanese immigrants in successfully creating and defining a market for their cultural products. The production and consumption of ethnicity is a growing factor in the larger dynamics of American social inequality and stratification.

ethnic groups

John Stone and Bhumika Piya

Ethnic groups are fundamental units of social organization which consist of members who define themselves, or are defined, by a sense of common historical origins that may also include religious beliefs, a similar language, or a shared culture. Their continuity over time as distinct groups is achieved through the inter-generational transmission of culture, traditions, and institutions. Ethnic groups can be distinguished from kinship groups in as much as ties of kin arise largely from biological inheritance. The term is derived from the Greek word *ethnos*, which can be translated as a people or a nation. The sociologist Max Weber provided one of the most important modern definitions of ethnic groups as "human groups (other than kinship groups) which cherish a belief in their common origins of such a kind that it provides the basis for the creation of a community."

There are two competing perspectives on ethnic groups: objectivist and subjectivist. Objectivists, taking an *etic* stance, assert that ethnic groups are inherently distinct social and cultural entities that possess boundaries which delineate their interaction and socialization with others. Subjectivists, on the other hand, embrace an *emic* perspective and regard ethnic groups as self-categorizations that determine their social behavior within and outside the group. Subjectivists like Frederik Barth argued that ethnic groups should be defined on the basis of self-identification or categorical ascription. Such a standpoint has led to the creation of legislation such as an Australian government policy in the early 1970s which classified Aboriginal people on the basis of self-identification by an individual and acceptance by an Aboriginal community. Conversely, the objectivists have adopted the idea that ethnic groups are characterized by cultural and historical traits that have been passed down from generation to generation rather than on pure self-conception. Despite the lack of consensus while defining ethnic groups, it is safe to assume that such groups are distinct entities with boundaries, be they real or constructed. The boundaries of ethnic groups often overlap with

similar or related categories such as "races" or nations. There is a consensus among scholars that "race" is a socially defined category that has no biological significance, despite lingering popular beliefs that still regard "races" as biological groups made up of a people with a distinct genetic heritage. There is no scientific evidence to support these notions. However, one could regard race as a variant of ethnic group, for racial groups are perceived to be physiologically different by outsiders, if not by the group members themselves.

The term nation implies a self-conscious ethnic group mobilized with the goal of creating or preserving a political unit in which it is the predominant or exclusive political force. According to Weber, nations are politically mobilized ethnic communities in which members and their leaders try to create a special political structure in the form of an independent state. Ethnic groups may also embrace solidarity and group enclosure in order to achieve advantages over other groups. Such enclosure tactics could take several forms, such as endogamous marriage, which is marriage within a social group, or business practices such as the dominance of Jews in the Antwerp diamond cutting industry.

In those societies that have been influenced by large-scale immigration – like the United States, Canada, Australia, New Zealand, and Argentina – the importance of ethnic groups can be seen as a central feature of their social, economic, and political life. However, it is useful to note that immigrants having the same region of origin are often categorized under generic ethnic groups despite the absence of cohesion and common culture. Systematic research on American ethnic groups can be traced to the sociologists of the Chicago School during the 1920s, led by W. I. Thomas and Robert Ezra Park, who were concerned with the processes of ethnic group assimilation into the dominant white Anglo-Saxon Protestant (WASP) mainstream. Park's *race relations cycle*, which outlined a sequence of stages consisting of "contact, competition, accommodation, and assimilation," implied that successive immigrant groups would be gradually absorbed into a relatively homogeneous US society. The underlying assumption of ethnic group theory was that these long-term trends would

result in the disappearance of separate ethnic communities as they merged into a wider American melting pot.

This model implying a straight line progression gave way to more pluralistic conceptions of ethnicity in the US, in which various dimensions of assimilation were identified by sociologists like Milton Gordon, who wrote the classic work on the subject. In *Assimilation in American Life* (1964), Gordon distinguished between cultural assimilation (*acculturation*) and structural assimilation, the former signifying the adoption of the language, values, and ideals of the dominant society, while the latter reflected the incorporation of ethnic groups into the institutions of mainstream society. While cultural assimilation did not necessarily result in an ethnic group's inclusion within the principal institutions of society, structural assimilation invariably meant that assimilation on all other dimensions – from personal identification to intermarriage – had already taken place.

Scholarly concern with ethnic groups and ethnic conflict became increasingly salient in the second half of the twentieth century. Inadequate assumptions about the nature of modernization and modernity have been demonstrated by the pattern of social change under capitalism, socialism, and in the developing world. Expectations that modernity might lead to a smooth transition from *gemeinschaft* to *gesellschaft*, accompanied by the gradual dissolution of ethnic group affiliations, were no longer plausible. Some social scientists argued that there was a primordial basis to ethnic group attachments, while others explained the apparent persistence of ethnicity as a criterion of group closure in more instrumental terms, as a political resource to be mobilized in appropriate situations which may be activated by power or guided by cultural factors. Not only has ethnicity failed to recede in industrial and post industrial societies, but also ethnic divisions have continued to stand in the way of movements to promote democracy and economic growth in large sectors of the non industrial or industrializing world. The failure of the political regimes in the communist bloc unleashed an upsurge in ethnic and national identity, some of which filled the void created by the demise of Marxism, while other elements of the same development, notably in

the former Yugoslavia, turned into bloody ethnonational conflicts and ethnic cleansing (Sekulic 2003).

The increasing visibility of ethnic diversity due to postcolonial migration and globalization has engendered remarkable responses, ranging from expulsion or persecution of ethnic groups to their integration and assimilation into dominant cultures. The extermination of Jews and Gypsies during World War II under the Nazi regime is a classic example of the persecution of people to dispose of “undesired” ethnic groups; hence, it is claimed, deterring potential ethnic discord. The expulsion of ethnic groups can take the form of a forced exodus as well. Forced eviction of more than 100,000 of the Lhotshampas ethnic groups from Bhutan, starting from 1989 and still continuing under the “Driglam Namzha” decree, is another example of ethnic cleansing. The royal decree, declaring the recent “one country, one people” policy, seeks to homogenize the Bhutan population by imposing the indigenous Buddhist culture of the majority Drukpa, including their language, dress code, and customs, on the rest of the people (Hutt 2003). In contrast to the aforementioned policies, the majority of contemporary responses have been toward assimilation or acculturation and pluralism.

The example of more or less voluntary assimilation is seen in the US, where ethnic groups, including immigrants and natives, have embraced the mainstream American culture. This is advantageous to ethnic minorities in terms of upward mobility in the economic and political spheres of the society. An archetypal pluralistic society is Switzerland, which has separate cantons for different ethnic groups. Ethnic groups remain socially and politically differentiated, and enjoy a certain degree of autonomy within the democratic federation. Besides assimilation and pluralism, a new trend of embracing pan ethnic identity is emerging. Ethnic groups form a conglomerate and join together under larger umbrella groups. Such practice is common among South Asians and Latinos in America.

The escalating incidence of interethnic conflicts has incited heated debate amongst policy makers and scholars as to how the state should respond to ethnic divisions. Some scholars such as Jürgen Habermas assert that all people

should be treated equally, regardless of their ethnic backgrounds or national origin. Hence, they are entitled to equal legal and political rights as autonomous individual subjects. Others, like Will Kymlicka, have criticized the notion of autonomous individual subjects as being impractical. Kymlicka advocates the recognition of ethnic group membership and a pluralistic approach in policymaking to accommodate the distinctive needs of ethnic groups. Some also stress the point that ethnic conflicts are not really "ethnic" but mainly political or economic.

At the end of the millennium, the focus of research on ethnic groups was shifting away from studies of specific groups toward the broad processes of ethnogenesis, the construction and perpetuation of ethnic boundaries, the meaning of ethnic identity, the impact of globalization (Berger & Huntington 2002), and the importance of transnationalism (Levitt & Waters 2002). While traditional patterns of international migration continue to play an important role in the generation of ethnic diversity, they have been modified and changed by political and economic factors in complex and unpredictable ways. In the United States, large numbers of Mexican migrants, both legal and undocumented, have contributed to the growth of the Latino population into the largest single minority group (Bean & Stevens 2003). In Germany, the central economic component of the European Union, the relations with immigrants and ethnic minority groups will be a crucial element in determining the progress and stability of the emerging political structure, no matter whether it becomes a superstate or remains a loose federation (Alba et al. 2003).

ethnic/informal economy

Jimmy M. Sanders

Ethnic/informal economies are inconsistently defined by scholars. This slows progress in explicating the social underpinnings of ethnic/informal economies and in understanding how these economic systems affect the socioeconomic well being of members of various ethnic groups. Fortunately, there is a common theme to the definitions one finds in the literature. All variants convey a sense of economic action embedded in solidaristic, co ethnic social relations. Economic behavior is influenced by informal rules and practices that govern the normative behavior of group members. Beyond this common theme, however, widely differing definitions involving self employment, employment niches among those who are not self employed, and geographical clustering have been applied. Light and Gold (2000) suggest three definitions as a way to reduce this chaotic

state of affairs. The first is the combination of business owners, unpaid family labor, and paid co ethnic employees (ethnic ownership economy). The second includes the first, but adds the requirement of spatial clustering (enclave economy). The third points to occupational and industrial employment niches (not business ownership) where the overrepresentation of an ethnic group enables its members to benefit from the advantages of informal control (ethnic controlled economy).

An informative literature has emerged despite the lack of consistency in defining ethnic/informal economies. Researchers concentrate on how foreign born groups establish and maintain economic niches that are usually accentuated by a profusion of small businesses. The field examines how limited acculturation and structural assimilation in the immigrant generation gives rise to collective action that promotes enterprising economic action. A substantial body of research documents how immigrant minorities draw on social ties in order to facilitate the development of informal economic relations. Family ties and ethnic group membership typically provide the social underpinnings of these economic relations.

The ability to draw on social connections in order to gain access to resources that are useful for economic action is an example of what scholars refer to as social capital. The literature describes many ways in which immigrants make use of family and ethnic based interpersonal connections in gaining access to resources such as business related information and financial credit. Understanding these practices, which are often steeped in informal institutionalized arrangements, is essential for understanding the origins and maintenance of ethnic/informal economies.

Bonacich and Modell's (1980) study of three generations of Japanese Americans reveals how hostility from the dominant group can generate a defensive reaction from minority groups. In the case of the Japanese on the US West Coast, this encouraged ethnic solidarity and strengthened social boundaries that were reinforced by a shared sense of ethnic identity. This strong sense of community, in turn, gave rise to cooperation and collective action that generated and distributed group resources that facilitated the rise and expansion of the Japanese ethnic

economy. This economic system was the basis of Japanese upward mobility prior to World War II. Scholars show how ethnic businesses fill niches created by the demand for goods and services in an ethnic community. These markets are partially closed to out group businesses due to cultural and ecological barriers. Research also considers the role of informal credit and savings associations in helping prospective entrepreneurs acquire startup capital and in expanding the availability of credit to those who already own a business. Such economic activities, embedded in social relations, necessitate a sense of interdependence among in group members that engenders trust and solidarity, and allows for sanctions to be imposed on those who violate the trust of others (Portes & Sensenbrenner 1993).

Interest in ethnic/informal economies is part of a larger scholarly interest in economic segmentation. This view conceives of the labor market as divided into a primary market where opportunities for advancement are prevalent and a low wage secondary market with little opportunity for advancement. In the wake of growing international migration in the 1960s and 1970s, scholars concerned themselves with the range of economic options encountered by immigrants. Concluding that these opportunities were limited, researchers began to explore how the economic advancement of immigrant minority groups might be generated in a context of labor market segmentation and ethnic based strategies of economic action.

Thus far, a large share of this research has been produced in the United States. This is not surprising given the importance of immigration in the history of the country's development, the large number of scholars at American universities who are engaged in research, and that the country has once again become the host society for large numbers of international migrants. But the United States is not alone in opening its doors to immigration. Research into ethnic/informal economies is also conducted in immigrant receiving societies such as Canada, Australia, and in several European nations. Earlier immigration to South America also receives a good deal of attention. Numerous studies from various societies are reviewed in Aldrich and Waldinger (1990). This excellent review considers how characteristics of an

ethnic group and the structural opportunities (or lack thereof) they encounter jointly influence the emergence of ethnic strategies that facilitate the rise and maintenance of an ethnic/informal economy. The review includes several historical and contemporary examples of the importance of both structural opportunity (e.g., elite sponsorship of middleman minorities in Southeast Asia, Africa, the Ottoman Empire, and tsarist Russia) and group characteristics (e.g., the rise of the Chinese Vietnamese informal economy in Paris). Inasmuch as some relatively rich Asian nations are making use of guest workers from poorer Asian nations, we will probably see more research from this part of the world in the future – to the extent that these workers establish ethnic/informal economies.

Studies of how ethnic strategies develop and support ethnic/informal economies often consider the importance of ethnic based social networks. Focusing on the role of social networks in generating economic opportunities, Portes and colleagues (e.g., Portes & Bach 1985) conducted an important study on an emerging Cuban economy in Miami. Ethnic solidarity facilitated the vertical and horizontal integration of a burgeoning business community. But an unclear picture emerged as to the economic implications of participating in the Cuban economy. Some of the research finds that working with fellow Cubans or other minorities negatively affects earnings and working under a Cuban boss has no effect on earnings. By contrast, other publications report that participation in the Cuban economy gives rise to advantages in occupational prestige, and occupational prestige positively associates with earnings. The importance of this latter finding is that it appears to counter the ecological hypothesis of assimilation theory, which contends that continued spatial segregation in terms of the labor market and residential patterns limits the upward mobility of ethnic groups.

An engaging debate arose over the question of whether the ecological hypothesis of assimilation theory was indeed inconsistent with the experiences of Cubans in Miami. The first exchange was initiated by the criticism that failure to distinguish between self employed Cubans and their employees accounts for the apparent disconfirmation of the ecological hypothesis. Sanders and Nee (1987) appear to

show that the positive association between participating in the Cuban economy and occupational prestige is largely due to the occupational prestige of business owners rather than that of their employees. Hence, business owners financially benefit from participating in the densely co ethnic regional economy, but their employees tend not to experience such a benefit. This pattern implies the Cuban experience is similar to that of earlier immigrant groups. The debate was rejoined by Jensen and Portes (1992) and Sanders and Nee (1992). An earnings advantage is confirmed for Cuban business owners, but no comparable advantage is found for Cuban employees. Indeed, for men, a negative main effect obtains for employment in the Cuban economy. The bottom line is that ethnic/informal economies, like other market driven systems, not only generate wealth, they also generate inequality.

The field was beginning to concentrate less on any supposed earnings advantage that ethnic/informal economies provide to employees and more on how shared ethnicity facilitates internal forms of social organization and institutional behavior that increase employees' chances of becoming self employed. Bailey and Waldinger (1991), for example, show how informal ethnic networks in New York City's Chinese garment industry provide information to employers that helps them recoup the cost of training employees. These networks also provide employees with inside information that increases their chances of becoming self employed. Several subsequent studies have documented that informal training systems operate in various ethnic economies. But these systems, by facilitating greater self employment within an ethnic group, can drive up the cost of co ethnic labor and therefore immigrant entrepreneurs often draw from out group minorities to fill their labor needs.

As the literature converged on the importance of ethnic/informal economies as an engine to increase self employment, and thereby improve opportunities for upward mobility, some scholars were questioning the evidence that ethnic small business owners experience an earnings advantage. A key part of this critique is that the economic benefit to ethnic self employment may be largely due to business owners practicing self exploitation by working

70 or 80 hours per week. Others recognize the long hours of work required of ethnic entrepreneurs, but the literature generally regards this to be one of the costs of economic success through self employment. Portes and Zhou (1996) examine the argument that ethnic self employment fails to produce an earnings advantage. They find a substantial advantage to self employment, but this advantage is concentrated among unusually successful entrepreneurs as opposed to being spread throughout the business community.

Toward the close of the twentieth century, scholars continued to refine their understanding of the social bases of ethnic entrepreneurship. Sanders and Nee (1996), for example, demonstrate that the family plays a key role in ethnic enterprise, much as it had with earlier immigrant groups. The family is a strategic resource in ethnic entrepreneurship because the social ties it embodies tend to be the most intense and trust evoking of all interpersonal relationships. This literature shows that, by focusing on the ethnic group as a resource for collective economic action, many scholars have overlooked the role of the smaller, more tightly integrated social institution of the family.

What has the literature taught us about the social bases of ethnic/informal economies? Researchers have revealed a number of informal mechanisms based on social relations that facilitate economic action. The most important outcomes of these mechanisms are the dissemination of employment and business related information, and providing access to informal financial institutions. Normative use of these resources and the repayment of debts are encouraged by enforcing trustful behavior under the threat of sanctions. Informal social bases of economic action tend to emerge among groups as members try to overcome limited economic options due to language barriers, poor human capital, or non fungible foreign earned human capital. And immigrant groups often face discrimination and prejudice. A tendency for group members to react to these problems by looking within their group for practical and emotional support encourages ethnic solidarity, which in turn encourages informal group practices that provide access to resources. Internally generated resources contribute to the growth of self employment and

this leads to increased opportunities for getting ahead. But there are winners and losers in the ethnic community. People seeking to better their lives and that of their family are involved in the rough and tumble environment of market economics. Even a modicum of success in small business usually requires outperforming some competitors and matching the performance of others. This is a daunting task because ethnic/informal economies tend to be hotbeds of competition between small businesses.

ethnic and racial division of labor

Michael Lichter

An ethnic or racial division of labor exists in a society in which ethnic or racial groups have distinctive concentrations or specializations in particular lines of work. Ethnic/racial divisions of labor may arise through relatively benign labor market sorting processes, or they may be the result of systematic acts of bigotry and discrimination, often with state sanction. Regardless of how they arise, ethnic/racial divisions of labor can be observed and traced over time, and they can have measurable effects on social and political dynamics within societies.

Ethnic/racial divisions of labor have a long history. For example, in Athens of classical antiquity, landowners and other free citizens were almost exclusively Athenian, but the slaves who performed the bulk of the society's work were typically (but not universally) ethnic outsiders, as were the *metic* and *xenoi* artisans and merchants who dominated many areas of trade. More recently, European colonial powers created ethnic divisions of labor across the globe, installing themselves as a ruling class and frequently selecting a specific ethnic group within a colonized territory to fill privileged positions in colonial administration or trade. Apartheid in South Africa and slavery and Jim Crow in the American South are two examples of legal systems in former colonies that enforced racial divisions of labor, reserving desirable positions for whites while largely restricting subordinated groups to menial occupations. Ethnic divisions of labor in many countries are among the most persistent legacies of European colonialism.

Social theorists have developed a number of explanations for the creation and maintenance of ethnic divisions of labor. Neo Marxists have

alternated between two seemingly contradictory positions. The first position, which dates back to Marx, holds that capitalists are the architects of ethnic/racial divisions of labor, offering privileged positions to some groups of workers while assigning the most onerous tasks to others. The capitalists' goal is to foster conflict and competition within the working class, keeping it divided and weak. So called radical theories of labor market segmentation mostly adopt this position. The second position, espoused most forcefully by Bonacich in the early 1970s, does not hold capitalists responsible for anything beyond creating a context that forces workers to compete with each other in order to survive. In Bonacich's scheme, when relatively privileged workers face a threat from ethnically or racially distinct others, they use ethnic solidarity, labor organization, and other social and political resources at their disposal to insulate themselves from competition. When they are unable to completely exclude the other group from the labor market, they are often able to create an ethnically/racially split labor market, reserving the best positions for themselves. The split labor market persists as long as ethnic/racial others remain a threat.

Development in these macro level neo Marxist theories has virtually stalled since the late 1980s. Most recent work has focused at lower levels of abstraction – the metropolitan area, the industry, or even the individual firm. Ecological approaches to the ethnic/racial division of labor, for example, typically concern metropolitan labor markets. These approaches treat local labor markets as metaphorical ecologies, with ethnic/racial groups pictured as metaphorical species struggling to find and expand their "niches." In his study of native blacks and white immigrants at the dawn of the twentieth century, Lieberman (1980) proposes a "model of occupational composition" that frames the ethnic/racial division of labor as the outcome of a struggle for group position within a fixed hierarchy of occupational positions. For a particular group, the outcome of this struggle is determined by the overall group composition of the metropolitan area, group members' "objective" qualifications, group members' occupational preferences, the desirability of particular occupations, and, perhaps most importantly, the ethnic/racial preferences

of employers and potential co workers and customers. This approach helps account for collective upward mobility among ethnic groups, although it does little to explain the extra efforts made by immigrant whites to exclude blacks.

While Lieberman focused on earlier immigrant waves, mass movements to the US and Europe since the mid 1960s have sparked considerable interest in understanding how ethnic divisions of labor are formed and transformed over time. In the 1980s and early 1990s, the phenomenal growth of immigrant enterprises and the role of these businesses in providing co ethnic workers with employment niches attracted much attention. Portes and his colleagues developed the notion of the ethnic enclave economy, a separate economy semi detached from the mainstream economy in which ethnic entrepreneurs both exploit co ethnic workers and provide new business opportunities for them. Among immigrant groups that bring entrepreneurial expertise and a modicum of capital, opportunities for small business play a major role in shaping the group's place in the overall ethnic/racial division of labor.

Views on the consequences of ethnic/racial divisions of labor vary. Few disagree about the destructive consequences of coercive systems like apartheid and Jim Crow. Contemporary immigration scholars who study the entry of comparatively small groups of newcomers into larger ethnic/racial divisions of labor, however, tend to view these divisions of labor as inevitable. They also often see the consequences as very favorable to the new immigrants. Some, however, point out that not all immigrants locate favorable niches and that, furthermore, immigrants may be squeezing native minorities out of opportunities.

Neo Marxists tend to view ethnic divisions of labor as wholly undesirable because they are based on discrimination, leave some groups disproportionately impoverished, and undermine class unity. Hechter's influential work on the "cultural division of labor" provided clarification on this last point. Hechter distinguishes two major dimensions to the ethnic or racial division of labor: the degree of between group hierarchy and the degree of group specialization or distinctiveness. To the extent that an ethnic or racial group is concentrated at one

level in the occupational hierarchy, whether at the top, bottom, or middle, it will share interests with other groups at the same hierarchical level and tend toward class politics. On the other hand, to the extent that a group specializes in particular lines of work, and thus has high levels of within group interaction and interdependence, the greater is the salience of ethnic politics.

Three areas promise to be most fruitful in the future study of racial/ethnic divisions of labor. First, studies of the "new second generation," the children of the post 1965 immigrants to the US, should expose the extent to which specifically ethnic and racial factors still structure the opportunities available to natives. Second, feminist scholars, particularly those studying immigration, have been making progress in gendering our understandings of ethnic/racial divisions of labor, and this progress is likely to continue. Third, as global integration grows more important, so does attention to its effects on national ethnic/racial divisions of labor. Continuing research on, for example, how the new "transnational" migrants fit into ethnic/racial divisions of labor will be invaluable.

ethnic, racial, and nationalist movements

Susan Olzak

Political expressions of ethnicity and nationalism range broadly, from small scale or sporadic protests that may be relatively peaceful (as in civil rights marches), to sustained campaigns of violence against authorities or others (such as ethnic cleansing). Though often analyzed separately, ethnic, racial, and nationalist (E/R/N) movements voice strikingly similar demands for sovereignty and invoke rights of self-determination. The major E/R/N movement categories are distinguished by claims, goals, tactics, and organizational forms. Once these definitions are established, some key explanations of the emergence, persistence, transformation, and decline of these social movements are outlined.

Social movements generate collective action advocating fundamental changes in the political or economic arrangements in a society. Social movements typically involve sustained activity over time and place (whereas collective action may be fleeting). Most scholars also find that adherents of a social movement tend to support a coherent set of values that define its core identity. Boundary perspectives further explore how race and ethnic groups use ethnic markers to demarcate membership with reference to core features of group identity (Barth 1969).

The defining feature of ethnic and racial social movements (E/R) is that, in such movements, claims are made based upon a particular identity or boundary, defined by the presence of racial or ethnic markers. These markers typically include skin pigmentation, ancestry, language, and history of discrimination, conquest, or other shared experience. For simplicity (and to avoid invoking unscientific assumptions about the genetic basis of race), many researchers prefer the more generic label of *ethnicity* over race.

Ethnic mobilization can be defined apart from ethnic solidarity. Solidarity is characterized as the conscious identification (and loyalty) with a particular race or ethnic population, measured by attitudes, institutional involvement (or organizational participation), and monitoring capacity. Mobilization is the capacity to harness resources (including solidarity, organizations, and material resources) in an effort to reach some collective goal.

Nationalist movements generally express claims over the legitimate right to govern a specific geographical area (Hechter 2000). The pursuit of sovereignty rights typically also provokes conflict (and perhaps also warfare) with existing regimes. Such conflict can remain quiescent for long periods of time, erupting suddenly into full blown armed guerrilla warfare, or civil war, depending on regime strength, outside support, primary export commodities, internal mobilization of resources, and reaction by state authorities to nationalist movements (Fearon and Laitin 2003, 2005).

It is important to note that nationalist movements do not always depend upon a shared race or ethnic identity. Instead, they may rest upon a group's geographical concentration, political jurisdiction and leadership, and/or legacy claims to legitimate authority. Alternatively, nationalist movements may claim sovereign rights by invoking other types of identities, based upon religious identities, as in the case of nationalistic Islamic movements. Other forms of nationalist movements make claims that they had been forcefully removed and dispersed from their ancestral homeland, as in the case of some diaspora movements. Members of nationalist movements may share a territory that lies under another jurisdiction (e.g., Québécois nationalism), or they may invoke a national

identity spread across multiple regions (e.g., Kurdish nationalism). A final type involves state building movements in which a single identity is being forged from many different, smaller ethnic or regional identities within an existing territory (e.g., pan Indian identity in the US) (Nagel 1996).

By sharpening the differences between ethnicity and nationalism, empirical studies of these movements gain precision and focus. While race and ethnicity are designated by reference to cultural markers, phenotype, outward expressions of loyalty, celebration, or self identification, nationalism is a social movement making a territorial claim. According to Hechter (2000), the distinguishing features of nationalist movements include the presence of claims for self determination and authority over a specified territory and the fact that these demands are not now satisfied. Gellner (1983) adds that nationalism is "primarily a political principle" in which a governing unit should not cut across nor exclude members who share a common cultural boundary.

Brubaker (1996: 6–12) categorizes nationalism as one of three types of collective action mobilized by national minorities, nationalizing states, and external national homelands. This tripartite definition has the advantage of treating the outcomes of nationalist movements as contingent upon the behavior of a nationalizing group in contest with an existing regime, empire, colonial power, or host nation. Put differently, ethnicity becomes transformed into nationalism when it makes specific historical claims and attempts to administer the group as a political community.

Social movement perspectives add the insight that movements can be further distinguished by their relative duration, target, tactics, violence, and audience. These distinctions yield six broad categories: (1) regional or national minority movements that demand sovereignty over a particular territory; (2) civil rights protests that demand expansion of a group's civil and economic rights or demand an end to discrimination; (3) antagonist movements directed against specific ethnic targets, including collective attacks ranging from genocide, ethnic cleansing, and mob violence, to symbolic threats; (4) state strengthening nationalism, which attempts to unify diverse cultures

(state building nationalism) or merge politically divided territories into one state (unification nationalism); (5) separatist or secession movements, claiming rights of withdrawal from formal state authority; and (6) genocide or ethnic cleansing, which is an extreme form of violent social movement against a target population.

While these definitions clarify some important distinctions, the application of these terms often becomes tricky when conducting research on E/R/N movements because race and ethnic boundaries are porous, dynamic, and flexible. From different political vantage points and at different times, the same movement may be seen as engaging in senseless violence or as a nationalist liberation movement. Moreover, movements commonly adapt to changing political environments, espousing new goals and engaging in new tactics. Such changes may engender fears that the movement has been coopted and that its authenticity has become compromised. While these transformative qualities of social movements undoubtedly create problems for researchers, there is a hidden advantage as well. Taking these shifts into account might reveal new information about how group identity becomes transformed into social movements.

CORE RESEARCH QUESTIONS

Questions about the origins, persistence, and success of movements drive research efforts in this area. First, how does ethnic, racial, religious, territorial, or national identity become transformed into active social movements? This question underscores the importance of maintaining a distinction between cultural expressions of identity (e.g., ethnic self help organizations, immigrant festivals, head scarves) from social movements that express claims for expanded rights to some set of authorities, or violence directed against specific groups. Accordingly, scholars ask under what conditions will specific boundaries (e.g., language vs. skin pigmentation) come to be *politically* activated (Barth 1969; Olzak 1992). By posing the issue of mobilization as a question, researchers can analyze the dynamics of ethnic mobilization (or nationalism) based upon ethnicity without assuming it.

Scholars have analyzed the transformation of identity into collective action in terms of the diffusion of protest (Beissinger 2002), event history analyses of rates of ethnic conflict among groups (Olzak 1992), and ethnic nationalism from a comparative/historical perspective (Brubaker 1996). Such studies highlight the instrumental importance of resources and organizational infrastructure support. The evidence further suggests that favorable changes in economic, legal, and political opportunities facilitate (or hinder) ethnic movements (McAdam 1982).

Second, what factors explain the emergence and persistence of E/R/N movements? Until recently, social scientists focused mainly on the internal characteristics of states to explain E/R/N movements. Thus, poverty, rough terrain, imposition of direct rule, warlord corruption, or some other structural feature of the political system or economy triggers have been identified as factors raising levels of ethnic conflict (Fearon & Laitin 1999, 2003). Others have drawn attention to the advantages of viewing social movements as a function of global and transnational mechanisms that transform local organizations into global movements of violence and claims making activity (Olzak 2006).

A third question asks whether ethnic movements are truly novel, or whether they are simply political movements that once, earlier in history, adopted other forms. Without undertaking a long historical analysis, answering this question is difficult. However, it seems plausible that social movements are now more likely to be couched in distinctly ethnic terms, as a function of self-determination norms and UN declarations on minority rights. Some scholars claim that E/R/N movements are distinct from other bases of political contests (such as regional or religious social movements) because they employ distinctly *modern* claims (Gellner 1983; Smith 1991). However, this characteristic does not imply that such movements espouse modern values or contemporary themes. Indeed, many nationalist movements (e.g., Islamic nationalist movements) have invoked themes demanding a return to the past. Instead, for most scholars, evidence that these movements are modern rests on the idea that there is a shared identity of a "people" with boundaries beyond a parochial village or town (Anderson 1991).

A fourth orienting question concerns the shift in the scope of activity: What are the mechanisms that cause social movements to expand their scope from local concerns to encompass national goals? Brubaker (1996) describes "nationness" as an institutional process that begins to crystallize with state expansion. Similarly, Anderson (1991) posits a causal relationship between the development of ethnic movements that coincided with state building and the spread of literacy; such models suggest a causal link between state building and ethnic mobilization. Yet recent research suggests that the density of international connections among states may be reducing the number of nationally based movements, as transnational movements now mobilize across state administrative units in reaction to global processes (Olzak 2006).

Another set of issues raises questions about the nature of the relationship between ethnic conflict and internal civil war. For instance, they ask, under what conditions does ethnic conflict promote civil war? Alternatively, others are concerned with the duration of conflict, asking whether the presence of ethnic conflict prolongs the duration of civil wars. Several innovative lines of research have suggested that there is a strong link between ethnic cleavages and violence, in which group differences mobilize and sustain the capacity for groups to incite civil wars. For instance, Sambanis (2001) finds that civil wars based upon ethnic and/or religious identities are more likely to erupt in countries with high levels of ethnic heterogeneity and low levels of political democracy. In contrast, in nonethnic (or revolutionary) civil wars, economic and development indicators (especially energy consumption) have more influence than do measures of ethnic heterogeneity and indicators of democracy.

Scholars have also explored a reverse causal argument. In this view, economic (or political) instability *results from* prior conflict, or economic decline follows the public's anticipation of civil unrest. In an attempt to sort out the causal ordering of economic effects on ethnic wars, current empirical evidence supports the notion that economic decline raises rates of internal civil war, rather than the reverse, but that political instability and state strength may be endogenous to the process of ethnic and nationalist mobilization (Olzak 2004).

Ethnic diversity also prolongs the duration of civil wars. Fearon and Laitin (2003) find that the duration of violent civil conflict increases when there are a small number of large ethnic groups, when there are conflicts over land use, and when rebels have access to external (or contraband) resources. Not surprisingly, the evidence shows that ethnic wars and civil wars are causally and temporally related.

LEADING THEORETICAL PERSPECTIVES

Perspectives offering explanations of the emergence, growth, and decay of E/R/N social movements emphasize one or more processes of changing economic, political, or social conditions. Each tradition has generated a number of important empirical studies, which are linked by common theoretical concepts and mechanisms.

Periods of nation building apparently play a central role in determining the nature of the identity of an imagined "nation." Thus, one explanation for the fact that ethnic movements take on different forms is related to the events surrounding a country's national origin. The literature on nation building has suggested that ethnic movements are most likely to turn violent early in (more or less legitimate) administrative unit stages of nation building, when contested claims of power and legitimacy remain unresolved (Hechter 2000). In this view, nations were "birth marked" by the nature of conflicts – religious, territorial, ethnic, or other wise – that prevailed during a particular historical period.

The legacy of colonialism provides a number of instructive lessons for understanding the emergence and timing of nationalist movements. Territorial boundaries drawn during periods of colonialist rule (especially in Africa and the Middle East) provide examples of how ethnic cleavages can turn into violent rebellions against attempts to subdue indigenous populations. During nation building and state formation, outcomes depend upon complicated negotiations between opponents, nation builders, and external participants. Reactive anti colonialist movements can become transformed into nationalist movements when regimes become perceived as illegitimate and artificial, when repression

recedes, and when allies infuse new resources into nationalist movements.

Ethnic movements are fundamentally embedded in (often contradictory) legends and myths about various group identities and actions that have shaped their histories. Language, religion, immigration, and migration histories all play a role in building the defining characteristics of a region. However, periods of nation building apparently play a central role in determining the nature of identity of an imagined "nation." Thus, one explanation for the fact that ethnic movements take on different forms is related to the events surrounding a country's national origin. The literature on state formation has suggested that ethnic movements are most likely to turn violent during the early (and less legitimate) stages of nation building, when contested claims of power and legitimacy remain unresolved.

During periods of instability within states or colonial empires, the content of ethnic claims (especially territorial rights) often brings them into confrontation with regimes that have not completely won the hearts and minds of the inhabitants of the contested territory. Outcomes depend upon complicated negotiations between opponents, nation builders, and often external participants, who may favor one or the other side. Although some theorists once assumed that the process of nation building could be analyzed as an evolutionary set of stages, such assumptions seem naïve today. Evidently the process of creating a legitimate nation with an accepted system of authority and leaders is better conceptualized as a dynamic set of negotiated meanings (Brubaker 1996). National identities and ethnic communities are constantly being reconstructed and boundary lines redrawn. Social construction theories of race/ethnic social movements have helped clarify Anderson's (1991) claim that nations are "imagined communities," whose organizational form serves obvious political purposes and ends, but may have little factual basis.

Anderson's work has provided a useful starting place for understanding why nationalist and ethnic movements aim to reconcile the lack of correspondence between state boundaries and national identity. Smith (1991), Hechter (2000), and many others have emphasized the fact that few (if any) nation states are homogeneous

entities; not only do states sometimes encompass many nations (as in the notion of multiculturalism), but also many nations exist without a state. If a "nation" is demarcated by a self-identified boundary, then one nation may be dispersed across multiple state boundaries (as in the concept of a Kurdish nation), which may ultimately acquire its own state (Brass 1991). This implies that, even if they are only temporarily successful, ethnic movements can undermine the legitimacy of a state attempting to unify under assumptions of ethnic homogeneity.

During the mid 1970s an important tradition emerged suggesting that the combination of economic deprivation and cultural subordination produces enduring cleavages facilitating ethnic political mobilization. Internal colonialism theory suggests that a combination of uneven industrialization and cultural differences among regions in core nations causes ethnic grievances to become the basis of enduring political contention (Hechter 1975). This tradition has also been applied to local markets that are based upon an ethnic stratification system. Within internal colonies, this theory suggests that a *cultural division of labor* often emerges, in which dominant ethnic populations monopolize administrative and supervisory occupations (and rewards), while subordinate ethnic populations are relegated to lower status occupations (often in extractive industries). As a consequence, ethnic and labor market cleavages triumph over other types of possible loyalties.

Competition theories of race/ethnic movements emerged during the early 1980s to counter these claims (Olzak & Nagel 1986). These perspectives suggested that economic changes and political opportunities that favor disadvantaged groups can intensify competition among groups, which in turn activates ethnic boundaries and provokes ethnic mobilization. According to competition theory, declining inequality among regions (or groups) promotes competitive conflict among groups. This is because declining inequality and intergroup contact release forces of competitive exclusion and conflict (Barth 1969). In this view, E/R social movements result from conditions of *niche overlap* (rather than from niche segregation, as in internal colonialism theory). For example, competition theorists

argue that ethnic conflict rises when ethnic groups within nations come to compete in the *same* labor markets and increase their access to similar sets of political, economic, and social resources (Bonacich 1972; Olzak 1992).

A key variant of competition theory is split labor market theory, which holds that ethnic antagonism peaks when two or more ethnically or racially differentiated groups command different wage prices within the same labor market niche (Bonacich 1972). This theory has been supported by evidence on Chinese laborers, the US labor movement, contemporary South Africa, analyses of post industrial racial conflict in the US, analyses of race and ethnic conflict in cities in the nineteenth century US, and the former republics of the Ukraine, Latvia, Estonia, and Lithuania (Beissinger 2002).

Rational choice theorists state that modern ethnic movements occur with regularity because ethnic groups lower monitoring costs and increase benefits attached to ethnic mobilization, allowing ethnic groups to overcome the free rider problems attached to other types of mobilization efforts (Hechter 2000). Because ethnic groups are able to form dense social networks easily, costs of monitoring commitment are minimized, which fosters ethnic mobilization. Building on rational choice models, Fearon and Laitin (1996) have linked the strategic aspects of ethnic identity to violence, as elites build on existing ethnic loyalties (see also Petersen 2002). Such loyalties can prove fatal to group members. Moreover, the presence of genocidal norms (defined as a threat of sanctions to in-group members who decline participation in ethnic mayhem) increases the scale of ethnic violence. These authors offer an explanation for one persistent and counterintuitive finding in the literature: despite a history of intergroup cooperation, tolerance, intermarriage, and trust among different groups interacting within a region, the intensity of ethnic killing and violence may remain high due to the presence of genocidal norms.

Similarly, theorists have extended prisoner's dilemma models to consider the implications of game theory for ethnic mobilization, including outbreak of ethnic war (Fearon & Laitin 1996). While armed ethnic rebellions tend to last longer than nonethnic ones (Fearon 2004), a variety of ethnic and cultural characteristics

have few systematic effects on the onset or duration of civil wars in general (Fearon & Laitin 2003).

Applying game theory models to four specific ethnic movements, Laitin (1995) compares violence in the Basque country and Catalonia in Spain and post Soviet Georgia to ethnic mobilization in the Ukraine. Laitin finds that three factors predict the outbreak of violence (holding a number of cultural and historical factors constant): (1) rural social structure, which facilitates group monitoring and expedites militant commando operations; (2) tipping game mechanisms that explain the conditions under which costs to joining nationalist campaigns (and recruitment of soldiers to nationalist armies) are reduced; and (3) sustaining mechanisms, which rely on several random shocks which trigger a culture of violence that becomes culturally embedded in regional and collective memories.

Political perspectives emphasize the role of shifts in political constraints and opportunity structures that influence the trajectory of E/R social movements. These theories emphasize institutional arrangements, court rulings and reforms, and regional concentration of ethnic populations as viable political instruments leading to mobilization. Two studies from India illustrate these points. Chandra (2004) argues that political systems based on ethnic patronage systems can inadvertently provide the foundation for permanent hostilities. Alternatively, Varshney (2002) finds that when business, civic, and voluntary associations integrate and/or cross cut ethnic lines, confrontations are significantly less likely to erupt.

In cross national studies of the influence of political structures, Gurr (1993) and Gurr and Moore (1997) emphasize the centrifugal force of ethnic political parties, which maintain ethnic loyalties through institutional arrangements and patronage based on ethnic loyalties. Such forces produce fierce loyalties when language, religion, or some other marker also distinguishes a population that is geographically concentrated (Fearon & Laitin 2003). Other scholars have argued that while ethnic regional concentrations are important, they do not necessarily lead to ethnic violence. Instead, these scholars emphasize proximate causes or triggering mechanisms, such as political changes in authority, collapse of

colonial authorities or empires, or transition to market economies or democracies.

Social movement perspectives suggest that shifts in political opportunities (either positive or negative) drive the rates of protest activity and insurgency. Political shifts in regimes or power arrangements that offer new opportunities for formerly disadvantaged ethnic minorities within the newly democratizing states can encourage mobilization. So the decline of authoritarian regimes seemingly coincides with the resurgence of E/R/N movements, because the retreat of strong repressive authorities leaves a power vacuum. As the former military and administrative structures recede, local level elites mobilize ethnic loyalties and take advantage of this vacuum.

Evidence from civil wars in Bosnia and Kosovo provides another example of how regime instability shapes opportunities for E/R/N movements. At the same time, policies that involve ethnic resettlement programs often concentrate ethnic populations and create new networks that provide new recruits for mobilizing ethnic violence, as examples from the West Bank in Israel, or the Kurds in Germany, suggest. Thus, transitions to democracy may mobilize ethnic movements by offering new political advantages to ethnic groups that were more easily submerged in repressive regimes.

States often respond to challenges from nationalist movements by alternating between strategies of repression and concession (Hechter 2000). For example, the evidence suggests that states shift from strategies of repression to accommodation, depending on both the virulence of dissident protest behavior and state capacity to repress these challenges. However, others have suggested the intriguing hypothesis that it is the vacillation of states itself that incites nationalist violence, signaling a weakness in the state's internal capacity to act (for reviews, see Olzak 2004).

The potential for ethnic separatism also influences the intensity of collective violence in a country and this effect is stronger in states with weakened political institutions. The evidence finds that the potential for ethnic separatism increases political violence overall, but that this relationship holds only in countries with relatively low levels of political institutionalization (defined by the presence of binding

rules on political participation) (Sambanis 2001).

The imposition of external political authority on ethnic minorities compared to imposition of structures of indirect authority has important consequences for ethnic and nationalist movements. Hechter (2000) has argued that the seeds of nationalist movements are embedded in specific political structural arrangements in which colonialist or federated authority cedes formal authority to local leaders. Under such conditions, local elites are delegated political power and authority by centralized authorities, yet the power of local elites is fundamentally based upon regional identities and loyalties. When central authority is weakened or challenged (by external events such as war, famine, or economic crises), or when central authority is withdrawn (as in the case of the Soviet Union), local elites can mobilize on the basis of regional/ethnic identity. According to this argument, the imposition of direct rule at this point can encourage both state building nationalism (due to its centralizing authority and integration processes) and peripheral nationalism, cultural politics, or regional subnational movements within states.

Brubaker (1996) reflects these themes in his work on "new nationalisms" in Western Europe. Instead of arguing that the erosion of Soviet power and authority allowed ethnic tensions to surface and diffuse across former Soviet territories, Brubaker argues that the federated system of regional and ethnically defined republics in the Soviet Union created the structural basis for the ultimate disintegration of these republics. Wilkinson (2004) finds empirical support for this argument, reporting that states in India with a high degree of institutionalization of ethnic parties produce significantly higher rates of ethnic violence and hostility.

Recent theoretical analyses emphasize both the cultural and cognitive components of social movements, suggesting that group identity is both an important mobilizing strategy and a consequence of mobilization. In particular, movements invoke one or more cultural themes of nationalism, rights of self determination, expansion of human rights, and basic rights of sovereignty (Smith 1991; Brubaker & Laitin 1998; Brubaker 2004). In this view, a socially constructed ethnic identity is not a given, but it

may be the *result* of prior collective action. This perspective allows researchers to study how social mechanisms of contact, conflict, borrowing, and other forms of interaction might influence the emergence of new ethnic or racial categories. Over time, as ethnic conflicts recur along the same cleavage lines, identities (and revenge tactics) fall along recognizable race and ethnic categories. As group violence and revenge escalates on either side to a conflict, small scale or individual skirmishes become redefined as collective events requiring a response. In analyzing forces escalating group conflict, social movement scholars tend to underscore the emergent properties of both identities and conflict.

Although useful for case studies of social movements that did happen, one drawback of a purely constructionist perspective is that it becomes difficult for researchers to determine the causal ordering of emergent group identity and ethnic mobilization. In studying the impact of ethnic identity on ethnic social movements, Smith (1984) provided a (as yet untested) framework that might unravel the causal steps implied by this process. Smith lists the conditions under which ethnic identity is likely to become activated. These include intervals (1) during prolonged periods of conflict and warfare, when group identities are under siege or are threatened by others (including third parties to the conflict, as in the Cold War), (2) during periods of secularization or cultural change, in which a technologically superior or economically dominant culture threatens a more traditional culture, and (3) during periods of intense commercialization, which integrate a society into a broader system of economic exchange dominated by more advanced technologies or more powerful adversaries.

Economic and political crises that once affected only local areas now have repercussions in vastly different and formerly unconnected regions and states. Since the advent of modern media, civil wars, terrorist acts, and acts by ethnic social movements have produced reactions across national borders. Transnational social movements (TSMs) are social movements that span multiple national borders, target forces of global integration, or are social movements that concern global level issues (e.g., global environmental concerns). Taking an international perspective helps clarify how

economic interdependence within states has reinvigorated ethnic politics. Regional associations such as the EU, OPEC, NATO, and other supranational organizations promote interstate migration and decrease reliance of regions within states on the military and economic power of the nation state (Olzak & Nagel 1986). Multistate organizations also provide an audience for insurgent groups demanding new sovereignty rights (Koopmans & Statham 2000). In this view, an increasingly dense network of international economic relations, exemplified by multinational corporations, growing trade and foreign investment, and supranational economic associations, will continue to produce more large scale ethnic movements.

A global strategy offers arguments about forces of globalization that produce inequality, competition, and mobilization. Olzak (2006) holds that integration of a world economic and political system has encouraged ethnic fragmentation within states. It does so by increasing the access of formerly disadvantaged groups to political resources, creating new political opportunities for mobilizing, and increasing levels of economic inequality in peripheral countries, which increases the potential for competition and conflict among groups within these states. Competition among groups escalates the number of demands for amelioration of injustice or ethnic inequalities. Moreover, the process of integration of the world's states has varying effects on different sectors of the world system.

As the world's states have become more directly linked through communication and media channels, information about inequality and claims for redress of this inequality have increased sharply. Thus, the global forces of integration tend to crystallize and empower local level cleavages, increasing solidarity and heightening the capacity to mobilize movements challenging state authority. Together, the dual trends of increasing political access and decreasing ethnic economic disparity shape ethnic protest.

This perspective suggests that individual states will become less powerful in negotiations when confronting non state actors and/or transnational movements than in the past. As state economies and politics become more integrated, international associations and events occurring outside state boundaries will become

increasingly salient. It seems likely that as integration of the world's states (politically, diplomatically, and economically) proceeds, ethnic groups within states will become less constrained by their own state authorities. The growing predominance of an integrated set of states ironically decreases the ability of any one state to dominate its internal borders. Highly integrated nation states cannot simply repress, jail, or torture the ethnic challengers without risking international condemnation, sanctions, and boycotts. Furthermore, neighboring countries may directly or indirectly finance campaigns of instability, using political refugees or exiles as mercenary soldiers. There is growing evidence on transnational environmental and human rights movements that supports these contentions (Olzak 2006).

Diffusion of ideologies, resources, and personnel accelerates these trends. Ethnic social movements occurring in neighboring countries have powerful diffusion properties, destabilizing or threatening nearby regimes. Sambanis (2001) argues that elite factions (or warlords) offering military and financial support from neighboring countries have played crucial roles in prolonging ethnic wars in Africa and Central Asia in recent years. Although it is difficult to study (because many of the transactions are clandestine and sources of data are unreliable), corruption feeds upon an increased flow of arms, mercenaries, and illegal drugs. It is likely that networks of local warlords also fuel ethnic wars (without state or international sanctions) in neighboring countries (Fearon & Laitin 2003; Fearon 2004).

Global perspectives suggest another way that an ideology supporting human rights has accelerated the spread and acceptance of an ideology supporting ethnic rights. In this view, as the worldwide human rights movement gained momentum, claims for national sovereignty, group rights, and freedom became intertwined. Recent analyses of the diffusion of world culture and ideology have shifted the emphasis of world systems theory to consider the ideological implications of the integration of the world system (for reviews, see Olzak 2006). In this view, the diffusion of human rights organizations and intergovernmental associations (including social movement organizations) has motivated social movements to increase demands for expansion

of group rights in states that declared independence since 1945.

Global approaches suggest that, as nation states became linked in networks of military and economic associations, national political boundaries weaken and political regimes become vulnerable to international and external challenges. The same forces that encouraged the diffusion of nationalism as an ideology also affect ethnic movements within and between state boundaries.

Several lines of research on ethnic conflict support these contentions. Thus, one (perhaps unanticipated) consequence of the integration of the European monetary system is that ethnic tensions have risen rather dramatically (for examples, see Koopmans & Statham 2000). Furthermore, as political and economic barriers have declined, labor (and capital) flow more freely across states. However, one potential consequence of increasing flows of foreign workers across borders has been that new right wing parties across Western Europe have mobilized sentiment against foreign workers. To the extent that the integration of the European Union has restructured local politics within European countries, the opportunity has arisen for ethnic politics on both sides of the immigration question. As a consequence, anti foreigner sentiment, nationalist political parties, and attacks on foreigners also appear to be rising in most Western European countries, especially in Germany, France, the Netherlands, and England (Koopmans & Olzak 2004).

Military interdependence constitutes an obvious way that international relations affect conflicts within countries. Although such strategies are not new, superpowers arm and train ethnic and subnational groups in order to stabilize or in some cases destabilize regimes. The cases of recent rebellions financed and supported by transnational forces (on both sides of the struggles) in civil wars in Afghanistan, Nicaragua, Vietnam, Iraq, and many other settings illustrate this point. If arguments suggesting a link between international networks and E/R/N movements are correct, then an increase in transnational processes could potentially weaken the viability of the nation state as a main organizing strategy for territorial authority and control.

A final international trend in social movements deserves attention. This is reactive movements that span national borders, making vague claims about identities that are contrary to existing modernization or development efforts by dominant countries, ideologies, or ethnicities. In the contemporary era, some of these movements have been characterized as loosely connected by anti modernist claims that have a basis in religious fundamentalism. These movements share a concern with symbols of identity politics (and with symbols that seem ethnic – such as the wearing of head scarves), but they diverge from most E/R/N movements because they rarely express specific claims to territorial rights and instead voice demands for ethnic/religious purity. Whether or not such movements will continue to gain momentum remains an open question.

EVALUATION OF VARIOUS PERSPECTIVES

Many scholars analyze different types of E/R/N movements separately, by historical period, regional groupings, and by specific goals or tactics. While it has become popular for scholars to claim that E/R/N movements are produced by a constellation of historically contingent factors, this strategy has hampered our ability to develop powerful explanations that identify some general mechanisms of social change. Yet other social scientists have demonstrated that there are substantial theoretical payoffs attached to analyzing the similarities across E/R/N movements. By paying attention to the commonalities among forms of ethnic and nationalist movements, we stand to gain more leverage over questions about how protest escalates and diffuses, or how spontaneous protests become transformed into sustained (or violent) social movements that challenge existing authority structures.

Approaches that seek to emphasize the continuities and discontinuities among social movements and their emergent forms allow cumulative and testable theories to be constructed and evaluated. In contrast, if multiple types of ethnic mobilization (from civil rights movements to ethnic civil wars) are analyzed separately by country, time period, and movement goals, it becomes

impossible to know when to stop creating new categories and crafting unique explanations to cover each new occurrence of a nationalist event or ethnic campaign. Truly comparative work that seeks to build theories that can be falsified empirically holds far more promise than does a strategy that views each movement as a unique and separate category. In the context of complex dynamics of transnational social movements, activists and organizations engage in activity that engages and activates ethnic identity within nations. Such reactive movements can have reverberations to kindred or diasporic groups beyond a single nation. Understanding the commonalities among these forms in the context of a global system seems especially relevant.

Assessing the relative importance of various causal factors explaining ethnic movements over time is also hampered by the fact that ethnic and racial boundaries (and labels) often change over time. Answers to questions about the nature and trajectory of ethnic movements lie in conducting careful empirical analyses and comparisons of different kinds of events – ethnic, civil rights, national, religious, civil wars, and autonomy social movements of various kinds that share some (but not all) root causes.

Recent trends have taken these dynamics into account by emphasizing the emergence of a more densely connected global system. The globalization of social movements has led current research on ethnic and national movements away from a sole emphasis on internal features of states and toward the international context of collective actions. Clearly, the internationalization of the world economy and political integration of organizational, diplomatic, and trade linkages have prompted us to reconsider previous assumptions that rest on stable characteristics of states. Research reviewed here depicts social movements that have produced strikingly similar social movements that share similar forms, goals, tactics, and ideologies. Thus, theories that focus solely on the internal bases of discontent now seem shortsighted. A resulting network of economic and political ties cuts across the state system. As a consequence, ethnic mobilization at the global level provides fertile ground for new types of movements based upon national, ethnic, and other cultural identities.

Applying lessons from colonialism and imperialist regimes to new forms of nationalism may allow us to better understand sources of fundamentalist nationalism, terrorist networks, and international networks of social movement recruitment and training. Such movements are both local and international in scope, and, because of this flexibility, they are able to shift direction quickly, often without warning. By turning to explanations firmly based on theories of international connections and processes, we may be able to understand the emergence of this new form of nationalism.

ethnicity

Richard Jenkins

The ancient Greek word *ethnos*, the root of “ethnicity,” referred to people living and acting together in a manner that we might apply to a “people” or a “nation”: a collectivity with a “way of life” – some manners and mores, practices and purposes – in common, whose members share something in terms of “culture.” Thus the anthropologist Frederick Barth (1969) defined ethnicity as “the social organization of culture difference.” Ethnicity is not only a relatively abstract collective phenomenon, however: it also matters to individuals. To quote another anthropologist, Clifford Geertz, ethnicity is “personal identity collectively ratified and publicly expressed” (1973: 268).

After kinship, ethnicity is perhaps the most ubiquitous way of classifying and organizing humans into collectivities. It requires shared perceptions that certain people are similar to each other and different from others. Ethnic inclusivity and exclusivity build on the cultural differences and similarities that people regard as significant to generate boundaries and dramatize them. How the nuanced complexities of culture are organized into ethnicity is, however, neither obvious nor straightforward. People may appear to differ enormously in terms of culture and yet be able to identify themselves as ethnic fellows: think, for example, about the diversity that is subsumed within Jewishness. Nor does apparent cultural similarity preclude strong ethnic differentiation. Viewed by an anthropologist from Mars, Danes and Norwegians, for example, might look very similar, or even the same; they, however, do not see things this way.

This suggests that our understanding of ethnicity cannot simply depend upon a crude

model of discrete and different cultures seen "in the round." Some cultural themes offer more scope for ethnic identification than others: language, notions of shared descent, historical narratives, locality and co residence, and religion have all proved to be particularly potent ethnic markers. Even so, a common language, for example, or shared religious beliefs and practices do not necessarily do the trick in themselves. Nor do shared space and place: living together may be a potent source of common identification, but space and place can also divide people. They may be a resource for which to compete and the interaction that is necessary for a sense of difference to emerge takes up space: it needs a terrain. Lines are drawn in the sand, and borders and boundaries come to delineate arbitrary group territories.

This further suggests that ethnicity is not a matter of definable degrees or obvious kinds of cultural similarity or difference. There is no checklist with which to determine whether or not members of Group A are *really* ethnically different to members of Group B, or whether Group C is an ethnic group or some other kind of collectivity. Enumerating cultural traits or characteristics is not a useful way to understand or identify ethnic differences. Human beings are distinguished by their voices, and the base line is always whether a group is seen by its members to be different.

Self definition is not *all* that matters, however. It is also necessary that a group be categorized as distinctive by others (Jenkins 1997: 51–73). This means that power – whose definition counts in any given situation – is always a lurking presence. There can be no such thing as unilateral ethnicity. Ethnicity always involves ethnic *relations*: connections and contacts between people who are seen to be different, as well as between those who are seen to be the same. A sense of ethnicity can only arise in the context of relationships and interaction with others: without difference there is no similarity. Defining *us* implies – if nothing stronger – an image of *them*. It is difficult to imagine a meaningful identification, ethnic or whatever, that is not at least recognized by others. It is not enough to assert, "I am an X," or "We are Xs," for either of these things to become so.

To say this, however, begs a question: what counts as "being an X" in the contemporary

world? Looking at the range of relationships of similarity and difference that might be said to involve "culture" reveals a broad spectrum of possibilities. Neighborhood and locality are among the more immediate. Local senses of belonging that we call "community" – built on an "us" and a "them," apparently shared understandings, and ways of doing things in common – are well documented (Cohen 1985). Kinship ties may also be invoked as criteria of membership. More abstract regional identities, such as the North–South distinctions that still play so well in England and the United States, are also clearly related. From here it is but a step to the nation (Anderson 1983). While the boundaries of community and region are policed by the informal powers of individuals and groups to accept or reject identity claims, national identity is a formal package that includes citizenship, a passport, political rights and duties within and without the national borders, and so on. This is a domain of formal power and authority. Even here, however, everyday practices such as language, taste in food, and perhaps religion may come into the picture: ways of life are still significant.

Descent and kinship may also be important in understandings of the nation (as in the German model of the national identity, defined in terms of "blood" rather than "soil"; Bauman 1992). This requires us also to look at "race," the belief in distinctive populations sharing common ancestors in the remote past, human stocks with their own characteristics. From this point of view, Germans are different from Poles, for example: they are not the same "kind" of people. And although "racial" categories may draw upon the visible features of bodies to assert the "naturalness" of particular similarities and differences, let us remember that "race" is culturally defined, not natural.

The words "ethnic" or "ethnicity" do not appear in the two paragraphs above. Yet in terms of the definition of ethnicity offered earlier, much of the similarity and difference that has been referred to looks something like ethnicity. This suggests some questions. Where does ethnicity end and communal identity, or local identity, or regional identity, or national identity, begin? What is the relationship between community and locality, or locality and region? And what are the differences

between all of these things? Where does "race" fit in with them? Are community, locality, region, nation, and "race" even the same kind of thing? The answer is no, and yes. No, in that they appear to be about different things, each evoking its own combinations of criteria of similarity and difference. No, in that some of these criteria are more flexible than others. Locality or citizenship, for example, are easier to change than descent based criteria such as family or "race." No, in that some of these identities are more likely than others to find expression through ideologies, such as nationalism and racism, which describe the world as it is believed to be and as it should be. But yes, in that the criteria of similarity and difference in each case are cultural. Yes, in that they all contribute to the social organization of a broad and distinctive genre of collective identification, which is not reducible to either kinship or social class, to pick only the most obvious comparisons. And yes, in that they all offer the potential for political organization.

Instead of searching for ever more precise definitions, a better approach might suggest that communal, local, regional, national, and "racial" identities are locally and historically specific variations on a generic principle of collective identification, ethnicity. Each says something about "the social organization of culture difference" and "the cultural organization of social difference." They are culturally imagined and socially consequential, a way of phrasing the matter which recognizes that distinctions between "the cultural" and "the social" may not be particularly helpful. These communal, local, regional, national, and "racial" identities also offer the possibility of "collectively ratified personal identity." They may make a considerable personal difference to individuals, both in their sense of self and in their judgment and treatment of others.

This broad understanding of ethnicity acknowledges that ethnic identification is a contextually variable and relative process. That ethnicity may be negotiable, flexible, and variable in its significance from one situation to another is among the most important lessons of the specialist social science literature (Cornell 1996). Which also means that, depending on cultural context and social situation, ethnicity may *not* be negotiable. There may not be much

of a choice. And when ethnicity matters to people, it has the capacity to *really* matter, to move them to action and awaken powerful emotions.

That ethnicity can be a source of powerful affect and meaning is at the heart of a long standing debate between "primordialists," who believe that ethnic attachments are immutable and irresistible, and "constructionists," who argue that they are a matter of strategy and negotiation; between what Marcus Banks (1996: 186–7) has evocatively described as models of "ethnicity in the heart" and "ethnicity in the head." There are several things to bear in mind about this debate. First, the degree to which ethnicity and its variants matter, and to whom, differs demonstrably from epoch to epoch and place to place. There is no consistency with respect to the strength of ethnic attachments, although that humans form ethnic attachments seems to be fairly universal. Nor do we need to resort to notions of essence and nature to explain why, when ethnicity matters to people, it can matter so much: the nature and content of primary socialization, the power of symbols, the implacability of some local histories, and the often considerable consequences of identification are probably sufficient to account for this. What matters is not whether ethnicity is a primordial personal and cultural essence, into which we are born and about which we can do nothing, but that many people fervently believe this to be so and behave accordingly.

Recently, questions have been asked about whether concepts such as ethnicity and identity actually explain behavior (Martin 1995; Brubaker & Cooper 2000). Does ethnicity shape what people do? Does it, in fact, *matter*? This is partly a response to ambitious postmodern claims about "identity politics," "hybridity," and the like. The argument is that words such as "identity" and "ethnicity" have been bandied about so much that they have become analytically meaningless. While it is easy to sympathize with this view, it is an argument for rehabilitating these concepts, not abandoning them.

The debate is also about the relationship between ethnicity and interests (Goldstein & Rayner 1994): is talking about ethnicity an analytical and political smokescreen to obscure the fact that people are, as they have always done, simply pursuing their material interests? We

are back here with Barth's original account of ethnicity as an emergent property of transactions and negotiations. Now, as then, we have to ask whether it is possible easily to disentangle identification from interests. For example, who I am, whether that is defined individually or collectively, will influence how I define what is in my interests and what is against them. From another direction, how other people identify me has some bearing on what they perceive my – and, indeed, often *their* – interests to be. What's more, my pursuit of particular interests may cause me to be identified in particular ways by myself and by others. Finally, how I identify others may have influences on which interests I pursue.

Interests and ethnicity are entwined in each other, not opposing principles of motivation: where ethnic identification is locally salient, one cannot be understood without the other. Locally – and ethnicity is always a local matter – primary socialization, the affective power of symbols, obstinate history, and the consequences of being identified in a particular way by others conspire to ensure that where it matters, ethnicity really matters. Ethnic attachments do not determine the choices that people make, but they cannot be ignored either.

ethnocentrism

Stephen E. Brown

Ethnocentrism is a belief that the norms, values, ideology, customs, and traditions of one's own culture or subculture are superior to those characterizing other cultural settings. The term was coined by William Graham Sumner in his *Folkways* (1906) and has long served as a cornerstone in the social analysis of culture. While ethnocentrism arguably is a universal phenomenon that facilitates cohesion and continuity at all levels of social organization, it provides the rationalization for attack on other cultures or subcultures in its more extreme forms. It may, for example, motivate criminalization of practices within subcultures or be used to justify going to war with other nation states. Ethnocentrism is intricately tied to definitions of deviance wherein the deviant is seen as not only different, but also as morally inferior or even evil. Members of the in group stereotype those in the out group as ignorant, bad, or even subhuman and these characterizations provide the basis for culture conflict.

Ethnocentrism falls on a continuum along which the more ethnocentric tend to hold to more absolutist or objectivist moral positions. That is, as ethnocentrism grows stronger, there is more acceptance of the notion that there is a single proper way to behave at all times and places. Conversely, cultural and moral relativism is associated with lesser degrees of ethnocentrism. The relativist views social reaction as playing an important role in defining norms

and deviance. From such an interactionist perspective people absorb the values and norms of their own culture through a process of enculturation. Cultural values are transmitted down through generations as a result of learning experiences within any cultural setting. Acknowledging such culturally specific learning processes serves to undermine harsher judgments of cultural disparities.

While ethnocentrism in its various degrees is considered a universal cultural phenomenon, a rare, but intriguing phenomenon is inverse ethnocentrism, wherein an individual holds a reverse cultural bias. The more usual derogatory stereotyping of other cultures is replaced by a tendency to see characteristics of other cultural milieus as inherently superior to those of one's own culture. Obviously, persons holding such views tend to be at odds with their own cultural environment and are likely defined by others as eccentrics, traitors, or other deviant identities. Another variation of this is the critique that the relativist is not firmly committed to any moral standards or is tolerant of moral abuses occurring in other cultural settings. The classic argument offered to bolster this concern is that complete relativity would withhold condemnation of atrocities such as genocide. Cultural relativism, however, is central to sociological and anthropological analysis, but does not mean that the sociologist cannot apply any moral criteria to the examination of cultures. It only means that one should not blindly apply the values and standards of one culture to another. Practices within a culture should be analyzed within their own cultural context and moral judgment held in abeyance until their meaning is identified.

Sensitivity to ethnocentrism is vital to understanding social relations because it constitutes blinded bias. Thus, ethnocentrism is at the heart of prejudice and discrimination toward out groups. Understanding the dynamics of ethnocentrism is thereby central to analyzing human conflict.

ethnography

Martyn Hammersley

Literally, ethnography means writing about people, or writing an account of the way of life of a particular people. In early anthropology, what was aimed at was a descriptive account that captured a distinctive culture. Initially, ethnography was contrasted with ethnology, which was concerned with the historical and comparative analysis of cultures based on ethnographic accounts, the latter often being produced by travelers and missionaries. Over time, the term ethnology has fallen out of favor, and ethnography has come to refer to a combination of theoretical interpretation of cultures and firsthand investigation carried out by anthropologists themselves. Moreover, the term has a double meaning, referring both to a form of research and to the product of that research: ethnography as a practice produces ethnographies. And, recently, a distinction has sometimes been drawn between doing ethnography and using ethnographic methods. This has been employed by some anthropologists in an attempt to mark off their own practice from what passes for ethnographic work within sociology and other areas (Wolcott 1999).

For most anthropologists in the past, ethnography required living with a group of people for an extended period, for a year or several years, in order to document their distinctive way of life and the beliefs and values integral to it. However, the term is used in a much looser way within sociology today, to refer to

studies that rely on participant observation and/or in depth, relatively unstructured interviews. As a result, there is considerable overlap in meaning with other concepts, these also often being ambiguous or having fuzzy boundaries, such as “qualitative research,” “fieldwork,” “interpretive method,” and “case study.” There is also no firm distinction between ethnography and the study of individual life histories, as the example of “autoethnography” shows, this term referring to an individual researcher’s study of his or her own life and context.

In practical terms, as a method, ethnography usually involves most of the following features:

- People’s actions and accounts are studied primarily in everyday contexts rather than under conditions created by the researcher, such as in experiments or highly structured interview situations. In other words, research takes place “in the field.”
- Data are gathered from a range of sources, including documentary evidence, but participant observation and/or relatively informal conversations are usually the main ones.
- Data collection is “unstructured” in the sense that it does not involve following through a fixed and detailed research design set up at the beginning. Nor are the categories that will be used for interpreting what people say or do built into the data collection process itself via prestructuring of observation, interviews, or documentary analysis.
- The focus is usually on a small number of cases, perhaps a single setting or group of people, typically small scale, with these being studied in depth.
- The analysis of the data involves interpretation of the meanings and functions of human actions and how these are implicated in local and wider contexts. What are produced, for the most part, are verbal descriptions, explanations, and theories; quantification and statistical analysis play a subordinate role at most.

As a set of methods, ethnography is not far removed from the means that we all use

in everyday life to make sense of our surroundings. However, it involves a more deliberate and systematic approach and, also, a distinctive mentality. This can perhaps best be summarized as seeking to make the strange familiar, in the sense of finding intelligibility and rationality within it, and making the familiar strange, by suspending those background assumptions that immediately give apparent sense to what we experience (Hammersley & Atkinson 1995).

Over the course of its development, ethnography has been influenced by a range of methodological and theoretical movements. Early on, within anthropology, it was shaped by German ideas about the distinctive character of history and the human sciences, by folk psychology, and by positivism. Subsequently, in the form of the case study approach of the Chicago School, it was also influenced by philosophical pragmatism, while in more recent times Marxism, phenomenology, hermeneutics, structuralism, and poststructuralism have all played an important role.

While these influences have led to a diversification in approach, ethnography still tends to be characterized by a number of distinctive methodological ideas about the nature of the social world and how it can be understood. As we shall see, these ideas overlap in their implications, but also conflict in some respects. To one degree or another, ethnographers tend to make the following assumptions about the nature of the social world:

- Human behavior is not an automatic product of either internal or external stimuli. Responses to the world are constructed and reconstructed over time and across space in ways that reflect the biographies and socio-cultural locations of actors, and how they interpret the situations they face.
- There are diverse cultures that can inform human behavior, and these operate not just between societies or local communities but also within them; and perhaps even within individual actors.
- Human social life is not structured in terms of fixed, law like patterns, but displays emergent processes of various kinds that involve a high degree of contingency.

In recent times, there has been significant dispute over the character of the phenomena that ethnographers study. We can formulate this as a tension between naturalism and constructionism. The first takes the task of ethnography to be documenting stable cultures, patterns of social interaction, institutions, and so on, as they exist in the world independently of the researcher. By contrast, constructionism is concerned with the interactional or discursive processes whereby cultures, institutions, etc. are continuously and contingently produced and sustained. In line with this, constructionists do not use informants' accounts as a source of information about the world, or even about informants' own experience, but rather study them as exemplifying discursive practices, narrative strategies, or distinctive voices. Moreover, in its more radical forms constructionism treats the social phenomena studied by ethnographers as effectively constituted in and through the research process itself, and especially through the process of writing (Clifford & Marcus 1986).

These assumptions about the nature of the social world are closely linked with ideas about how we can understand it. And here too significant tensions come to the surface. One of these is between a focus on the details of what happens in particular contexts on particular occasions, and a concern to locate what has been studied within the context of some larger whole, or even to use it to show what is happening within that larger whole. Over the past few decades there has been a trend towards more micro focused ethnographies, perhaps stimulated by the availability of highly portable audio and video recording equipment which generate large amounts of data, and also by the rise of discourse analysis. By contrast, in the past, under the influence of functionalism and Marxism, there was emphasis on locating what is studied in a wider context, where the unit of analysis was usually taken to be a particular community or society. More recently there have been calls for ethnographies to take account of global social forces. Parallel to this have been criticisms of much ethnography for being preoccupied with describing and explaining what happens in relatively short time periods, thereby neglecting longer term trends. One response to this has been to advocate

longitudinal ethnographies, for example following the development of a group of people's lives over several years and focusing on the patterns of change experienced. Also relevant here are attempts to link ethnographic with historical work.

A second tension is between seeking to study cases in all their uniqueness or being concerned with producing generalizations or engaging in comparative analysis to build theories. Ethnographers vary considerably in their position on this spectrum, but most seek to satisfy all these demands in one way or another. The concept of thick description represents one sort of trade off, where theories are relatively low level and are means for understanding what is going on in particular cases. Towards the other end of the spectrum are grounded theorizing and analytic induction, where the product of ethnographic work is some kind of general theory, albeit instantiated in detailed analysis of particular cases.

A third issue concerns whether the primary task is seen as explicating the perspectives, or cultural orientations, of the people being studied, or as explaining why they see the world and act in the ways that they do, and the consequences of this. The first approach emphasizes the role of careful description, of understanding what people say and do in its own terms; whereas the second often produces accounts that raise questions about the validity of people's beliefs about themselves and their world. This may involve explaining why people believe what they believe and do what they do in terms of causal factors whose existence or significance they do not acknowledge or even explicitly deny. Indeed, there may be a hermeneutics of suspicion in operation which assumes that what people say hides as much as it reveals. There is variation here in the extent to which an aim is to challenge official appearances, or the fronts people display, in order to find out what they really believe or what really goes on; or whether social life is viewed as inevitably a matter of performative fronts, with the task of analysis being to study the processes or strategies by which people bring off particular performances on particular occasions.

Even for those ethnographers who place emphasis on understanding insider perspectives, there are questions about how far it is

ever possible or necessary for ethnographers to understand participants' perspectives "from the inside." It has been suggested that this involves reducing the Other to the Same, forcing what is different into terms that are familiar. At the same time, ethnography has also sometimes been accused of "othering," of rendering other societies exotic and alien, a criticism that parallels Said's discussion of "orientalism" (Said 1978). Closely related are criticisms of the totalizing orientation of much older ethnography, where cultures are described as if they were objects in the world, and as if membership of a culture determined everything of importance about any individual person.

In its early forms, ethnography involved a concern to capture the beliefs and actions of the people being studied in such a way as to minimize the effects of the research process. As a result, ethnography was usually distanced from concerns with practical improvement, and therefore adopted a non judgmental or appreciative orientation (Matza 1969). However, in the mid twentieth century there developed forms of applied anthropology that treated ethnography as a basis for interventions designed to improve the lives of the people being studied. And, later, some ethnographers adopted Marxist or "critical" perspectives in which the phenomena studied were to be located within a political perspective generating evaluations and recommendations for social change. The influence of feminism and anti racism reinforced this tendency, while that of poststructuralism and postmodernism challenged reliance on political positions involving metanarratives in favor of subordinating ethnographic work to local struggles, with one of its tasks being seen as liberating those repressed forms of knowledge to be found on the margins of conventional society.

Closely associated with these developments have been pressures to do ethnographic work *with* people rather than *on* them, in the manner of various participatory forms of inquiry. In some cases this built on a commitment to advocacy by anthropologists and on the notion of indigenous ethnography, while within sociology it derived from feminist and other approaches to research ethics which challenged what was seen as the hierarchical relationship between

researcher and researched. However, there is a tension here not only with older approaches to ethnography but also between subordinating research to participants' orientations and using it as a means of raising their consciousness, in the form of a "critical" orientation designed to generate desirable social change.

There has also been increasing pressure to recognize the extent to which and ways in which all research, including ethnography, plays a political role in the world. To some degree this began long ago with criticism of how anthropological ethnography was implicated in western imperialism. In more recent times the concern with the politics of ethnography has become much broader, reflecting the influence of new social movements of various kinds. On the part of some commentators what is at stake is not simply how research might be distorted by its social context, or even the consequences that it could have, but rather how the whole enterprise of research is political through and through, in the sense that it cannot but involve reliance on value assumptions, and that these cannot but reflect the identity, commitments, and social location of the researcher as a person. This runs against earlier forms of ethnography where research was treated as concerned simply with producing objective scientific knowledge about diverse cultures, an orientation that is now regarded by many, though not all, ethnographers as simply an ideological disguise for political interests that serve the status quo.

As indicated earlier, ethnography refers not just to a process of inquiry but also to a particular type of product: to the written account generated by ethnographic research. Prior to the early 1980s the task of "writing up" ethnographies was given relatively little attention in the methodological literature. Most of the focus was on problems surrounding data collecting and analysis. However, in the last three decades there has been considerable interest in this topic, not just from a practical point of view but also in terms of analyzing how ethnographic accounts represent or effectively constitute the social contexts and people investigated. Epistemological, political, and ethical concerns are intermingled in what has come to be seen as a "crisis of representation."

Developments in technology have also had an important impact on ethnographic work over the past few decades. In particular, the availability of easily portable audio and video recorders has meant that fieldnotes have come to play a subordinate role in much ethnographic work, and as noted earlier it may have encouraged an increasingly micro focus concerned with the details of what is said and done on particular occasions. Furthermore, video recording has built on earlier developments in visual ethnography that employed photographs and film. The development of microcomputers and of software for processing qualitative data is another important area of development, one where there is disagreement about whether the technology serves or distorts ethnographic practice. What seems clear, though, is that digitization of data and the increased capacity of computers to handle multimedia material will open up considerable opportunities for ethnographers, as well as no doubt also raising new problems, or old problems in novel forms. Closely related here is the development of the Internet and the opportunities that this provides, not just as a source of information but as a collection of virtual sites that can be studied by ethnographers (Hine 2000).

Finally, it is worth mentioning a significant feature of the changing environments in which ethnographers seek to carry out their work. Both anthropologists and sociologists have encountered increasing barriers in gaining access to settings in many societies. These stem from a variety of factors, among which are increasing governmental control, commercialization, and forms of regulation within both privately owned and publicly funded organizations. Another important external factor is increasing ethical regulation, notably in the field of health, but also more widely for research sponsored within universities. The ethical codes on which this is based often assume a model of research that is at odds with both the theory and practice of ethnography.

ethnomethodology

Douglas W. Maynard and Teddy Elizabeth Weathersbee

Ethnomethodology is an area in sociology originating in the work of Harold Garfinkel. It represents an effort to study the methods in and through which members concertedly produce and assemble the features of everyday life in any actual, concrete, and not hypothetical or theoretically depicted setting. Ethnomethodology's proposal – one that is incommensurate with respect to other sociological theory (Garfinkel 1988) – is that there is a self-generating order in concrete activities, an order whose scientific appreciation depends upon neither prior description, nor empirical generalization, nor formal specification of variable elements and their analytic relations. Moreover, raw experience – the booming buzz of William James – is anything but chaotic, for the concrete activities of which it is composed are coeval with an intelligible organization that actors already provide and that is therefore available for scientific analysis. Members of society achieve this intelligible organization through actual, coordinated, concerted, procedural behaviors or *methods* and *practices*.

Garfinkel was a student in Harvard's Department of Social Relations where he went to study with Talcott Parsons, although Garfinkel's developing concerns with the empirical detail of ordinary life and activity came to be at odds with Parsons's emphasis

on conceptual formulation and theoretical generalization. While at Harvard, Garfinkel deepened his knowledge of phenomenology – an interest that had been sparked at the University of North Carolina where he had completed a master's degree – by meeting with Alfred Schütz and Aron Gurwitsch, who were both European “philosophers in exile” at the New School for Social Research. There is a strong influence of phenomenology on ethnomethodology, but Garfinkel deemphasized perceptual knowledge as a mental process or activity in favor of a concern with embodied activity and the practical production of social facts as that production resides in lived experience, whether that experience involves rhythmic clapping, responding to a “summoning” phone, traveling in a freeway traffic wave, standing in a service line, or any other ordinary matter.

After finishing his degree at Harvard and a short stint at Ohio State University, Garfinkel moved to Kansas where Harvard classmate Fred Strodtbeck invited him to help with a project on jury decision making. While working on how jurors, in their deliberations, struggle with issues of evidence, demonstration, relevance, facts versus opinion, and other “methodological” matters, Garfinkel turned to the Yale cross cultural area files and came upon terms such as ethnobotany, ethnophysiology, ethnophysics, and others. It was then he realized that *methodology* was something jurors were producing as a prominent and serious feature of their deliberations. Hence, Garfinkel coined “ethnomethodology” (see Garfinkel 1974) to refer to the study of how members of the jury engage in practices whereby they could decide indigenous problems of adequate accountability, description, and evidence in relation to the deliberative outcomes they produced.

In the fall of 1954 Garfinkel joined the faculty at UCLA. While there, he trained several generations of students and produced his most well known work, *Studies in Ethnomethodology* (Garfinkel 1967). To obtain access to members' methods in a variety of settings, Garfinkel introduced his famous “breaching experiments,” which reversed the usual sociological preoccupation with factors that contribute to social stability. Breaching involves asking what can be done to make for trouble

in everyday events, and demonstrates that troublesome events are themselves revelatory of the ordinary practices whereby stability is achieved.

A tic tac toe exercise, for example, involves the experimenter inviting a participant to play. After the participant starts the game by placing an “X” in a square formed by the tic tac toe matrix, the experimenter puts an “O” on a line of the game matrix rather than in a square. The trouble thereby created brings members' methods to the fore as sources of order. These methods are manifest in the restorative or reparative efforts of participants. When a participant protests to the experimenter, “Is this a joke?” it shows that an ordinary game is to be engaged seriously and by respecting common sense practices for placing Os and Xs. The practices of common sense are employed not by following rules of the game but by behaving in ways that are retrospectively consistent with those rules. In other words, behavior is to be accountable to rules and this means engaging in concrete and embodied practices that are orderly in their own right and are not explained or provided for in the rules that these practices make visible.

However, Garfinkel also went beyond experimental breaches to examine more naturally occurring disruptions to everyday life. In his influential *Studies* chapter on Agnes, a male to female transsexual, he set the agenda and tone for many subsequent investigations into the accomplishment of “gender.” Garfinkel's extensive interviews and observations concerning Agnes provide access to something that is utterly routine in everyday life: the achievement of one's visible and objective status as a man or woman, boy or girl. Because Agnes did not experience her gender visibility as routine or taken for granted, Garfinkel was able to document how members regularly employ tacit means for securing and guaranteeing the rights and obligations attendant upon being seen as a normal, natural, adult female. Agnes was a “practical methodologist” and artfully displayed what is required of anyone who claims to be a bona fide woman.

Garfinkel notes that he initially attempted to use a game metaphor in order to comprehend the various occasions in which Agnes had to “pass” or come across as the normal female

person. But he realized that Agnes's passing eluded attempts to reduce it to playing a game by the rules. There are, he argued, various "structural incongruities" between playing a game and sexual passing. Unlike a game, to pass as a member of a particular gender has no "time outs," no exits from the work of passing, and only limited capacity for planning one's strategies for passing because of the ubiquity of unanticipated happenings. Agnes could not be a strategic actor in the way that sociologist Erving Goffman portrays the matter, because she could never know in advance exactly what would be required of her for displaying herself as the natural female in any given interaction. She was learning what it took to be a woman even as she acted as if she were none problematically a woman in the first place.

In 1959, while on sabbatical from UCLA, Garfinkel met Harvey Sacks, who was pursuing his law degree at Yale but would eventually move to the department of sociology at Berkeley for graduate work. Sacks remained in touch with Garfinkel, who brought him to Los Angeles in 1963. Sacks's lectures and thinking formed the beginning of what would become the field of conversation analysis. Mutual influences between Garfinkel and Sacks are of considerable interest. Their collaborative endeavors are partially embodied in a joint publication, "On Formal Structures of Practical Actions" (Garfinkel & Sacks 1970), where they argue that sociological reasoning has often aimed to distinguish between "indexical" expressions, whose sense derives from their relation to aspects of the immediate context in which they are used, and objective expressions, whose sense is purportedly context free. Garfinkel and Sacks argue that the quest for objective expressions is endless, because such expressions always depend upon an orderliness that necessarily ties them to the situation of their use. Accordingly, Garfinkel and Sacks recommend a policy of "ethnomethodological indifference," whereby investigators abstain from judging the status of objective expressions in terms of their adequacy, value, or consequentiality. Instead, the orderliness of any and all human expressions – the practical means by which those expressions attain their sense – is to be brought under study. The orderliness that

Sacks and collaborators in conversation analysis began to pursue was the sequential organization of everyday talk and interaction, although there is also a stream of conversation analytic work on "membership categories" as devices that are deployed for purposes of making interactional sense.

Meanwhile, Garfinkel's own interests developed in the direction of scientific and work practice, and his contributions have been taken up in sociological studies of technology and science. In the 1980s, Garfinkel and his students turned to the examination of technical competencies in mathematics and the natural sciences, including astronomy (Garfinkel et al. 1981) and other domains. These studies probe the details of "shop work and shop talk" that form the tangible fabric of scientific practice. There is always "something more" to methodological practice than can be provided in highly detailed instructions, formalized guidelines, or accounts of inquiry. The "something more" includes routine practices at the workbench in laboratories and other settings of work. Indeed, lately Garfinkel (2002) has become preoccupied with what he calls the "shop floor problem," having to do with how generic descriptions of work settings, which attempt to specify the constituents of practice within those settings, confront "details in structures" or coherences in embodied practices that cannot be anticipated by, and utterly defy, the generic descriptions.

In his recent book, Garfinkel (2002) makes more explicit the central claim of ethnomethodology – namely, that it is in the business of working out Durkheim's aphorism, "the objective reality of social facts is sociology's fundamental phenomenon." Rather than claiming that order can only be revealed by aggregating across large sets of data and replacing the concrete, observable detail of "immortal ordinary society" with concepts, ethnomethodology claims that there is a plenitude of order that is lost to the formal analytic theorizing as it exists in the field of sociology and elsewhere in the human sciences. Indeed, ethnomethodology "respecifies" Durkheim's aphorism in a way that formal analytic techniques do not and in fact cannot. Garfinkel is careful here to emphasize that ethnomethodology is not proposing itself as an alternative to formal analysis as if

it were possible to escape from the search for objective expressions by engaging in a more interpretive endeavor. Rather, ethnomethodology proposes *alternates* that are not only coeval but also autochthonous, i.e., grounded practices that spring up and exist alongside formal analytic inquiries. The ethnomethodological alternate is, however, asymmetrical to formal analytic theorizing, meaning that ethnomethodology – but not formal analysis – makes it possible to investigate how members of any grouping achieve, as practical, concerted behaviors, the sense of formal truth and objectivity as this sense is necessarily embedded in their everyday casual and work lives.

ethnonationalism

Walker Connor

Ethnonationalism (variant: *ethnic nationalism*) connotes identity with and loyalty to a nation in the sense of a human grouping predicated upon a myth of common ancestry. Seldom will the myth find support in scientific evidence. DNA analyses of the patrilineally bequeathed Y chromosome attest that nations tend to be neither genetically homogeneous nor hermetical, and analyses of the matrilineally bequeathed mitochondrial DNA customarily attest to still greater heterogeneity and transnational genetic sharing. However, the popularly held conviction that one's nation is ethnically pure and distinct is intuitive rather than rational in its wellsprings and, as such, is capable of defying scientific and historic evidence to the contrary.

Ethnonationalism is often contrasted with a so called *civic nationalism*, by which is meant identity with and loyalty to the state. (Until quite recently the latter was conventionally referred to as *patriotism*.) The practice of referring to civic consciousness and civic loyalty as a form of nationalism has spawned great confusion in the literature. Rather than representing variations of the same phenomenon, the two loyalties are of two different orders of things (ethnic versus civic), and while in the case of a people clearly dominant within a state (such as the ethnically Turkish or Castilian peoples) the two loyalties may reinforce each other, in the case of ethnonational minorities (such as the Kurds of Turkey or the Basques of Spain) the two identities may clash. World political history since the Napoleonic Wars has been increasingly a tale of tension between the two loyalties, each possessing its own irrefragable and exclusive claim to political legitimacy.

The concept of political legitimacy inherent in ethnonationalism rests upon the tendency of people living within their homeland to resent and resist rule by those perceived as aliens. Evolutionary biologists classify xenophobia as a universal which has been detected on the part of all societies studied thus far (Brown 1991). Butressing this finding of universality are the histories of multi ethnic empires – both ancient and modern – which are sprinkled with ethnically inspired insurrections. The modern state system has proven even more vulnerable. In the 130 year period separating the Napoleonic Wars from the end of World War II, all but three of Europe's states had either lost extensive territory and population because of ethnonational movements or were themselves the product of such a movement. Ethnonationalism's challenge to the multinational state continued to accelerate during the late twentieth century, culminating in the dissolution of the Soviet Union and Yugoslavia.

During the course of its development, the equating of alien rule with illegitimate rule came to be called *national self determination*, a phrase probably coined by Karl Marx and subsequently frequently employed by the First and Second Internationals. Two points are worth noting. (1) The phrase only gave name to a force present throughout history; it did not create it. Marx was no proponent of national self determination, but he had come to recognize its influence and the wisdom of appearing to ally with it as a means of fostering the proletarian revolution. (2) Although national self determination is often described as a principle or a doctrine, the impulse underlying it is far more universal and deeply felt than either term conveys.

National self determination holds that any group of people, simply because it considers itself to be a separate nation (in the pristine sense of a people who believe themselves to be ancestrally related), has an inalienable right to determine its political affiliations, including, *if it so desires*, the right to its own state. *If it so desires* is a key consideration. The essence of self determination is choice, not result. The Soviet Union on the eve of its decomposition offers a number of illustrations of ethnonational groups opting for separation: a poll conducted in October 1990, for example, indicated that

91 percent of the Baltic nations (Estonians, Letts, and Lithuanians) and 92 percent of all Georgians favored secession. Similarly, in September 1999, 78.5 percent of those East Timorese who risked death to vote, voted for independence from Indonesia. On the other hand, in the overwhelming number of cases for which there are attitudinal polling data, a majority – usually a substantial majority – of homeland dwelling people are prepared to settle for something less than independence. However, the attitudinal data also show that a substantial majority of each of these same homeland dwelling people do desire alterations in their state's power structure, alterations which would result in greater autonomy. The minimal changes that will satisfy the ethnonational aspirations of those individuals desiring greater autonomy can vary across a broad spectrum from homeland primacy in policymaking over matters involving education and language to everything short of full independence. But when aspirations for greater autonomy are denied, the appeal of separate statehood strengthens.

The willingness of nationally conscious homeland dwelling people to remain within a state in which they are a minority if they are granted sufficient autonomy should not be viewed as a renunciation of their right of self determination. Autonomy has the potential for satisfying the principal aspirations of the group. Devolution – the decentralization of political decision making – has the potential for elevating a national group to the status of master in their own homeland. As reflected in their chief slogan – *Maître Chez Nous* – the Québécois feel that within the homeland of Québec they must have ultimate power of decision making over those matters most affecting ethnonational sensibilities and nation maintenance. Such power within the homeland may be quite enough to appease the self determination impulse. Ethnonational aspirations, by their very nature, are driven more by the dream of *freedom from* – freedom from domination by outsiders – than by *freedom to* – freedom to conduct relations with states. Ethnocracy need not presume political independence, but it must minimally presume *meaningful* autonomy.

Growing acknowledgment by the central governments that the national self determination impulse can perhaps be accommodated within a

sufficiently decentralized multinational structure is becoming increasingly manifest. Whereas the tendency prior to the very late twentieth century was toward the ever greater concentration of decision making power in the center, evidence of a possible countertrend is now present. Belgium, Canada, Italy, Spain, and the United Kingdom are examples of well established states with a tradition of centralized control that have transferred significant powers from the center to ethnic homelands in order to assuage ethnonational resentments. But while perhaps portentous, such cases are still exceptional. The central authorities of most multi homeland states have tended to perceive any significant increase in autonomy as tantamount to, or an important step toward, secession. As a result, the challenge of ethnonationalism to the territorial integrity of states continues to spread.

eugenics

Gabriele Abels

The term eugenics is derived from the Greek *eugenes* ("good in birth" or "noble in heredit"). Eugenics refers to a set of ideas and activities aiming to improve the quality of the human race by deliberate selection of parents

and their offspring. In contrast to Social Darwinism, which applies categories of evolutionary biology (survival of the fittest) to the social world, the key feature of eugenics is *deliberate* selection of the "genetically fit" and corresponding active policies. Eugenics relies on two strategies: (1) manipulation of heredity or breeding practices in order to produce "genetically superior" or "fit" people ("positive" eugenics), and (2) extermination of those considered "genetically inferior" ("negative" eugenics).

The history of eugenics goes back to ancient Greece (Kevles 1985). For example, Plato proposed the idea of "breeding better people" and government control over human reproduction. Sir Francis Galton (1822–1911), an English anthropologist and cousin of Charles Darwin, founded modern eugenics and coined the term in 1883. He defined eugenics as "the science which deals with all influences that improve the inborn qualities of a race; also with those that develop them to the utmost advantage." According to him, the social status of Britain's ruling class was determined by inherited leadership qualities. He advocated improving the human race in the manner of plant and animal breeding.

Eugenics is based, firstly, on the development of genetics as a scientific discipline in the late nineteenth century and, secondly, on new concepts of social planning and rational management. The social context is the development of industrial society, which went along with urbanization, the growth of a poor "working class," and also the rise of the labor movement and socialist political parties. Eugenic "science" was considered by its proponents to be the application of human genetic knowledge to social problems such as pauperism, alcoholism, criminality, violence, prostitution, mental illness, etc. Such problems were thought to have biological roots based in people's defective genetic make up and biological "solutions" were proposed. Thus, the early concept of eugenics had a strong class and racial bias.

In the early twentieth century eugenics became a social movement first in Great Britain and then in the US, as well as in many other (European) Protestant countries. The First International Congress of Eugenics was held

in London in 1912. In the 1920s and 1930s eugenics became part of popular culture. Eugenic societies organized public information campaigns using eugenic exhibits, educational movies, “fitter family contests,” etc. and eugenics was widely taught in schools and at universities. Influential biologists such as Hermann J. Muller, Aldous Huxley, and Charles B. Davenport advocated eugenics.

Concurrently, eugenics entered public policy and found support from across the political spectrum, ranging from conservatives (e.g., Rockefeller Foundation) to progressives (e.g., Civil Rights activist W. E. B. Du Bois and feminist and founder of Planned Parenthood, Margaret Sanger) and leftists (e.g., social democratic parties and the social author H. G. Wells). While there was agreement on some eugenic principles (e.g., biological foundation of social problems), there was, however, disagreement about policies, means, and political aims (e.g., the role of coercion; social change). Many countries introduced eugenically motivated sterilization laws or laws requiring premarital screening for genetic or mental illnesses. The first such law was adopted in 1896 in Connecticut, USA; it prohibited the marriage of “feeble minded” persons and was later enforced by compulsory sterilization. Similar laws to sterilize not only the mentally ill, but also epileptics or criminals were adopted up to 1917 in 15 US states. After World War I, eugenic sterilization laws were also introduced in many European countries. Some were still in effect into the 1970s (e.g., Sweden and Canada), while in the US compulsory sterilizations came to an end in the 1960s. In general, European eugenicists were preoccupied with class issues, while the focus of eugenic policies in the US was on racial and ethnic minorities. For example, the Racial Integrity Act and also the 1924 US Immigration Act were informed by eugenic ideas.

The largest and most radical eugenic movement was German Fascism. In the 1920s the Nazi concept of “racial hygiene” was associated with eugenics (Weingart et al. 1988). Immediately after Hitler’s rise to power in 1933, the Law for the Prevention of Defective Progeny was adopted and put into force. Until 1945 about 360,000 compulsory sterilizations were conducted. In addition, tens of thousands of people belonging to minority groups considered

“not worth living” (*lebensunwert*) – such as Romanies and Sinti, disabled and mentally retarded persons, and homosexuals – were killed in a policy called euthanasia or mercy killing. By referring to eugenic arguments, the Nazi “selection and eradication” program claimed to have a scientific basis – a reasoning later used by the Nazi defendants in the Nuremberg trials. This program of the extermination of minority groups can be regarded as an ideological and practical bridge to the genocide against the Jewish population, the Holocaust. In addition to coercive “negative” eugenics, the Nazis also implemented policies of – coercive as well as voluntary – “positive” eugenics aiming at the breeding of “Aryans.” Examples are the introduction of rewards for “Aryan” mothers with large numbers of children (*Mutterkreuz*), a program for impregnating “racially pure” single women by SS officers (*Lebensborn*), and the prohibition of abortion for “Aryan” women.

Eugenic policies were justified on grounds of societal or state interests: those deemed “genetically unfit” were stigmatized as an *economic* and *moral* burden. The Nazis also referred to genetic damage to the healthy *Volkskörper* (the nation’s body). Eugenics became discredited after World War II, firstly on political grounds because it was associated with Nazi politics; and secondly, scientists started to question the scientific foundation of the “old” eugenics. However, some “reform eugenicists” (Kevles 1985) such as Muller, Huxley, and J. B. S. Haldane proposed developing sound scientific human genetics free of any racial and class bias; many eugenicists became highly respected scientists in related disciplines. With new discoveries (e.g., the double helix structure in 1953) and the rise of molecular biology, human genetics was slowly “freed” from its eugenic heritage. Yet some scholars argue that there are not only continuities among the promoters of eugenics and human genetics as a scientific discipline, but also ideological continuities. A prominent example is the 1962 CIBA Symposium “Man and his Future.” Twenty seven well known geneticists and molecular biologists (e.g., Huxley, Haldane, Muller, Joshua Lederberg) met in London to discuss their visions for human genetic manipulation and enhancement.

Historically, eugenics has been part of an oppressive and discriminatory ideology; it was

defended on societal interests and often mandated by the state. Critics believe that this is part of the very nature of eugenics. However, since the 1980s a public debate has begun on whether or not there has been a rise of a “new” eugenics and how to assess the development normatively. There is agreement that the justification of eugenic policies has changed over time. Modern eugenics is based on the notion of individual rights instead of societal interests; it is not the state that decides on selection criteria, but individuals themselves. State neutrality distinguishes the old from a “new” or “liberal” eugenics. It is freed of its classist bias, yet not totally of its racist or ethnic bias (cf. the “bell curve” debate).

This debate developed against the background of technological progress in the field of human genetics and genetic engineering. A major application of human genetics is prenatal diagnosis, which identifies the genetic status of the unborn. If the embryo or fetus has a genetic or biological “defect,” the only alternatives usually available are carrying it to term or aborting. Sometimes abortion laws allow for (late term) abortions based on embryopathic or eugenic reasons (i.e., the fetus is diagnosed as potentially disabled). This practice is criticized especially by anti abortion activists and also by (some fractions of) the disability rights movement as a threat to their “right to life.” A recent additional technology is preimplantation genetic diagnosis (PGD) on the early *in vitro* embryo. In case of a “defect,” the embryo is not used in the follow up IVF procedure, but discarded. PGD allows for the selection of embryos not only for therapeutic, but also for eugenic reasons. With the advent of “reprogenetics” (i.e., the linking of genetic engineering with new reproductive technologies), “designer babies” via genetic manipulation or even human enhancement via germ line engineering, exchanging genes, or adding new ones, now seem possible. Once again, eugenics and genetic manipulation have reappeared in popular culture; in particular, the genre of science fiction has taken up genetic engineering.

Two arguments have been raised against human genetic engineering: firstly on technological grounds (i.e., the techniques are not (yet) safe), and secondly on the basis of ethics. While the first of these may be overcome in time, the

second one is a matter of principle. Philosophers and bioethicists have begun to debate the ethics of eugenics and human genetic engineering. Some distinguished scientists involved in the Human Genome Project, for example, have announced their support for voluntary eugenics. Proponents of eugenic practices that rely on genetic manipulation are labeled liberal eugenicists. Fletcher (1974) laid the groundwork for liberal eugenics; he proposed active family planning via deliberate genetic control instead of the natural “reproductive roulette.” Since the 1990s, proponents of liberal eugenics (e.g., Agar 2004) argue in favor of individual choices: parents should have the right to choose if they want to enhance the genetic traits of their offspring as part of their parental authority (e.g., by choosing egg and sperm or direct manipulation), at least as long as the eugenic freedom of parents does not collide with the personal freedom of children. They criticize the distinction between genetic and social (i.e., educational) modification (e.g., dietary improvement, use of non medical drugs, or cultivating the child’s talents) as incoherent, and they speak out against a remoralizing of human nature. A further voice promoting human selection and enhancement is the transhumanism movement (e.g., Hughes 2004), a philosophy that is in favor of improving the human condition by the use of science and technology such as genetic engineering.

Some utilitarian bioethicists are proponents of extending selection practices to newborns, thereby linking eugenics to euthanasia. The most prominent examples are the Australian philosophers Peter Singer and Helga Kuhse, who argue for the euthanasia of severely mentally retarded newborns (infanticide) by excluding them from medical treatment. They argue that those newborns lack substantial qualities of personhood such as self awareness. “Letting them die” would on the whole maximize happiness for the parents.

Anti eugenicists and critics of liberal eugenics (e.g., Jonas 1985; Fukuyama 2002; Habermas 2003) are overall in favor of therapeutic options of biomedical technologies, but oppose any form of enhancement. Furthermore, they argue that the therapeutic/eugenic distinction is not clear cut. They fear that allowing new technological options for genetic

engineering opens a “backdoor to eugenics” (Duster 1990) or inevitably leads to a slippery slope of unethical measures. They also criticize the economic approach to procreative behavior. The new eugenics is “privatized” and takes the “free market” route: “old eugenics meets the new consumerism” (Michael J. Sandel). Therefore, many critics argue in favor of absolute moral limits. They also argue against an instrumental and utilitarian perspective on human life, which is more ubiquitous in Anglo American bioethics. Their key argument, usually based on Kant’s post metaphysical categorical imperative, is that genetic manipulation, enhancement, and human cloning are a violation of human dignity and rights, and, as some claim, also of human nature. Habermas, for example, opines that all enhancements, even if they are favorable ones such as musical talent or athletic prowess, can violate children’s right to choose their own lives, thereby constituting an encroachment upon their autonomy.

Many countries have started the legal regulation of genetic engineering and its application to humans; profiting from medical progress while avoiding eugenics is a prominent theme. Also, international (e.g., UN) and European (e.g., Council of Europe) regulation has only just begun. The “old” eugenics is well researched. The future development of eugenics and its normative assessment depend on the dynamic interlinkage between technological and social change. Therefore, research on modern eugenics has to link social studies of science and technology to normative bioethical debates.

Eurocentrism

Syed Farid Alatas

Eurocentrism is a particular case of the more general phenomenon of ethnocentrism. Ethnocentrism refers to the regard of one’s own ethnic group or society as superior to others. Other groups are assessed and judged in terms of the categories and standards of evaluation of one’s own group. Eurocentrism, therefore, is defined as a thought style in which the assessment and evaluation of non European societies is couched in terms of the cultural assumptions and biases of Europeans and, by extension, the West. Eurocentrism is a modern phenomenon and cannot be dissociated from the political, economic, and cultural domination of Europe and, later, the United States. It may be more accurate to refer to the phenomenon under consideration as Euroamericocentrism. Eurocentrism is an important dimension of the ideology of modern capitalism (Amin 1989) and is manifested in both the daily life of lay people and the professional lives and thought of sociologists and other social scientists. Furthermore, although Eurocentrism originates in Europe, as a thought style it is not confined to Europeans or those in the West.

Eurocentrism in sociology is defined as the assessment and evaluation of European and other societies from a decidedly European (read also American) point of view. The European point of view is founded on concepts derived from European philosophical traditions and popular discourse which were gradually applied to the empirical study of history, economy, and society, giving rise to the various social science disciplines including sociology. The empirical field of investigation is selected according to European criteria of relevance. Constructions of history and society are based on European derived categories and concepts, as well as ideal and material interests. Generally, the point of view of the Other is not presented (Tibawi 1963: 191, 196; Tibawi 1979: 5, 13, 16–17).

There was concern with the phenomenon of Eurocentrism before the term itself came into usage in the nineteenth century among thinkers living in colonial societies. The Muslim thinker and reformer Sayyid Jamal al Din al Afghani (1838/9–1897) debated against western constructions of Islam and was conscious of the need to appropriate relevant western ideas without blindly imitating the West. Among the earliest of thinkers to critique Eurocentric perspectives was the Filipino José Rizal (1861–96), who attempted revisions of Filipino history from a Filipino point of view via his annotation of Antonio de Morga's history of the Philippines (Morga 1962 [1890]). The first sociologist to critique the dominance of Eurocentric constructions was probably the Indian Benoy Kumar Sarkar (1887–1949), who wrote against the prevailing Indology of his time, noting its one sided emphasis on the idealistic, mystical, and metaphysical aspects of Hinduism (Sarkar 1985 [1937]). One of the first among the Dutch in particular, and Europeans in general, to raise the problem of Eurocentrism in the social sciences was Jacob Cornelis van Leur (1937, 1940). He was critical of Eurocentric tendencies in Dutch scholarship on the Netherlands Indies and is well known for his critique of perspectives arrived at from “the deck of the ship, the ramparts of the fortress, the high gallery of the trading house” (1955: 261). For example, he questioned the appropriateness of the eighteenth century as a category in the history of the Netherlands Indies, as it was a category borrowed from western history (1940).

Van Leur, nevertheless, was himself Eurocentric in several of his pronouncements and remarks. Joseph Needham wrote on the basic fallacy of Europocentrism, namely, the view of the universality of European culture (Needham 1969 [1955]: 13–14). In 1956, Syed Hussein Alatas from Malaysia referred to the “wholesale importation of ideas from the Western world to eastern societies” without due consideration of their sociohistorical context as a fundamental problem of colonialism.

The traits of Eurocentrism as manifested in sociology and other social sciences include (1) the subject–object dichotomy; (2) the foregrounding of Europeans; (3) the view of Europeans as originators; (4) the imposition of European categories and concepts; and (5) the view of the objective superiority of European civilization.

The subject–object dichotomy: Europeans are the knowing subjects while non Europeans remain as unheard objects whose standpoints are conveyed only through the agency of Europeans. Non Europeans are passive, non participating, non active, non autonomous, and non sovereign (Abdel Malek 1963: 107–8). Non Europeans are like Flaubert's Egyptian courtesan who never represented herself. Rather, it was Flaubert who spoke for her (Said 1979: 6). This “omniscience” resulted in problematic constructions of non European or “Oriental” history and society. These constructions had come under attack at three levels – they do not fit empirical reality; they overabstract, resulting in the erasure of empirical variety; and they are founded on European prejudices (Wallerstein 1996: 8).

Europeans in the foreground: Europeans are foregrounded, resulting in the distortion of the role of non Europeans. For example, modernity is seen as a specifically European creation and encounters with non Europeans are not viewed to have brought about significant changes relevant to the emergence of European modernity.

Europeans as originators: Europeans are generally seen as originators of modern civilization where in fact there should be the consideration of its multicultural origins. In texts, Muslim philosophers are often seen as having simply transmitted Greek thought to the European world of the Renaissance. Alfred Weber, the younger brother of Max Weber and author of

a history of philosophy, notes that the Arabs were “apt pupils of the Greeks, Persians, and Hindoos in science. Their philosophy . . . is more learned than original, and consists mainly of exegesis, particularly of the exegesis of Aristotle’s system” (Weber 1925: 164n).

The imposition of European categories and concepts: Tibawi brought attention to the “persistence in studying Islam and the Arabs through the application of Western European categories” (1979: 37). To the extent that the process of modernization in Europe was universal and replicable elsewhere, so too were the social sciences that explained modernization. Non European societies are regarded as worthy objects of analysis but rarely as sources of concepts and ideas.

Belief in the objective superiority of European civilization: Modern civilization as modernity is a European creation and is due to European superiority whether this is viewed in biological, cultural, or sociological terms.

While the Eurocentric nature of sociology and other social sciences has been noted, efforts to address the problem in the teaching of sociology and in research has not been forthcoming. In the teaching of both the history of sociological theory and sociological theory itself, the five traits of Eurocentrism are present.

In most sociological theory textbooks or works on the history of social thought and theory, Europeans are the knowing subjects, that is, the social theorists and social thinkers. To the extent that non Europeans figure in these accounts, they are objects of the observations and analyses of the European theorists, such as the Indians and Algerians in Marx’s writings or Turks, Chinese, and Jews in Weber’s works. They do not appear as sources of sociological concepts and ideas. In works on the history of social thought, the focus is on European thinkers at the expense of thematizing intercivilizational encounters that possibly influenced social theory in Europe. For example, Maus does not refer to any non European in his chapter on the antecedents of sociology (Maus 1962 [1956]: ch. 1). This absence can also be seen in teaching. The *Resource Book for Teaching Sociological Theory* published by the American Sociological Association contains a number of course descriptions for sociological theory. The range of classical theorists whose works are

taught are Montesquieu, Vico, Comte, Spencer, Marx, Weber, Durkheim, Simmel, Tönnies, Sombart, Mannheim, Pareto, Sumner, Ward, Small, Wollstonecraft, and several others. No non European thinkers are included.

European (and by extension, western) sociologists continue to be foregrounded in works on the history of the discipline, although there are exceptions. Becker and Barnes in their *Social Thought from Lore to Science*, first published in 1938, devote many pages to the social thought of Ibn Khaldun. While non western sources of sociology have been acknowledged by some in the West in a few early works, they are not discussed in mainstream theory textbooks and other works.

Europeans, therefore, tend to be seen as the sole originators of sociology. There were a host of other thinkers in India, China, Japan, and Southeast Asia during the nineteenth and early twentieth centuries who would qualify as modern social thinkers but who are only briefly mentioned in the early histories of sociology (e.g., Maus, Becker & Barnes) or totally ignored in more recent works. Not all European thinkers, however, ignored their non European counterparts. For example, Becker and Barnes discuss the influence of Ibn Khaldun on Gumplowicz (1928 [1899]) and Oppenheimer (1922–35), a theme that was never taken up in later accounts of the history of social thought. The generations after Gumplowicz, Oppenheimer, and Becker and Barnes have erased non European thinkers from the history books.

Connected with the above is the dominance of European concepts and categories in sociology at the expense of non European ones. This dominance also translates into research. In the study of religion, for example, the bulk of concepts originate from Christianity. Concepts in the philosophical and sociological study of religion such as church, sect, denomination, and even religion itself are not devoid of Christian connotations and do influence the social scientific reconstruction of non Christian religions. The field of the sociology of religion has yet to enrich itself by developing concepts and categories derived from other “religions” such as Islam, Hinduism, Judaism, and so on. Underlying this is an assumption of the greater suitability of categories and concepts developed in the social sciences in Europe and North America.

There is a danger that the critique of Eurocentrism in sociology may lead to nativism, that is, the trend of going native among western and local scholars alike, in which the native's point of view is elevated to the status of the criterion by which descriptions and analyses are to be judged. This involves an intolerant stance with regard to western knowledge. Nativism is founded on an essentialist approach. For example, there is a tradition in Japanese sociology that is defined by *nihonjinron* (theories of Japanese people), which are informed by essentialized views on Japanese society, with the stress on cultural homogeneity and historical continuity. This remains squarely in the tradition of western scholarship on Japan with the difference that the knowing subjects are Japanese. Hence the term auto Orientalism as discussed by Lie (1996: 5). The challenge, therefore, is to correct the Eurocentric bias in sociology.

A more universalistic approach to the teaching of sociology as well as research in sociology would have to raise the question of whether it is possible to identify examples of sociological theorizing and concept formation outside the western/European cultural milieu. This would in turn imply radical changes in sociology theory curricula (Alatas & Sinha 2001). This does not require that western sociological content be removed from the sociology syllabi. Rather, more and more sociologists are recognizing the need to look to additional sources of concept formation and theory building from outside the usual corpus of knowledge that is confined to one civilization.

euthanasia

Clifton D. Bryant

The dictionary defines euthanasia as an “act or method of causing death painlessly so as to end suffering: advocated by some as a way to deal with victims of incurable diseases.” This is something of an over simplification, however. The practice of euthanasia has long been a contentious issue and a matter of disputatious debate. Some have termed euthanasia “mercy killing” (Vernon 1970: 310), but others have reported that some critics have labeled it as murder (Sanders 1969; Charmaz 1980: 112).

While euthanasia has generally taken place within a medical context, historically, euthanasia, as a humanitarian act, has also occurred within other contexts, such as war. There are historical accounts (from all wars) of soldiers encountering badly wounded fellow soldiers or wounded enemy soldiers. If their wounds were severe and it appeared they would not survive and they could not be transported to a medical facility, the soldiers sometimes killed the wounded individual out of compassion, administering the “coup de grace” – in effect, putting the wounded man out of his misery (Leming & Dickinson 2002: 283). Euthanasia most frequently, however, has occurred within a medical context, and this term has come to be associated with terminal illness and the medical setting. The discomfort of terminal illness is not the only motivating factor in euthanasia. Grossly deformed infants have sometimes been euthanized (or it was intended that they be euthanized until a court intervened) (Vernon 1970: 310; Charmaz 1980:113; DeSpelder & Strickland 2002: 203–4).

There are two distinctly different modes of operationalizing euthanasia: *positive* euthanasia and *negative* euthanasia (Charmaz 1980:112). Positive euthanasia refers to the practice of deliberately ending the life of a patient through active means (e.g., giving the patient an over dose of sedatives, knowing that this will kill the individual). This practice is sometimes euphemistically termed “snowing.” Negative euthanasia describes the practice of discontinuing interventive treatment, or withholding some life sustaining “drugs, medical devices,

or procedures” (DeSpelder & Strickland 1999: 200). Charmaz (1980: 113) describes positive euthanasia as an act of *commission* and negative euthanasia as an act of *omission*. DeSpelder and Strickland (1999: 200) indicate that “this distinction is sometimes characterized as the difference between ‘killing’ and ‘letting die.’” Some writers (e.g., Leming & Dickinson 2002: 290, 294) apply the terms *passive* euthanasia (rather than negative) when treatment and drugs are withdrawn or withheld, and *active* euthanasia (rather than positive euthanasia) when “the individual is helped to die.”

Another dimension of euthanasia is the matter of who makes the decision concerning the termination of the life of an individual. Most writers bifurcate euthanasia into *voluntary* euthanasia, where a competent individual requests and gives informed consent to withhold treatment, and *informal* euthanasia, where the decision to terminate an individual’s life is made by others. One set of writers (Corr et al. 2003), however, suggest that there are three variations of decision making in euthanasia. They also articulate the definitions of the variations somewhat differently. As they conceptualize the paradigm, *voluntary* euthanasia refers to the instance of an individual asking for and/or assenting to their death. Where the individual is unable to make such a decision (such as a person who is unconscious or in a coma, or, perhaps, an infant) and “a second person somehow intentionally contributes to the death of this sort of person, it is *nonvoluntary* euthanasia.” They further assert that where a person wishes to be kept alive but someone else elects to terminate the individual’s life, the process should be correctly labeled *involuntary* euthanasia (more like homicide than like a “good death”).

Euthanasia, whether active or passive, voluntary or involuntary, or nonvoluntary, is socially (and legally) controversial. Assertive and persuasive arguments concerning euthanasia have been advanced by both proponents and opponents. According to Charmaz (1980: 112) there are “three interrelated ethical questions constituent to the controversy.” First, should individuals have the right to *elect* and *control* death? Second, at what *point* might an individual legitimately exert these rights? Third, whose *interests* are going to be given priority, those of the individual or those of the society?

Euthanasia (and also sterilization) has some times been carried out with the presumed best interest of the society as rationale. This is essentially an operationalization of "the utilitarian doctrine of the greatest good for the greatest number" (Charmaz 1980: 114). Opponents often cite examples of the programs of euthanasia such as those where individuals considered to be "unproductive," "defective," and "mentally unfit," such as handicapped and retarded persons, Gypsies, Jews, and homosexuals, were systematically euthanized (exterminated) at concentration camps like Auschwitz for the so called benefit of society (Leming & Dickinson 2002: 300). This is known as the "slippery slope to Auschwitz" argument (Potter 1993; Wilkinson 1995).

"Altruistic" euthanasia has not only occurred in Nazi Germany. Some years ago a famous American novel, *Not As a Stranger* (Thompson 1954), chronicled the experiences of a young idealistic physician who had just begun to practice medicine in a small town in the upper Midwest in the 1930s. The young physician learned, to his horror, that the administrator of the local county hospital was systematically having long term elderly senile patients placed in beds in a cold room with open windows at the rear of the hospital during the winter. Predictably, the elderly patients contracted pneumonia and died. This freed up additional bed space for younger sick patients coming in for treatment. This initiative was viewed by the hospital administrator as a necessary effort for the good of the community. While the account is fictional, there is little doubt that this and other similar instances of systematic euthanasia have been carried out in real life for the presumed "good of society."

Arguments for and against euthanasia were advanced many decades ago and have proved to be quite durable. Charmaz (1980: 114), for example, articulated four potent arguments in favor of voluntary euthanasia. These include:

- 1 Individuals have the right to choose their deaths.
- 2 This right is underscored by the fact that technological medicine obscures the moral dimensions of the dilemma and usurps choice.

- 3 Individuals may decide that suffering is of a magnitude to warrant release through death.
- 4 Individuals may specify that they do not wish dying to be prolonged when irreversible damage results in the loss of human attributes.

Charmaz also detailed the arguments against euthanasia. These include the belief that euthanasia is immoral on religious grounds; that it is incompatible with the belief in the sanctity of human life; that the state of knowledge (errors in tests and diagnosis, sudden new medical breakthroughs) may radically alter the circumstances; and that there is no way of knowing what patients would want once they are unable to communicate.

More recent arguments in favor of intentionally ending a human life have been summarized by Corr et al. (2003: 495–6), who articulate three such arguments, including prevention of suffering, enhancement of liberty, and quality of life. They also point to arguments against intentionally ending a human life, including a commitment to the preservation of life, the slippery slope argument, and additional arguments ("Medicine is at best an uncertain science; medicine moves quickly and ... new therapies and new cures are discovered at unknown moments; ... assisted suicide and euthanasia ... may detract from the role of the physician as healer and preserver of life").

The main thesis of voluntary passive euthanasia is that in the case of terminally ill patients, they may desire that no *extraordinary* methods be used to prolong life. There is great ambiguity in the term *extraordinary*, however. Corr et al. (2003: 493) have provided several criteria for a refined definition of these terms. They indicate that *ordinary* means of treatment are those that have outcomes that are predictable and well known, offer no unusual risk, suffering, or burden for either the person being treated or others, and are effective. *Extraordinary* means of treatment, on the other hand, fail to meet one or more of these criteria. Such means of treatment have sometimes been referred to as "heroic measures," suggesting that interventional initiatives of this variety tend to constitute treatment efforts "above and beyond" what might be

normally expected within conventional medical protocol.

Much of the controversy surrounding euthanasia rests on the issue of the priority of two disparate perspectives or values. These two ideological value postures are the *sanctity of life view* and the *quality of life view*. The former invokes the notion that “all ‘natural’ life has intrinsic meaning and should be appreciated as a divine gift” (Leming & Dickinson 2002: 284). In the instance of the latter, these writers assert “the quality of life orientation holds that when life no longer has quality or meaning, death is preferable to life.” Both views have obvious merit, but the question of primacy is both philosophically weighty and obviously disputatious.

Passive (or negative) euthanasia, generally speaking, is legal in the US. Active euthanasia, by and large, is not legal, although there is some degree of social toleration for this procedure. Such toleration might include such examples as a physician actively bringing about the death of a terminally ill patient, with the knowledge and tacit assent of nurses and medical staff, who do not report such an act to law enforcement officials. Another example might be an instance of jury nullification, whereby an individual who killed a terminally ill spouse or parent is not convicted, contrary to law and the facts, by a jury who viewed the murder as a mercy killing (Sanders 1969; Vernon 1970: 310).

While active euthanasia is illegal, there are nevertheless organizations that support that mode of death. The Hemlock Society advocates active euthanasia for persons who have terminal illnesses and who are experiencing unrelieved pain, or who are facing a “life devoid of meaning and purpose” (Leming & Dickinson 2002: 299). The Hemlock Society makes a distinction between suicide, self deliverance, and mercy killing. According to Leming and Dickinson, the Hemlock Society describes suicide as a socially condemned stigmatized act, “religiously selfish,” and an “overreaction of a disturbed mind,” and self deliverance as “a positive action taken to provide a permanent solution to long term pain and suffering for the individual and her or his significant others faced with a terminal condition.” Mercy killing is essentially homicide, although temporary

insanity and compassion may be invoked as defenses.

Generally speaking, most religious faiths, including Christianity, Judaism, Hinduism, Islam, and Buddhism, condemn active euthanasia as morally unacceptable (Walker 2003).

Euthanasia as a controversial concept overlaps with several other controversial issues. These include abortion, which has been classified by many as involuntary (or nonvoluntary) active euthanasia. Another overlapping issue is suicide, which can be technically viewed as self directed voluntary, active euthanasia. This would seem to be especially the case if the suicide is conceptualized as self deliverance as articulated by the Hemlock Society. Similarly, assisted suicide and particularly physician assisted suicide would be tantamount to voluntary active euthanasia. Arguments pro and con are essentially the same for all of these processes.

The enactment of legislation recognizing the legal legitimacy of “living wills” in all 50 US states and the District of Columbia has effectively institutionalized passive euthanasia. Active euthanasia, while currently illegal in almost all states, may well undergo a legal metamorphosis in the US in the decades ahead. In 1994 Oregon passed the Death with Dignity Act, which allowed physician assisted suicide. Physicians can legally prescribe lethal medication for patients who request it, who have requested hastened death three times, who are 18 years of age, and who have a life expectancy of 6 months or less. There are additional requirements. This legislation effectively legalizes active euthanasia. Oregon renewed the act by referendum in 1997 (Walker 2003). Undoubtedly, other states will follow suit. In 2001 the Netherlands passed a law that decriminalized active, voluntary euthanasia.

With an aging population in the US and in many other countries of the world, euthanasia will assume more and more relevancy with time. Passive euthanasia is legal and widely practiced and active euthanasia is obviously moving more in the direction of social acceptance. Euthanasia would seem to be an idea whose time has arrived.

evaluation

James R. Sanders

Evaluation is a systematic process of determining the merit or worth of some entity, which is commonly referred to as the evaluand (Scriven 1967, 1991). Evaluation, like research, is a form of disciplined inquiry (Cronbach & Suppes 1969). As such, emphasis is placed on public examinations of arguments and inquiry methods, on discussion of limitations and margins of error in conclusions, and on adherence to generally accepted standards of practice, which

include impartial, detailed, and unambiguous methods of inquiry. The systematic processes of evaluation and research can be compared on several dimensions. This conception of evaluation contrasted to research began with discussions of the emerging methodology of evaluation in the late 1960s, as described by Worthen and Sanders (1973).

The goal of evaluation is to determine value (merit, worth) of an evaluand, while the goal of research is to develop generalizable knowledge. The roles of evaluation include use for product, performance, and program improvement, as well as use for guiding choices among decision alternatives. The roles of research include building a body of knowledge on which theories and product development can draw. The motivation of evaluators toward what to study is primarily external, whereby evaluators provide services to others. The motivation of researchers in choosing what to study is primarily internal, whereby curiosity and a desire to extend existing knowledge are prime stimuli for research. Related to motivation of the inquirer is autonomy of the inquiry. Evaluators mostly serve clients and are accountable to them. Researchers often establish their own problems and direction of inquiry.

Investigative techniques used by evaluators must be diverse so that a broad range of questions that comprise the conception of value of an evaluand can be addressed. Researchers will often pursue a small number of important questions that require few investigative techniques. Evaluators are methodological generalists, while researchers tend to be methodological specialists. The disciplinary base and, consequently, the breadth of training of evaluators is necessarily broad in order to enable them to seek answers to a broad range of questions. The disciplinary base of researchers is usually found in mastery of a single field of study. Psychologists conduct psychological research, sociologists focus on sociological problems, and so on. And researchers tend to use the methodologies of their home disciplines.

Standards for judging the adequacy of evaluations include utility, feasibility, propriety, and accuracy (Joint Committee 1981, 1988, 1994, 2003), while research is judged on

internal and external validity of the inquiry, as well as its contribution to the existing knowledge base (Campbell & Stanley 1963; Cook & Campbell, 1979). The salience of the value question in evaluation is high, while judging the value of an object of study does not dominate research.

These distinctions are useful for making the point that research and evaluation are different in important ways, even though there are areas of overlap. In the real world of inquiry, more over, many of these distinctions blur, as complex projects may have multiple roles, goals, and motives, where both research and evaluation are needed.

METHODOLOGY OF EVALUATION

Discussions of a methodology of evaluation grew in the late 1960s when it became evident that traditional research methodologies could not address the needs of evaluators who were being asked to evaluate existing and newly funded social, educational, economic, engineering, health, and technological programs, products, and performances. A seminal work that established a foundation for the theory and practice of modern evaluation methodology was published in 1967 by Michael Scriven. In this work, Scriven distinguished between the roles of formative and summative evaluation, and the implications of this distinction for evaluation methodology. Formative evaluation was defined as feedback during the developmental stages of an evaluand that serves to improve it. It is kept internal to the group engaged in development. Summative evaluation was defined as information about a finished evaluand that is used to make decisions such as continuation, termination, adoption, and funding level.

A distinction must be made between formative/summative roles of evaluation and process/product questions about an evaluand. Confusion often appears when formative and process evaluation are seen as synonymous, and summative and product evaluation are seen as synonymous. They are not. Perhaps the best way to illustrate these distinctions is through the following matrix:

	<i>Formative</i>	<i>Summative</i>
<i>Process</i>	Evaluation of means to some ends as a way of improving the means.	Evaluation of alternative means to some ends in order to select the best means.
<i>Product</i>	Evaluation of the ends accomplished by an evaluand under development as a way to identify where changes may be needed.	Evaluation of the acceptability of ends of competing evaluands in order to identify the evaluand with the best ends.

Formative process and formative product evaluations are aimed at improving means and ends, respectively, during developmental stages. Summative process and summative product evaluations are aimed at selecting the best means and ends from among competing alternatives.

EVALUATION APPROACHES

Depending on such factors as the training background and experience, the philosophical orientation, and methodological preferences of the evaluator, and the stated needs for evaluation, evaluators have developed different evaluation approaches, sometimes called models for evaluation. Stufflebeam (2001) has identified 22 different approaches. Among the most popular are those that are:

- *Goal based:* The focus is on achievement of desired ends as a basis for judging an evaluand.
- *Program theory based:* The focus is on the logical relationships and adequacy of program inputs, activities, and outcomes as a basis for judging programs.
- *Decision based:* The focus is on addressing the administrative decisions faced by managers in organizations. Planning, designing, budgeting, monitoring, and accountability decisions are all important sources of evaluation questions.
- *Consumer based:* The focus is on product decisions faced by consumers.
- *Expert based:* The focus is on standards and criteria identified by credible and qualified experts in the specific field of the evaluand.

- *Participant based:* The focus is on issues and concerns identified by stakeholders in the evaluand. Stakeholders are defined as those who are affected by the evaluand and those who affect the evaluand in some way (such as staff and funders).

EVALUATION DESIGN

The design of evaluation studies begins with the questions that are to be addressed in the evaluation. Some designs are narrow in scope because they seek to address one or a small number of questions. Others are very broad in scope because they seek to address many, often complex and diverse, questions related to the value of the evaluand. Some evaluators see their role as having the responsibility of determining the questions to be addressed. Others see the questions being generated by a negotiation process between evaluator and client (the funder of the evaluation), while still others see the questions being determined by stakeholders of the evaluation.

Evaluators typically begin designing an evaluation by identifying potentially important value questions. This is called the *divergent* phase of the design (Cronbach 1982). Once questions are listed, the evaluator determines for each question (1) the information needed to answer the question, (2) the source(s) of this information, (3) the tasks or steps required to generate answers, (4) who will perform each task, and (5) the cost of completing each task. A draft budget, time schedule, and staffing plan can then be prepared so that the *feasibility* of the design can be seen. If the design needs to be reduced in scope, as is usually the case, the evaluator begins the *convergent* phase of the design, during which some questions are eliminated. The questions that are dropped constitute in part the *limitations* of the evaluation.

Most evaluators agree that it is impossible and imprudent to identify the final set of evaluative questions at the beginning of the study. Evaluators learn as they become engaged in the evaluation, and consequently the evaluation design evolves. The distinction between *preordinate* evaluation designs (where all questions are determined beforehand) and *responsive* or emergent evaluation designs (where questions emerge as

learning about the evaluand takes place) is described by Stake (2004).

EVALUATION TECHNIQUES AND PROCEDURES

Stufflebeam (1969) defined five processes involved in evaluation: design, data collection, data analysis, reporting, and management of the evaluation. Design was covered in the preceding section. The remaining four processes will be discussed next.

Data collection involves the gathering of information needed to answer the questions posed for the evaluation. These data may be quantitative (numerical) or qualitative (non numerical). Quantitative techniques and procedures have been well developed by researchers in the social and physical sciences. They include such methods as testing and psychometrics, surveys, physical measurements, cost analysis and econometrics, sociometrics, and scaling. Qualitative techniques and procedures have also been well developed by researchers, particularly in the social sciences. They include such methods as ethnographies, case studies, and observation, including participant observation, focus groups, document analysis, narrative interviews, unobtrusive measures, and photography.

In addition to the data collection techniques and procedures that have been developed by researchers there are data collection methods that have been developed by evaluators to serve the unique demands of evaluation. These methods include needs assessment, advocate team studies, logic models and program theory, values analysis and validation, goal free evaluation, and cluster evaluation.

Data analysis involves the reduction and summarization of data so that evaluative meaning can be derived for the complex combination of data generated by most evaluation studies. Descriptive and inferential statistics, graphs, tables, and charts are most often used to analyze quantitative data collected during an evaluation. Searching for key incidents, patterns, and categories is a common method of qualitative data analysis. Analytic induction in qualitative data analysis involves several steps, including (1) exploring qualitative data and forming impressions, (2) identifying themes, (3) focusing

for further observation and documentation, often using working hypotheses, (4) verification and support of tentative conclusions, and (5) assimilation into the broader context of what is known about the evaluand.

Data analysis in evaluation also involves a valuing process whereby conclusions based on evidence are combined with values to arrive at evaluative interpretations. It is this aspect of data analysis that sets evaluation apart from other forms of disciplined inquiry.

The reporting process of evaluation can take many forms, ranging from daily updates and discussions to compilations of written final reports. The utility of evaluation is highly dependent on the reporting and communications process (Fitzpatrick et al. 2004: ch. 16). Characteristics of effective evaluation reporting include accuracy, timeliness, frequency, balance, fairness, clarity, level of detail, communication style, and providing an opportunity to intended users for reviewing draft reports.

Evaluation management begins at the design stage of the evaluation process and continues through helping users of the evaluation to move from evaluative conclusions to application and action. Coordinators of evaluations must ensure that adequate time, funds, expertise, and communications are present. They must supervise and direct evaluation operations so that the results of the evaluation are as accurate and valid as the limitations of the evaluation study allow. Delivering a product that is on time, within budget, and meets professional standards and principles (Joint Committee 1994; American Evaluation Association 1995) depends on sound evaluation management.

METAEVALUATION

All evaluations inevitably have some degree of uncertainty and bias, as do any other scientific undertakings. For this reason the professional evaluator will typically plan for a metaevaluation, or evaluation of the evaluation. Internal review can be a continuous part of the evaluation process, whereby qualified colleagues can provide formative feedback to the evaluator beginning with the evaluation design, and continuing through the evaluation process and final communications with the client. External

reviews can be arranged with independent qualified consultants who may prepare reports and recommendations at discrete points in the evaluation process, such as when the design is submitted, when reports are delivered, and when the evaluation has been completed. These outside reviewers most often report to the client with an opportunity for the evaluator to respond. The metaevaluation process is intended to strengthen the evaluation and to increase the certainty that may be placed on evaluative findings.

everyday life

Martha Easton

Everyday life, in the field of sociology, has been positioned as a condition, a social space, a political goal, and a methodological analytic. Its meaning has shifted with time, and its potential consequences have shifted with its meaning. One thing that has not changed has been the home of the concept, under the wing of the conflict school of theory. But while everyday life started its move into theory as a negative extension of Marx's idea of alienation, it has evolved into a celebrated realm for modern day feminist sociology.

Henri Lefebvre, one of the most important French Marxist sociologists of the mid century, first wrote of everyday life as a mind numbing, alienating set of social conditions. His book *Critique of Everyday Life* was published in 1947. In it he linked what he called "everydayness" to Marx's theory of alienation. According to Lefebvre, everydayness was a modern day extension of the grip of alienation, part of the consequence of the rise of a modern form of capitalism. Lefebvre argued that capitalism had gotten so powerful that it had grown beyond organizing our productive and social relations in society; it also actually sucked the meaning out of everyday life. Alienation, the feeling of exhaustion, stress, and poverty consequential from the act of being forced to sell one's labor, was experienced more painfully under modern capitalism precisely because the experiences of everyday life outside of work had been invaded by capitalism. Without the

genuine meaning and connection that had once taken place in everyday life outside of work, modern workers turned to consumption to fill the gap. The lifestyle of consumption grew stronger and stronger under modern capitalism, and everyday life was marked by the purchase of commodities, which furthered the cycle of alienation.

Lefebvre's view of everyday life as a kind of negative alienating condition shaped by the structural influences of capitalism was a powerful position in social theory during the mid twentieth century. But by the 1960s, a different view of everyday life began to emerge in social theory.

Everyday life got a new set of meanings along with the reemergence of arguments about the public sphere and the private sphere. As the concept of the public sphere began to be increasingly defined as the world of work, politics, and the service of citizenship, the private sphere began to be seen as the space of everything else, or the space of everyday life. This loaded the idea of everyday life with the content of all that was seen as somehow being personal and private: love, family, sex, relationships, housework, emotions, and so on.

It was in this context that feminist sociologists retrieved the idea of everyday life, and reinterpreted it as a social space that primarily contained that which was seen as belonging to women. The public sphere was the world of men, while the private sphere (and everyday life) was the realm of women. Feminist sociologists argued that the world of women and the social relations of everyday life should be celebrated and valued. Some also argued that the line between the public and private sphere should be obliterated, allowing women into the public realm and, more important, removing value judgments from the assessment of the realms in which people pursue social interaction. In other words, the obligations of everyday life – like helping a child with homework – are just as important as the work of the public realm – like participating in the work of a political party.

The women's movement politicized the idea of everyday life. Home, and the private world, were sites for battle over the work and role of women. The "personal is political" was a key theme for analysis and activism, and everyday life became a battleground.

By the 1970s, feminist sociologists such as Dorothy E. Smith had added an important new dimension to the concept of everyday life. They argued that the social reproduction of inequality could be seen in the normal interactions of everyday life. This analytical insight helped reshape the focus for feminist research. As a topic of analysis, the social relationships of everyday life became increasingly important. New empirical research during this time period began to focus on topics that had formerly been seen as banal, or unimportant, or too “everyday.” Topics such as domestic violence, housework, mental illness, and childrearing emerged as critical – and controversial – areas for research. Everyday life was not just what was left over from the important work of the public realm, but was in itself a set of social relations that created and reproduced social inequalities. The experiences of everyday life were important pieces of knowledge about our social world, and everyday life became a key focus of empirical study.

In addition, everyday life anchors an important feminist methodological tradition. The practice of institutional ethnography depends on a close analysis of the ways in which normal people experience and know their own everyday lives. Dorothy E. Smith first articulated the importance of this method in 1983, growing out of her previous work on the knowledges of women’s everyday experiences in the private sphere. This method looks at the institutions that organize the experiences of everyday life, and works backwards from individual experience to make visible the power behind the relations of ruling. Smith takes as an example her experiences as a single mother dealing with the school her children attended. As she worked with the school to help one of her children who had a problem with reading, she began to see that the problem was that she was a single mother. Helping a child learn to read was not seen as work, and yet the school was highly dependent on the work of mothers in socializing their own children. The institution of education rested on unrecognized class and gender assumptions: that essential child socialization would be done by women who had no other jobs (i.e., were middle class). Children raised by families that did not conform to middle class gender and social standards were

constituted by their everyday behavior as abnormal or problemated. By reading backward from the experiences of everyday life, institutional ethnography can explicate the power relations behind important social institutions.

Everyday life is an important part of social theory. It is a condition, a political focus, and a set of experiences. Historically, the idea of everyday life was associated with Marxist ideas of alienation. Currently, the concept of everyday life is strongly associated with feminist sociology, and is an important focus of the feminist work.

evolution

Amanda Rees

The concept of evolution has a vexed and often misunderstood history as far as the social sciences are concerned, and one that has consistently been mired not just in intellectual and scientific debates, but also in political and economic confrontations and conflicts, ranging from the eugenic policies practiced by many western nations at the beginning of the twentieth century, to the execution and exile of Soviet biologists unwilling to toe the Lysenkoist party line in the 1950s, to the decision of the Kansas Board of Education in 1999 to delete the teaching of evolution from the state’s science curriculum. There are a number of reasons why this concept – which at its simplest can be defined as the way things (people,

societies, ideas, environments) change over time – has been bogged down in so many confusions and conflagrations, most of which can be found in the particular contexts and purposes in which evolutionary ideas are and have been expressed.

At present, the idea of evolution is most commonly associated with Charles Darwin's (1859) theory of evolution through natural selection. This is based on four key assumptions: that more individuals are born than can possibly survive; that each of these individuals differs in some distinctive way; that these differences will mean that some of these individuals will be better able to survive in particular environmental circumstances than others; that those better able to survive will leave more offspring than those less well adapted to their environment. In other words, to use the phrase coined by an early Darwin enthusiast, Herbert Spencer, evolution is a process based on the "survival of the fittest." Clearly, this account of how populations evolve or change over time is based on an entirely contingent match or "fit" between individual characteristics and current environmental context: if the demands placed on the individual by the environment change, then so will the nature of the characteristics that promote survival. Dinosaurs were enormously well "fitted" to the environment that existed prior to the atmospheric upheavals known to have taken place at the K/T boundary, but it was the small, rat like mammals that were to prosper in the millennia that followed that ecological catastrophe.

Nonetheless, one of the key reasons for the confusion surrounding the concept of evolution in social and political theory and thinking has been the persistent ambiguity attached to the term "fittest." In the classic sense, it refers to the "fit" between individual and environment; however, it was in both the nineteenth and the twentieth centuries also used to refer to the ideal of progress. Evolution could be taken to mean "evolving toward" ever more complex or ever more intelligent organisms or individuals, progressing toward the attainment of ever higher levels of biological, social, and psychological being. Consequently, for the social sciences, it became associated with particularly hierarchical conceptions of the political and cultural world, both within and between particular

societies and communities. It was used as, and was taken to be a justification for, the dominance of men over women, of white people over black, of Christians over Jews, of Europeans and North Americans over the peoples of Africa, Asia, and South America. As a result, and for these good historical reasons, a distaste for explanations of society and social interactions based on explicitly biological evolutionary theory developed among the social sciences and the humanities, an unease which first became unequivocal in the aftermath of World War II, and then was exacerbated during the 1970s with the publication of E. O. Wilson's *Sociobiology* (1975) and the UNESCO declaration on race and racial prejudice (1978). Social theorizing based on biological principles was declared anathema, and the extent of the opposition to the intrusion of biology into sociology can perhaps be judged from the famous incident where Wilson, speaking at an American Association for the Advancement of Science meeting in 1978, was drenched with water by a group of activists who had stormed the stage chanting "Racist Wilson, you can't hide, we charge you with genocide" (Segerstrale 2000).

Yet the story of evolution is far more complex and complicated than this. The concept itself was not the sole product of the biological sciences, but was a key element in the work of many nineteenth and twentieth century social theorists. Even within the biological sciences, the word "evolution" was and is not restricted to Darwinian natural selection, but can be taken to mean many different aspects of the way in which populations change over time. The use of the concept for political purposes was not restricted to fascist, or even conservative, social thinkers, but can also be tied to the development of socialist and Marxist philosophy. Ironically, bastions of conservatism, particularly in the United States, have explicitly rejected evolution and evolutionary thinking, condemning it as the source of moral laxity, the emergence of the permissive society, and the breakdown of social and community spirit. Finally, and perhaps most interestingly, the latter half of the twentieth century has also seen the emergence of a perspective that uses evolutionary principles to put forward an explicitly feminist agenda. Evolution as a word, as a concept, and as a rule is slippery at best, and predictably unpredictable at worst.

It is clear that many different scientific interpretations of “evolution” have existed, different interpretations that have both been firmly based within particular cultural contexts and had social and political consequences. So, for example, the development of the concept of evolution in the eighteenth and nineteenth centuries was tied to the development of geology and natural history, and based on the emergent cultural acceptance that the myth of creation outlined in Genesis did not explain or even necessarily accord with the conclusions that natural philosophers were reaching with regard to the age of the earth or the existence of fossilized creatures unknown and unrecognizable to modern eyes. This period saw an increased willingness to seek out and to create accounts of the world that did not involve the work of intangible or preternatural forces, but instead could be shown to depend on the interaction of material and utterly apprehendable rules of nature. The most famous alternative to Darwin’s theory emerged in the early years of the nineteenth century – the work of the chevalier de Lamarck. Writing many years prior to the publication of Darwin’s theory, Lamarck focused on what has come to be called the “inheritance of acquired characteristics.” This is the presumption that parents can pass to their offspring those characteristics that they have physically achieved in their lifetimes. So, for example, giraffes acquired their extraordinarily long necks because each generation of giraffes stretched their necks as far as they could to eat the leaves on tall trees, passing this on to the next generation who in turn stretched their necks a little further. Alternatively, to give a human example, this interpretation of evolution would mean that a blacksmith’s son would be blessed with significantly stronger muscles than the son of a clerk. This was the version of evolution that was to be taken up by Trofim Lysenko in the USSR during the 1950s, as a much more acceptable kind of evolutionary thinking than that based on the cutthroat individualistic competition of Darwin’s natural selection. Lamarck preceded Darwin, but even after the publication of *The Origin of Species*, scientific debates continued on the nature of evolution and the mechanisms through which it proceeded. By the end of the nineteenth century and the beginning of the twentieth, Darwinism had

been abandoned by most biologists. Evolution as a concept, and understood to refer to “change through time,” remained unquestioned, but the principles of natural selection had been rejected – not least because they were unable to explain exactly how new species could emerge. Lamarck’s views seemed much more useful here, and other perspectives such as orthogenesis (evolution toward fixed goals) flourished. It was not until the fusion of Darwinian natural selection with Mendelian principles of inheritance in the 1930s and 1940s that the place of Darwin in the history of evolution was assured.

However, the nineteenth century had also seen the adoption of evolutionary principles by many social philosophers. In contrast to the conception of society commonly held before the Enlightenment – that “mankind” was in the process of steadily declining from the achievements of antiquity – the eighteenth and nineteenth centuries had seen a steady growth in the confidence of European societies, aided by the material achievements of the Industrial Revolution, the intellectual accomplishments of the Scientific Revolution, and the political and military consequences of the developing European imperial project. Anthropologists were quick to make use of evolutionary and hierarchical ideas to explain the different levels of technological and political development achieved by the different societies that were increasingly coming under, not just the European gaze, but also European political and economic control. Writers such as Lewis Henry Morgan and Edward B. Tylor argued that all cultures were in the process of evolving from the simple to the complex, and that each encountered society could be placed correctly on the hierarchy of progress. European societies, naturally enough, occupied the highest steps, but other societies were in the process of evolving toward such heady pinnacles – they had simply not progressed up the ladder of progress from savagery to civilization as far as they might. This perspective was to become one of the key justifications of imperialism and colonialism, as administrators and politicians spoke of their “civilizing mission,” the “burden” placed on the “white man” to provide the example, and the education that would enable these communities to accelerate their social evolution.

Several of the founding fathers of sociology were also eager to adopt the notion of development through time, not so much to explain the relationships between different societies as a means of making sense of the nature of the social developments that were occurring within European societies. The idea of progressive evolution was at the heart of Auguste Comte's positivist philosophy, with the assertion that human understanding of the world was naturally constituted so as to pass through three stages – the theological, the metaphysical, and the scientific – each constituting a more complex and more accurate comprehension of mundane reality. As people proceeded through these stages, so society itself would evolve toward a higher state, and part of the reason for his desire to establish a scientific sociology was his belief that the existence of such a science would aid humanity in its progress toward the most superior kind of society. Similar approaches to the notion of social evolution can be found in the work of Émile Durkheim and Karl Marx. Durkheim cast his account of society in terms of the consequences of the shift from mechanical solidarity to organic solidarity; from simple solidarity based on shared understanding of the nature of a largely agricultural community to a complex interdependence based on the increasing complexity of the division of labor in an increasingly industrial society. Again, we see evolution presented as the movement from the simple to the complex, heavily overlaid with the assumption that by these means, social progress is achieved. Similarly, Marx and Engels drew on the notions of change over time not just to develop their materialist account of the immediate and antique past, but also to project into the future their understanding of the nature and apparatus of social change and progressive evolution toward a more perfect form of society. Inherent in all of these approaches to the study of human cultures is the idea that there are universal laws that govern the development of all forms of society – and that these laws can be best apprehended through the principles of evolution and progress. It was this notion of “universal laws” of human development that was to come under such sustained critique over the course of the twentieth century.

Perhaps the most famous nineteenth century social evolutionist, however, was Herbert

Spencer. It was he who coined the phrase “survival of the fittest,” with all the ambiguity which that entails, and it was he who did most to introduce the philosophy known as “social Darwinism” to a wider public. However, he was not a Darwinist in the sense that he accepted natural selection as the principal means through which evolution operated. Instead, Spencer chose to stress the influence of external forces on the organism or society, and additionally, maintained a strong Lamarckian perspective. Moreover, for him, “social progress” meant the progression toward a society in which individuals experienced ever more freedom, leading him to oppose the introduction of governmental programs intended to alleviate the suffering of the poor and needy. Spencer had accepted the Malthusian argument concerning the role of population pressure, and considered this to be both the means through which the unfit were eliminated and the dynamo behind economic development: increasing population meant a constant drive to improve technological capacity in order to prevent people's needs entirely outstripping scarce resources. However, the logical result of the application of social Darwinism would be the adoption of an extreme form of *laissez faire* capitalism, with the state restricted from any interference. The market alone would determine success or failure, and individuals must be left to sink or swim according to their capacities. This attitude toward cutthroat economic competition, combined with the increasing popularity among the middle classes of the eugenic theories first put forward by Darwin's cousin, Francis Galton, meant that by the turn of the twentieth century, evolutionary theories and concepts were not just being used to justify the class system as a reflection of natural reality, but were in some cases being used in an attempt to manipulate the composition and interrelationships between social classes in order to create a more perfect and progressive society.

The particular nature of that society, however, depended on one's political philosophy. There was nothing about the concept of evolution that marked it as the natural ally or particular property of one party or another. Having read *The Origin of Species*, Marx is said to have been so impressed with its account of the competitive basis of individual survival that he offered to dedicate part of *Das Kapital* to

Darwin. This story has been shown to be a myth, but it is one that reflects the close correspondence that many authors have felt exists between a description of the biological struggle for the "survival of the fittest" and the ruthless competition characteristic of the late Victorian capitalist society that Marx analyzed. Similarly, Lysenko's adoption of a Lamarckian conception of evolution was endorsed by the Soviet authorities because it eliminated the random competition characteristic of Darwinian evolution, and emphasized the potential for the development of a self improving society. But the link between Darwinism and capitalism is not unproblematic, nor is it necessarily the result of controversy between the natural sciences and social sciences: the most vicious evolutionary debates of the twentieth century have been conducted not between biologists and social scientists, but within biology itself, as "Marxist biologists" have battled "sociobiologists" for the ultimate prize of inheriting Darwin's biological legacy.

This debate began in 1975, with the publication of E. O. Wilson's magisterial *Sociobiology: The New Synthesis*. For 26 chapters, Wilson, an entomologist based at Harvard University, provided a state of the art review of what was then known about how and why animals behaved in the way in which they did. The book was a synthesis of the revolutionary new thinking about the ways in which selection and adaptation could work on a population, and introduced the word "sociobiology" to the wider public. Essentially, "sociobiology" was a project intended to explain the rules that both encouraged and made it possible for animals to live in social groups, showing how Darwinian natural selection could be supplemented by theories of kin selection and inclusive fitness (or the idea that an animal's "fitness" is measured not only by his or her own reproductive success but also by the success of close genetic relatives) to elucidate the basis on which altruism, for example, might evolve. After all, if the business of an animal is to concentrate on maximizing the genetic contribution to the next generation – that is, have as many offspring as possible – then why should any animal be willing to share resources or to refrain from reproduction? The answer was to be found in the closeness of the relationship between the altruist and the recipient and in the adoption

of a perspective that considered the reproduction of the gene to be more significant than the reproduction of the individual, a position now associated most publicly with the work of Oxford biologist Richard Dawkins. J. B. S. Haldane encapsulated this calculative, genetic perspective when he joked, in response to the question of whether he would lay down his life to save that of his brother, "No, but I would for two brothers, or for eight cousins." Since one shares half of one's genes with one's brother, and one eighth with a cousin, Haldane was specifying the conditions under which it would make sociobiological sense to risk one's life. This perspective on the evolutionary basis of social behavior was uncontroversial (and has remained largely so) when applied to animals. However, in Wilson's twenty seventh chapter, he extrapolated these rules of animal behavior and applied them to human beings. And the result was explosively dramatic.

Wilson's final chapter was, in practice, the first sustained attempt to analyze the impact that human biological evolution might have had on the development of human culture and society since World War II had ended. Opposition to Wilson's speculative attempt to extend his account of animal society to human society was immediate, intense, and passionate. However, what was interesting was that this hostility initially arose not from the social sciences – who had, by the 1970s, reached a consensus that biology was irrelevant as an explanatory factor in dealing with human society – but from other biologists. In fact, and ironically, the core of the opposition to Wilson's sociobiology was to be found in the office beneath his own at Harvard's Museum of Comparative Zoology – the office belonging to Richard Lewontin, another Harvard biologist, but one who was at that point committed to the development of a holistic, Marxist biology that would work toward the attainment of greater human freedom and equality. Lewontin was a key figure in the establishment of the Sociobiology Study Group, which along with the Boston based organization Science for the People wrote a letter to the *New York Review of Books*, which condemned sociobiology on two fronts: first, the absence of adequate scientific evidence in its support, and second, the restrictive and anti democratic political philosophy that they

felt underpinned the theory. When the letter was published in November 1975, it compared Wilson's account of human sociobiology to the eugenic sterilization laws introduced in the years before World War II by the United States, and to the gas chambers of Nazi Germany. Wilson's final chapter may not, as he maintains, have been an attempt to demonstrate that aggression, war, and xenophobia were inevitable and natural aspects of human society, but it certainly provoked violence and intemperate language on both sides of the debate, including the public and physical assault on Wilson himself – a rare event in modern scientific debate, but one which demonstrated the depth of the passions that had been provoked by the suggestion that human culture and society might have their basis in biological evolution.

Biological opponents of sociobiology, such as Lewontin and his late Harvard colleague Steven Jay Gould, adopted a holistic rather than a reductionist account of how evolutionary processes might work, opposing the adoption of an overwhelmingly genetic perspective and attacking what they considered to be the adaptationist assumption. They criticized the presumption that most, if not all, of an organism's features must be "adaptive" – that is, must have some kind of biological purpose – as the modern version of the older assumption that evolution must in some sense be progressive, and emphasized the difficulty of identifying individual genes, much less specifying what they might prove to be genes "for." They stressed the need to consider gene and environment in interaction, drawing much more strongly from the themes and methods of natural history rather than the experimental tradition in biology. Rather than attempting to isolate genes in the laboratory, they chose to use particular historical and observational examples to demonstrate the way in which, for example, the particular genetic heritage of an individual (their "genotype") is limited in its physical expression (the "phenotype") by the nature of the environment in which the individual finds itself. In one of their most famous examples, they pointed to the fact that while genetics determines how tall an individual could potentially grow, it is the environment that determines the extent to which that potential will be realized. Individuals with the capacity to

grow to 6 feet 2 inches will not reach that scale in the absence of adequate childhood nutrition – and in fact, may turn out to be shorter than individuals with a smaller genetic capacity but a better nurturing environment. If the ultimate cause of a clearly measurable and unarguable factor like height can be so difficult to define, then they emphasized that it must be even more important to consider the environmental (social, cultural, economic) context when examining such politically charged and difficult to define notions as "aggression," "intelligence," and the differences between the sexes.

By the early 1990s, the sociobiological dust had largely settled, but the role of evolution in explaining human society and culture had by no means been settled. At least three different sets of linked debates were now taking place in academic discussions of evolution. In the first place, while sociobiology *per se* had for the most part disappeared, in its place had emerged two different disciplines. One, behavioral ecology, applied a sociobiological perspective to animal behavior. The other, evolutionary psychology, worked from the premise that the human mind, like the human brain, was the product of evolution, and that if one wished to explain how the mind worked, the place to start was from the evolutionary perspective. In the second place, what has become known as the "Science Wars" had broken out between groups of scientists and social scientists. Ironically enough, at least part of the impetus for these "wars" had been the attempts by some sociologists and historians to study and to explain science and scientists; just as the social scientists had been affronted by the presumption that natural science could explain the complexities of human social behavior, so natural scientists were perturbed by the premise that scientific activities might have social or cultural explanations. Thirdly and finally, another new discipline had emerged, in the United States at least – that of "scientific creationism," the idea that it was possible to provide a scientific explanation of the events in the biblical story of Genesis – or at least, that it was possible scientifically to disprove the theory of evolution.

Evolutionary psychology, along with associated disciplines like memetics and gene-culture coevolution, sought to take the sociobiological project a few steps further, basing their

approach on the idea that it was both possible and useful to identify specific mechanisms within the human brain that were the product of evolution, in the sense that they could be shown to impact on the presumed reproductive success of a given individual. While the term evolutionary psychology had been coined in the 1970s, it was not until the publication of Leda Cosmides and John Tooby's book *The Adaptive Mind* (1992) that the term came to be widely used, and in 1995, the "Darwin@LSE" research group was established at the London School of Economics, with the intent of raising the public profile of Darwinism both within the social sciences and with regard to a more general audience. At the heart of evolutionary psychology was the premise that there existed within the human mind "evolved psychological mechanisms," which are universal to the human species, but may be expressed in one sex rather than another, or at particular points in the life cycle of the individual. These psychological mechanisms were largely identified by reference to what evolutionary psychologists call the "environment of evolutionary adaptedness" (EEA) – or the hypothesized, hunter-gatherer type societies in which humanity evolved, and which were therefore the environments in which, unlike industrial urban capitalism, humanity is biologically adapted for success. Thus, for example, one controversial explanation for the apparent fact that men prefer younger, slimmer women, and women prefer older, richer men, could be that in the EEA female fertility could be directly linked to youth and the pattern of bodily fat deposits, or the hip to waist to breast ratio (hence, "slimness"). Men would therefore prefer to mate with those females whose physique seemed to offer the best chance of reproduction, while those females who restricted their reproductive activity to males with adequate resources (wealth) to take care not only of them, but also of any children that might result, would reap larger benefits in terms of their contribution to the next generation.

This perspective has attracted much criticism from social scientists. Like sociobiology, the basic premise of evolutionary psychology was that universals of human nature existed, but the question remained of whether such universals can be proven to have a biological

or psychological existence, or whether they are the product of the dominance of certain cultural stereotypes – were they the result of socialization rather than evolution? Similarly, many critics have pointed out that paleoanthropology can realistically be certain about very few of the characteristics thought to be associated with the posited "environment of evolutionary adaptedness," making many evolutionary psychology hypotheses seem speculative at best, and at worst attempts to naturalize the political and sexual inequalities of western industrial capitalism. Similar critiques were made of the other novel disciplines that emerged in the 1990s with the intent to apply evolutionary insights in order to explain human culture and society. Memetics, for example, sought to treat culture in the same way that biologists dealt with the body, searching for the "memes" that formed the basis of cultural interaction in the same way that "genes" were the basis of sexual reproduction – but defining "memes" was shown to be problematic at best, since examples of memes provided by memeticists tended to range from advertising jingles to western Christianity.

However, the 1990s also saw the emergence of what has become known as the Science Wars, and the debate surrounding the place of evolution in cultural and public life soon became caught up in the wider struggles over the relationships that existed, or were thought to exist, between science and society. In 1994, Paul Gross and Norman Levitt, a biologist and a mathematician, published a book called *Higher Superstition*, which sought to expose and to denounce what they considered to be the insidious attacks on science and rationality that were being made by feminists, multiculturalists, environmentalists, and sociologists. They argued that the programs for understanding the social context of science that had been in the process of development since the publication of Kuhn's *Structure of Scientific Revolutions* (1962) were not in fact intended to study science at all, but to subvert and to denounce it by demonstrating that science was "merely" a cultural construction. Exacerbated by Alan Sokal's "spoof" article in the journal *Social Text*, the Science Wars blazed for most of the latter half of the decade, and at their heart was the question of whether scientific knowledge was a true representation of natural reality or the product

of social constructionism. Since many of the debates surrounding the role and impact of evolution on the understanding of human social life tend to turn on a similar pivot, it is understandable that they came to be partly subsumed within the bigger picture. However, it was unfortunate, since it led to a situation in which battle lines became drawn even more deeply than might otherwise have been the case. As in the example of sociobiology, this also divided biologists. Many biologists were unhappy with a situation in which what they considered to be speculative and tentative claims about the evolutionary basis of human society were being treated as hard fact and presented to the public as such. In response, they found themselves lumped by their colleagues with unspecified hardline feminist multiculturalists, were accused by these colleagues of being unwilling to accept the existence of "facts," and were, for example, invited to "test" the law of gravity by jumping out of an upper story window.

In some senses, particularly in the American case, there were genuine grounds to fear that science, and especially evolution, was indeed under attack. The potential for conflict between the revealed truth of the Christian religion and the developing scientific worldview had existed since geological and paleontological research had indicated as far back as the eighteenth century that the earth might be far older than the Bible suggested, and the relationship between science and religion in the West had been seriously damaged by the publication of Darwin's theory of evolution. However, in most cases and countries the debate was resolved in science's favor, even though it took the pope until 1996 to recognize that evolution was more than a hypothesis. Science and scripture could largely live in peace, since the one concerned itself with *how* things happened, the other with *why* these things occurred. The prominent exception to this separate spheres argument could have been found in the Bible Belt of the American Midwest. Opposition to the teaching of Darwinism and evolution had grown more fervent after the end of World War I, culminating in the state of Tennessee's Butler Act of 1925, which forbade the teaching of evolution in public schools. This Act directly led to the Scopes trial of 1925, in which Christian fundamentalism won the battle but eventually lost the war; John T. Scopes was

found guilty of teaching evolution and fined, but the coverage of the trial made creationists, as they were shortly to become known, into a laughing stock. However, by the late 1970s, fundamentalism was on the rise in the United States once more, and with increased numbers, self confidence, and a new theoretical twist focusing overwhelmingly on the notion of "intelligent design," creationists began to set in train a number of legal challenges to the teaching of evolution.

By 1980, a number of institutes such as the Institute for Creation Research and the Center for Scientific Creation had been established and the pattern of the modern day battle between science and religion had been set. A key difference between the present day debates and those characteristic of the past has been the role played by "science," and incidentally, by the sociology of science. Emphatically, modern opponents of evolution have done their best to don the robes of science. The names "scientific creationism" and "creation science" themselves indicate the extent to which creationists have attempted to adopt the language, rhetoric, and at least ostensibly, the methodology and philosophy of science to justify their position in the public sphere, presenting themselves as more "scientific" than their opponents. So, for example, creationists have tried to demonstrate that the theory of evolution is not falsifiable in the Popperian sense, and therefore cannot be scientific. They have adopted Kuhn's account of paradigm change as a justification for the existence of two incompatible but equally scientific accounts of life on earth – that given according to the theory of evolution by natural selection, and that provided in Genesis. They have seized on evolutionary debates such as those surrounding punctuated equilibrium (the idea that major biological change might occur suddenly and swiftly, rather than steadily and gradually) as evidence that the evolutionary consensus was falling apart, requiring more and more special pleading to be allowed to stand as science. A number of legal challenges to the teaching of evolution in schools were made in the closing years of the twentieth century, and more have occurred in the new millennium. In early 2005, the Kansas State Board of Education again held hearings on the topic of the scientific status of evolution and concluded

that it was indisputably in doubt. Opponents of evolution have, in some cases successfully, managed to portray evolution publicly as a theory in crisis, and to accuse scientists of fraudulently seeking to hide this in planning school textbooks. Ironically, the theory that was initially criticized by social scientists for naturalizing and therefore legitimizing the social and political inequalities of capitalist society is itself now the target of ultra conservatism in the United States.

At the same time, another strand of evolutionary theorizing has developed over the course of the twentieth century, a position that has become known as feminist sociobiology. Initially, one of the major criticisms of sociobiological thought had been that it portrayed men and women as fundamentally and naturally different types of beings with separate spheres and interests, which therefore accounted for the fact that most societies are patriarchal to a greater or lesser degree, that there is inequality between the sexes, and that woman's ultimate concern was with her children. This depiction of the woman's place as firmly situated within the home had been one of the key reasons for the intense and furious feminist opposition to sociobiology when it emerged in the late 1970s – and the emergence of such a perspective at the point when the equal rights movement was gaining ground on both sides of the Atlantic was not treated by activists as a coincidence. However, during the late 1980s and the 1990s, an increasing number of scientists and social scientists have been willing to put themselves forward as “feminist sociobiologists.” The intent of writers such as Sarah Hrdy, an anthropologist from UC Davis, Barbara Smuts (a primatologist at the University of Michigan), and Patricia Gowaty (a biologist from the University of Georgia) has been to address the initial feminist critique of sociobiological thinking and to seek to use insights from evolutionary theory to understand the nature of gender relations in the twenty first century as a first step to learning how to change them. They have revolutionized the way in which biology has studied and portrayed reproduction in humans and other animals, most famously by challenging the association between the feminine and the passive, demonstrating the active role that female animals take in making

reproductive decisions. Overall, this new take on understanding the nature of evolution represents an active attempt by some scientists to combine their feminist politics with their scientific practice, identifying and avoiding both the naturalistic (that what *is* is what *ought* to be) and the moralistic (that what *should not* be *is not*) fallacies, in order to develop new perspectives on both sexual politics and evolution as well as the reconsideration and the reordering of the relationship between evolutionary theory and human societies in the new millennium.

exchange network theory

Henry A. Walker

Exchange network theories focus on the processes through which network structures affect power distributions, power exercise, and benefits gained in exchange. Sociologists use the term exchange network theory to describe several theories, models, and research programs. The field grew out of research in social exchange theory – an orienting strategy that traces its roots to Aristotle and other philosophers of classical antiquity. George C. Homans's *Social Behavior* (1961, 1974), John Thibaut and Harold H. Kelley's *The Social Psychology of Groups* (1959), Richard M. Emerson's paper on "Power-Dependence Relations" (1962), and other contemporaneous works are responsible for reinvigorating exchange research in the late 1950s and early 1960s.

Modern exchange theories focused initially on dyadic relations. Homans (1961) discussed triads, but exchange network research awaited theoretical statements from Emerson (1972), James S. Coleman (1973), and David Willer and Bo Anderson (1981). Their theories directed the attention of exchange analysts to the unique properties of triads and larger networks.

Emerson (1972) extended the dyadic power dependence theory to networks and devised the standard definition of a network as a system of two or more connected exchange relations. Two relations are connected if exchange in one affects exchange in the other. For example,

the system A B C is a three actor network built by connecting two dyads, A B and B C, at B. Power dependence researchers were also responsible for the innovative use of resource pool relations rather than exchange relations in experiments. Positions in resource pool relations do not exchange valued resources. Instead, they bargain for shares of a resource pool but gain nothing if they fail to reach agreement. Although they are not true exchange relations, the payoff matrices for resource pool negotiations mirror those in exchange situations.

Coleman's theory, *The Mathematics of Collective Action* (1973), was the first to create systematic procedures that locate power in network structures, describe power use and resource flows, and predict payoffs at equilibrium, i.e., the amounts at which exchanges stabilize in the long run. Willer and Anderson began work on elementary theory in the mid 1970s and presented it in *Networks, Exchange, and Coercion* (1981). Elementary theory presented models that make clear the distinctions between social exchange, economic exchange, conflict, and coercive relations. The late 1980s and early 1990s brought new developments. Elementary theory spawned network exchange theory (Markovsky et al. 1988; Willer 2000), Friedkin (1992) developed the expected value model, and Bienenstock and Bonacich (1992) applied game theory to network structures.

Exchange network theories differ in their assumptions about the processes that link structure to power. They also have different scope limitations, including the numbers and types of network connections to which their analyses apply. Finally, they use different procedures to locate power and to predict power use and payoff structures.

NETWORK CONNECTIONS

The distribution of power in exchange networks varies with the types of connections within them. Power dependence theory uses two characteristics of network relations – symmetry and valence – to devise a typology of connection types. Consider an A B C network. It is connected *unilaterally* if AB exchange affects BC exchange but BC exchange does not affect AB exchange. It is *bilaterally* connected if

AB exchange affects BC exchange and BC exchange affects AB exchange. The network is *positively* connected if exchange in one relation increases the likelihood of exchange in the other. Finally, it is *negatively* connected if exchange in one relation reduces or precludes the possibility of exchange in the second. Four connection types are possible: unilateral positive, unilateral negative, bilateral positive, and bilateral negative.

Network exchange theory uses alternative classifications that have the advantage of compatibility with standard logical operators (e.g., *conjunction* and *disjunction*). The classification takes into account N_i , the number of positions connected to a position i ; M_i , the maximum number of relations from which i can benefit; and Q_i , the minimum number of relations within which i must exchange before it can gain any benefit. Given two or more relations connected at i , the five connection types are defined as follows:

inclusive connection : $N_i = M_i = Q_i > 1$

exclusive connection : $N_i > M_i \geq Q_i = 1$

null connection : $N_i = M_i > Q_i = 1$

inclusive exclusive connection : $N_i > M_i \geq Q_i > 1$

exclusive null connection : $N_i = M_i > Q_i > 1$

For example, the A B C network is *inclusively* connected at B if B can benefit from exchanges with A and C, and B must exchange with both before gaining any benefit ($N=2=M=2=Q=2>1$). The network is *exclusively* connected if B can benefit from exchange with either A or C (but not both), and *must* exchange with one in order to gain any benefit ($2>1\geq 1$), and similarly for the remaining connection types. Dyads are a special connection type for which $N_i=M_i=Q_i=1$; they are *singularly* connected.

PROCEDURES FOR LOCATING POWER

Power, as structural potential, affects the benefits that positions gain in exchange. Early network research on ideas drawn from other theoretical perspectives (e.g., field theory)

identified a positive relationship between a position's centrality and its capacity to influence other positions. Bavelas's (1950) studies of communication networks are classic examples. Bavelas's work was followed by important advances in the mathematical theory of graphs, theories of structural and cognitive balance, and in other field theoretic conceptions like French's (1956) theory of power. Students of power and influence used that research to infer that positional centrality is an important determinant of power and influence.

Power dependence researchers explored the possibility that centrality had important effects on power distributions. Their experiments showed that centrality is not a reliable indicator of power in exchange networks (Cook & Emerson 1978). Moreover, the failure of network centrality as a criterion for locating power led theorists to develop alternative methods for locating power in exchange networks.

Coleman introduced a theory based procedure that can be applied to any number of actors who hold varying quantities of any number of valued resources. The procedure uses two matrices to characterize network structures. The first is an N (number of positions) \times R (number of resources) interest matrix (X) that describes the proportion of each position's interest in every resource. The second is a $R \times N$ control matrix (C) that describes the proportion of each resource controlled by every position. Matrix operations are used to estimate a final control matrix (C^*). Coleman's theory predicts that equilibrium is reached when the resources of a position, j , committed to control an event, i ($r_j x_{ji}$), are equal to the value of full control of the event times the proportion of the event j controls at equilibrium ($v_i c^*_{ij}$). That is, equilibrium is achieved when $v_i c^*_{ij} = r_j x_{ji}$ is true for all positions in the network. A very limited number of experiments and simulations have tested Coleman's ideas but the experimental networks include several types of network connections.

Power dependence theorists initially devised procedures that used the graph theoretic concept of *vulnerability* to measure a position's dependence. One measure, reduction in maximum flow (RMF), indexes the degree to which a network is disrupted by removal of a position. A revised procedure, CRMF, is based on removal

of a line, but both measures proved inadequate for analyzing a variety of networks. Current power dependence procedures measure B's dependence on A as the amount of resources that B can gain from exchanges with A minus the resources B can gain from alternative exchange partners (e.g., C in the A B C network). The theory claims that B will exchange with A (or C) over successive exchanges until they reach the point at which the partners are equally dependent on one another. With few exceptions, power dependence procedures have been applied to negatively connected networks.

The first elementary theory experiments had participants exchange resources, but researchers using network exchange theory typically use the resource pool paradigm. Network exchange researchers initially used a graph theoretic power index (GPI) – a weighted function of the non intersecting lines in a network's graph – to predict the distribution of power. Today, network exchange theorists use elementary theory's law of resistance to predict the distribution of power. The law of resistance holds that exchanges occur at the point at which partners are equally resistant to a proposed exchange. Analysts use an "iterative seek" procedure in which actors are presumed to negotiate exchanges in decreasing order of benefits. They negotiate exchanges in high benefit relations before turning to relations from which they can expect to gain lower maximum benefits. The law of resistance is highly general and the method has been applied to networks with several connection types, although most studies have examined exclusively connected networks.

Researchers using the expected value model use a five step process to calculate payoffs in exchange networks. First, identify the network structure. Next, identify *every* possible exchange. At the third stage, use empirical findings or theory to identify or calculate the probable frequency of occurrence for each exchange. The fourth stage requires calculating the amount of resources that can be acquired by each position in the network. Finally, calculate the expected values of payoffs and use them to infer power distributions. Researchers in this tradition were the first to apply their procedures to a variety of networks in which relations have unequally valued resource pools (Bonacich & Friedkin 1998).

Bienenstock and Bonacich's (1992) application of game theory to exchange networks is based on the core solution for cooperative games. The approach is organized around the characteristic function, v . For every subset of positions in a network, $v(S)$ is the total payoff members can gain no matter what other positions do. The core solution is the set of all payoffs that satisfies individual, coalition, and group rationality. Individual rationality exists when no position in a coalition will accept a payoff less than it could gain on its own. Coalition rationality exists if no set of actors will accept total benefits that are less than they could earn in a coalition and that is true of every coalition in the network. Finally, group rationality exists when a grand coalition of all members maximizes its total reward. Game theory implies that networks for which there is a core will have stable outcomes. Those without a core will have unstable outcomes because some positions can improve their payoffs by joining a coalition. The core solution has been applied to exclusively connected networks, but the method can be applied to a range of situations including many that fall outside the scope of exchange network theories.

FUTURE RESEARCH

Exchange network theories have substantially advanced sociological understanding of network power processes, but the limited range of settings to which they have been applied tempers their success. Exchange networks are dynamic. They change as ties are broken, as new and different ties with different network connections are added, and as resources gain or lose value in cycles of plenitude and scarcity. Studies of dynamic systems will probably require settings in which actors with many valued resources make real exchanges. Revised theories will take into account and integrate understandings of other processes – like status and legitimacy – that affect network behavior. These are daunting challenges and much difficult work lies ahead.

exchange-value

Rob Beamish

Exchange value – the most misunderstood concept in Marx’s analysis of the commodity – is best grasped by moving from the immediate to the complex. Useful things found in nature or procured without exchange and used for private consumption (directly or in the creation of something else for private use) have a qualitatively distinct, concrete, natural form. Their utility is what matters; they have no relevant social substance even if they are produced through labor. They are not exchanged; they do not contain value.

Useful things intended for exchange are procured or produced by social labor. Exchangeable commodities have a visible, concrete, useful form and an invisible social substance of quantitatively comparable units of congealed, socially necessary, simple, abstract, labor time. This invisible substance is value; the commodities’ “plain, homely, natural form” is the physical repository of their value (Marx 1976: 138).

To be exchanged, the abstract value congealed within each commodity must achieve a particular form of expression. That form only arises in the social relations of exchange; it is, therefore, a social form. As the formal expression of value arising through exchange, Marx termed it the commodity’s exchange value.

It is often thought that value and exchange value are interchangeable concepts; they are not. Commodities’ value – the socially necessary, simple, abstract labor time congealed within them – only exists abstractly. One cannot directly see, touch, taste, smell, or hear value; immediately its reality is invisible. Value becomes manifest only in exchange – exchange value is the manifest expression of value.

Commodities’ values first became manifest in simple exchange. The congealed value of 20 yards of linen first became manifest in the “the equivalent form of value” – an equivalent form that could be seen, touched, etc. (one coat, for example). The coat became the visibly manifest, equivalent form of value for the linen – it is the manifest exchange value of the linen. The equivalent form is a particular instance of exchange value; it arose in the social process of exchange and because it became manifest in exchange, it was, and remains, a social form. Use value is the concrete form of the commodity, exchange value its visible, social form, while value remains abstract and not directly visible.

As exchange expanded, the particular social form of value changed (as did the name of each particular form). The “expanded, relative form of value” represented exchange where a number of commodities manifested each other’s value (e.g., 1 coat = 10 lb. of tea = 1 ton of iron = 20 yards of linen). The “general form of value” arose as one commodity began habitually to represent the abstract value of others (e.g., the value of 1 coat, 10 lb. of tea, 1 ton of iron was expressed in the form of 20 yards of linen). As one commodity habitually became

the general form – most often a precious metal – the “money form of value” arose. A sum of money became the mature, social expression of exchange value.

exercise and fitness

Joseph G. Grzywacz

Exercise, physical activity, and fitness are distinct but interrelated concepts (Caspersen et al. 1985). Physical activity is any bodily movement produced by skeletal muscle, while exercise is planned and repeated physical activity that is structured into individuals' lives with the purpose of maintaining or improving some attribute of either health or skill (i.e., fitness). Exercise, therefore, is a subset of physical activity that is characterized by being patterned and purposeful, and fitness is a consequence of exercise. Exercise and fitness are of major interest because they are implicated in premature death, a wide variety of disease states, and quality of life (US Department of Health and Human Services [USDHHS] 1996).

Sociological inquiry around exercise and fitness expanded and changed during the past 25 years. In the early to mid 1980s a small number of studies were catalogued in sociological abstracts delineating social status predictors of exercise and between group differences in beliefs about exercise. In the late 1980s to early 1990s research activity doubled. During this time researchers documented how different social processes such as victimization and job stress were associated with exercise among adults, and papers began describing exercise as a form of consumption. Research doubled again in the mid to late 1990s, with research

continuing to illustrate differences in exercise patterns *between* different groups (e.g., class), as well as examinations of exercise *within* specific contexts (e.g., rural) and social groups (e.g., age and gender groups). Body image research and papers examining the role of exercise in the social expression of self also established a foothold during this period. Research doubled again from the late 1990s to the present. New strands of research in this period included comprehensive models examining determinants of exercise from multiple levels, the role of exercise (and other health behaviors) in health trends over time and health disparities between groups, and essays examining the political agenda underlying the promotion of exercise.

This broad summary of the literature illustrates three major points about sociological research around exercise and fitness. First, exercise has only recently become an explicit area of sociological research. Second, there has been exponential growth in exercise research beginning in the mid 1990s. This growth coincided with ongoing initiatives to promote exercise as well as ongoing evaluations documenting limited success toward those goals (McGinnis & Lee 1995). Finally, the majority of research is characterized predominantly as “sociology for exercise” or the application of sociological concepts and tools for understanding variation in exercise so as to better refine or develop techniques for promoting exercise and fitness (Thorogood 1992).

There are several issues and areas for additional sociological analysis that would contribute to advancing middle range theorizing about exercise and fitness. Two lines of future inquiry that are particularly important are outlined below. The first advocates more sociological analyses that expose the inherent values and assumptions underlying the meaning of exercise and the widespread promotion of exercise (i.e., sociology of exercise). The second line of advocated inquiry involves continued application of sociological concepts and tools to enhance understanding of exercise (i.e., sociology for exercise).

Critical analysis of the interests and values underlying exercise is needed. Consider two individuals: the first person walks 3 miles each day for diabetes control whereas the second person walks 3 miles each day to work.

By definition (Caspersen et al. 1985), the first person is "exercising" while the second person is not; yet, the physiological (and presumably the health related) consequences of each person's structured and repeated activity are similar. (Recent public health recommendations have shifted from physical activity with the explicit goal of health maintenance or improvement to simply regular sustained physical activity [USDHHS 1996]; nonetheless, discourse around exercise continues to prioritize leisure time physical activities that benefit cardiorespiratory health.) This example raises important questions, such as: "Whose interests are being served by widespread attempts to promote exercise?"; "Which values are being prioritized through advocacy and surveillance of exercise?"; and "What are the social consequences of defining exercise in terms of health intentions?" (Thorogood 1992).

A related area for critical analysis is an examination of the alternative approaches to health promotion that remain underdeveloped while social attention is directed toward exercise. Without question, exercise contributes to a variety of salutary outcomes; however, these same outcomes are frequently equally influenced by other factors. For example, results from the Alameda County study indicated that the nine year mortality risk for both women and men attributed to health behaviors (including physical activity) was comparable in magnitude to the mortality risk attributed to social integration (Berkman & Breslow 1983). Why is there widespread effort to increase the number of people who exercise, but no widespread effort to increase the number of people who volunteer in their communities or participate in civic organizations? Likewise, a focus on exercise and what are typically considered individual lifestyle "choices" diverts discourse from other strong determinants of poor health such as social inequalities and poverty. To what extent does public attention toward exercise distract from other viable targets for improving population health? Answers to questions such as these will expose the values and interests underlying a focus on promotion of exercise, and they would offer important insight for building comprehensive theories of exercise.

A second line of future inquiry involves more dynamic and multifaceted applications of

sociological concepts and tools for understanding exercise. Additional analyses in three areas appear particularly fruitful for theory building. First, additional analyses addressing the structure versus agency debate is essential for explaining trends in exercise over time, and for guiding attempts to increase rates of exercise. Kerry McGannon and Michael Mauws (2002) exemplify how sociological tools can be combined to explain how social and temporal contexts constrain exercise while they are simultaneously being created and recreated through individual activity and social discourse. Next, more research is needed that links exercise to social processes at multiple levels in the social ecology. Scholars have speculated exercise and other health promoting behaviors have been undermined by macrostructural changes such as modernization and deindustrialization (e.g., Kumanyika et al. 2002). However, very little empirical support exists corroborating these claims, nor is there documentation of the mechanisms through which these changes might occur. Finally, more research examining the complex influence of multiple social structures and processes on exercise is needed. Catherine Ross's (2000) analysis of neighborhood crime, neighborhood poverty, individual poverty, and fear of victimization illustrates the relevance of multifaceted models of exercise, and it exemplifies the convergence of sociological methods of sampling, measurement, and analysis that allows for this type of research.

Sociological analyses around exercise and fitness have accelerated over the past 10 years; yet, sociology has much more to offer for building theory that adequately explains exercise. Two lines of future inquiry for advancing exercise theory have been advocated. The first involves critical analysis of exercise. The goal of this sociology of exercise is to more clearly expose the interests, values, and assumptions underlying exercise and the widespread promotion of exercise in the population. The second line of advocated research involves the continued study of exercise using sociological concepts and tools. The goal of this sociology for exercise is to move toward a more dynamic and multifaceted understanding of exercise. Results from each line of inquiry alone are insufficient, but together they provide the building material for useful theories of exercise.

exhibitionism

Brendan Gough

Sexual exhibitionism is often regarded as “deviant,” both in commonsense discourse where (male) “flashers” are categorized as “perverts,” and in psychiatric discourse where terms denoting pathology (such as antisocial and obsessive compulsive) are applied. In the

Diagnostic and Statistical Manual of Mental Disorders IV (DSM IV, American Psychiatric Association, 1994), exhibitionism is considered a paraphilia in which sexual fantasies and behaviors involve exposing one’s genitals to a stranger. Diagnosis of exhibitionism is dependent on sexual fantasies and/or sexual behavior eliciting clinically significant distress or impairment in social, occupational, or other important areas of functioning.

The vast majority of literature on sexual exhibitionism can be located in a psychomedical context and is based on the assessment and treatment of men who have been incarcerated for criminal and/or disturbing behaviors. Despite this body of work, there is little consensus as to the defining characteristics of this population. While some researchers portray this group as shy, inhibited, and non assertive, others point to low self esteem, difficulty expressing anger, and poor self control. In addition, some research reports an association between men who exhibit and later violent sex offenses, such as rape and pedophilia.

The virtual omission of women from the literature on sexual exhibitionism is significant since the practice of exhibitionism by women is now more prevalent than ever. In early work on women exhibitionists, gender differences were highlighted. The implicit assumption is that women’s exhibitionism is somehow less real or less serious compared to that of men. For example, it has been claimed that a woman could not become erotically aroused by exposing her genitalia – unlike a man. It was thought that women are driven to exhibit themselves to gain attention and to prevent feelings of worthlessness. This emphatic disavowal of sexual desire for women who exhibit can be linked to wider cultural discourses which constrain the expression of an independent, assertive female sexuality – what has been termed the “missing discourse of desire.” Indeed, feminists have long criticized the role of medicine and psychology in reinforcing traditional gender relations through pathologizing “gender inappropriate” behavior. In particular, the unitary conceptualization of paraphilia within psychiatry does not account for variations in practice, context, and reception of sexual exhibitionism.

However, more recent work with non clinical samples of women exhibitionists and

strippers points to the liberating and transgressive potential of exposing one's body to others, including Internet exhibitionism, part of a burgeoning industry in interactive sex entertainment. For example, interviews with women exhibitionists highlight themes of personal fulfillment and control, peer group support, and a sense of responsibility concerning when and where to exhibit. Sociological and feminist debate, however, considers the social construction of women's exhibitionism in social contexts where patriarchal ideals and practices prevail. For example, while sexual exhibitionism might be regarded as emancipatory on an individual level, critical analysis may implicate this practice within the conventional male gaze on female "objects." It is clear that further theoretical and empirical work is needed to interrogate the place and meaning of women's exhibitionism in different contexts. In addition, research is required on male exhibitionists which is not constrained by psychiatric constructions of dangerous and deranged "flashers" so that the complexity and variability of this phenomenon are examined. Future work should thus explore exhibitionism with diverse samples differentiated by gender, age, social class, sexual orientation, and ethnicity.

existential sociology

Joseph A. Kotarba

Existential sociology emerged in the late 1970s as the most recent version of everyday life sociology. Writers in this perspective have attempted to integrate symbolic interactionism's powerful concepts of the self and the situation, phenomenological sociology's emphasis on the social construction of reality, and ethnomethodology's telling critique of conventional sociological theory and methods, with an innovative argument for the centrality of embodiment and feelings to human agency. Thus, *existential sociology can be defined descriptively as the study of human experience in the world (or existence) in all its forms*. A key feature of experience in the (contemporary) world is change. Existential sociologists expect, if not assume, change to be a constant feature of people's lives, their sense of self, their experience of the social world, the other people that populate the social world, and the culture that provides meaning for life. Everyday life is more than merely situational and problematic, a point on which all the varieties of everyday life sociology generally agree. Everyday life is *dramatic* – in an aesthetic sense – and experienced as such. In contrast to Erving Goffman's dramaturgical model of social life, the drama that existential sociologists see in everyday life does not follow anyone else's script. The actor is simultaneously writer, producer, and actor on a stage not necessarily of his or her choosing, but one that cannot simply be exited without confrontation with the producer/director (e.g., agents of social control).

At a more general and intellectual level, existential sociology can be seen as part of the broad intellectual trend that can be traced back to the Copernican revolution that supplanted the Aristotelian belief in an inalterable and immutable universe. Since then, modern thought has progressed from the search for absolute and eternal ideas to a reconceptualization of reality as change, flux, complexity, and uncertainty. Robert Baumer (1977: 20) has referred to this historical trend as the movement from "being to becoming," that is, to "a mode of thinking that contemplates everything – nature,

man, society, history, God himself – *sub specie temporis*, as not merely changing but as for ever evolving into something new and different.” The notion of *becoming* is central to both existential philosophy and existential sociology.

Existential sociology reflects the renaissance occurring in existential thinking with, for example, renewed interest in the work of Friedrich Nietzsche, which served as a precursor to existentialism through its illumination of the dark and non rational side of humanity. Historical events also occasion a reconsideration of existentialist thought. The revitalization of intellectual life in the recently democratized central and eastern European societies has freed writers there to explore pro individualistic and anti collectivist paradigms such as existentialism. For example, Leszek Dzielicki's *Paradise in a Concrete Cage* (1988) is a first person account, written by this well known Polish ethnographer, of the strategies developed by intellectuals in post World War II Poland to maintain a semblance of individuality and intellectual legitimacy within that gray and depressing Stalinist era.

EXISTENTIAL (SOCIAL) THOUGHT

Existentialism gained its greatest popularity and acceptance in the years after World War II, at first in Europe, and then several years later in America. The writings of French philosopher and writer Jean Paul Sartre, as well as the novels and essays of Albert Camus, are among the most important reasons for existentialism's initial popularity and acceptance (Craib 1976). The formal literature of the existentialist tradition is known by its emphasis on these central themes: the nature of the individual; the central role of the passions and emotions in human life; the nature and responsibilities of human freedom; and the non rational aspects of life. Diverse existentialisms have arisen to address these questions, and all express a certain attitude of rebellion. It is a rebellion against the received and inherited “wisdom” of one's culture, against what most people think, against what most intellectuals consider true, against the herd mentality and its popular culture, against conformity. From

this, it is not surprising that existentialists have aligned themselves with the full range of human values and opinions, including fundamentalist Christianity, anti Christianity, atheism, humanism, communism, anti communism, socialism, anti socialism, left wing politics, right wing politics, anti politics, pro democracy, anti democracy, and so on. Even on some of the fundamental intellectual or philosophical issues, existential thought runs the full gamut: Sartre says that individuals have absolute freedom, whereas for Nietzsche, freedom is a philosophical myth.

Existentialist ideas began influencing the social sciences more than four decades ago. In 1962, Edward Tiryakian published *Sociologism and Existentialism*, an influential work of sociological theory, which sought to resolve two very different ways of thinking about human social life and existence. The first is “sociologism,” a term commonly associated with the seminal sociological scholarship of Émile Durkheim. The idea behind sociologism is very simple to grasp: individuals don't matter very much. Social reality is a reality *sui generis*, or in and of itself, to use Durkheim's phrase. The larger social structures of society are seen as superseding and transcending the lives and meanings of individuals, and are not dependent on individuals in any meaningful way. The second perspective is that of “existentialism,” and this view tends to place a much greater emphasis on individuals, their choices, their responsibilities, their passions, their decisions, their cowardice, their virtues, and so on. Tiryakian proposed to bring these two seemingly incompatible perspectives together in a manner that would retain the integrity of each. In 1967, Peter Berger and Thomas Luckmann published *The Social Construction of Reality*, which, like Tiryakian's work, sought to bring together two prevalent social science views about life. Berger and Luckmann used the terms *man in society* and *society in man* to draw a similar analytical contrast (see also Manning 1973).

In 1977, Jack Douglas and John Johnson edited a collection of essays titled *Existential Sociology*, in which the authors engaged structuralists and other cultural determinists, stressing the relative freedom of individuals, and the partial independence of individuals from their social and cultural contexts. They emphasized

that social and cultural realities are not determined, but rather are socially constructed, meaning that the agency, choice, will, intention, and interpretation of actual individuals were decisive for the determination of meaning. That early work additionally stressed the relative independence and dominance of feelings and emotions over thoughts and cognition, and in addition their relative independence and dominance over values.

FEELINGS AND EMOTIONS

Emotions and emotionality underlie all human experience and social life, shaping all subjectivity, intersubjectivity, everyday interaction, social exchange, social bonds, and social divisions. Emotions are not only inevitable, and not only forces destructive to the social order. Emotions are also essential for forming and perpetuating human societies.

As Candace Clark (2002) notes, since the scientific community made the conceptual and linguistic shift from the *passions* to *emotions* 300 years ago, most of the disciplines in the social and natural sciences – including sociology – proceeded to ignore emotions and emotionality. In short, for most of western history, common wisdom has presumed that emotion and reason are separate and contradictory, and the bias has been against emotions and in favor of cognition. In the midst of this overrationalized view of life, Jack Douglas strongly reminded other sociologists to take seriously the notion of *brute being*, the core of feeling and perception that is our innermost selves, our beings. He argued that we must recognize the crucial role that passions play in social life.

The study of feelings and emotions in existential sociology stresses the importance of seeing how people experience affect in concrete situations when they are attempting to define and master immediate problems and issues. Put differently, existential sociology argued early for the ethnographic study of feelings and emotions. Every culture and subculture includes its own emotion labels, definitions, feeling rules, roles, values, “knowledge,” and “social logics” pertaining to emotions and emotionality. Together, these make up what Clark refers to as *emotional culture*. The taken for granted

“knowledge” and “social logics” concerning when emotions occur, how emotions affect the individual, and what happens when emotions are expressed or displayed to others are also extremely variable. Emotional culture in western societies includes such capitalistic phenomena as the greeting card industry, which instructs us in the proper feeling rules toward mothers, fathers, friends, birthday boys and girls, the bereaved, benefactors, the sick, recovering addicts, valentines, and marriage partners through which authentic sentiments are reduced to small pieces of paper – with accompanying envelopes to facilitate delivery.

THE EXISTENTIAL SELF

In 1984, Joseph Kotarba and Andrea Fontana edited a collection of essays titled *The Existential Self in Society*. The book was an effort not only to refine the existential sociology perspective, but also to respond to a movement within sociology toward renewed interest in humanistic and interpretive concepts of the self as opposed to positivistic and measurable concepts. The concept of the existential self is concerned with the experience of individuality – through the perspective of the subject – as it unfolds, adapts, and copes in concrete, everyday life situations. Since existential sociology is designed to monitor closely the tone of and trends in contemporary life, attention is given to the many people in all walks of life who are dissatisfied with both their own sense of who they are and society’s demands of who they should be. Furthermore, new social forms, whether they are entirely innovative or simply reconstructions of existing social forms, are reflections of new and innovative ways in which members of our society are coming to think and feel about themselves. The conceptual relationship between innovative social forms and changes in the self is complex. But it is clear that many members of our society are actively seeking new ways of fulfilling and expressing themselves.

The following working definition of the existential self is intended to display the relative fluidity of the modern self and to account for the internal as well as external manifestations of the process of making sense of one’s being.

The existential self refers to an individual's unique experience of being within the context of contemporary social conditions, an experience most notably marked by an incessant sense of becoming and an active participation in social change. The following is a brief discussion of the major features of the existential self.

The existential self is embodied. Being within the world means that feelings and primordial perception precede rationality and symbol use and, in fact, activate them. Joseph Kotarba's (1983) research on chronic pain clearly illustrates the limitations on the rational/scientific/medical strategies for making sense of and mastering bodily afflictions. Most people in western societies, regardless of social class, trust modern medicine to alleviate pain. Yet, when pain fails to go away or respond to modern medicine, the person is likely to abandon unquestioned faith in modern medicine in favor of whatever alternative healing modalities promise help (e.g., chiropractic, faith healing, holistic health care). The primary definition of being sick comes from the person's body. Even the social definition, "it's all in your head" (or more professionally, "psychosomatic disease") that refers *directly* to the self, is disregarded. The wellness movement is another example of the ways people in late capitalistic American society attempt to perfect the self by perfecting the body in terms not only of health but also of appearance (Kotarba & Bentley 1988).

The existential self is becoming. Jean Paul Sartre, in his philosophical and literary writings, argued dramatically that we are condemned to be free, condemned to choose continually who we are, because existence in itself is empty and meaningless. The phenomenologist Maurice Merleau Ponty takes a more moderate view, and one more conducive to the sociological project, by insisting that our becoming must be grounded in the real, social world if we have any intention of being effective in coping with the given world. The individual is encouraged by the brute reality of life to acquire some distinctive *style* of self actualization. Freedom, therefore, is viable only to the degree that it allows us to *control* the goals of our endeavors and to utilize them for our own personal growth. Put differently, existentialism presents an image of the self to society relationship that is quite apropos to today's world: the image of

the self *confronting* society. We constantly attempt to shape and manipulate society – that is, society as we experience it – in order to have it as a meaning resource for fulfilling our most basic needs and desires. Existential sociology examines the various social activities in which people engage to preclude or escape meaninglessness including, for example, religion, spirituality, recreational drugs, music, dance, art, sex, athletics, self actualization, and intellectual endeavors.

The existential self evolves continuously throughout the life course. Joseph Kotarba (2003) has described the way rock 'n' roll music informs the becoming of self among middle aged people in our society. Rock 'n' roll can affect adults' sense of self in many ways: as continuing rock 'n' roll fans, as parents of rock 'n' roll fans, as adults who construct lifestyles and work styles incorporating rock 'n' roll, as citizens contending with the political and ethical issues surrounding rock 'n' roll, and simply as people who, over the course of their lives, have come to use rock 'n' roll music and culture as a source of meaning for their joys and their sorrows.

The existential self occasions social change. The sociological literature on social change commonly places the self in the position of dependent variable. From the existential perspective, the self is seen as an active agent in the process of social change. The intention is not to swing the pendulum of causality in the opposite direction, by asserting the preeminence of the Meadean "I" over the "me," but only to view the process of social change *reflexively*. By focusing on the self, we can arrive at the following tentative model of social change. The individual perceives an uncertainty or change occurring in the segments of the social world that impinge on his or her existence. This uncertainty, whether it is "real" or imagined, can occur at the level of technology, attitudes, values, rules, or any other realm of social life. What is crucial is that the individual views these changes as *critically relevant* to maintaining a coherent and satisfying self. This relevance can take two forms. The individual may decide that uncertainty in social conditions leaves existing modes of self actualization obsolete. Or the individual may perceive new possibilities for self actualization emanating from

changing social conditions. In either case, the individual will seek new means for self actualization, usually in the form of new social roles. This search is likely to be a *collective* endeavor, for the individual will either actively cooperate with others who are experiencing similar concerns for self and are therefore instituting new social forms, or he or she will passively share in new social forms created by others. The process is then perpetuated when these new social forms provide still other individuals with a new basis for perceiving uncertain social conditions. The recently evolved role of the ex nun and the emergence of the primitive house church are examples of the ways people respond to uncertainty occurring in organized religion (Kotarba & Fontana 1984).

THE POSTMODERN TURN IN EXISTENTIAL SOCIOLOGY

In 2002, Joseph Kotarba and John Johnson edited *Postmodern Existential Sociology*, a collection of essays examining similarities between the two perspectives, such as distaste for the master narratives of the Enlightenment and an appreciation for rich and metaphoric writing. Furthermore, the advent of postmodern thinking in sociology over the past 15 years or so provides some useful strategies for the continuing evolution of existential sociology.

An important similarity between postmodernism and existential sociology is the heavy emphasis both place on understanding the mass media. Postmodernism sees the mass media as virtually synonymous with culture in late capitalistic society. In existential sociology, the mass media are becoming one of the most compelling audiences to the self, supplanting religion, the community, and even the family to some extent (Altheide 2002). While it is clear that the mass media significantly shape politics, from an existential perspective politics and power reside in the same everyday life world as personal feelings and perceptions. Existential sociology views macro phenomena like politics and power as practical processes and tasks that are conducted and accomplished by real people in concrete situations. Following the existential notion of agency, politics becomes an organized method for people to manage personal feelings,

perceptions, and objectives. The techno/rave scene in popular music, for example, illustrates the way young people have given up on the politics of their (baby boomer) parents by dis regarding the political values of the 1960s (e.g., revolt against tradition, commitment to changing the world) in favor of *existential strategies* (Hitzler & Pfadenhauer 2002) by which youth struggle dramatically for individuality through obstinate aesthetic tendencies, private preferences, or simply conspicuous patterns of consumption.

One of the most fruitful points of compatibility between the existential sociology project and postmodernism is in the area of research methods. Both perspectives agree that there is no inherent hierarchy of methods in terms of power or truthfulness. Research is inherently political/organizational and practical, and it is designed and conducted for practical reasons (e.g., journal editorial policies and contract obligations to funding agencies). Both perspectives also agree that the composition and style of research reports and the dissemination of research findings are personal to the writer. Finally, both perspectives argue that the researcher has an extremely wide range of presentation styles to choose from, many of which can be borrowed from the humanities as well as the social sciences. Innovative methods include video ethnography, such as Kotarba's (2003) portrayal of the impact of popular music on everyday family interaction, and the short story, such as Fontana's (2001) vivid autobiographical description of working as a pit crew member while studying racing at the Bonneville Speed Week.

Finally, existential sociology is critical of certain features of postmodern social thought. In addition to their tendency to rely on arm chair theorizing instead of direct observation of the everyday life world, some postmodern sociologists discard one of the most important concepts in everyday life sociology: the subject. The term "subject" refers to the object/actor we study in sociology. As Stanford Lyman (1997) notes, in everyday life sociology, including existential sociology, the subject is a real person of flesh who navigates through life encountering situations and making the best decisions possible, not merely a *narrative* or story created by mass mediated culture.

expectation states theory

Joseph Berger and David G. Wagner

Expectation states theory is a set of closely related theories concerned with various processes by which social interactants or *actors* draw information from their social and cultural environment and organize that information into expectation states that determine their interaction with others. Together with research testing these theories and other research applying them to problems in everyday interaction (such as interracial interaction in schools), expectation states theory constitutes a *theoretical research program*.

POWER AND PRESTIGE THEORY

The earliest work in the expectation states program concerns the process by which actors come to develop differentiated performance expectations even in groups where there are no significant social or cultural differences among the group members. Extensive research by Bales and his colleagues (see, e.g., Bales et al. 1951) revealed that inequalities in the initiation of activity, in the receipt of activity, and on ratings of best ideas and group guidance regularly emerged in such groups. Moreover, these inequalities were highly stable and, with the possible exception of sociometric rankings, tended to be intercorrelated. Berger (1958) and Berger and Conner (1969) conceptualized these inequalities in their power and prestige theory as components of an *observable power and prestige order* (OPPO) consisting of four intercorrelated behaviors: (1) chances to perform (action opportunities); (2) problem solving attempts (performance outputs); (3) communicated evaluations of problem solving attempts (rewards); and (4) changes of opinion when confronted with disagreement (influence). They argued that actors communicate their evaluations of one another's contributions in the normal course of interaction, eventually leading members to anticipate differences in their future performances, and thus to develop differentiated expectation states for these actors. Once these states emerged, they determined the

group's OPPO. While OPPO behaviors are functions of the underlying expectations, they also operate to maintain these expectations. Consequently, the power and prestige order of the group tends to be stable. An important consequence of a generalized version of this theory (Berger & Conner 1974) is that inequalities in any of the OPPO components can determine an actor's position in the OPPO.

STATUS CHARACTERISTICS THEORY

While the power and prestige theory deals with groups in which actors initially are similar in terms of status, status characteristics theory is concerned with groups in which actors initially differ on such status distinctions as gender, race, or occupational positions. Extensive research already existed in the 1950s and 1960s that showed that such status distinctions consistently determine the distribution of power and prestige positions in task groups, whether or not the distinction is related to the group's task. The initial status characteristics theory (Berger et al. 1966, 1972) was formulated to provide a theoretical explanation for this important relation. Subsequently, this theory was elaborated and formalized (Berger et al. 1977).

Berger et al. (1977) explain the powerful effect of such statuses as gender or race on the basis of the activation in the group of cultural beliefs about these status distinctions. A coherent set of such beliefs defines a *diffuse status characteristic* (D). A characteristic (say gender) is a D for members of a given group at a given time if and only if they (1) differentially evaluate two or more states of D (e.g., men are in general more highly valued than women), (2) stereotypically relate these states to evaluated states of other characteristics (e.g., men are more mechanically skilled than women), and (3) stereotypically relate these states to similarly evaluated generalized expectation states (e.g., men are more capable at tasks in general than women).

Beliefs about D become *salient* in a group if D is relevant to the group's task (e.g., the task is believed to favor males or females) or if D is a basis of discrimination in the group (as in a mixed gender group). If salient and not initially

relevant, D will normally become relevant to the group's task by a *burden of proof* process, unless its relevance is challenged or it is dissociated from the task. By virtue of this process, status advantages tend to be generalized from situation to situation. If new actors enter the group, a *sequencing* process takes place. Status information relating to the new actor is processed by the original actors through the salience and burden of proof processes and adjoined to their previously processed information as long as the original actors remain in the situation.

If multiple status characteristics become relevant to the group's task, actors will combine the information in these characteristics in forming performance expectations for themselves and the others. This *combining process* takes into account whether the status information creates expectations for success or failure at the task, and the weight of that information, that is, how relevant it is to the group task. Finally, by the *basic expectation* assumption, once actors have formed expectations for self and others, their power and prestige behaviors are determined by these expectations.

Status characteristics theory is abstract and general and has been used to describe status processes involving a variety of status distinctions including gender, race, ethnic identities, educational attainment, occupational position, sexual orientation, physical attractiveness, and the status structures of work teams. In addition, the theory's arguments and consequences have been supported by extensive empirical studies (e.g., Wagner & Berger 2002).

GROWTH OF THE PROGRAM

Over the years the expectation states program has grown in different ways. Formulations have been constructed that represent theoretical *elaborations* of the core status characteristics theory described above. One such extension is the reward expectations theory that describes how reward expectations are formed in status situations, and how reward allocations generate performance expectations. Other formulations have been constructed that represent *integrations* of different theories in the program. This is the case with the behavior status theory that

Table 1 Expectation states theory^a

<i>Theory</i>	<i>Phenomenon of concern</i>
Power and prestige	Emergence and maintenance of differentiated OPPOs in status-undifferentiated groups
Status characteristics and expectation states	Formation of expectation states based on socially established status characteristics; maintenance of OPPOs in status-differentiated groups
Distributive justice	Reward expectations and justice norms arising from the relation of reward expectations to actual reward allocations
Sources of evaluation	Formation of expectations and their effects on behavior based on evaluations of actors with legitimated rights to evaluate others
Evolution of status expectations	Evolution of status expectations as actors move through different task situations with different others
Status cues	Role of verbal and non-verbal cues in attributions of performance capacities and status categories; their dependence on actors' established status positions
Reward expectations	Interrelation of status, task, and reward expectations and the inequalities created by these interrelations
Behavior-status	Integrates research from the power and prestige and the status characteristics branches
Evaluations-expectations	Integrates research from status characteristics and source theory branches
Legitimation	Legitimation and delegitimation of OPPOs
Sentiments and status	Interrelation of affect and sentiment processes with status and expectation state processes
Multiple standards	How multiple standards maintain prevailing status distinctions
Status construction	How institutionalized status characteristics are socially constructed and diffused through society

^aOPPO stands for "observable power and prestige order."

integrates concepts and principles of the power and prestige theory with those of status characteristics theory. Finally, there are formulations that represent *proliferations*. These theories tackle new substantive problems while building on the concepts and principles already established within the program, as with Foschi's theory of multiple standards. Table 1 presents a summary of the major current branches of the program.

An examination of two of these branches will illustrate how the concerns of the program have expanded and deepened. The first of these branches extends the core status characteristics theory to deal with the legitimation of power and prestige orders. The second focuses on an important new problem within the program concerned with the creation of status characteristics.

STATUS LEGITIMATION THEORY

Ridgeway and Berger (1986, 1988) have constructed an extension of the core status characteristics theory that describes the conditions and processes under which the power and prestige order in a group becomes legitimated. First, they argue that the cultural framework within which the group operates incorporates consensual beliefs about how high and low valued status positions are generally allocated to individuals, based on their status characteristics, capacities, and achievements. One such belief, for example, is that men occupy more highly valued status positions than women in contemporary American society. The theory describes the conditions under which such beliefs become salient to the members of a given task oriented group.

Actors use these consensual beliefs to form expectations regarding who will occupy which status positions in their immediate group. In turn, these expectations determine differences in the generalized deferential behaviors – the respect, honor, and displays of social importance that actors accord to different members of the group. Assume, for example, that the generalized deferential behaviors accorded to a high status member of the group are validated by the behaviors of others in the group. Then, the greater the number of others validating the original deferential behaviors, the greater the probability that the power and prestige order involving that high status member becomes a legitimated order. Behavior is *validated* if others engage in similar behavior, or at least engage in no behavior that contradicts the original behavior.

With legitimation, expectations become *normative* and there is a presumption that group members will collectively support them. The high status actor, for example, has the right to initiate problem solving behaviors for the group and to expect others to be receptive to such behaviors. At the same time, others have the right to expect more valued contributions from that actor than from the low status actor. In addition, high status actors come to have rights to exercise controlling behaviors, such as dominating behaviors, over the actions of others. Berger et al. (1998) extended this theory to explain how a legitimated power and prestige order can become delegitimated. This formalization shows, among other things, how the number of status distinctions in a group, the consistency of these status distinctions, and their relevance to the group's task each affect the likelihood that a power and prestige order becomes legitimated.

The legitimation theory explains why low status group members meet resistance when they engage in task behaviors that are "above their rank." It also explains the resistance that women and other minorities generally face when they employ directive behaviors while in task leadership positions. The theory argues that, because of their low external status, when such individuals become task leaders they are more likely to be working from a non legitimate OPPO, and therefore controlling and directive

behaviors are less likely to have collective support in the group.

The legitimation theory, like other theories in this program, is multilevel. Action in a group is conceived of as occurring with a pre given cultural framework. A particular process begins with the activation of status categories or cultural beliefs from that framework. But for a structure to emerge (say, a power and prestige order) or for it to be transformed (say, from a non legitimated order to a legitimated order) requires the contingent behaviors of the members of the group, whose expectations and validating behaviors are involved in creating the local realities within which the group operates.

STATUS CONSTRUCTION THEORY

Cecilia Ridgeway (1991, 1997) has theorized about the construction of institutionalized status characteristics. She argues that such characteristics are most likely to emerge out of what she calls *double dissimilar situations*. Imagine a population in which individuals are discriminated in terms of a characteristic, call it N, whose states partition the population so that there are two types of people, N(a) and N(b). Further imagine that there are differences in this population in the resources (rewards) possessed by individuals so that there are individuals who are resource rich and those who are resource poor. These resources or rewards may be either tangible (like honorary titles and corner offices) or intangible (like friendship or social acceptance).

Now consider an interaction situation involving N(a) and N(b) type individuals such that, say, the N(a)s are rich and the N(b)s are poor. Because of the resource difference in the group, Ridgeway argues, a power and prestige structure will emerge where those in higher positions tend to be the resource rich and those in lower positions are resource poor. On the basis of this inequality in behavior, individuals are likely to develop beliefs in the abilities of the N(a) and N(b) individuals that correspond to their different positions in the OPPO. In general, if particular states of N are consistently associated with high and low resources, and if they occur frequently enough, eventually

individuals come to attribute differences in individual abilities to their respective states of N. A new status characteristic will thereby emerge. Finally, for such an evolving characteristic to become part of actors' cultural framework, it must be diffused through a social population.

CONCLUSION

Expectation states theory is a cumulative program. Current theories say more than what was said in earlier theories, and current empirical research upon which these theories rest is more extensive than that of an earlier stage. Further, investigation of expectation states processes has spread beyond the United States, now including research in Israel, Germany, Australia, Canada, Holland, and Turkey. At the same time, researchers are tackling new theoretical and applied problems while working with the concepts and principles within the program. (For a more detailed review of much of this work, see Wagner & Berger 2002). Thus, although it clearly has grown (see Table 1), expectation states theory is still a program in progress.

expectations and aspirations

Stephen L. Morgan

Expectations and aspirations, within sociological research on education and social inequality, are stable prefigurative orientations composed of specific beliefs about one's future trajectory

through the educational system and one's ultimate class or status position. As adolescents age, these expectations and aspirations are presumed to condition current behavior and, in the process, become self fulfilling prophecies.

Expectations are sometimes distinguished from aspirations in theory, with the former stipulated to refer to realistic appraisals rather than idealistic goals. Nonetheless, almost all empirical research has utilized the same straightforward operationalization for both concepts. Educational expectations and aspirations are usually answers that adolescents give to questions such as: "Do you plan to go to college?" and "As things stand now, how far in school do you think you will get?" Occupational expectations and aspirations are responses to questions such as: "What type of job do you plan or expect to have at age 30?" These survey questions elicit future plans which are generally quite optimistic, thereby qualifying as sufficiently idealistic for the analytic and explanatory purposes of those who wish to have a measure of aspirations.

Measurement of expectations such as these began with the work of educational psychologists employed by the Educational Testing Service in the early 1950s. Since then, sociologists have dominated their study. The 1953 article entitled "Educational and Occupational Aspirations of Common Man Boys," written by Joseph A. Kahl, is perhaps the most influential early piece, as it was completed as a research report for the Mobility Project led by Talcott Parsons just as structural functionalism was in its ascendancy. The central question of Kahl's study was: "What influences the aspirations of the boys in the lower middle levels of the status range whose environment gives them a wide choice?" (Kahl 1953: 189). In order to show that "these boys must make a conscious and pointed decision at some stage of their careers," he reported the results of in depth interviews with 24 boys of middling social origins, only half of whom expected to go to college. His goal was then to "explore the decision making of such boys," whose beliefs about the future were not predetermined either by expectations grounded in their class origins or by their cognitive abilities. And, out of this effort, he sought a reasonable causal account of how beliefs about

the future are shaped by one's social context and then compel future behavior.

Kahl identified parental pressure as the most crucial determinant. Corresponding roughly to two types of students, he saw two types of parents: those who sought to raise "getting by" children and those who sought to raise "getting ahead" children. Many of the factors that determined whether parents adopted the getting ahead rearing strategy were idiosyncratic, and yet there were some systematic differences, relating primarily to parents' own experiences with the labor market. The extent to which parents saw college as having a genuine payoff for occupational attainment, based on their own experiences in the workplace, was crucial.

Expectations and aspirations then became the central mediating variables in status attainment research, especially following the publication of what became known as the Wisconsin model of status attainment, which was based on early analyses of the Wisconsin Longitudinal Survey (a random sample of all high school seniors in the state of Wisconsin in 1957). The full model was first fully specified in two influential articles published in the *American Sociological Review* (Sewell et al. 1969, 1970) that reported results from both the original 1957 data and the follow up 1964 data on the educational and early occupational careers of young men. Beyond Kahl's focus on exploring the formation of college plans, these articles aimed to explain the entire process of educational and occupational attainment.

According to the original 1969 Wisconsin model, the joint effects of a high school student's family background and mental ability on his eventual educational and occupational attainments can be completely explained by the expectations that others hold of him. In particular, significant others – parents, teachers, and peers – define expectations that students then internalize as educational and occupational aspirations. Because the underlying theory assumes that students are compelled to follow their own aspirations, the model is powerfully simple and implies that significant others can increase a student's educational and occupational attainment merely by increasing their own expectations of him.

Regarding the specific processes of aspiration formation, the principal social psychological theorist, Archibald Haller, maintained that aspirations are formed in three ways: imitation, self reflection, and adoption. Once formed, Haller (1982: 5–6) wrote that aspirations are embedded in “approximately consistent and mutually reinforcing cognitions” which then “have an inertia of their own and are expressed in corresponding behavior.” Thus, students’ educational and occupational aspirations become stable abstract motivational orientations (see Spenner & Featherman 1978), and the measured Wisconsin model variables – college plans and expected future occupation – are merely realistic indicators of these latent status aspirations.

Although the theory underneath the original Wisconsin model was bold, its creators were well aware of its many limitations. Almost immediately upon publication, they began to qualify its basic mechanisms, and in the process they weakened its most parsimonious theoretical claims by allowing for the addition of supplemental direct effects of socioeconomic status on all endogenous variables. The addition of paths not predicted by the original socialization theory presented problems for the powerful claims of the 1969 article. In particular, the claim that significant others could raise students’ educational and occupational attainments by simply imposing higher expectations on them began to seem less credible. Instead, the revised models of the 1970s and 1980s suggested that significant others and educational institutions have direct effects on the educational and occupational attainment process. If so, then it had to be conceded that structural constraints (and perceptions of them) could play an important role in models of educational and occupational attainment.

These revisions were, in part, a response to research critical of the Wisconsin model and its supposed origins in structural functionalist sociology. Critics argued that structural constraints embedded in the opportunity structure of society should be at the center of all models of educational attainment, and hence that concepts such as aspirations and expectations offer little or no explanatory power. Most famously, Pierre Bourdieu dismissed the work of sociologists who assert that associations between

aspirations/expectations and attainments are causal. Rather, for Bourdieu, the unequal opportunity structures of society “determine aspirations by determining the extent to which they can be satisfied” (Bourdieu 1973: 83). And, as such, aspirations and expectations have no autonomous explanatory power, as they are nothing other than alternative indicators of attainment.

Critiques such as these helped to bring an end to the brief dominance of status attainment theory in the study of social inequality. The cutting edge of research in the sociology of education then shifted toward studies of institutional and demographic effects on educational achievement and attainment, as researchers generally sought to avoid debates over whether social psychological models unnecessarily blame the victims of a constrained opportunity structure. Even so, variables measuring expectations continued to be deployed as standard covariates in the sociology of education for the analysis of a variety of outcomes (for a review, see Morgan 2005: ch. 2).

In the most recent research, however, new models of educational attainment are now attempting to account for the beliefs that determine educational attainment. Some researchers have begun to focus on changes in post industrial society and how these are reflected in the processes by which adolescents plan for their futures. Others, seeking to integrate sociological and economic approaches, have attempted to build models of educational achievement and attainment that are sensitive to the exogenous impact of shifts in costs and benefits but that also give substantial scope to independent belief formation processes that can overwhelm narrow expected utility calculations. By and large, this new work has the potential to help determine how structural dynamics should be incorporated into models of educational attainment, as structure that is imposed from the outside as the rigid constraints maintained by institutions or via individual responses to perceived structural constraints.

experiment

Javier Lezaun

Experiments play a central role in most theories of science as the key mechanism through which theories and hypotheses are corroborated or refuted. Most especially in the work of Karl Popper, the acceptability of a theory – the extent to which it can be conceivably characterized as “scientific” – is determined by its falsifiability, that is, by whether it can be put to the test in an experiment. Experimentation is thus the foremost *trial of strength* for knowledge claims, and the sociology of science has investigated the particular social practices on which this validating function rests.

Despite its centrality to most analytical accounts of the scientific enterprise, experimentation, as a social practice in its own right, has remained largely unexamined by philosophers

of science, partly because their emphasis tended to be on theory and theoreticians. Also, it was often assumed – rather than proved – that experiments were fundamentally logical processes reducible to a series of analytical steps, and thus capable of determining unambiguously the validity of a knowledge claim if conducted according to formal instructions.

In the 1980s the sociology of science began to take a closer look at how knowledge is put to the test under experimental conditions. This investigation was influenced by the groundbreaking historical work of Kuhn (1962), and received much of its inspiration from innovative reinterpretations of the history of science. A sociologically informed history of science and a historically grounded sociology of science have since walked hand in hand.

One of the most influential treatments of experimentation in the sociology of scientific knowledge (SSK) was offered by Collins (1985). Collins’s main target was the idea of replication: that success or failure in repeating of an experiment could provide unambiguous and definitive proof of the validity of a knowledge claim. The notion of replication can appear deceptively straightforward in most empiricist philosophies – a matter of simply repeating an experiment under slightly different conditions to prove or disprove a previous result. Yet Collins showed that the practice of replication cannot be reduced to a set of formal rules. A judgment of sameness or difference is always required, and such a judgment is irreducibly social. If, for instance, Experiment B fails to reproduce the result of Experiment A, the experimenters must still decide whether this is because Experiment A was faulty or wrong, or rather because Experiment B was dissimilar from A in key aspects and thus failed to truly replicate and therefore disprove it. According to Collins, any effort to formulate a set of definitive rules about this decision, the attempt to turn what is a matter of socially embedded judgment into a series of formalized, logical steps, would lead to an “experimenter’s regress.” The meaning of a particular experiment is thus a matter to be determined by a community of expert practitioners making a socially contingent judgment, a judgment that is dependent on, among other things, the distribution of tacit skills and instruments

among experimenters. This notion of a regress, or an incapacity to reduce the social practices and processes of experimentation to a set of formal instructions, was developed as the “testers’ regress” by MacKenzie (1989, 1990) in his sociological studies of technological communities and missile accuracy.

A similar concern with the role of material context and technical instruments, skills and tacit knowledge, the social organization of scientific groups, and the enculturation of its practitioners characterizes the work of Galison (1987) on the history of twentieth century experimental physics. Galison focused on the decision to end an experiment and declare an experimental inquiry completed. His study drew attention to the extent to which experimentation had become, at least in the field of physics, a distinct epistemological tradition and a social practice in its own right, shaped by the particular social and material conditions under which it was conducted (for a continuation of this research program, see Galison 1997).

Another strand of historical research helped shed light on the social uses of experiments and on the role of experimental practices in the production of public demonstrations of truth. The book of Shapin and Schaffer (1985) was groundbreaking in its analysis of the context in which experimentation emerged as a particularly forceful and persuasive form of demonstration in early modern England, and in its parallel treatment of experimentation as an instrument of knowledge production and as a disputed component in the political philosophies of the time. Shapin and Schaffer contrast the opposing philosophies of Boyle and Hobbes, which reflected diametrically different views of the epistemological value of public experiments, as well as of the proper ordering of a political community. Central to Boyle’s ultimately victorious emphasis on observable experiments as the key machinery for the production of “matters of fact” was, Shapin and Schaffer argue, a logic of witnessing, by which the public testimony of those watching the proceedings (or, eventually, of those reading the experimental report) was fundamental to the legitimacy of the trial and the trustworthiness of its results. Science and experimentation were an essentially public form of knowledge making, to be conducted and displayed, literally or

virtually, before the eyes of reliable audiences. The rise of scientific experimentation in England, Shapin and Schaffer argued, went hand in hand with forms of political experimentation that also granted public witnessing a central role in political affairs. In further articles, these authors explored in more detail the role of the particular sites where experiments are conducted (Shapin 1988) and the function of the experimental apparatus in the production of conviction (Schaffer 1989).

The public nature of experiments, the degree to which audiences and their influence are central to the logic of experimentation, has become a central theme in the sociology of science (Gieryn & Figert 1990). It is contestable whether, as Collins (1988) has argued, the sociology of science should still try to draw a distinction between proper experiments, in which the result is up for grabs and an element of surprise cannot be ruled out, and mere “displays of virtuosity” or “demonstrations,” in which previous rehearsals reduce to a minimum the possibility of upsets, revelations, or failures, and whose purpose is simply to illustrate a principle to an audience.

Finally, the sociological and historical interest in the experimental production of knowledge in the natural sciences has more recently been extended to experimentation in the social sciences, particularly economics (Guala 2005; Muniesa & Callon 2006) and psychology (Dehue 2001; Brannigan 2004).

experimental design

Roger E. Kirk

Experimentation involves the deliberate manipulation of one or more independent variables followed by the systematic observation of the

effects of the manipulation on one or more dependent variables. The emphasis on experimentation in the sixteenth and seventeenth centuries as a way of establishing causal relationships marked the emergence of modern science from its roots in natural philosophy (Hacking 1983). According to the nineteenth-century philosopher John Stuart Mill, a causal relationship exists if (a) the cause preceded the effect, (b) the cause was related to the effect, and (c) we can find no other plausible alternative explanation for the effect. Carefully designed and executed experiments continue to be one of science's most powerful methods for discovering causal relationships. An *experimental design* is a plan for assigning experimental units to treatment levels and the statistical analysis associated with the plan (Kirk 1995: 1). The design of an experiment involves a number of interrelated activities:

- 1 Formulation of statistical hypotheses that are germane to the scientific hypothesis. A *statistical hypothesis* is a statement about (a) one or more parameters of a population or (b) the functional form of a population. Statistical hypotheses are rarely identical to scientific hypotheses – they are testable formulations of scientific hypotheses.
- 2 Determination of the treatment levels (independent variable) to be manipulated, the measurement (dependent variable) to be recorded, and the extraneous conditions (nuisance variables) that must be controlled.
- 3 Specification of the number of experimental units required and the population from which they will be sampled.
- 4 Specification of the randomization procedure for assigning the experimental units to the treatment levels.
- 5 Determination of the statistical analysis that will be performed (Kirk 1995: 1–2).

In short, an experimental design identifies the independent, dependent, and nuisance variables and indicates the way in which the randomization and statistical aspects of an experiment are to be carried out.

The seminal ideas for experimental design as it is practiced today can be traced to Ronald A. Fisher, a statistician who worked at a small agricultural research station 25 miles north of

London. The publication of Fisher's *Statistical Methods for Research Workers* in 1925 and *The Design of Experiments* in 1935 gradually led to the acceptance of three key principles of experimental design: randomization, replication, and local control or blocking. Fisher's idea that experimental units should be randomly assigned to treatment levels initially met with disdain. Prior to Fisher, most researchers used systematic schemes, not subject to the laws of chance, to assign experimental units. According to Fisher, random assignment has three important benefits. First, it helps to distribute the idiosyncratic characteristics of experimental units over the treatment levels so that they do not selectively bias the outcome of the experiment. Second, random assignment permits the researcher to compute an unbiased estimate of *error effects* – those effects not attributable to the manipulation of the independent variable. Third, random assignment helps to ensure that the error effects are statistically independent. Through random assignment, a researcher creates two or more groups of experimental units that at the time of assignment are probabilistically similar on the average.

Sometimes, for practical or ethical reasons, random assignment cannot be used. It is necessary, for example, to use preexisting or naturally occurring experimental units when the research question involves the effects of a particular illness. In such cases, a *quasi experiment* that is similar to an experiment except for random assignment can be used. Unfortunately, the interpretation of the results of quasi experiments is always ambiguous. In the absence of random assignment, it is difficult to rule out all variables other than the independent variable as explanations for an observed result. In general, the difficulty of unambiguously interpreting the outcome of research varies inversely with the degree of control that a researcher is able to exercise over randomization.

Fisher popularized two other principles of good experimentation: replication and local control or blocking. *Replication* is the observation of two or more experimental units under the same conditions. According to Fisher, replication enables a researcher to estimate error effects and obtain a more precise estimate of treatment effects. *Blocking*, on the other hand, is an experimental procedure for isolating

variation attributable to a nuisance variable. As the name suggests, *nuisance variables* are undesired sources of variation that can affect the dependent variable. Three experimental approaches are used to deal with nuisance variables:

- 1 Hold the variable constant.
- 2 Assign experimental units randomly to the treatment levels so that known and unsuspected sources of variation among the units are distributed over the entire experiment and do not affect just one or a limited number of treatment levels.
- 3 Include the nuisance variable as one of the factors in the experiment.

The third experimental approach uses local control or blocking. The procedure, which is illustrated later, isolates variation attributable to the nuisance variable so that it does not appear in estimates of treatment and error effects.

A statistical approach also can be used to deal with nuisance variables. The approach, which is called *analysis of covariance*, combines regression analysis with analysis of variance. The procedure involves measuring one or more concomitant variables in addition to the dependent variable. The *concomitant variable* represents a source of variation that has not been controlled in the experiment and one that is believed to affect the dependent variable. Through analysis of covariance, the dependent variable is adjusted to remove the effects of the uncontrolled source of variation. The potential advantages are (a) reduction in error variance and, hence, increased power and (b) reduction in bias caused by differences among experimental units where those differences are not attributable to the manipulation of the independent variable. Researchers often combine analysis of covariance with one or more experimental approaches in an effort to control more nuisance variables. The three principles that Fisher vigorously championed – randomization, replication, and local control – remain the foundation of good experimental design. Next, the layout and randomization for several simple experimental designs are described.

One of the simplest experimental designs is the randomization and analysis plan that is used with a *t* statistic for independent samples.

Consider an experiment to compare the effectiveness of two ways of presenting nutritional information – newspapers denoted by a_1 and TV denoted by a_2 – in getting obese teenage boys to follow more nutritious diets. The dependent variable is a measure of improvement in each boy's diet one month after the presentation. Assume that 30 boys are available to participate in the experiment. The researcher assigns $n = 15$ boys to each of the $p = 2$ presentations so that each of the $(np)!/(n!)^p = 155,117,520$ possible assignments has the same probability. This is accomplished by numbering the boys from 1 to 30 and drawing numbers from a random numbers table. The boys corresponding to the first 15 numbers drawn between 1 and 30 are assigned to treatment level a_1 ; the remaining 15 boys are assigned to a_2 . The layout for this experiment is shown in Figure 1.

The t independent samples design involves randomly assigning experimental units to two

levels of a treatment. A completely randomized analysis of variance design extends this strategy to any number of treatment levels. Again, consider the media experiment and suppose the researcher wants to evaluate the effectiveness of three media – newspaper, TV, and the Internet. Assume that 45 obese teenage boys are available to participate in the experiment. The boys are randomly assigned to the three media with the restriction that 15 boys are assigned to each. The layout and randomization procedures for the experiment are the same as those for the t independent samples design in figure 1, except that the completely randomized design has an additional treatment level, a_3 .

The two experiments just described use independent samples. Samples are independent if a researcher randomly assigns experimental units to p groups or randomly samples units from p populations. In both experiments, the nuisance variable of gender was held constant: only boys were used. Other nuisance variables such as initial obesity and age were probabilistically controlled by random assignment. Differences in improvement of the diets of the boys who received the same treatment level provide an estimate of error effects. Error effects reflect the idiosyncratic characteristics of the experimental units – those characteristics that differ from one unit to another – and any other variables that have not been controlled. Designs that are described next permit a researcher to use local control or blocking to isolate and remove some sources of variation that contribute to error effects.

One design for isolating a nuisance variable is the randomization and analysis plan used with a t statistic for dependent samples. As the name suggests, the design uses dependent samples. Dependent samples can be obtained by any of the following procedures:

- 1 Observe the experimental units under each treatment level.
- 2 Form sets (blocks) of experimental units that are similar with respect to a variable that is correlated with the dependent variable.
- 3 If the experimental units are people, obtain sets of identical twins in which case the units have similar genetic characteristics.

		Treatment Level	
Group ₁	Boy 1	a_1	$\bar{Y}_{.1}$
	Boy 2	a_1	
	M	M	
	Boy 15	a_1	
Group ₂	Boy 16	a_2	$\bar{Y}_{.2}$
	Boy 17	a_2	
	M	M	
	Boy 30	a_2	

Figure 1 Layout for a t independent-samples design. Thirty boys are randomly assigned to two levels of a treatment with the restriction that 15 boys are assigned to each level. The mean diet improvement for the boys in treatment levels a_1 and a_2 is denoted by $\bar{Y}_{.1}$ and $\bar{Y}_{.2}$, respectively.

- 4 If the experimental units are people, obtain units who are matched by mutual selection (e.g., husband and wife pairs or business partners).

Let us reconsider the media experiment. It is reasonable to assume that responsiveness to nutritional information is related to the amount by which a boy is overweight. The design of the experiment can be improved by isolating this nuisance variable. Suppose that instead of randomly assigning 30 boys to the treatment levels, the researcher formed pairs of boys so that prior to administering a treatment level the boys in each pair are overweight by about the same amount. The boys in each pair constitute a block of matched units. A simple way to form the blocks is to rank the boys from least to most overweight. The boys ranked 1 and 2 are assigned to block one, those ranked 3 and 4 are assigned to block two, and so on. In this example, 15 blocks of dependent samples can be formed from the 30 boys. After all the blocks have been formed, the two boys in each block are randomly assigned to the two media presentations. Clearly, the randomization plan for the t dependent samples design is more complex than that for a t independent samples design. However, the added complexity is usually accompanied by greater power to reject

	Treatment Level	Treatment Level
Block ₁	a_1	a_2
Block ₂	a_1	a_2
Block ₃	a_1	a_2
M	M	M
Block ₁₅	a_1	a_2
	$\bar{Y}_{.1}$	$\bar{Y}_{.2}$

Figure 2 Layout for a t dependent-samples design. Each block contains two boys who are overweight by about the same amount. The two boys in a block are randomly assigned to the treatment levels. The mean diet improvement for the boys in treatment levels a_1 and a_2 is denoted by $\bar{Y}_{.1}$ and $\bar{Y}_{.2}$, respectively.

Figure 3 Comparison of designs with crossed and nested treatments. In (a), treatments A and B are crossed because each level of treatment B appears once and only once with each level of treatment A and vice versa. In (b), treatment B is nested in treatment A because b_1 and b_2 appear only with a_1 while b_3 and b_4 appear only with a_2 .

a false null hypothesis. The increased power results from isolating the nuisance variable – amount by which the boys are overweight – so that it does not appear in the estimate of the error effects. The layout for this experiment is shown in Figure 2.

The layout and randomization procedures for the t statistic for dependent samples design can be extended to a design with any number of treatment levels. The design is called a *randomized block analysis of variance design*. It has $p \geq 2$ treatment levels and n blocks of dependent units. When the design has two treatment levels, the layout and randomization procedures are identical to those for the t dependent samples design shown in Figure 2.

Often, researchers want simultaneously to test hypotheses for two or more treatments each having two or more levels. This can be accomplished by using either a factorial design or a hierarchical design. As shown in Figure 3, a factorial design uses crossed treatments in which each level of, say, treatment B appears once and only once with each level of treatment A and vice versa. In a hierarchical design, each level of treatment B appears with only one level of treatment A . A hierarchical design has at least one nested treatment; the remaining treatments are either nested or crossed. For a discussion of these and other experimental designs, the reader is referred to the books on experimental design in the References and Suggested Readings.

experimental methods

Henry A. Walker and David Willer

An experiment is a research method for which the investigator plans, builds, or otherwise controls the conditions under which phenomena are observed and measured. Experiments are the investigative method of choice in the physical sciences, and increasingly in economics, but they are used less frequently in sociology. Experimental sociologists are disproportionately located in the research subfields of (small) group processes and social psychology.

There are two interdependent reasons why sociologists rarely use experiments. First, very few sociology training programs include courses or course materials that focus on the experiment as an investigative technique. As a

result, researchers unfamiliar with experiments turn to commonly used research techniques to study problems even if they are better studied experimentally. In turn, low demand for information about experimental methods contributes to the scarcity of systematic training. Second, limited information about experimental methods combines with unresolved debates within sociology to reduce further the numbers of sociologists willing to design experimental investigations. Unresolved issues include (1) the possibilities and uses of abstract explanatory theory in sociology, (2) the unique character of social phenomena, (3) the suitability of physical science techniques for sociological research, and (4) the artificiality of experiments.

Many sociologists and some non sociologists associate experimental research with theoretical explanation. They assume that experiments only test abstract theories and point to research in physics, chemistry, and other physical sciences as the standard. Abstract explanatory theories are presumed to be in short supply, if they exist at all, in sociology. In the most optimistic view, theoretical development in sociology is stalled by the unique character of social phenomena.

Those who presume that the uniqueness of social phenomena precludes application of experimental methods to them can hold any or all of several positions. Some take the position that sociological phenomena are temporally bound – much like events studied by historians. This position is often used to buttress a related idea – that social phenomena are inconstant – and it reinforces the (false) assumption held by many that science only explains immutable phenomena. In this view, temporal specificity and inconstant phenomena make social behaviors and processes unfit candidates for theoretical analysis and experimental tests of theory. Finally, some sociologists point to the artificiality of experimental situations as an objection to experimentation in sociology. They claim that experiments use artificially contrived settings and, in the worst case, studies of artificial situations are uninformative. In the best case scenario, experimentation can make only limited contributions to sociological knowledge.

Experimental sociologists recognize that each experimental study is only one stage in a

complex, multistage research process. The process begins when a researcher identifies constructs, conditions, or factors that are thought to be important for understanding the phenomenon of interest. For some experiments, researchers devise hypotheses – concrete statements about relationships between variables or operational measures – and identify *initial conditions*. Initial conditions are concrete empirical conditions that create a framework for the experiment. In many instances, the initial conditions persist for the life of an experiment, ending only at its conclusion. Experimental researchers also identify or develop *measures* to track changes in variables and to record *intermediate* and *final conditions*. Experimental data include measurements taken before, during, and at the end of an experiment. Taken as a whole, an experiment begins when a researcher creates or establishes the initial conditions. It continues with measurements of the processes under study and ends with observation, analysis, and interpretation of outcomes.

OBJECTIVES OF EXPERIMENTS

At the conceptual level, there are two and only two kinds of experiments. One class of experiments is designed to explore or discover phenomena and the other is designed to test theories. All experiments bring evidence to bear on hypotheses but only *theory driven experiments* test hypotheses drawn from theories or theoretical models. Exploratory experiments investigate purely speculative or pre theoretical hypotheses. Experimenters who design exploratory experiments create conditions in order to learn (or discover) what happens when a particular factor is present or absent in varying degrees. Researchers hope to uncover phenomena or relationships between phenomena. The conditions they create do not follow from the application of contrasting theoretical models. Instead, their designs follow the logic of Mill's (1919 [1875]) canons or of statistical tests. Most exploratory experiments have clearly defined *experimental* and *control* conditions. A typical control condition measures outcomes when a variable under study is absent (i.e., its value is set at zero). Results from control conditions are compared with results drawn from other

experimental conditions for which the value of the variable under study is non zero.

Many medical experiments are methods of discovery. A research team administers a new drug or treatment to a group of patients and observes changes in their conditions. Observations taken on participants in the experimental conditions are compared with participants in the control condition who do not receive the treatment. Control participants are often given placebos in medical experiments. Since placebos do not affect the phenomena under observation, the “experimental” variable under study is set at zero. Researchers use placebos to hold constant the effects of social psychological processes that might be triggered by the participant's awareness that she is being treated and observed.

Experiments designed to test theory investigate contrasting models that explain relations between theoretical constructs. Said somewhat differently, theory driven experiments observe relations between variables that measure key theoretical constructs in theories and models. As such, it is arbitrary to classify the conditions they study as either experimental or control conditions. For example, in his pioneering test of status characteristics theory, Moore created a condition in which female participants believed they had high education status compared with their partners. Moore compared results from that condition with a second condition in which female participants believed they had low education status relative to their partners. Actually, neither treatment condition is a control condition. Moore's objective was to determine whether variations in status affected behavior consistent with hypotheses drawn from the theory's basic arguments.

Exploratory and theory testing experiments have different roles in science and it is inappropriate to characterize either type of experiment as “better.” A researcher's choice of design depends on the question under investigation and the state of theory development in her field of endeavor. Researchers exploring questions that ask for systematic description or historical/empirical explanations will build method of discovery experiments. Researchers who have a well developed theory in hand will use the theory to design experimental tests of theory.

UNITS OF ANALYSIS

Participants in many sociological experiments are drawn from available pools of university students. The use of college students leads many non experimentalists to conclude that experimental researchers only study individual phenomena. The perception is accurate, but only for a select group of experiments. Experiments that investigate social psychological phenomena often focus on individuals. For example, many classic studies in the literature on equity and justice processes (Hegtvedt & Markovsky 1995) measure individual responses to situations that produce varying degrees of injustice. Data are collected on individuals and the individual is the proper unit of analysis.

By way of contrast, other studies conducted by sociologists who study group processes and social psychology collect data from individuals but relations and social structures are the proper units of analysis. Moore's study of status organizing processes involved participants who had either high or low status relative to their (simulated) partners. Observations were taken on individual participants but the data are informative of the processes that create power, prestige, and influence hierarchies in collectively oriented task groups. Neither the theory under test nor researchers in the status characteristics theory tradition are concerned primarily with the behavior of individuals.

Exchange network theory brings individuals into situations that require them to negotiate resource distributions under a variety of structural conditions. All exchange network theories make predictions for exchange outcomes – outcomes that vary with the structural conditions of exchange. The focus of such research is not on individuals' behaviors during negotiations but on how contrasting kinds of social structures affect the exchanges they make. Here, the exchange relation as it is embedded in a structure is the proper unit of analysis.

EXPERIMENTAL SITUATIONS

Researcher control is the hallmark of experimental investigations. However, sociological experiments are conducted in a variety of situations (or sites) and the degree to which

researchers can exercise control varies substantially across research sites. We describe natural, field, survey, and laboratory experiments in order of increasing experimenter control.

Natural Experiments

As the term implies, natural experiments occur in settings free of artificial contrivances. At times, researchers are able to take advantage of naturally occurring events to study important social phenomena. Natural experiments are distinguished from other forms of experimentation by the *absence* of experimenter control of key events. Natural experiments can either test existing theory or uncover phenomena that require theoretical explanation. The Nixon administration's implementation of a draft lottery during the Vietnam War is an example of an event that permitted natural experimentation.

The draft lottery organized men's eligibility for the military draft by randomly selecting days of the year. Men whose birth dates were selected early in the lottery were very likely to be drafted. Those whose birth dates came later (e.g., number 340) could anticipate being bypassed by the draft. As such, the lottery created "natural" experimental groups, for example, (1) men with low numbers who would almost certainly be asked to report for the draft, (2) men who had a high probability of being asked to report, and so on. Researchers have found that those with low draft numbers had higher long term, non military mortality rates than those with high numbers (Hearst et al. 1986). In an unpublished study, Walker found that draft eligible male students with very low lottery numbers (1–50) expressed more positive attitudes toward the Vietnam War than students with high or very high numbers. The finding was explained by applying cognitive dissonance theory to the findings.

Field Experiments

Field experiments, like natural experiments, are conducted in naturally occurring situations. However, field experimenters exercise some degree of control over participants, events, and key theoretical or practical factors. Social

psychological research on bystander intervention is an example of field experimentation. Piliavin et al. (1969) chose particular subway cars but they could not select the passengers who became their experimental "participants." Their sample is properly described as an accidental or convenience sample. However, characteristics of the "victims" in need of assistance were under strict experimental control.

Piliavin et al.'s research can be contrasted with the Robbers Cave experiments conducted by Muzafer Sherif and his colleagues (Sherif et al. 1961). Sherif et al. exercised substantially greater control over conditions in their studies. The researchers exercised some control over (1) the process used to select youthful participants, (2) key elements of the site at Robbers Cave State Park in Oklahoma, (3) the assignment of boys to two groups (e.g., putting friends in separate groups), and (4) events that were presumed to affect relationships between the two groups.

Survey Experiments

Survey experiments combine all the advantages of experiments with many desirable characteristics of survey research. Survey researchers can conduct studies with large samples, control the selection of participants, and randomly assign participants to treatments. The result can be a powerful tool for discovering important social relationships or for testing sociological theory. Small scale surveys may use face to face interviewing or survey administration of survey instruments. However, many contemporary surveys use computer assisted interviewing (CAI) and they can be conducted by telephone or through Internet connections.

Experiments using the vignette technique pioneered by Rossi (1979) are increasingly common in sociological social psychology. Participants in contrasting experimental treatments respond to situations described by vignettes embedded in survey instruments. Jasso and Webster's recent research studying gender of evaluators, gender of putative employees, and assessments of just (fair) wages is an outstanding example of this experimental form. Other social psychologists control important features of the situations under which participants

respond to survey items. For example, Krysan and Couper varied the presence of interviewers (whether in the room or on a video screen) and interviewers' race. Their experiment studied the responses that black and white participants gave to surveys that contained items designed to measure attitudes toward race or ethnic groups and issues important to race relations. Among their important findings, Krysan and Couper discovered that "subtle" items designed to expose hidden or covert race prejudice were the most sensitive to race of interviewer and presence effects. Their findings are inconsistent with the rationales that previous researchers had advanced for incorporating subtle items in survey research on politically and personally sensitive topics.

Laboratory Experiments

Laboratory experiments offer the greatest opportunities for experimental control. Laboratory scientists can select participants and control the conditions under which participants are studied. The ability to select participants can be very important when an experiment is testing a scope delimited theory. As an example, we can use Moore's selection of women from a particular community college for his study of status organizing processes. Since all were women and students at the same institution, Moore could tell participants that their simulated partners were also women who differed from them on a single characteristic – the school the partner attended. The high degree of control was important because one scope restriction on the theory under test required group members to differ on one (and only one) characteristic.

Experimenter control is also crucial in the Krysan and Couper study described above. Krysan and Couper's surveys were administered in a laboratory. Under laboratory conditions, the researchers could standardize the actions of virtual and live interviewers. Participants in the virtual interview treatment saw the interviewer on a split screen monitor as they read survey instructions. Participants in the live interview treatment read survey instructions on the same computer screens but interviewer images were not projected on their screens. The high degree of control that is exercised in

laboratory experiments permits more accurate and useful tests of hypotheses drawn from theory.

THE FUTURE OF EXPERIMENTATION IN SOCIOLOGY

Experimental research in sociology appears to have a bright future. First, social scientists in other disciplines are increasingly aware of the utility of experimental research as a technique for testing theory. Experiments were very rare in economics and political science as recently as the 1960s. Today, experimental economics is a burgeoning field and experimentalists in economics, political science, and sociology are using the Internet to conduct experiments in virtual laboratories (Willer et al. 1999). It remains to be seen whether the spread of experimental techniques to other social and behavioral sciences will increase their visibility in all fields and create greater demand for sociologists trained in experimental methods.

expertise, "scientification," and the authority of science

Stephen Turner

The problem of the role of experts in society may seem to be a topic marginal to the main concerns of sociology, but it is in fact deeply rooted in the sociological project itself. Sociologists and social thinkers have long been concerned with the problem of the role of knowledge in society. Certain Enlightenment thinkers, notably Turgot and Condorcet, believed that social progress depended on the advance of knowledge and the wider dispersion of knowledge in society. But Condorcet especially recognized that this idea had complex political implications. On the one hand, it required science, which for him included social science, to be supported by the state, yet retain independence or self governance in order to advance without political interference. On the other hand, he recognized that social advance required that the most enlightened be the rulers, and that this conflicted with the ideas of democracy and equality.

Condorcet's solution to this problem was education. But he also recognized that even the educated citizen would never be the equal of the scientist. Thus, his conception of the role of the expert in politics depended on the hope that a more educated citizenry would defer politically to the most enlightened, thus bringing about *de facto* expert rule through

democratic means. Saint Simon extended this reasoning, but it was made into a sociological system by Comte, and, in the course of doing so, Comte created the term sociology.

Comte's central idea was the law of three stages, which held that every science goes through the successive stages of theological, metaphysical, and positive. He argued that sociology was to be the last science to reach the positive stage, and that this law itself was the first and most fundamental positive law of sociology. Comte also believed that consensus was a central requirement for order and orderly progress in society and looked to science to provide the intellectual basis for this consensus.

Comte regarded freedom of opinion as inappropriate to an age of knowledge. If the facts of a social life could be reduced to science, the principles of this science should be the basis of state action rather than the misguided views of citizens, who, if they disagreed with the principles, were merely ignorant and needed education rather than the right to voice their ignorance. Expertise thus would correct the anarchy of opinion of liberal discussion. The authority of science was to be the basis of state authority. This posed the problem of education, to which Comte had an authoritarian solution: the lessons of sociology should be inculcated in the masses through the same kind of techniques that the Catholic church in the past had used so effectively to inculcate religious dogma.

His critics, such as John Stuart Mill, saw in this a kind of authoritarianism, but acknowledged the logic of his position. Later thinkers such as Karl Pearson defended similar views about the necessary role of experts. These ideas in turn influenced such movements as Fabianism in Britain, technocracy in the US, and the social relations of science movement of the 1930s, whose ideas were a precursor to the modern sociology of science. The social relations of science movement was dominated by communists, and communism itself may be understood as a form of expert rule in which experts direct social life "scientifically" (through planning) on behalf of the people rather than as their instructed representatives.

In the 1940s and 1950s the sociology of science concerned itself with the related problem of the authority of science. Robert Merton was

particularly concerned with conflicts between science and democracy. In some of his later writings he discussed what he called the ambivalence of ordinary citizens to science and expertise. Later sociologists of science, influenced by social constructionism in the study of the generation of scientific facts, turned their attention to expertise as well. They identified specific mechanisms, such as "boundary objects," through which scientific or expert claims were constructed into a form of "fact" that was usable by the public, and considered issues about the construction of the appearance of expert knowledge and the kind of citizenship education that might be required in the face of a politics in which expert claims played a large role. Some influential research in this tradition concentrated on failures of expertise and the problem of integrating relevant lay knowledge with expert opinion, one of the sources of failure in the application of expert knowledge in concrete situations.

Other research focused on the social and organizational roles of experts, the place of expert knowledge in the law, judges' construction of expert knowledge, and the implicit conception of science which is assumed in legal decision making about scientific questions. This literature deals with such issues as the gap between the law's treatment of scientific results and scientists' view of them.

Another body of research related strategies came from the professionalization literature in American sociology in the mid twentieth century and focused on the professionalization of domains of practice and the consequent transformation of these domains into subjects governed by expert knowledge. An important example of this is the medicalization of issues (e.g., behavioral issues) which had previously been regarded as matters that could appropriately be dealt with by lay knowledge. Many forms of social behavior, such as child abuse and alcoholism, were transformed in this way. Subsequently, a social constructionist literature grew up discussing the process by which these transformations occurred.

These discussions had the effect of questioning the concept of expert knowledge itself, and pointing to the difficulties of judging expertise. Experts may have specialized knowledge, but they are not universal experts. They often do

not have the local knowledge necessary to apply this knowledge correctly, and are often unaware of the limitations of their own knowledge. Lay people also may have specialized forms of knowledge that need to be integrated into decision making in order for knowledge to be effectively used. Thus, there is a problem of aggregating or bringing expert knowledge and other forms of knowledge together. Similar issues arise when experts from different fields must cooperate in decision making. Experts in one field become lay people when faced with expertise in another field, and must make non expert judgments about the validity, relevance, and significance of the expert claims made by other experts.

The issues raised by Condorcet about the conflict between expert knowledge and democracy are still relevant today. They point to a fundamental conflict between a participatory model of democracy and the undeniable fact that many of the issues that face modern states are understandable only by experts. The newer literature on expertise points to the fact that expert knowledge, and the "facts" which citizens accept as matters of expertise and act on, are the product of complex processes of social construction, and thus of a kind of politics.

exploitation

Andrew Kliman

Exploitation occurs when someone or something (e.g., a material resource, an opportunity) is used or taken advantage of. Social scientists are chiefly concerned with the exploitation of people and classes, who are generally considered exploited if they are required, by force or by circumstances, to contribute more to some process than they receive in return. Crucially important to Marxian thought, the concept of exploitation is also employed in neoclassical economics and related sociological work. Yet the concept is controversial among sociologists; many eschew it entirely.

Karl Marx held that working people are exploited if some of the labor they perform is surplus labor, labor for which they receive no equivalent. The extraction of surplus labor is most transparent in the *corvée* system, in which serfs worked part of the time for themselves on one plot of land, and for the lord, on another plot of land, during their remaining working time. This division of working time is not so transparent in other cases, but Marx regarded it as a feature of all class-divided societies. Workers in all such societies, he argued, are compelled to perform surplus labor because they lack access to land and other means of production. To survive, the workers must work for other people or companies. The latter can require the performance of surplus labor because they have exclusive ownership or control of the means of production.

Marx employed this theory in three main ways. First, he defined classes and identified divergent class interests and antagonisms in terms of surplus labor extraction. Exploited working classes perform surplus labor; exploiting non-working classes live off of it. The former have an interest in ending this exploitation; the latter have an interest in perpetuating it. Class antagonisms and struggles arise as a result

of: (1) these contrary interests; (2) efforts by one side or the other to lessen or augment the amount of surplus labor performed; (3) domination, oppression, and violence employed in order to perpetuate and augment this exploitation; and (4) social conditions associated with it, such as alienation, poverty, and inequality.

Secondly, Marx distinguished among different class divided societies in terms of their different "forms," or systems, of surplus labor extraction. He argued that a society's other economic and political relationships are based upon and correspond to its specific form of surplus labor.

Finally, and most controversially, he utilized the theory in order to explain the existence and magnitude of surplus value, or profit, under capitalism. Marx argued that surplus labor is the exclusive source of surplus value and its subcomponents (profits of industrial firms, rent, interest, etc.). Although capitalists seemingly pay for workers' labor, and thus workers seemingly receive as wages a sum of value equal to the value that their labor adds to the product, Marx (1990) argued that capitalists actually purchase workers' *labor power*, or capacity to work. The amount of labor they subsequently perform is therefore not determined by the wage contract. Consequently, surplus value arises when, and to the extent that, workers are made to work longer than the amount of time during which their labor adds an amount of new value equal to their money wages.

The magnitude and rate of surplus value, or rate of exploitation, thus depend upon struggles over the length and intensity of work, as well as wages. Marx argued that, owing to the dynamics of the business cycle and the replacement of workers by machines, wages cannot rise to levels that would seriously threaten the generation of surplus value.

Many Marxist and non Marxist authors maintain that the production of surplus value cannot rightly be deemed exploitative unless an ethical argument is provided. That workers are required to perform surplus labor is insufficient. Marx, on the other hand, held that the exploitation of workers is fair and lawful, violating none of their rights. From the perspective of present day society, there is nothing to criticize. It admits of criticism only from the perspective of a future classless society.

Marx's profit theory seems to contradict the fact that industries which extract the same amounts of surplus labor obtain quite different amounts of profit. Although he acknowledged this fact, Marx (1991) argued that if some industries obtain more profit than they generate by means of surplus labor extraction, others must obtain less, and the gains and losses exactly offset one another in the aggregate. It is thus at the level of the aggregate economy that surplus labor is the exclusive source of profit.

Critics have persistently claimed, however, that Marx's demonstration of this proposition has been proven internally inconsistent. The alleged inconsistency has profoundly affected the trajectory of subsequent profit theory and class analysis. It is the principal reason given for rejection of the exploitation theory of profit. Theorists seeking to preserve some elements of that theory, but to jettison Marx's theories of value and surplus value, also invoke the alleged inconsistency as their principal justification. This latter category includes economists who have advanced revised versions of the exploitation theory of profit, Marxist sociologists who seek to ground class analysis in a revised account of surplus labor extraction (e.g., Wright 2000), and a non Marxist sociologist who proposed a different concept of exploitation as the basis for class analysis (Sørensen 2000).

Key to the attempted reformulations of the exploitation theory of profit is the fundamental Marxian theorem (FMT). The FMT has widely been held to have rigorously proved, without the use of Marx's value concepts, that surplus labor is necessary and sufficient for the existence of profit. Thus, even though he was supposedly wrong to claim that aggregate profit and surplus value are equal, the FMT has seemed to confirm Marx's conclusion that surplus labor is the exclusive source of profit.

The FMT was also at the basis of Roemer's (1988) effort to root class differences and surplus labor extraction in initial differences in wealth. In his rational choice model, initial differences in wealth lead, with rare exceptions, to strictly corresponding differences in class and exploitation status. Moreover, the initial distribution of wealth is the sole determinant of the class and exploitation hierarchies. Whether poor people become proletarians, or independent producers exploited in credit

markets, makes no difference. These results significantly influenced the thinking of many economists, sociologists, and philosophers. Prior to Roemer's work, many Marxists had simply assumed that labor markets and capitalist control of the labor process were important determinants of the degree of exploitation.

Yet recent counterexamples may have demonstrated that the FMT actually fails to prove that surplus labor is either necessary or sufficient for profit. If these counterexamples are valid, they show that the theorem applies only to very special cases – static equilibrium and an economy in which all physical surpluses of all goods are always positive. (If, on a given day, the steel industry produces less steel than the auto, construction, and other industries use up, then the physical surplus of steel is negative.) Given even a slight relaxation of these special case restrictions, profit can be negative when surplus labor is extracted and positive without surplus labor having been extracted, according to the FMT's definitions (Kliman 2001).

This does not mean that profit theory and class analysis rooted in surplus labor extraction have necessarily come to an end. During the past quarter century, a new school of Marx interpretation claims to have refuted the alleged proofs of internal inconsistency in his value theory. It maintains that the apparent inconsistencies, including the one discussed above, are simply the byproducts of a particular mathematical formalization of his theory, since the inconsistencies disappear under this school's alternative interpretation (see, e.g., Freeman & Carchedi 1996). If these findings are correct, they do not prove that Marx's profit theory is empirically correct, but they do remove the standard justification for dismissing his theory as logically unsound.

Unequal exchange theory, pioneered by Emmanuel (1972), is often understood as a theory of exploitation. However, Emmanuel himself did not refer to unequal exchange as exploitative; he sought to supplement, not replace, Marxian exploitation theory. He argued that less developed countries (LDCs) receive relatively low earnings, and developed countries (DCs) receive relatively high earnings, for their exports. The distortion of export earnings serves to retard economic growth in the LDCs while stimulating it in the DCs. Unequal exchange theory is thus

closely associated with dependency theory, especially with the notion that underdevelopment is an active process, not a static condition.

The source of unequal exchange, proponents of the theory argue, is the confluence of unequal international wage rates and the tendency of rates of profit to equalize. Wages and thus costs of production are high in the DCs and low in the LDCs. If rates of profit are equal, prices will likewise be high in the DCs and low in the LDCs.

The reason why exchange at these prices is deemed unequal is that the earnings of LDCs are low, and the earnings of DCs are high, in relation to the amounts of labor that workers in these countries perform. Yet since this inequality is mainly the result of LDCs' relatively low *productivity*, other authors deny that a distinct theory of unequal *exchange* is needed in order to account for it. For instance, some hold that Marx's value theory already accounts for it: low productivity producers create less value ("social value") per labor hour than high productivity producers.

In contrast to Marx's theory, neoclassical economics implies that exploitation of capitalists by workers (through, for instance, the formation of unions) is as likely as the exploitation of workers by capitalists. All people who provide productive inputs (labor, machinery, etc.) are considered exploited if they are paid less, or exploiters if they are paid more, than what neoclassical theory regards as the input's contribution to production: the value of its marginal product. The marginal product is the extra physical output that results from the employment of an extra unit of the input; the value of this extra output is the hypothetical price it would command if the economy were perfectly competitive and in equilibrium. Exploitation would therefore be absent in a perfectly competitive equilibrium, but the conditions needed for perfect competition – perfect information and the inability of any seller or buyer to set prices – cannot be satisfied in the real world.

Another key difference is that, while Marx assessed workers' contributions to production in terms of the amount of labor they perform, neoclassical theory assesses an input's contribution to production in terms of the extra physical output it yields. This procedure is frequently criticized as conceptually dubious. Critics argue that physical output is the result

of many inputs operating in concert, and that it is frequently impossible, even in principle, to ascribe distinct contributions to each. If, for instance, every delivery requires a driver and a truck, then the marginal product of an extra driver or extra truck (given no increase in the other input) is zero, so there is no way of determining whether the trucking firm exploits its drivers or vice versa.

The recent work of Sørensen (2000) seeks to make the neoclassical concept of exploitation the basis for sociological class analysis. He argues that those who can exact what neoclassical economists call “rent” – payments for their inputs that exceed the minimum amount needed to make the inputs available – constitute exploiting classes. Not only are they better off, and others worse off, than if there were no rent, but the very purpose of rent seeking behavior (e.g., lobbying the government for protection from competition) is to enhance one’s well being at the expense of others. As an adaptation and application of neoclassical exploitation theory, Sørensen’s work shares its main features and possible shortcomings.

The various theories of exploitation are controversial partly because of their political and ideological implications, and partly because assessment of whether individuals and groups are exploited gives rise to significant conceptual problems. Although some key controversies – particularly those surrounding Marx’s theory, the FMT, and neoclassical exploitation theory – can seem to be purely technical controversies over measurement, they are, at a deeper level, controversies over these difficult conceptual problems.

extracurricular activities

Anna Strassmann Mueller

Extracurricular activities such as band, debate, or soccer are optional activities offered by the school that complement the academic curriculum and enhance the school’s sense of community. These activities provide settings within schools for adolescents to develop facets of their personalities that contribute to their emerging independence and their eventual assumption of adult roles. Extracurriculars offer opportunities for leadership, travel, skill development, and social engagement and integration in the school. There is growing evidence that adolescents who are involved in extracurricular activities are generally happier and healthier than their uninvolved peers. In particular, research suggests that extracurricular participation positively influences adolescents’ psychosocial development, problem and risk behaviors, relationship formation, and, perhaps most importantly, their academic achievement.

Since James Coleman’s classic study *The Adolescent Society*, researchers have recognized that schools serve as the primary location for adolescent social development. In schools, adolescents meet friends, internalize values, and develop interests and talents. Often, extracurricular activities play a major role in these processes. Because adolescents choose to engage in

extracurricular activities, these activities can become important defining experiences for their budding sense of identity. In fact, there are close ties between adolescent participation in particular activities such as sports or debate and self reported identity, as, for example, a “jock” or a “brain” (Barber et al. 2001). These self reported identities then shape other aspects of adolescents’ lives, such as drinking and marijuana use, or college matriculation and graduation. Additionally, extracurricular activities may provide a forum for the development of adolescent gender identity. Athletic extracurricular activities for males and cheerleading for females may contribute to the development of traditional gender roles because of the emphasis on competition found in sports as opposed to the emphasis on appearance found in cheerleading (Eder et al. 1995). Though girls are significantly less likely to participate in team sports, those who do may experience a non traditional gender socialization that includes skills that may help them succeed in domains of life outside of sports.

The status hierarchy of extracurricular activities within the school can also shape how extracurricular involvement impacts students’ lives. In some schools there is substantial overlap between the schools’ learning objectives and officially sponsored extracurricular activities. In these schools, extracurricular activities become another way for schools to promote their academic goals. Another common emphasis in schools is on athletic competitions such as football: athletes in these schools may find that their athletic identity is central to their sense of self. If the school sponsors events such as pep rallies that increase the visibility of athletes, being an athlete may also come with more social status and increased popularity with peers (Eder et al. 1995). Though extracurriculars can reinforce or create adolescent status hierarchies, they can also provide adolescents safe alternative contexts in which they can explore identities that do not match the popular norms of the school. For example, nerds may take refuge in extracurriculars that allow them to be themselves and not worry about adhering to popular student norms (Kinney 1993). Thus, extracurricular activities serve an important social function for the school. They diversify the school experience for adolescents and allow

students to feel integrated and connected to the school. They also provide a physical and social location in the school where school policies and priorities can shape the adolescent culture.

Because keeping students engaged and enrolled in school is an important policy issue, the role of extracurriculars as a tool for improving students’ achievement has been considered seriously in the academic literature. This body of literature has demonstrated that extracurricular activities have an important impact on adolescents’ academic achievement. Even after controlling for socioeconomic status and family background, adolescents involved in extracurricular activities do better in school and have more positive attitudes toward their education. Students who are extracurricularly involved have higher grades, attend school and complete their homework more regularly, and are more likely to select college preparatory coursework. They also feel more confident in their academic work and both plan and realize higher educational goals (like attending college) more than students who are not involved in extracurriculars. In low class and middle class schools, where less than half the students go on to 4 year colleges, identifying as an athlete is particularly strongly associated with higher grades and higher educational aspirations. Though it is possible that in this body of research better students are more likely to participate in extracurricular activities (rather than the extracurricular activities improving the students who participate), similar results have been obtained in longitudinal studies controlling for relevant behaviors prior to participation. This implies that extracurricular activities to some extent do improve the academic achievement of participants. In addition to improving the achievement, being involved in extracurriculars can be crucial for students who are seriously struggling in school, as it can dramatically reduce their likelihood of actually dropping out.

In addition to better integrating students into schools, extracurricular involvement can improve students’ experiences during the sometimes difficult adolescent years. Students who participate in the extracurriculum tend to make better life decisions particularly with regard to high risk behaviors. They take fewer risks sexually and are less likely to engage in delinquent or problem behaviors. Generally,

students involved in extracurriculars are less likely to drink, smoke, or use drugs, although some research has shown that students who participate in team sports (such as football) consume more alcohol. Perhaps even more importantly, adolescents who participate in extracurricular activities tend to exhibit better mental health as indicated by higher self-esteem and healthier self-concept. They also tend to report greater self-efficacy and more control over their lives, an important developmental step toward a healthy adulthood. Furthermore, involved adolescents generally experience higher levels of life satisfaction than their peers who do not participate. These positive influences do not necessarily end during adolescence. Extracurricular involvement can shape adolescents' adult lives, producing more conscientious citizens in early adulthood. For example, extracurricular participation has been linked to greater civic involvement, such as voting and volunteering.

While much research has focused on how participation in extracurriculars improves adolescents' developmental and academic trajectories, participation in these events also provides an invaluable opportunity for adolescents to form social relationships with adults. During a period of adolescent development that involves large gains in independence from parents and families, extracurricular activities offer an institutionally structured opportunity to engage in extra-familial relationships. These activities provide opportunities for adolescents to connect with adults who can guide them on their academic paths and serve as advocates if necessary, helping to maximize the school's ability to meet students' needs. Research has shown that adolescents involved in school-based extracurricular activities do tend to seek out educational and occupational advice more frequently and from a wider range of adults than their uninformed peers. These sources of engagement with encouraging adults outside of the household are particularly important for at-risk adolescents, who generally lack access to such social support. In addition, extracurricular activities can strengthen the social ties between students, parents, and the school. When parents and school personnel know one another (thus increasing the social capital available to adolescents within the school), the school can

more effectively realize its developmental and academic goals for students.

Just as extracurricular activities structure relationships between students and adults, they can shape who adolescents are exposed to within the school context. In particular, extracurricular activities provide a potentially unique opportunity within the school structure for exposure to students from different backgrounds. Unlike classes which tend to draw students with similar academic histories (and thus from more homogeneous family backgrounds), extracurricular activities draw anyone with talent or interest. This opportunity, the influence of institutional support, and the equal contribution and contact of a group of individuals combine to position extracurricular activities as a conduit by which to promote positive race and ethnic relations. However, this potential is limited by race and gender differentials in individuals' likelihood to participate in extracurriculars and how participation affects students' academic and personal trajectories. Further, how integrated extracurricular activities are may vary by school, and in some schools opportunities to participate may be extended to only a small number of students.

Because extracurricular activities appear to have a resoundingly positive role in adolescent life, these inequalities in participation are of concern, as they imply that involvement works better for some adolescents than for others. Although across race and ethnic groups, girls' participation in sports is increasing, their rates still lag behind those of boys. The reverse is true of non-athletic activities and school and community service activities: girls participate in much higher percentages than boys (American Association of University Women 1999). Girls are underrepresented in activities that encourage exercise, which has important implications for health, while boys are underrepresented in non-athletic activities, which can play an important role in their academic achievement. In addition to being stratified by gender, participation rates differ based on socioeconomic background: students from families with higher socioeconomic status are more likely to participate in extracurriculars, particularly sports, academic clubs, and music. School size and school sector (public or private) also influence the rates and effects of participation.

Though the majority of research on extra-curricular activities is based on the experiences of US adolescents, there is some research that suggests leisure and extracurricular activities are important cross nationally (Verma & Larson 2003). Internationally, these activities seem to serve a similar developmental purpose: they provide adolescents with opportunities to gain skills, to integrate into social groups, and to develop personal interests and talents. Though there are some commonalities in participation across countries (the popularity of sports is almost universal), the national context does shape the role of participation in adolescent life. For example, in Japan where achievement and competition are important elements of the national culture, extracurricular activities are viewed as an additional way for students to cultivate discipline and become well rounded. Because of this motivation, participation tends to add stress to Japanese adolescents' lives and is linked to negative emotional states. This is contrary to findings from the US and Europe and points to the importance of international research on extracurricular activities and adolescent development.

Academic achievement and engagement, health and risk behaviors, and formation and maintenance of social relationships have been linked to high school extracurricular activities. Students spend many intense hours in extracurricular settings during their adolescent years, rendering these contexts crucial to understanding how adolescent society operates in schools and how experiences in extracurriculars influence adolescent identity and behavior. Though these generally positive forces have been widely explored in the literature, there is still much that researchers do not know. For example, extracurricular participation may not be stable over the high school years. Students may experience a trajectory of extracurriculars; they may focus on drama one year and basketball the next. How do these trajectories affect the developing adolescent? Continuing to explore adolescents' dynamic experiences in extracurriculars over the course of the middle and high school years should be an important goal of future research. An improved understanding of participation in extracurricular activities will enable policy makers to more effectively harness the school

as a powerful force in shaping adolescent culture and outcomes.

exurbia

Jeff Crump

Exurbia is a form of residential development that straddles an often ill defined zone between densely packed suburbs and rural and small town locations. Although its boundaries are usually indistinct, exurban development begins somewhere beyond the sprawling suburbs and lies outside easy commuting distance to the central city. At its far reaches, exurbia does

not so much end as it blends into the surrounding agricultural countryside. Residents of exurbia occupy an uneasy middle ground between the perceived ills of the city and adjoining suburbs and rural places where it is believed that people live in harmony with the bucolic rural landscape (Marx 1964).

At the core of the debate over exurbanization is the question of whether exurbia represents a "clean break" in prevailing patterns of suburban development or if it is simply another form of suburban sprawl (Nelson & Sanchez 1999). Proponents of the "clean break" hypothesis argue that exurbia represents a new settlement form populated by a distinctive group of residents who seek out particularly rural environments. The residential choices of exurbanites are driven by an anti urban bias which leads them to seek out idealized rural and small town locations (Nelson 1992).

Here, the argument is that exurbia and exurbanites are somehow unique and their choice to live in exurbia is reflective of a different set of values than those of people who choose to live in suburbs (Nelson & Dueker 1990). Exurban residents are said to base their residential location decision on a calculus that places an overriding value on the perceived environmental amenities offered by a rural location. Rural environments, open space, privacy, and the pursuit of "hobby farming" (e.g., raising a few head of cattle or a 5 acre vineyard) are characteristics that set exurbanites apart (Crump 2003).

Not everyone accepts the argument that exurban development is distinctive. By contrast, those arguing against the uniqueness of exurbs argue that exurban development is simply another form of suburbia. For example, Nelson, who at one time argued for the distinctiveness of exurbia, recently found that exurbanites are no different than those who seek solace in more traditional suburbs (Nelson 1992; Nelson & Sanchez 1999).

Much of the writing on exurbia is found in the popular literature. For example, the terms exurban and exurbanite were first popularized in 1955 with the publication of *Exurbanites* by the journalist A. C. Spector (1955). According to Spector, exurbanites are a unique group seeking relief from the "rat race" of Manhattan. The exurban émigrés transformed

many formerly rural enclaves such as Westport, Connecticut.

Anti urbanism is often cited as the main motivating factor for exurban migration. Marx (1964) argued that Americans have a prevailing anti urban bias which leads them to idealize rural life and seek out rural environments in which to live. In addition to anti urbanism, improved transportation and communication were crucial to the development of exurbia. Increasing affluence, when coupled with advances in transportation and communication, has also allowed people to express their residential preferences more easily. In this process, a new kind of city is being created which defies traditional definitions over what is and is not urban.

Interest in exurbanization reached a peak during the 1970s and 1980s. In the 1980s the increased research on exurban growth was largely stimulated by significant rural population gains. Termed the "rural renaissance," rural population growth represented a reversal of long term patterns of rural depopulation in the US. However, although there was little doubt that rural areas were growing, the question was why. Several surveys of rural residents identified two major factors. First, anti urbanism was leading people to seek out exurban locations. Second, industrial growth in rural areas was also expanding the employment options available in rural locations.

Exurban expansion has led to the spread of residential development across wide swaths of formerly rural landscapes (Davis et al. 1994). The ever growing exurban landscape is the result of innumerable local planning decisions that result in a sprawling, patchwork quilt of development. Controlling exurban development is difficult as developers resist growth limitations and seek jurisdictions that present the easiest path toward profitable development. They leapfrog places that seek to control growth, thereby increasing the cost of service provision.

Although academic interest in exurbanization has waned in recent years, newer studies find that the continued decentralization of employment is an important factor in exurban growth (Nelson 1992). Certainly, numerous employment nodes have grown on the edge of US cities and provide employment options for exurbanites. Termed "edge cities" by the

journalist Joel Garreau (1991), satellite business and retail centers now characterize the freeway interchanges that mark the beginning of exurbia in the 1990s.

Hayden (2003) develops a three way classification of exurban development. According to Hayden, the three emblematic landscapes of exurbia are reluctant suburbs, hot towns, and Valhallas. Reluctant suburbs are rural towns that often find themselves overwhelmed by population growth. Hot towns are well off locations that attract telecommuters, sometimes termed "lone eagles." Certainly, telecommuting has grown apace with the advent of high speed Internet service and allows exurban residents to avoid long and tiring commutes. Yet, even though the proponents of telecommuting celebrate the end of the conventional commute, critics argue that telecommuting destroys the boundary between home and work (Hayden 2003). Many telecommuters, especially women, find themselves on call 24/7. For them, telecommuting means balancing household chores with job demands. Lastly, there are the exurban Valhallas. These exclusive communities are located in environmentally attractive areas. However, access to nature's bounty is restricted to high income residents who can afford to purchase homes within the confines of high security gated "communities."

Interest in exurbia continues, particularly in the popular media. Here, exurban residential development is often linked with the growth of edge city employment and retail centers. Some observers go so far as to claim that exurbia is now the trendsetting political landscape

for America (Brooks 2004). Interestingly, that's the same claim made by Sectorsky in 1955.

F

facework

J. I. (Hans) Bakker

The concept of “facework” (or face work) was articulated by Erving Goffman in 1955 in his book *Interaction Ritual*. He provides a “subject–object” model of human symbolic interaction in which individuals interact with other individuals in terms of subjective perceptions. Whatever is “universal” about human beings, it is not – according to Goffman – something automatic. Instead, it is a matter of self regulation and the ritual recreation of “face.”

He defines the term “face” as “the positive social value a person effectively claims for him self.” If a person makes “a good showing,” then the image of him or her is perceived by that social actor as approved by members of the reference group. If there is a mismatch between expectations and events, there is likely to be a negative emotional reaction. When a person presents a certain face, then we say she “has” that face. In conventionalized encounters there is little choice about which face to “be in” or “maintain.” A person can be said to be “in wrong face” or “out of face” when she cannot integrate the situation or deal with it in expected ways. When one is out of face there may be a sense of shame, while being “in face” tends to be associated with pride.

An interaction involves people trying to follow expected patterns. Expected signs such as glances and gestures are either given or withheld (Collins 1988: 16). Greetings and farewells are ritualized ceremonies which compensate for previous or future separations. The tendency, according to Goffman, is for all actors to support one another’s face, an idea similar to the “etcetera principle” in ethnomethodology.

Moreover, human encounters help one to construct a sense of one’s own face, or “self image.” People tend to try to protect their own inner idea of themselves even when, like the proverbial schoolboy, they may rebel in open or hidden ways. The ritual code requires that self regulating members of an interaction express a “face” and help preserve the “faces” of other participants. If a ritual order is going to be sustained, then a great deal of facework has to be done in the course of any social activity in order for the group to maintain equilibrium. There is an element of “make believe” (Winkin 1999: 33). Thomas (1923: 1–69) stresses that “recognition” from others is one of the key “wishes” and that it is related to the “definition of the situation.”

These ideas can in principle be applied to any symbolic interaction at any level of social organization, from dyads and small groups to neighborhoods and communities, although Goffman tends to stress examples from small groups. (In other works he often makes more macro statements.) In complex formal organizations such as the military or industry there is also a process of “saving face.” The unwritten rules are followed by most social actors most of the time. One not only tries to “save” one’s own face, one also tries to arrange things so that others will not lose face. (The Chinese saying is “to give face.”) The visual imagery of the concept of “face” is very concrete and Goffman claims it is manifest in a person’s whole bodily demeanor, not just the expression on one’s face.

The idea of facework is heuristic but can be criticized empirically and epistemologically. At the empirical (“ontological”) level, one limitation of Goffman’s approach is that he does not give adequate recognition to the possibility that one’s “voice” (Walker 1999: 279–82) may be silenced and that this “loss of face” is not just determined by a ritual process that occurs

within the smaller collectivity. Especially in larger groups – such as complex formal organizations or national level institutions – there may be utilitarian, goal rational exchange principles at work as well as the internal social constructions that Goffman is more directly concerned with. Epistemologically, the idea of facework tends to reinforce a Cartesian split between the “inner self” of the subject and the “objective” status of the “other” in the environment. The stereotypical version of the ethnographer is that of a bit of a loner, a lone “subject,” a utilitarian rational actor and streetwise researcher who is not easily duped (Winkin 1999: 35). An example would be Nels Anderson (1923), author of one of the first Chicago School ethnographic studies. His work was done before the modern concept of “participant observation” emerged (Platt 1996: 117–22). But that highly “individualistic” epistemological stance may reduce awareness of the embeddedness of all social relations and the importance of “the field,” or what Goffman himself refers to as “syntactical relations” (Goffman 1967 [1955]: 2). A more Peircian pragmatist epistemology, by stressing the way in which all subject–object relations are mediated by “signs,” might have made it possible for Goffman to more easily generalize his conclusions about the construction of face to all “syntactical” forms of symbolic interaction in general, providing a way for him to more easily connect his earlier work on explicit interactionist events of the 1950s with his later, more implicit and “structurationalist” analysis of “frames.” The key linking concept might be “frame attunement” as a ritual and system requirement (Collins 1988: 31).

fact, theory, and hypothesis: including the history of the scientific fact

Stephen Turner

The terms theory, fact, and hypothesis are sometimes treated as though they had clear meanings and clear relations with one another, but their histories and uses are more complex and diverse than might be expected. The usual sense of these words places them in a relationship of increasing uncertainty. A fact is usually thought of as a described state of affairs in which the descriptions are true or highly supported. A highly corroborated or supported hypothesis is also a fact; a less well corroborated one is still a hypothesis. A hypothesis which is not supported by or corroborated by other evidence would not be a fact, but could become a fact if it came to be corroborated to a high degree of certainty by other evidence. Similarly, a theory, which is a logically connected set of hypotheses, could come to be a fact if the hypotheses in the theory were to be highly corroborated by the evidence.

THE CONCEPTUAL CHARACTER OF "FACTS"

Even with this simple picture of the relationship between these terms, one can see a number of potential difficulties and raise a number of difficult questions. Begin with the notion of corroboration. If a fact is a highly corroborated hypothesis, this would seem to mean that there is a level that is prior to facts which supplies the evidence that goes into corroboration. If the corroborating evidence consists of other facts, one would want to know how these facts were corroborated. So it is more common to talk about some more fundamental level of evidence, such as data. "Data" literally means "given." But the idea that there is something in the world that is simply given, and true or valid as such, has its own difficulties.

However, when we collect data we have already described them or have a conceptual category for them. Since the "data" are already in a predefined category, we are not dealing directly with the world but with an already categorized world. This idea of fact as already conceptual had a long history in writing about science and is particularly associated with the nineteenth century philosopher William Whewell. Whewell said the following: "*Fact and Theory* correspond to Sense on the one hand, and to Ideas on the other, so far as we are *conscious* of our Ideas; but all facts involve ideas *unconsciously*; and thus the distinction of Facts and Theories is not tenable, as that of Sense and Ideas is" (Whewell 1984: 249). And this raises the questions of where the categories themselves come from and what their status is. In 1932, L. J. Henderson wrote an article which was cited by the sociologist Talcott Parsons (Parsons 1968: 41) which defined a scientific fact as an "empirically verifiable statement about phenomena in terms of a conceptual scheme" (Henderson 1932). What this implied, especially for Parsons, was that to be a fact it was necessary to be a part of or to depend on a conceptual scheme. And conceptual schemes were not givens but were, like theories, invented for the purpose of enabling us to make statements such as the statements in theories.

The question of where categories come from and how something becomes a fact has been a major concern of sociologists of scientific

knowledge. An important book by Ludwig Fleck (1979), a physician scientist, provided the basic framework for this study. Fleck argued that to be accepted as a fact required something social, which he called a "thought collective," in terms of which a concept is transformed from idea into accepted truth. The emphasis was on the social phenomenon of acceptance, something which, Fleck showed, did not merely result from the accumulation of evidence, but rather from the activity of a community of persons, with a common thought style, exchanging ideas. This implied that "discovery" was never an individual act, but rather collective; and that conceptual content was part of the collective thought of the community, which developed in the course of exchange. Only retrospectively, once the discovery had been fit into the collective thought of the community, could the significance of discoveries be fully understood.

INDUCTIVISM VS. HYPOTHETICO DEDUCTIVISM

The methodological understanding of science that fits best the insight that facts are already conceptual is hypothetico deductivism, which contrasts to a different view of methodology called inductivism. Inductivism was the traditional understanding that science consists of generalizations which can be built up on the basis of the collection of information or data which can then be arranged into generalizations. The problem with inductivism is that there is no logical way to get from a collection of finite singular pieces of information to a generalization which goes beyond the particulars that have been collected. Hypothetico deductivism deals with this limitation by turning the problem upside down by beginning with hypotheses that are generalizations and asking whether the observable particulars are consistent with (because they are implied by) the generalization. The hypothesis "all crows are black" has the potential to be contradicted every time we see a crow. Thus, each particular crow can be used as a test of the hypothesis and the more stringently we test the hypothesis, the more secure we are in our belief that the hypothesis is true.

Hypothetico deductivism has an advantage over inductivism as a method in that hypothetico deductivism can be used to corroborate theories where the concepts in the theories are not themselves directly observable. The wave hypothesis in physics is a traditional example of this. The hypothesis logically implied generalizations for which observations could be collected. Because the theory correctly predicted these and other facts that could be observed, the claims about what could not be observed were themselves corroborated. This is an especially important possibility in sociology because many of the concepts in sociology do not directly apply to observable facts in the world, but instead to grounding concepts such as "society," or "role," or "attitude." These concepts can be understood as having observable manifestations, but are not limited to or equivalent to observable manifestations.

In physics the term observation and the notion of the logical relations between claims in a theory had a more straightforward meaning. The logical relations were mathematical. The way in which an implication was derived from a theory was by deriving it mathematically through a proof. The theories of sociology, in contrast, rarely if ever have this structure, although in many cases theories are presented with verbal formulations which have "logical connections" in a looser sense, namely that the claims in the theory provide a good reason, in context, for expectations that can be tested or applied to cases. Sociological theories thus resemble physical theories in the hypothetico deductive sense in some ways, but differ in others. A "theory" may be a part of a theoretical structure, such as a system of conceptual categories which enable description. But it may instead be a description of unobservable forces or unobservable mechanisms, such as the mechanism that reinforces social hierarchy by selectively excluding members of the lower classes from the paths which lead to positions of wealth and power.

SENSE MAKING IN THEORIES

The major difference between sociological and physical theory is that the concepts in sociology are typically sense making: they serve to enable

a fact described in its terms to be more fully intelligible. Making a fact more intelligible will usually make its consequences more predictable. If I even do something as simple as characterizing an action as a product of the agent's beliefs and positive attitudes towards some outcome specified by the agent's beliefs, I have improved the prediction over alternative descriptions or over chance. This is not the same thing as a prediction in physics, but it is predictive nevertheless.

If the sociologist can add to this simple situation of explaining in terms of beliefs and attitudes by characterizing the set of beliefs that support the particular belief that relates directly to the action, for example by understanding a religiously motivated action in terms of a typology of religious belief, and if the sociologist can explain how those beliefs come to be distributed in particular groups, she will have something that begins to look like a theory that explains those actions sociologically, that is to say at some level beyond the level of the individual. Similarly, for characterizations about such things as role, for example. If an individual's behavior can be characterized in terms of the roles which they are fulfilling, this explanation can be extended by accounting for the process of socialization into the role in question and the ways in which role behavior is enforced as normative, or enacted and supported by the expectations of other agents.

These descriptions of mechanisms are more general claims than the explanation of the individual's action; they are "social" in the sense that they serve to organize the behavior of individuals in relation to a limited category of individuals. The characterizations are sense making in that they explicate the beliefs and expectations of the people involved, and predictive in the sense that they improve our own expectations about what people will actually do and what role conduct is likely to persist or appear in different social settings. Similarly, a good categorization scheme using intelligibility enhancing concepts (e.g., Weber's categories of legitimate authority) will enable the sociologist equipped with it to improve expectations as well as achieve understanding.

Sociologists have traditionally differed with respect to the emphasis they place on different aspects of these kinds of loose theories.

Parsons, for example, was particularly concerned with the elaboration of conceptual distinctions which could be used to organize comprehensively the concepts of sociology and relate them to one another and to the concepts of other disciplines. Parsons placed little emphasis on making individual actions or beliefs intelligible and little emphasis on prediction; although he envisioned future possibilities of prediction he also believed that many of the central variables of sociology were unquantifiable and that this was an inherent limitation on sociological theories approximating physics.

DIVERSITY IN THEORY IN SOCIOLOGY

Some sociologists have tried strictly to adhere to the idea of deductive theorizing as modeled on physics. Typically, these sociologists have attempted to devise experimental settings in which limited variables or sets of variables can be measured in relation to other variables in such ways that predictions can be made and confirmed. This strategy has the potential of illuminating basic concepts which can then be applied to social life outside the laboratory as fundamental theories which approximate the more complex realities of actual social life. One problem with this strategy is that there are often alternative theories which are equally effective or ineffective as means of making sense of and predicting in the more complex actual settings of the real world.

Some theories, generally called interpretive theories, are focused primarily on intelligibility itself. For these theorists, providing a more fully realized and rich interpretation of the actions, attitudes, and beliefs of individuals is the appropriate and most productive strategy for dealing with a world of agents, that is to say a world of individuals who are themselves interpreters of one another and who act in terms of these interpretations.

Other theories, such as rational choice theory, borrow the theoretical structure of decision theory, game theory, or economics to provide a particular kind of intelligibility to actions of individuals who are treated in abstraction from considerations about the specific actual beliefs and attitudes of the individuals, and the explanations are evaluated in terms of their ability to

predict the choices of these individuals. In one sense this represents the highest level of intelligibility, namely rational choice. In another sense it is removed from the subjective experience and ongoing interpretive activities of individual agents and thus serves as a poor guide to these aspects of experience.

factor analysis

Bruce Thompson

Factor analysis is a statistical method for empirically identifying the structure underlying measured or factored entities (e.g., variables). The three purposes for which factor analysis can be used are (1) empirically creating a theory of structure (e.g., Cattell's Structure of Intellect model), (2) evaluating whether factored entities (e.g., variables) cluster in a theoretically expected way (e.g., construct validity evaluation), and (3) estimating latent variables scores (i.e., factor scores) that are then used in subsequent statistical analyses (e.g., MANOVA, descriptive discriminant analysis) in place of the measured factored entities (e.g., variables).

In common analytic practice, the factored entities are usually (1) variables, although (2) people and (3) occasions of measurement also can be factored (Thompson 2000). Factor analysis statistical software does not know if it is factoring variables, people, or time, and from a statistical point of view, the mathematics of factor analysis can sensibly be invoked for any of these possibilities.

The data matrix for the analysis is created such that the entities to be factored (e.g., variables) constitute the columns of the matrix. The rows constitute the dimension over which patterns of association (e.g., correlation, covariance) among the factored entities are estimated. The factors are then estimated based on these association statistics.

Cattell (1966) identified six possible two mode combinations of factored entities and raw data matrix row replicates of the association patterns: (1) *R* technique factor analysis, which factors variables with people defining the rows of the raw data matrix, with measurement at a single time; (2) *Q* technique factor analysis, which factors people with variables defining the rows of the raw data matrix, with measurement at a single time; (3) *O* technique factor analysis, which factors occasions with variables defining the rows of the raw data matrix, with measurement of a single person (or use of a single group mean or median for each unique combination of occasions and variables); (4) *P* technique factor analysis, which factors variables with occasions defining the rows of the raw data matrix, with measurement of a single person (or use of a single group mean or median for each unique combination of occasions and variables); (5) *T* technique factor analysis, which factors occasions with participants defining the rows of the raw data matrix, with measurement using a single variable (or use of a single group mean or median for each unique combination of occasions and participants); and (6) *S* technique factor analysis, which factors participants with occasions defining the rows of the raw data matrix, with measurement using a single variable (or use of a single group mean or median for each unique combination of occasions and participants).

Although factor analysis is relatively old, the required mathematics are so complex that the methods were not widely used until the advent

of modern computers and statistical software. There are two major classes of factor analytic methods (Thompson 2004). First, exploratory factor analysis (EFA) can be used when the researcher has no theory about structure, or does not wish expected structure to be invoked as part of the analytic calculations. EFA dates back to the first decade of the 1900s, when Spearman (1904) conceptualized the method to address questions such as the nature of IQ. Second, confirmatory factor analysis (CFA) requires that the researcher has a theory of factor structure, and this theory must be declared as part of the analysis, and is used in the analysis to limit which parameters are and are not estimated. CFA originated in the 1960s and 1970s, largely in the work of Jöreskog (1969).

Factor analysis can be used to address three primary research questions. These three issues involve (1) the number of factors, (2) which factored entities (e.g., variables, people) are most associated with a given factor, and (3) how correlated the factors are with each other.

In EFA, either four or five decisions must be made, in turn. First, which matrix of association statistics to analyze (e.g., a Pearson *r* matrix, a covariance matrix) must be decided. Second, how many factors to extract must be decided. There are numerous ways to inform this EFA decision, including use of Guttman's suggestion to extract all factors with eigenvalues greater than 1.0 (sometimes erroneously called the "Kaiser > 1" rule), Cattell's scree plot (based on a plot of eigenvalues), and more sophisticated methods, such as parallel analysis or the bootstrap (see Thompson 2004). Third, a statistical method for computing the factor pattern coefficients, which are weights algebraically equivalent to beta weights in regression, or standardized function coefficients in descriptive discriminant analysis or in canonical correlation analysis, must be decided. Common factor extraction methods include principal components analysis and principal axis methods. Fourth, a factor rotation method must be selected, if more than one factor is extracted. Rotation is necessary to ensure the interpretability of the factors. Two classes of rotation methods are orthogonal rotation, in which the uncorrelated initial factors are rotated such that they remain perfectly uncorrelated, and oblique

rotation, in which the uncorrelated initial factors are rotated such that they become correlated. The most commonly used orthogonal and oblique rotation methods are varimax and promax, respectively.

Orthogonal rotation is more parsimonious, and consequently varimax rotation tends to yield results that (1) fit sample data less well than oblique methods (because there is less opportunity to capitalize on sampling error), but (2) replicate better in future samples (for the same reason). Thompson (2004) estimated that varimax rotation works well in roughly 85 percent of applied EFA research situations.

Fifth, if factors scores are to be used in a subsequent analysis (e.g., MANOVA), a factor score computation method must be selected. However, if principal components has been selected as the analytic method, the various factor score algorithms all yield identical factor scores. Another benefit of principal components analysis is that only with this method do the correlations of the factors with each other and of the factor scores with each other exactly match.

Commonly used statistical packages have as the default choices factor extraction from the Pearson r matrix, principal components extraction, and varimax rotation. Most applied researchers rely on these defaults, and thus the preponderance of published EFA research invokes these choices. However, these choices do often work quite well for many data sets.

In CFA, most of the same analytic decisions must be made. However, in CFA factors are never rotated. Instead, a “simple,” interpretable factor structure is realized in CFA by fixing certain factor pattern coefficients to be zero, and freeing other factor pattern coefficients to be estimated. Researchers make these decisions to free and fix parameter estimates such that the nature of the factors is interpretable.

Fajnzyblber, Fernando (1940–91)

Norma Rondero López

The vastness of Fernando Fajnzyblber’s work clearly places him among the most important Latin American thinkers. Rather than highlighting the many documents he wrote or the many projects he participated in, it is indispensable to note that what is outstanding in Fajnzyblber’s work is not only its importance as a critical vision of the development conditions in Latin America, but also the influence his ideas had on the development of policy strategies for the region.

Born into a family of Jewish immigrants in Santiago de Chile in 1940, Fernando Fajnzyblber studied economic sciences in Chile. His work is without doubt a detailed analysis of the economic conditions in developing countries in Latin America. It is nevertheless important to acknowledge his influence on the development of sociology in Latin America in the 1970s and 1980s thanks to his contributions toward an explanation of the social and political

problems in Latin America that showed the conditions of inequity of the poorest populations in the region based on the economic formulae Fajnzylber developed to reach economic growth.

Fajnzylber's work was mainly based on case studies and comparative studies between countries or sectors and/or productive branches. Fajnzylber's research was typically based on empirical work, the generation of studies that could provide "first hand" information, which allowed him to master a method of carrying out research on industrial organizations based on recognizing the non linear causal relationships between growth, international competitiveness, technical progress, and equity.

Fajnzylber's most important work started with the publication in 1970 of *Sistema industrial y exportación de manufacturas: análisis de la experiencia brasileña*, an analysis of the Brazilian industrial system and the export of manufactured goods. He studies the role transnational corporations play in industrial development and the potential of industrial spaces considered "sectors that carry technical progress" to expand competitively and the capacity to develop the productive apparatus.

During the early 1970s, Fajnzylber's work focused on the analysis of international industrial organizations. These studies led Fajnzylber to lay down one of the primary lines of his research: the growth problems in the manufacturing sector. This created the foundation for concepts that would emerge in his later work. Among the most important of these concepts is the notion of "sectors that carry technical progress." He would later analyze them as "endogenous nuclei of growth" because of the role they played in industrial development. These sectors are typically spaces with a high technological content that articulated with a broader productive apparatus to allow substantial advances in crucial productive sectors and branches.

In this sense, Fajnzylber's first works, which include the research he carried out on Mexican industry, "Las empresas transnacionales y el sistema industrial de México" ("Transnational Firms and the Mexican Industrial System") (1975), configured the core issue Fajnzylber never abandoned: the macroeconomic determination of competitiveness. In these first studies,

Fajnzylber emphasized the structural analysis of export oriented industries, the development of export strategies for the countries in the region, and, to a lesser extent, the analysis of business strategies related to international markets.

The competitiveness axis stands out due to the notion of the prevailing need for national industries to link up with areas of production that are better positioned in the international markets. This issue was based on notions that took into account the importance of advanced technologies of certain productive areas, the incorporation of diversified structures, and, in general, the strategies set forth by leading firms that could be incorporated by industrial branch or sector, considered nuclei of competitive development.

As can be seen in this first stage of Fajnzylber's work, the core problem is located in the organizational analysis of certain industrial branches (export oriented goods and manufactured goods). Although this stage of Fajnzylber's work is haunted by topics associated with the development of industrial leaderships and nuclei of technological development, Fajnzylber's thinking and analytical elaborations had not yet reached their greatest complexity.

In the 1980s, exiled in Mexico, Fajnzylber participated directly in the United Nations Industrial Development Organization (UNIDO), focusing on the analysis of technological modernization and the export possibilities of Latin American industry. With works like *La industrialización trunca de América Latina (The Truncated Industrialization of Latin America)* (1983), Fajnzylber was developing a system of associated ideas with a greater emphasis on recognizing technological lags and the lack of an industry of capital goods as elements that explain the region's development problem more firmly. This axis of his work thus incorporated more complex concerns: the capital goods industry in itself is not enough for economic development. It is here that Fajnzylber developed more specifically the theme of the endogenous nuclei of growth, since it is their articulation with the whole of the productive apparatus that enables the branches in which it is possible to compete internationally to become more dynamic.

This brought an understanding of the actual export possibilities of the Latin American

industry. It should be noted that the kind of studies set forth in this stage see Latin America as a whole, acknowledging differences between the countries that have relatively stronger economies, such as Mexico and Brazil, which Fajnzylber considered to be economies that had important lessons to teach regarding exports. Diagnostics and projections in specific industrial sectors allowed Fajnzylber to set forth specific strategies that would serve as points of reference for the generation of concrete industrial policy and actions of the regional institutions for development.

Later on, in the second half of the 1980s, Fajnzylber went back to Chile where he joined the Economic Commission for Latin America and the Caribbean (ECLAC) as director of the Department of Industrial Development. By 1987, a new stage was initiated in the analysis of themes associated with development. This stage was opened with the publication in 1987 of “La industrialización de América Latina: de la ‘caja negra’ al ‘casillero vacío’” (“Industrialization in Latin America: From the ‘Black Box’ to the ‘Empty Locker’”). In this work, again based on empirical comparisons, Fajnzylber analyzes technological development in a more refined way: this is theme of the “black box” for Latin America, which, as Fajnzylber shows, constitutes the shadow of Latin American industrial development. In addition, he delved more deeply into issues that he had already set forth, such as productive dynamism and competitiveness.

From this point, technical progress will constitute an important aspect of Fajnzylber’s reflections and contributions to the formulation of development strategies. It is therefore important to record that it is now that one of Fajnzylber’s most polemical themes emerged: the differences between the more traditional structuralist perspectives of ECLAC members and Fajnzylber’s so called “neo structuralist” vision. In his perspective, Fajnzylber uses the same diagnosis as the original structuralist perspective, but recognizes that in the 1980s the conditions in Latin America, given the economic crisis it was going through, were substantially modified. This recognition is in fact his core innovation. He therefore set forth new development options for the Latin American countries. These options were contrary to

previous formulae of “inward growth” and suggested promoting new pathways to development within the framework of international markets as well as industrial strategies that would place productive sectors in a more competitive position vis à vis international markets.

Fajnzylber developed in greater detail the aforementioned ideas, such as creative integration into the international economy based on strengthening the endogenous nuclei of growth. This integration aimed to incorporate not only the more developed industries with foreign markets but also all those agents involved in the implementation of more general industrial and economic policies. In other words, it did not exclude the state as an important agent. Had he excluded the state, he would have left the possibility of promoting development exclusively in the hands of market conditions. Above all, he gave transnational corporations an important role to play, which generated intense polemics especially in comparison to ECLAC’s traditional structuralism.

Fajnzylber’s core idea of “empty lockers” refers to the incapacity of the countries in the region to relate sustained growth with equity. It refers to a more specific development of the problems related to social inequality, social opportunities, and even some ideas associated with social mobility. All the works Fajnzylber headed as coordinator of the ECLAC work teams addressed these issues.

With this step, we find one of the most interesting lines in Fajnzylber’s research profile: it is here that his work is enriched through its adoption of a more sociological perspective. The studies of problems of economic development, competitiveness, industrial strategies, and the promotion of endogenous nuclei of development are now accompanied by studies on inequality and equity as crucial problems to be faced in order to achieve sustained growth, based on an evaluation of the real conditions of the third world economies focusing on social equity.

In these studies, equity is embedded in a context that includes other countries beyond the Latin American region. These studies aim to approach the issue of globalizing trends and the changes experienced in national policies on technological development. These globalizing tendencies are related not only to the opening

of markets but also to the crisis of the Taylorist–Fordist model of production, until then followed by the countries of developed capitalism in the western world. Fajnzylber therefore turned his eyes to the East Asian countries, in comparison to which the Latin American countries lack technological development, the “black box” and the “empty locker” of distributional equity.

From this perspective, the themes of Fajnzylber’s later works diversified, constructing a more complex vision. Fajnzylber later looked into themes such as the structures and working conditions of labor that lead to low productivity in the region and associated this problem with the social conditions that can have an adverse impact on competitiveness.

The inclusion of these social issues strongly reinforces the arguments of the analysis and proposals on structural strengthening and competitiveness. Fajnzylber thus comes up with another crucial concept, for the understanding of his position of “authentic competitiveness” incorporates equity as a fundamental factor because of its direct relation to technical progress and therefore to competitiveness and growth.

The analysis linked to this new concept is directly associated with the public policy making processes. The core recommendations incorporated equity not only in areas such as labor but also in impulse reforms within national institutions, as the concept of equity that is set forth not only refers to addressing and integrating the sectors of the poor, but is also a concept that aims to articulate society as a whole: from the poor to the entrepreneurs.

This point leads to a fair understanding of the complexity of Fajnzylber’s thought around the more global idea of regional growth. It implies understanding the role played by both national and transnational firms especially in the space of the endogenous nuclei of development, these nuclei’s drive toward technological progress, and the recognition of the global conditions of competitiveness and national institutional conditions. All these spaces are composed of public and private actors who could influence the development and implementation of national policies. In this sense, Fajnzylber clarifies that it is not a question of transferring formulae from other countries, but

of recognizing and seeing to the specific local and national contexts.

This is why institutional reforms that promote equity are gaining increasing importance. They set out by considering inequalities not only or even primarily as an economic problem, but as a challenge to be faced by the various political, economic, and social actors. It is no longer a question of seeing to the poor sectors through a welfare state, as ECLAC’s past perspective foresaw. It is now a question of integrating all the social sectors in a structural transformation.

The most refined development of these ideas was materialized in an ECLAC document, *Transformación productiva con equidad* (*Productive Transformation with Equity*), published in 1990. Although this document is signed by ECLAC as a product of institutional authorship, it was the product of the hard work of a team headed by Fajnzylber, recognizing the so called “renovation of ECLAC thought.” In this document, we can find once again the construction of more complex versions of the concepts originally incorporated in earlier works. It refers to authentic competitiveness, but with a systemic character. The specific proposals for institutional reforms are precisely systemic. It is now a question of reaching a transformation that goes beyond partial agreements between unconnected levels that take decisions around sectoral public policies.

This transformation should be sought not only in the economic sector but also in the political realm. This is clearly expressed in the emphasis placed on the theme of democracy, which is understood as an indispensable, but not sufficient, condition in the search for equity since it broadens the possibilities of participation of sectors that have so far been excluded. It is thus a transformation that is based on the possibility of having a “framework of social and political coexistence.”

According to this work, institutional change, indicated in the political system, should include broad sectors and institutions. Education is one of the most important sectors that will gain significance with the ideas associated with the development of necessary and indispensable human resources to promote productive and technological development.

Bringing in the educational issue offers a very interesting shift in what we have

recognized as one of Fajnzylber's most important sociological contributions. *Transformación productiva con equidad* introduces the possibility of exploring the analysis and search for strategies to deal with the relationship between technological development and the productive system, on the one hand, and education, training, science, and technology, on the other. This relationship is based on ideas that became part of the education policies in the late 1980s and early 1990s and which are guided by the notion of a "society of knowledge," based on the consideration that access to knowledge – i.e., educational equity – is the essential foundation for the development of both individuals and nations.

The emphasis on education is also placed on the process of institutional transformation. This is the reason why, beyond the reforms to economic and political spaces, educational institutions at all levels must also be reformed. In this sense, it is indispensable to talk about another of ECLAC's works that delves more deeply into the need to face a series of conditions of educational equity and the development possibilities of the productive system: *Educación y conocimiento: eje de la transformación productiva con equidad* (*Education and Knowledge: An Axis of Productive Transformation with Equity*). This work was published in 1992, after Fernando Fajnzylber's death, but the research and the work behind this publication were still carried out by Fajnzylber. An introductory note in the document mentions Fajnzylber's guidance.

Fajnzylber's influence can still be appreciated in this document, which sustains the arguments set forth in their initial stage in ECLAC's previous works: the need for institutional reforms, the systemic character of growth and competitiveness, as well as the need to train and develop human resources not only to face the technological changes coming from other countries, but also to participate in the technological drive of the Latin American countries.

The role sustainability plays in economic development is just as important as the role of education. Fajnzylber's thinking always included the ecological dimension, particularly in *Transformación productiva con equidad*, and in ECLAC's *El desarrollo sustentable: transformación*

productiva, equidad y medio ambiente (*Sustainable Development: Productive Transformation, Equity, and the Environment*), published in 1991. The ecological dimension was also considered a basic condition linked to economic development and was set forth as a "condition that enables competitive patterns to be sustainable."

In retrospect, these latter ECLAC publications can be considered Fajnzylber's first steps in a new line of work that was even more complex than the initial publications. Unfortunately, this new line of work only remained as a proposal since Fajnzylber's early death interrupted what promised to be the consolidation of this "new ECLAC perspective."

Those who study ECLAC and Fajnzylber's work have recognized that his ideas, concepts, and analysis were constructed while foreseeing the changes he was studying. The apparent simplicity of Fajnzylber's developed, detailed, and deep research work, mostly based on comparative experiences, allowed him to present his ideas in an accessible and understandable way.

Over 20 years of uninterrupted production (publications, courses, conferences, and documents) distinguished Fernando Fajnzylber. His work never ceased to reflect his commitment to Latin American development. Fajnzylber's work is not only an exemplary analysis of Latin American economic conditions, but also managed to be transferred into direct action in developing and implementing public policies for the productive sector that faced economic growth and social justice at the same time. While Fajnzylber had an undeniable influence on economics, his contribution to sociology was equally important.

Faletto, Enzo (1935–2003)

Ricardo Gamboa Ramírez

Enzo Doménico Faletto Verné was born in Chile in 1935 and died in Santiago de Chile on July 22, 2003. He studied history in the Faculty of Philosophy and Education at the University of Chile and received an MA in sociology at the Latin American Faculty of Social Studies (FLACSO). Faletto must be considered as a representative of social sciences and humanities in Latin America, two disciplines which achieved the peak of their development in the early 1970s.

Faletto's social and humanist vocation can be appreciated in the various disciplines treated in his books and articles, as well as in the lectures he gave while a teacher at the Sociology Department of the University of Chile and at FLACSO. From 1967 to 1973 he taught classes to students of sociology and journalism at the University of Chile. In addition, Faletto was a researcher at the Latin American Institute for Economic and Social Planning (ILPES), and after 1973 he worked as an expert in the Social Development Division of the United Nations Economic Commission for Latin America and the Caribbean (ECLAC). He also worked in several foreign universities, including the University of Rosario in Argentina, which awarded him an honorary doctorate.

Faletto combined his academic career with political activity in the heart of the Socialist Party of Chile, where he was part of a group known as the “Swiss” faction which included Ricardo Lagos, president of Chile (2002–6),

among its members. Two important aspects of Faletto's political career should be highlighted.

The first is that, despite the intellectual and friendship bonds he enjoyed for most of his life with Fernando Henrique Cardoso and Ricardo Lagos, presidents of Brazil and Chile at the end of the twentieth century and beginning of the twenty first, Faletto refused to be present when they assumed their respective terms of office. After Lagos had won the elections in 2000, Faletto even warned him that he would not see him again until the end of his term in 2006. This attitude reveals how Faletto, a convinced social democrat, understood the kind of relationship that an intellectual should have with the highest political circles.

The second aspect is that after the coup d'état which overthrew president Salvador Allende on September 11, 1973, Faletto decided to remain in Chile instead of living in exile. Even though this decision led to many problems on account of the military junta's censure, it also offered Faletto the opportunity of holding a point of view on the Chilean reality during the hard years of the military dictatorship different from that of his exiled colleagues.

Nevertheless, the circumstances imposed by the repression made him abandon the university to "take labor refuge" in the heart of ECLAC and FLACSO, until finally in 1990 he was reinstated to his academic work at the house of Andrés Bello, where he was the head of the Seminar of Social History of Latin America until his death.

As with his vast written work, the name of the seminar was only a pretext to develop an analysis of the reality of Latin America, where economy, sociology, politics, and history merged in a multidisciplinary exercise that gave rise to works that constitute real milestones of social knowledge. Before the avalanche of the so called unique thought characteristic of neoliberalism, these works deserve to be rescued in a double sense: as a sample of the history of social thought in Latin America, and as an example of a methodological and epistemological approach that nowadays should be incorporated into the knowledge of disciplines such as sociology and particularly economy, which has strayed so far in recent years from its social and humanist origins.

HISTORICAL CONTEXT OF ENZO FALETTO'S WORK

Throughout his academic career, Faletto published a wide range of books and articles in specialized journals. To gain an idea of the extent of his written work, it should be mentioned that in January 2005 the dean's office of the University of Chile announced the creation of the Enzo Faletto Seminar. During this ceremony Carlos Ruiz, a disciple, colleague, and friend of Faletto, mentioned that work had just begun on compiling the scattered writings of this prominent scientist, and so far there were already 80 titles.

Faletto published articles in specialized journals, the most relevant ones since 1990. Without doubt, the circumstances associated with the fall of the Soviet bloc, as well as the predominance of social, political, and economic individualism imposed by neoliberal policies, motivated his work on topics such as the role of the state in contemporary capitalist societies, particularly in Latin America; modernity and the role of social classes in today's world; the relation between democracy and political culture; and the theory of dependency and its role in the neoliberal project at the end of the twentieth century.

Of all the books by Faletto, undoubtedly the most powerful is that co written with Fernando Henrique Cardoso, *Dependencia y desarrollo en América Latina (Dependency and Development in Latin America)*, first published in 1969. Because of its number of printings (30 until 2002), this is one of the most important social science publications throughout the world; it has also been translated into other languages, including English and Portuguese. The importance of this work lies in the fact that it was the first attempt to systematize an interpretive model of the economic development of Latin America, having as the focal point of its line of argument the dependency relation between developed countries and the periphery, from the first world expansion of capitalism in the sixteenth century to the internationalization of capital in the second half of the twentieth.

Nevertheless, as with other intellectual undertakings, this book is not a product of chance. It was written by professors Faletto and Cardoso at the peak of a process in which

the relationship between academia and politics, between the theoretical and the ideological, would define many of the characteristics of political culture in Latin America after 1950.

The background of 15 years' work by ECLAC interpreting Latin America's economic development, taking as its starting point the relationship between center and periphery, was one of the primary influences in Faletto and Cardoso's work. ECLAC was created in 1948 by the Economic and Social Council of the United Nations. This international organization was headed for almost 15 years after its foundation by the Argentinean economist Raúl Prebisch.

The Latin American and Caribbean Demographic Center (CELADE) as well as ILPES were created inside ECLAC. In 1964, the second event influencing the intellectual trajectory of Cardoso and Faletto's work occurred. Following the 1964 coup d'état in Brazil, a group of Brazilian intellectuals and scholars sought refuge in Chile where they could continue developing their academic and political reflection. At this time important figures in the academic world could be found at ILPES, such as Ruy Mauro Marini, Theotonio Dos Santos, Fernando Henrique Cardoso, American professor André Gunder Frank, and the still young Enzo Faletto. The discussions inside ILPES daily recreated many of the topics of interest defined by ECLAC, which considered that an essential element of Latin America's backwardness was the unequal relations in terms of technology, productivity, and commercial exchange established between central and peripheral countries.

There are three overarching topics. The first two relate to the industrialization of Latin America and to the state's role in developing that process as a way of analyzing the unequal conditions imposed by the core-periphery relation. The third consists in a thorough understanding of the economic problems faced by Latin American countries as a result of structural conditions historically confronted by those nations, and not only of monetary phenomena such as price rises and inflation.

Another important factor in Faletto and Cardoso's work was the publication in 1960 of Washington Whitman Rostow's *Stages of*

Economic Development. In this work, Rostow argues that the underdeveloped nations must repeat the economic growth styles of developed countries, particularly in their definitions of economic policies, in order to move beyond the stage of underdevelopment. This apparently simple formula met with immediate criticism from Latin American social scientists, especially in relation to its ahistorical, indeed anti historical, nature, since it left aside an element that would afterwards be taken up again by Faletto and Cardoso: the historical nature of dependency relationships between center and periphery.

Rostow's position in relation to the economic takeoff was influenced by the German historicist stream of thought at the end of the nineteenth century, but above all by the quantitative historical studies on the economic variables associated with growth promoted mainly by the American economist Simon Kuznets. The transposition of economic growth behavior from the central countries to the underdeveloped nations faced immediate theoretical rejection from the different streams that merged in ECLAC and in the Chilean ILPES.

This theoretical rejection emerged from a cultural tradition in Latin America that stressed the importance of understanding the historical process of the development of nations and states, as well as the inequality of prevailing conditions in the region. This tradition began in the nineteenth century in the context of the struggles for independence and in the political processes that gave rise to the formation of Latin American states.

The Cold War and its particular features in the area provide an additional element in the context in which Faletto and Cardoso wrote the book. The victory of the Cuban Revolution in 1959, and its early definition as a socialist revolution, cleared the way for the possibility of economic development different from the capitalist system. This essentially ideological discussion prevailed among Latin American social scientists beginning in the 1960s. Moreover, the determined political attitude and affiliation of many of these intellectuals made it inevitable that their theoretical developments would be accompanied by an essentially anti capitalist definition.

DEPENDENCY AND DEVELOPMENT IN LATIN AMERICA

Most Latin American experts agree on characterizing the work of Faletto and Cardoso as part of the structuralist stream that finds in dependency the key to explaining the roots of Latin America's underdevelopment. Structuralism attributes the main causes of economic backwardness to the deformations and imbalances in the economic structures of Latin American countries.

In Faletto and Cardoso's book, the imbalances in the economic structure are determined by the dependency relations established between peripheral and central countries, dependency relations that have their own historical features depending on the kind of integration within the global market that developed after the colonial pact was broken off. The characterization of the different historical stages of integration within the global market is one of the book's major contributions. The first stage is outward development, the second is the transition to capitalism, the third is the consolidation of the inner market and the beginning of the industrialization process, and the final stage relates to the internationalization of Latin American economies. In this historical model, Faletto and Cardoso distinguish between consolidated national economies and enclaved economies. However, this structuralist vision surpasses the economic sphere. As Faletto repeatedly stressed, his intention was to give a sociological dimension to economic backwardness and to dependency.

One of the main contributions of Enzo Faletto's work can be found in the definition of the sociological dimension of dependency and economic backwardness, which is still useful for the analysis of contemporary societies in the early twenty first century. For Cardoso and Faletto, the problem of backwardness in Latin American countries cannot be considered only from the point of view of economic variables, least of all by comparing them to how they behave in developed countries. Comparison makes no sense unless the following elements are considered:

- The special features of historical processes that led to the formation of national economies.

- The role of the state in the formation of the economic structures of individual countries.
- The formation of the different social classes, particularly the entrepreneurs and the oligarchy, as well as the working class.
- The way in which these social classes are linked with the oligarchies of the central nations.
- The way in which the national economies integrate into the international market.

In this respect, an essential element emerges for an understanding of the neoliberal order in recent years. From the publication of *Dependency and Development in Latin America* and in later articles and essays, Faletto defines Latin American national economies as capitalist economies integrated into the world market, particularly since the internationalization of capital that took place after 1950.

This definition is neither obvious nor point less. Since so called globalization turned out to be a kind of leitmotif of social analysis after 1990, there was a tendency to define Latin American societies as isolated from the tendencies of the market that supposedly encouraged capitalist development after the Bretton Woods Agreements in 1944. The contributions of Faletto demonstrate that there is nothing more distant from reality; the presence of capitalism and integration within the global market has been constant in the history of Latin America.

The consequence of the loss of sociological perspective, in the sense that Faletto understood it, was the emphasis on market forces as the means by which the nations of Latin America would gain access to economic development. This led to the idea that it was sufficient to imitate the so called emergent market economies, like those in Southeast Asia, in order to achieve high standards of economic growth and welfare. The revision of economic takeoff theory, now based on the impulse of market forces and of so called economic miracles, suffers from the same flaws as its distant and forgotten predecessor devised by Rostow: its clearly unhistorical element, which in itself makes it necessary to return to theoretical aspects developed by Latin American social scientists, of whom Enzo Doménico Faletto Verné was one of the main exponents.

false consciousness

Brian Starks and Azamat Junisbai

False consciousness is a Marxist theoretical concept referring to the circumstance, or state of being, in which workers hold views that are contrary to workers' objective class interests. This subjective consciousness does not arise organically from among workers, but is imposed (or foisted) upon them by the dominant ideology of the capitalist class. False consciousness and class consciousness are intimately linked. Whereas class consciousness

denotes workers' awareness of their historical position and enables the transformation of society, false consciousness denotes workers' failure to recognize their position and bring about the transformation of society. Because of its elitist and arguably negative view of workers (as dupes), the concept of false consciousness often offends modern democratic sensibilities. Not only that, but with its apparent reference to objective truth, false consciousness in an era of postmodernism smacks of intellectual arrogance. Perhaps for these reasons, the concept has fallen into disuse among sociologists.

It appears that the term was first coined by Friedrich Engels; there is no evidence that Karl Marx himself ever used this in his writing (Eagleton 1991). The term's initial appearance in print was in a letter written by Engels to Franz Mehring in 1893:

Ideology is a process accomplished by the so-called thinker consciously, it is true, but with a false consciousness. The real motive forces impelling him remain unknown to him; otherwise it simply would not be an ideological process. (Tucker 1978: 766)

The concept, as developed in Engels's letter and in later writings, is rooted in the earlier writings of Marx and Engels in *The German Ideology*. While theorists have debated whether Marx himself would have accepted the precise term *false consciousness*, the concept is closely tied to Marx's notion of a "dominant ideology" and is useful for understanding Marx's theory of historical change. As with many sociological ideas, the meaning of false consciousness has varied and changed over time as new theorists have drawn upon it and as these new formulations have been challenged and contested (see Eyerman 1981; Eagleton 1991).

Engels, for example, tended to equate false consciousness with ideology and applied the concept primarily to intellectuals and capitalists, whom Marx and he had always criticized for producing a distorted picture of reality. Somewhat idealistically, Marx and Engels tended to credit the working class with freedom from illusions due to its subordinate position in capitalist society. Aware that not all of the working class fit this description, however, they reasoned that the working class was composed

of not just the proletariat but also the lumpen proletariat, or rabble who failed to act as revolutionaries. Later Marxists, such as Antonio Gramsci and Georg Lukács, expanded upon these ideas in their elaborations on false consciousness.

For Gramsci, the concepts of dominant ideology and false consciousness are distinct. False consciousness refers to flawed perception on the part of workers, whereas the dominant ideology is understood as a system of ideas and propositions espoused by owners to support the status quo. In an effort to understand the power of capitalist ideology over the working class, Gramsci examined the effect of culture and especially religion (part of Marx's superstructure) on the ideas and consciousness of the working class. Gramsci argued that hegemonic rule, in which a majority of the population supports or accepts the status quo, requires that owners manufacture consent and this is made possible by false consciousness on the part of the oppressed. Gramsci believed that movements for progressive social change must reeducate the masses to liberate them from false consciousness. Workers' support for gradual political and economic reforms rather than revolutionary action is a sign of their false consciousness or failure to recognize the true origins and proper means to end class based oppression. Thus, genuine reeducation would occur only with the illumination of Marxist ideology, which offers an explanation of exploitation and poverty to workers. For Gramsci, false consciousness is a problem of working class (mis)perception that can be countered only by a competing ideology (i.e., Marxism).

Whereas Gramsci emphasized the need for Marxist ideology to combat capitalist hegemony, Georg Lukács argued that false consciousness is not purposefully manufactured by the bourgeois intellectuals to subjugate the proletariat; rather, it is an outcome of living and working in a capitalist society permeated by exchange relations and commodity fetishism (in which people commodify and objectify not only things but themselves). Consequently, capitalist societies create a veil of mystification that precludes a true understanding of the social order. Functioning in a world of commodity relationships, in which markets appear to determine outcomes and in which the value

of something is understood as its price in exchange rather than the labor contained within it, inevitably produces false consciousness. To the extent that commodity fetishism dominates, false consciousness becomes the normal way of perceiving and acting within capitalist society, thereby concealing the true nature of capitalism from all involved. While this mystification is beneficial to the bourgeoisie, the working class suffers from it. For Lukács, not surprisingly, only the working class is structurally capable of achieving a total/real understanding of itself and of capitalism as a social system, and eventually transforming it into a more rational system. This is because of its location at the center of the main capitalist contradiction and irrationality – the workplace where surplus value is extracted.

Lukács's approach to false consciousness served as a point of departure for members of the Frankfurt School (Max Horkheimer, Theodor Adorno, Herbert Marcuse, Erich Fromm, etc.). These scholars sought to understand the striking absence of working class opposition to the rise of fascism in Germany in the 1930s. They argued that a full explanation of working class acceptance of Nazi authoritarianism must examine workers' activities outside of the labor process and must take into account their unconscious or "irrational" impulses and emotions. For example, Fromm added an affective psychological dimension to the study of false consciousness and attempted to synthesize Marxist and Freudian theory. Consequently, he argued that working class experience in a capitalist society produces not only a false perception of one's economic interest but also a false sense of self/identity. Thus, false consciousness has an emotional as well as cognitive dimension and is not easily demystified or transcended by a mere rational ideology such as Marxism. As the Frankfurt School broadened the definition of false consciousness to include self and identity, it became increasingly difficult to speak of "objective" class interests and discussions of false consciousness became embroiled in philosophical debates regarding the nature of "true experience."

While the term false consciousness has been variously used by a number of European scholars, sociologists in the US have rarely used it. A modern day application of the concept of

false consciousness, however, can be found in some explanations of American exceptionalism. The absence of a well developed working class party in the US has lent itself to many different hypotheses and explanations over the years. Whereas some sociologists and historians have sought to explain the lack of a working class labor party by reference to the US's higher standard of living, increased capitalist organization and resistance, and/or absence of an aristocracy, others have argued that it is the widespread ideology of the American Dream that has hampered the development of working class consciousness.

In this latter view, the American Dream of "rags to riches" and "opportunity for all" is the dominant ideology in America. It serves to legitimize inequalities within the US by providing workers with "false promises." When workers believe promises that they will be able to get rich in the future, they accept their disadvantaged positions in the present (Robinson & Bell 1978). As Aronowitz (1973) recounted, the labor movement in the US emerged largely as a trade union movement seeking a place at the table rather than to revolutionize the means of production itself. This is due, in no small part, to the fact that workers are focused on moving up economically rather than in transforming the capitalist system itself. In accepting this system, however, Americans often end up blaming themselves, rather than the economic system, for their own lack of success (Sennett & Cobb 1972).

While belief in the American Dream can thus be understood as a form of false consciousness, the term false consciousness is almost never used by these researchers. The conspicuous absence of this term may simply reflect a diminished Marxist influence on sociologists in the US. More likely however, its absence from modern American sociology underscores most sociologists' attempts to grant authenticity to workers' own views, even if these views sometimes have negative repercussions for workers themselves. Much to the chagrin of committed Marxists, in the current age of identity politics, the prospects for this term in US sociology appear bleak.

falsification

Andrew Tudor

The concept of falsification is indelibly marked by the methodological doctrine of falsificationism, associated above all with the work of Karl Popper. He first developed the elements of his position in the early 1920s as part of a project to establish a logically defensible criterion of scientificity, culminating in the publication of *Logik der Forschung* (later translated as *The Logic of Scientific Discovery*) in 1934. Falsifiability emerged as the basis of his solution to the so called "problem of demarcation." Much elaborated over subsequent years, his analysis of falsification became the foundation for the Popperian school in the philosophy and history of science and the central feature in their influential account of scientific growth. However, in the 1960s and 1970s, dissatisfaction with this analysis, not least among some of Popper's own

followers, gave rise to variously radical revisions of the basic falsificationist position. Today, both the Popperian doctrine and the concept of falsification should be understood as component elements in a more diverse, though perhaps less rigorous, conceptualization of theory testing in science.

Falsificationism was inextricably bound up with the problem of demarcation: the perceived need to distinguish science from a variety of other intellectual activities, not least what Popper called "pseudo science" – a category within which he included the theories of Freud and Marx. His argument begins with the recognition that the traditional view of science as based on systematic, inductive generalization is logically indefensible. Echoing Hume, Popper suggests that there is no reason why we should expect that further instances of a phenomenon will resemble those that we have already experienced: famously, however many white swans we may observe will not justify the conclusion that all swans are white. There may be a black swan just around the corner.

What, then, does distinguish the statements of empirical science? By the logic of the *modus tollens* it is permissible to argue from the truth of a singular statement (this swan is black) to the falsity of a universal one (all swans are white). So, although we cannot confirm a general statement without fear of subsequent contradiction, we can falsify it. This, then, is the criterion of demarcation: "it must be possible for an empirical scientific system to be refuted by experience" (Popper 1968: 41). In principle, scientific conjectures must always be open to refutation.

Taken as an isolated logical point about the relation between hypothesis and evidence, this view attained widespread legitimacy in the social sciences and elsewhere in the mid twentieth century. Indeed, as late as 1993 the US Supreme Court elaborated its *Daubert* criteria for scientific expert witness testimony in unashamedly falsificationist terms. However, interpreted thus, falsificationism is little more than a dogmatic application of the Popperian view. Even "naïve falsificationism" – the term Lakatos (1970) uses to describe Popper's initial formulation – is not as reductively simplistic as this. Falsifiability in principle, after all, is a general criterion of scientificity, not a specific methodological instruction. Furthermore, when

a statement is actually falsified, it is the whole system from which it is derived that is rendered suspect, and quite what aspect of that system is taken to be problematic remains a matter for scientists' practical decision making. As Duhem and, later and more forcefully, Quine suggested, there is no simple thread of falsification relating the world of observables to that of theory. And as sociology of science studies of scientific controversies suggest, the reasons for actually rejecting a hypothesis or theory are many and varied.

Nevertheless, there always remains an element in the falsificationist doctrine which understands the growth of scientific knowledge in terms of the successive improvement of theories in consequence of attempts at falsification: "severe tests," as Popper describes them in his discussion of corroboration. It is this core belief that scientific progress is fostered by critical rational method which was increasingly to founder on the rocks of historical evidence. Scientists, it was observed by historians and sociologists of science, did not behave as the falsificationist model proposed. To such observations Popper was inclined to reply, well they should, a reflection of his perception of philosophy of science as an essentially normative endeavor. But that commitment was increasingly at odds with the more relativistic tenor of the times, and criticism of falsificationism became more vocal even from within the Popperian camp.

The most interesting of the critical revisions, and certainly the one most focused upon issues of falsification, was that advanced by Imre Lakatos (1970). He suggested that Popper's position had been misrepresented as a somewhat naïve and dogmatic account of falsification. While in some respects the Popperian model was dogmatic, there was also an implicit, more "sophisticated" Popper who was aware of the limitations that needed to be placed upon the initial, naïve model. Thus, although Popper does not fully incorporate the insights of other more conventionalist and historically aware accounts of science, his views do not exclude that possibility. So in proposing his "methodology of research programmes," Lakatos sets out to modify falsificationism accordingly. In effect, he replaces the core supposition, that specific theories must be falsifiable, with a

more pluralist account which emphasizes (in) consistency among theories. "It is not that we propose a theory and Nature may shout NO," he writes; "rather we propose a maze of theories, and Nature may shout INCONSISTENT" (Lakatos 1970: 130).

Nonetheless, Lakatos remains committed to the characteristically Popperian view that, although much of scientific inquiry is a matter of convention, science is at heart a critical rational enterprise. He wants to "save science from fallibilism." Extensive historical and sociological study of science and scientists in the later twentieth century has made that an increasingly difficult position to defend, with the result that falsificationism is no longer central to academic debate. However, the issues of method raised under its flag remain vital to any full understanding of the processes whereby we seek to confront our statements about the world with what Quine once called "the tribunal of sense experience."

families and childhood disabilities

Valerie Leiter

Families of children with disabilities experience challenges that other families do not face. They may experience stigma as a result of having a child with a disability and may perform health care and advocacy work for their children beyond that performed by other families. The extent of these additional concerns varies tremendously across families, depending upon the nature and severity of the children's disabilities and the social context in which the meaning of the children's disabilities is interpreted and acted upon. At the individual level, some children may have disabilities that affect their functioning slightly, while others may have disabilities that affect their functioning severely, across multiple areas, including physical, cognitive, emotional, and behavioral functioning. At a broader social level, some children with disabilities live in families and communities that attempt to eliminate social barriers that could result from disability, while others live in social contexts that do not strive to promote children's full participation.

While it is important to acknowledge these ways in which children with disabilities and their families are "exceptional," it is equally important to acknowledge that families of children with disabilities are in many ways just like other families. Over the past four decades, parents of children with disabilities in the US, UK, and Canada have sought recognition for the caring labor that they perform, and some have fought against the ways that some professionals, researchers, and public programs have treated them as pathological and in need of intervention.

Disability is often stigmatized in the way that Erving Goffman described in his 1963 book, *Stigma: Notes on the Management of Spoiled Identity*, and families may face what Goffman called "courtesy stigma" when individuals stigmatize the entire family because of the child's disability. In its most severe form, this stigmatization of families may be found in Bruno Bettelheim's 1967 book, *The Empty Fortress*.

There, Bettelheim presented his “refrigerator mother” theory of autism, which blamed mothers for their children’s autism. Less severe forms of courtesy stigma may also be found in social science research and in service systems that focus only or primarily upon families’ needs and weaknesses, ignoring their knowledge and strengths. Recent social research and public policy provide a more balanced view of families of children with disabilities, and of the children themselves, acknowledging that they face added concerns and stresses as a result of disability, but also documenting the capabilities, expertise, and strengths that children and families may bring to these challenges.

These changes in policy and professional attitudes regarding families of children with disabilities are the result of parental activism over the last 40 years. Children with disabilities and their families were largely invisible in public policy until the 1960s and 1970s, when the parents organized on behalf of their children, transforming the nature and location of therapeutic care and education for children with disabilities. Until the 1960s in the US and the 1970s in the UK, parents had to choose between keeping their children at home and not receiving any public services, or placing their children in residential institutions, called “schools” in the US and “long stay hospitals” in the UK (Read 2000; Leiter 2004).

In the UK, the thalidomide disaster and problems regarding vaccine damage created public concern regarding children with disabilities (Read 2000). Parents’ organizing began a little earlier in the US, in the 1960s and 1970s, when parents borrowed tactics from the Civil Rights Movement to fight for community based services that would allow them to keep their children at home. Most of those battles centered on public education, resulting in the US Congress passing the Education of All Handicapped Act in 1975, which is now called the Individuals with Disabilities Education Act (IDEA). Then in the 1980s, parents collaborated with professionals who provided services to children with disabilities and lobbied the US Congress to extend public services to children with disabilities from birth. This parent–professional collaboration resulted in the creation of additional community based public services, in substantial changes in the way that

public programs describe families, and in additional legal rights for parents. There is now considerably more emphasis upon families’ strengths, knowledge, and capabilities in programs that serve children with disabilities. Parents also have more rights to participate in making decisions about their children’s health care and education. Parents’ uptake of those rights varies tremendously, and parents with higher levels of education are more likely to advocate for their children within service systems. While parental rights have been an important tool for families when advocating for their children within public programs, this rights based approach to social change has put the burden of creating change upon parents rather than upon the professionals within public programs who wield decision making authority.

In addition to advocacy work, families may also provide substantial health and therapeutic care to children with disabilities (Read 2000). Although fathers may perform some carework, most carework is performed by mothers, due to traditional gender roles that emphasize mothers’ provision of care to children and fathers’ economic support of the household. There is an important distinction here between the carework that mothers *typically* provide, such as taking care of children when they have colds, etc., and the *additional, atypical* carework that mothers provide that is associated with their children’s disabilities. Both the extent and scope of carework are greater within families of children with disabilities. Within a sample of mothers of children with special health care needs, Leiter et al. (2004) found that almost one fifth of the mothers performed 20 hours or more of carework per week, doing therapies, dressing changes, care of feeding or breathing equipment, and so on. Mothers’ provision of carework to their children with disabilities can also have other ripple effects within the family. For example, mothers may cut down their working hours or stop working altogether, and families may have less income as a result.

Much of the current knowledge regarding families of children with disabilities focuses upon the early parts of a family’s life course, when the child is still a minor, with few exceptions (such as Krauss & Seltzer 1997). Far less is known about families of children with

disabilities later in life, providing a rich area for future sociological research.

family and community

Betty Hilliard

From the earliest days of sociology, family and community have been central concerns of the discipline. The dense interpenetration of these two dimensions of life was associated in particular with simple societies. This is especially evident in the work of early social thinkers such as the German Ferdinand Tönnies and the Frenchman Frederick Le Play.

The development of more complex societies brought with it the emergence of specialized

institutions catering to discrete aspects of social life which previously were catered to within the family and local community (e.g., economic, educational, and religious activities). With the development of these more complex societies the nature of social relationships also changed. It was thought that both family and community, if not actually in decline, were certainly less pivotal than before in the life of society. This was the theme of much work in English language sociology in the middle decades of the twentieth century. Aspects of it may even be traced in the writings of the highly influential American sociologist Talcott Parsons in his discussions of societal differentiation, the narrowing of the functions of the family, and the sometimes misrepresented concept of the “isolated” nuclear family.

In subsequent decades of the twentieth century the study of family and community became less fashionable in sociology, as an overview of many textbooks of the time will testify. It seemed that in modern society community extended beyond the locality and the family, and their interrelationship no longer seemed unproblematic. In practice, empirical research continued to attest to the persistence of both family and community, and in more recent times the centrality of the family, the significance of community, and the continued importance of the relationship between them have been reasserted (Crow & Maclean 2004).

MEANING OF FAMILY AND COMMUNITY

The definition of these concepts is contested. In empirical terms what constitutes a family has varied throughout history and between cultures. For present purposes the discussion of family and community refers only to these phenomena in western societies. In sociology the debate around a standard definition of family dates from the late 1960s. A functionalist definition of the family as an adaptive system which takes responsibility for a particular range of tasks had been dominant, particularly in the middle decades of the twentieth century. These tasks may include the reproduction, socialization, and maintenance (emotional as well as physical) of members, as well as the exercise

of social control and the transmission of culture. However, it is widely recognized that the existence of different family forms across time and cultures makes it very difficult to formulate a definition of family which is both comprehensive and concise.

As a result, many writers now prefer to speak of "families" (Allan & Crow 2001), "family life" (Cheal 2002), or "family practices" (Morgan 1996) rather than deal in such a contested term as "the family." Recent practice in many western welfare systems has expanded the concept of family units to nonmarital cohabiting couples and in some countries to same sex marriage and partnerships. There is an ideological complexion to much of the debate on what should or should not be regarded as a family. The empirical reality is of course that "family" is not a static construction, but a dynamic phenomenon which is negotiated and renegotiated in relationships, always within the context of a social structure which itself is subject to change. Also, a family exists as part of a network of kin relationships, the salience of which may vary significantly even within a culture, and certainly across cultures.

Similarly, the concept of community refers to a dynamic phenomenon which does not readily lend itself to narrow definition (Crow & Allan 1994). Over 50 years ago Hillery (1955) identified over 90 definitions of community even then. Tönnies's (1963: 65) idea of community as a group of people "essentially united in spite of all separating factors" is still relevant. The concept is essentially associated with a body of people who, although unrelated in a family sense, are conscious of having some things in common which contribute to a sense of shared interests, shared identity, and feelings of solidarity, whether weak or strong. In societies where mobility is limited, people share a common life, and there is much neighborly contact, the resultant interaction builds up a sense of solidarity and "we ness" associated with a locality, or in the case of nomads, a tribe. Even in neighborhood communities, however, relations of solidarity are not simply between neighbors as a category, but between particular neighbors who have developed sufficiently close relationships. In more recent times the concept of community has been expanded to include groupings beyond the local. Giddens (1990: 21)

asserts that social relations have suffered a "disembedding," meaning "the 'lifting out' of social relations from local contexts." Even as Giddens made this claim, however, there was ample evidence to suggest that in fact locality still persisted as a vibrant dimension of community life in many settings.

INTERWEAVING OF FAMILY AND COMMUNITY IN SOCIAL RESEARCH

As in the theoretical discussions of the nineteenth century, in the middle decades of the twentieth century sociological research reflected a close relationship between the concepts of family and community. Community studies were especially popular at this time, with the emergence of several classic works such as those of the Chicago School in America, Gans's Boston study published as *The Urban Villagers* in 1962, the 1950s Bethnal Green studies in Britain, and the 1930s County Clare study by Arensberg and Kimball in Ireland. Many of these community studies were closely interwoven with accounts of family life. Indeed, some of them may not have been so successful were it not for the involvement of the researcher with families in the community, as was the case with Whyte's association with the Martini family in his study of *Street Corner Society* (1943). This interpenetration of family and community is further borne out in Frankenberg's (1966) overview of community research in Britain.

Similarly, much family research was inextricably linked to community, as for instance the seminal study of *Family and Kinship in East London* (1957) by Young and Willmott. What is evident from much of this work is the identification of family and community with a spatial location; the social linkages are primarily those of family, kin, and neighbors, who were often also friends.

It would not be fair to say that these social linkages did not extend into other domains; frequently, the world of work is a central feature of family and community study. However, there was a particular emphasis on the identification of family and community with a spatial location, and the spatial reconfigurations of modern society impacted on this. The mobility and dispersion which became a more common

feature of family life in the 1960s fed into concerns regarding the “eclipse of community,” arising from the growth of the suburbs and the establishment of dormitory towns and commuter belts. Indeed, with such change, it has been suggested that family and kinship relations came to be perceived as “the chief, if not the sole, carrier of the idea of community or of a sense of locality” (Morgan 1996: 5). There is a great deal of evidence that family and kin continue to be highly significant in modern society, fulfilling many community like functions; however, family and community are not interchangeable terms.

Besides significant spatial reconfigurations in modern society, a number of developments in sociology from the 1960s on contributed to what was sometimes perceived as a separation of the two areas of family and community as interrelated foci of sociological research. Penetrating critiques of the sociology of the family, from feminist sources in particular, opened up the family unit to considerable scrutiny and to a recognition of the individual interests, economic dimensions, and power relations within the group.

The subsequent concern with relations *within* the family contributed to moving the focus away from community dimensions of family life. This has been further exacerbated by the emphasis in more recent work on the individual rather than the group, as portrayed in the work of Giddens (1991), Beck (1992), and Beck and Beck Gernsheim (2002) on individualization. These writers point out that modern society presents us with a myriad of choices not available to earlier generations, which necessitate a degree of personal reflexivity more conducive to individual action than to a collective orientation. Beck (1992) alerts us to the expanded possibilities for individual choice regarding participation in community, and others have identified communities which need roots in neither family nor locality (Willmott 1986). Families, however, continue to be studied in context and that context includes the local spatial setting.

FAMILY AND COMMUNITY IN SIMPLE SOCIETIES

The portrayals of family and community in earlier societies, and particularly in relatively

simple peasant societies, indicate that these dimensions of life, if not exactly coterminous, were at least closely interwoven. For example, Tönnies conceptualized simpler societies as those characterized by close, intimate, holistic bonds of a primary nature, with the dominant social relationships being those of kinship, neighborliness, cooperation, and fellowship (*Gemeinschaft*), and more developed societies as characterized by rational calculation and segmented, specialized, secondary type association or relationships (*Gesellschaft*). These two terms have been commonly translated in the sociological literature as community and society, respectively. An example of the portrayal of a *gemeinschaft* type society is to be found in the classic work by the Harvard anthropologists Arensberg and Kimball (2001), *Family and Community in Ireland*. This book, based on ethnographic research in the 1930s, paints a picture of rural life characterized by familism, where family ties are the main organizing and structuring principle in the community, both as a social and an economic system. Economic life in particular revolved around the cooperative interpenetration of family and community. The *meitheal* was a common feature of life in this peasant society; this was a cooperative work group where neighbors worked alongside each other to complete various farm tasks which necessitated help beyond that of the immediate family, such as saving the hay in season. Such cooperative practices brought about an identification of the family with the wider community. This identification of course comes also from many other shared experiences, including local schooling, shared social activity, and participation in group religious practices, identified by Durkheim as a particularly powerful form of community cohesion.

One of the features of community type societies is an orientation towards the collectivity, as distinct from a focus on the individual. Family members put the collective interests of the group before their own individual needs; this is especially the case as depicted by Arensberg and Kimball (2001) in relation to landownership and inheritance. (Their portrayal of such issues as non conflictual has been robustly critiqued: see Gibbon 1973.) Le Play saw this collective orientation as revolving around family enterprises, which acted as a sort

of magnet keeping the larger family grouping together in a specific location as a form of community.

Tönnies's ideas were developed, not only theoretically (e.g., by Parsons in his discussion of the pattern variables), but also in the empirical research of the Chicago School, of which Redfield was an exemplary member. While Tönnies recognized that kin networks were not incompatible with urban life, Redfield hypothesized from his comparative research on families and communities in Mexico that the embeddedness of an individual in his family and neighborhood group was a feature of non city life. In his view, as peasant societies come into contact with urban culture they tend to change in the direction of *Gemeinschaft* type society. Redfield contrasted "folk" with "urban" societies and associated the latter with a weakening of the cohesive nature of community.

For Le Play and others, the advent of the industrial revolution, and with it the growth of cities, changed the close identification of family and community described above. In his view the movement of individuals off the land to seek paid employment in centers of industrialization led to individualism, self interest, and a rootlessness which threatened the family. It gave rise to smaller family forms of the type now called nuclear, which lacked the strong structural ties of local community and pre industrial kinship systems; for this reason he identified the new type of family as "unstable" as compared to what he believed to be the "traditional" stem family (*la famille souche*).

He was not alone in seeing industrialization as a threat to group cohesion. Tönnies and others believed that the modernization which accompanied it was eroding the old ways of life and with them the interpenetration of family and community.

INDUSTRIALIZATION AS A THREAT TO FAMILY AND COMMUNITY

The identification by Le Play and others of nineteenth century industrialization with an unraveling of ties between family, the wider kin group, and the community became a dominant theme in twentieth century sociology.

A rapidly changing division of labor was seen as leading to the disruption of social solidarity. The demise of the so called "traditional" family was linked to the theme of the eclipse of community. In revisiting the research interests of Arensberg and Kimball 30 years later, for example, Brody (1973) represented the changed roles of family members in the community as coinciding with the overthrow of the traditional family.

The mainstream perception of the role of industrialization in the unraveling of the ties between family and community, with the decline of both, has been widely challenged. Many argue that the most significant change factors for social relations occurred much earlier, with Stone (1977) claiming that significant changes in the nature of family relations can be dated to the mid seventeenth century with the development of affective individualism. Others pointed out that despite theoretical claims concerning the collapse of community, empirical research indicated that community was indeed alive and well. Not only that, it would seem that the concepts of community and family are still perceived as interconnected; Dempsey's (1990) concept of community as "one big happy family" is strongly evocative of Tönnies's perception of communities as large families. To evaluate the extent to which industrialization, along with its attendant features of urbanization and mobility, has indeed caused an unraveling of the interpenetration of family and community, it is necessary to consider these themes in modern sociology.

Family and community exist within the context of society, and the changes in developed western society cannot but be reflected in its members, however they are grouped. Thus the phenomena of globalization and of individualism, so central to discussions of modernity and postmodernity, are also central to discussions of family and community in developed western societies. The development of the concepts of choice, reflexivity, individualization, and globalization in late twentieth century sociology contributed to a rethinking of the bases of social cohesion in groupings such as family and community. For example, Beck (1992) suggests that there is now a much greater element of individual choice regarding participation in community. Giddens (1991) emphasizes the centrality

of reflexivity in the project of the self as an aspect of contemporary life, with its attendant obsessive anxiety and lack of focus on the collective. This theme of individualization was further developed by Beck and Beck Gernsheim (2002). All of this suggests a movement away from the ascribed nature of group membership associated with family and community.

Nonetheless, as Bauman (1988: 53) asserts, "the need for freedom and the need for social interaction – inseparable, though often at odds with one another – seem to be a permanent feature of the human condition." This, in his view, gives rise to the "dream of community," a fantasy embraced to alleviate the twin fears of loneliness and lack of freedom. Community is in a sense an aspiration. It is one, however, which has tended to enjoy widespread and continuing support, despite exaggerated rumors of its demise. Even very recent work on community attests to positive associations with the concept, despite attention to its potentially negative dimensions.

In the late twentieth century new conceptions of community emerged. Cohen (1985) made a distinction between community as structure and community as symbol. Willmott (1986) distinguished three bases for community; these were locality ("place community"), communities of interest (e.g., occupational groupings), and communities of attachment (e.g., ethnic communities, or groups of people identified as sharing a disability such as deafness). Although it is impossible to draw firm boundaries around these different conceptions, it would seem that the first one, place community, is most likely to be involved with family. Occupational groupings, for example, are less likely to involve all members of a family, although there are many exceptions to this, as in the case of large scale local employment, local family businesses, or among clergy families. Some have written of "personal communities" beyond the confines of locality, encompassing friends and colleagues as well as kin. Others draw on the concept of "imagined communities," which involve a sense of identification with a notional grouping which does not necessarily involve direct contact (e.g., the idea of nationhood). Recently, too, the idea of Internet communities has also been receiving attention. Clearly, concepts of community in

modern and postmodern times emphasize that community does not *necessarily* imply propinquity, although it is a relevant dimension of some kinds of community.

In traditional community studies, however, where there was an interpenetration of family and community, the type of community in question was overwhelmingly that which was associated with a geographical locality. The locality was frequently used as the title of the published study, albeit disguised. Examples of this are *Greenwich Village* by Ware (1935), *Middletown in Transition* by Lynd and Lynd (1937), Littlejohn's (1954) *Westrigg*, Mogeys's (1956) work in Oxford and Williams's (1956) in Gosworth, Durant's (1959) *Watling*, Stacey's (1960) work in Banbury, *Yankee City* by Lloyd Warner (1965), Brody's (1973) *Inniskillane*, and Dempsey's *Smalltown* (1990). It has also been noted that the interpenetration of family and community continues to be an important aspect of life in more recent times in places where there is little geographic mobility. It can be argued, then, that while the interpenetration of family and community can be seen to survive in such studies, it is bound up with geographic locality and the significance of shared place for the establishment of personal relationships. However, geographic locality is not an essential feature of the many new conceptualizations of community identified earlier. Further, even in small, relatively static communities, the amount of face to face interaction may be lessened with the advent of high levels of car ownership and usage.

A relevant feature of the relationship between family and twentieth century concepts of community is the privatization of the domestic sphere. This is hypothesized as coinciding with the separation of paid and unpaid work, most especially perhaps in the middle decades of the twentieth century, and suggests the physical restriction of family life to a limited area. Once communities extending beyond the boundaries of geographic locality became common, and family life became more privatized, the interpenetration of family and community could no longer be taken for granted. Perhaps because of this, family and kin often came to be thought of as a community in itself. Crow and Maclean (2004) draw attention to studies showing the enduring nature of kin support even in the face of geographical mobility.

As the aspiration to some form of community has persisted, so has the aspiration to family. Despite the enduring claims of family crisis – which indeed stretch back into at least the nineteenth century – and individual negative experiences, people still look to this human grouping with hope and longing. Both small scale locally specific and large scale international empirical research attest to its continued importance for ordinary individuals in everyday life. There is also strong evidence for the persistence of intergenerational bonds. In that family continues in general to embody such attributes as supportiveness, solidarity, and identity, it is sometimes represented as a form of community in itself.

However, an essential aspect of community is that it exists on a more inclusive level than that of family. Even in the geographically local community there are networks of friends and neighbors as well as kin. In other forms of community family may not be of more than tangential significance. Community as it is commonly understood in both a traditional and a contemporary sense is greater than individual families and households. It has essential elements of linkage between individuals and the larger social structure which are on a scale different from the linkages offered by family and kin. In that sense it is always different from, even if sometimes interwoven with, family.

It must also be borne in mind that great variations exist in the relations between individual family members and the family's networks. Such relations are often highly gendered. In Arensberg and Kimball's (2001) study, for example, while the men went out "visiting" (*ag bothántaíocht*), women, once married, were largely confined to the home place. In other studies of traditional industries like mining, men are often portrayed as socializing with workmates while their wives were, again, far more home and kin centered. Women have often been seen as central to community life, especially in urban working class settings. In some welfare provision there may even appear to be a confusion of "community" with "women"; there has been much comment on how the state has embraced a version of "community care," which in practice has meant imposing heavy responsibilities for care on the

family, and usually on women in the family. In another vein, Bott in her classic study *Family and Social Network* showed that spouses' linkage with their wider networks varied with the nature of the conjugal role relationship. Other structural factors are also of significance for variations in the family – community relationship, including age, class, ethnicity, and differential power. The significance of *local* community networks is often a feature of an individual's stage in the life course. A potential local network is likely to be much more salient for families with young children than for young single employed persons.

A particularly important development is the now widespread engagement of mothers in the paid labor force. This has prompted a rethinking of gender roles. Much of the putative change is in attitude rather than in behavior, but one outcome has been the emergence of a new concern with work–family balance. This in turn has led to a new interest in the related areas of community, work, and family. Indications of this focus are seen in the establishment of the journal *Community, Work, and Family* in 1998. While the orientation may be changing, there can be no doubt that the themes of family and community will continue to exercise the sociological community on into the twenty first century. While there is change, there is also continuity, and above all there is diversity in the relations between the two phenomena.

CONCLUSION

Having considered some of the issues relating to the interrelationship of community and family, it is clear that these two aspects of society continue to be of major concern to sociologists. Both are understood differently today, however, than they were by the social theorists of the nineteenth century. Various concepts of community have developed which no longer assume that family is a central component. The emergence of communities of interest and of attachment suggest that the interpenetration of family and community associated with simpler societies is no longer an *indispensable* feature of community. Globalization contributes to the development of occupational communities not rooted in family or

kinship networks (although in the case of employment by transnational corporations in less developed societies these links may endure). However, family and community continue to be closely interwoven in settings characterized by limited geographical or social mobility. Even where there are high levels of such mobility in modern western societies, shared place remains an important basis for the establishment of personal relationships, and technological advances in transport and communication facilitate the maintenance of such relationships. While the relationship between the concepts of family and community has changed, and the dense interpenetration of these phenomena has become attenuated, it is by no means defunct. Notwithstanding the reality of expanded choice and its attendant anxieties in modern society, both family and community have remained central values in western cultures, albeit with more developed conceptualizations of each. These are, after all, the contexts within which most people spend the major part of their lives.

family conflict

Jean Kellerhals

Although present since the nineteenth century, particularly in Marxist thinking (more specifically in Engels's work), interest in family conflict within the sociology of the family only really developed as a theme during the 1960s and 1970s.

In the 1950s the dominant functionalist perspective tended to analyze the family in terms of internal equilibrium and its complementarity to the global society. Parsons's point of view (notably, Parsons & Bales 1955) is that the values of competition, achievement, and rationality in relation to the workings of the economic, educational, and political systems find a necessary counterweight in the family. This privileges affective expression, emphasizing "being" over "having," and the totality of the person over his or her division into functions. In addition, the division of work between the

man and the woman ensures good management of the expressive group dimension (by the woman) and the instrumental group dimension (by the man), and assures adequate socialization of the children. Through this process of socialization on the one hand, and the stabilization of the adult personality on the other, the family was seen to provide society with motivated and well oriented "normal" people, and at the same time procure the resources and abilities necessary for the family to function.

Important socio demographic changes started intervening in the western world during the 1960s, including rapid growth in divorce rates, falls in marriage, significant declines in fecundity, increases in cohabitation, and higher levels of employment of married women (Roussel 1985). Somewhat paradoxically, research attention was drawn at this time to concerns about overloading the family system; the reproduction of the inequalities in marriage and the family; the effect of cultural tensions on domestic intimacy; and the lack of resources available to some families.

As much in conservative theories as in radical ones, conflict has consequently been viewed as an intrinsic component of family dynamics, with its nature and causes being investigated along with its management.

MODELS OF FAMILY CONFLICT

In examining the nature of family conflict, we need to be clear about some commonsense assumptions. First, separation and divorce are not valid indicators of family conflict overall: a frequent observation is that many marriages are very stable, although unhappy or conflicting. Second, family conflict is not limited to open fights: quite often, tensions in the couple or the family remain silent; quite often also, they are not perceived as such by the entire family. And third, reciprocated differences of opinion or taste do not necessarily entail family conflict. More constructively, family conflict can be understood as relational tensions – overt or latent – arising out of the difficulty the family group has in defining its objectives, in finding the resources and the organizational structure suitable for reaching its goals, or in safeguarding

sufficiently its members' individual interests. In broad terms, five distinct models for explaining the reasons for such family conflict have been produced.

"Deficit" Model

This model highlights the role of socialization, arguing that inadequacies in people's socialization experiences contribute to family conflict. For example, those who marry at a young age tend to be relatively immature psychologically and socially. This is liable to compromise how well they adapt to marriage and family life, a factor linked to high rates of separation and divorce. Similarly, growing up in a disunited or conflictual family not only increases the probability of maladjustment but is also likely to limit opportunities for learning suitable modes of relating. Poverty and economic insecurity of the family during one's childhood are seen as undermining processes of childhood socialization and increasing the risk of conjugal conflict in adulthood. Low levels of educational achievement are also seen as compromising the development of aptitudes for negotiation and communication, both of which are judged as essential for success in contemporary marriage. Above all, the deficit model stresses the lack of resources available in particular families (Cherlin 1999: 365–422). In these, the gap between the family's objectives and the means at its disposal becomes too great, resulting in high levels of frustration (Webster et al. 1995). From the same point of view, such families may also be deprived of support because they lack the social integration and/or links with kin which can help prevent conflict (Shelton 1987).

"Overload" Model

This model takes a more historical perspective and stresses the extent to which the progressive weakening of public participation has led to individuals placing too great an emphasis on the private sphere of home, family, and children (Ariès 1978). Under these conditions, the individual is led to expect the family to compensate for the failings of the wider society by meeting all his or her needs. Some, such as

Sennett (1974), see this as the product of the disappearance of the "public man." Others, like Donzelot (1977), see it as the consequence of specific family policies designed to undermine class consciousness and solidarity. Either way, the family as a refuge is transformed into the family as a ghetto. The growth of family conflict as expressed through increasing levels of divorce is thus interpreted, by Berger and Kellner (1964) for instance, not as a loss of family functions, but as the expression of this excessive investment in these very important expectations of family and conjugal life (Roussel 1985).

"Cultural Tensions" Model

In this model the emphasis is placed on the gap that exists between the commitments required by and implicated in family life and the importance attached to the individual in contemporary culture. For authors such as Bellah et al. (1986), the individual today is seen above all as having a moral responsibility to search for personal identity and authenticity of the self. That is, they have a "duty" of "self discovery" and "self fulfillment." This endless quest for the self translates into a weakening of family commitments and responsibilities. It is this same critique of the growth of individualism within contemporary social life that makes Popenoe (1988) state that the family is functioning increasingly less effectively as a mediator between the individual and society.

"Conflict of Interest" Model

In this model the drive for equality in contemporary family relationships is seen as in opposition to broader structural inequalities affecting both employment and the domestic sphere. More specifically, the growth of dual career families has not translated into conjugal equality, as most wives continue to carry a far greater responsibility than their husbands for domestic labor and household management. Moreover, in spite of increasing educational achievements, women are generally the ones who adapt their employment commitments to family needs, thereby often compromising their promotion prospects. In contrast, husbands are more often

able to use the family resources as a springboard for their occupational mobility. Of course, this tension between equality and inequality frequently leads to feelings of injustice which are sometimes expressed in divorce, sometimes in psychological distress, and sometimes in violence towards the children. However, as equity theory would suggest, feelings of injustice are not directly proportional to the degree of inequality: different cognitive processes often lead to both the husband and wife tolerating this for the sake of higher interests judged to be more important. From this point of view, the concept of power acquires great importance. The first empirical studies on this theme notably showed that decision making powers in the family are strongly correlated with the gap in the respective socioeconomic resources of the spouses (Blood & Wolfe 1960). Moreover, later studies drawing on resource theory also show that family negotiation depends heavily on the resources available to each spouse outside the nuclear family. While these gender divisions may benefit the family collectively, they also increase the social distance between the husband and wife.

"Anomie" Model

This model focuses on the degree to which contemporary couples are required to negotiate the organization of their relationship individually because traditional models of marriage are no longer considered appropriate or legitimate. Among other things, this involves defining family priorities; organizing the division of work inside and outside the home; defining the areas of intimacy and privacy; agreeing on the sharing of material resources; and defining the extent and intensity of contacts with the world outside. Yet these constructions are often rendered conflictual by (1) subjective uncertainty toward the duration of the union; (2) incompatibilities between individualist aspirations and fusional models of conjugal relationships; and (3) tension between the equalitarian aspirations and the unequal status of the husband and wife. This situation can generate very high levels of stress, particularly when children are young (Kellerhals et al. 2004).

MANAGEMENT OF CONFLICT

Various sociologists have been concerned with investigating ways in which family conflict can be resolved. Many recognize that ideologies of love often result in the husband and wife feeling guilty about any conflicts they have, with the result that any potentially positive consequences of these conflicts tend to be masked. Not only can this compound the conflict, but it may also lead to a more serious crisis (Eshleman 1997; Olson & DeFrain 1997).

Different approaches have been developed to facilitate conflict resolution. Some, such as Kilmann and Thomas (1975), focus on the degree of aggression and cooperation within the relationship, and on this basis define different strategies for conflict resolution – collaborative, competitive, compromise, avoidance, accommodating. Other approaches oppose “task oriented” strategies with “relation oriented” strategies (Kellerhals et al. 2004), with conflict resolution being dependent on the equilibrium established between these two. A synthesis of studies on this theme lead Olson and DeFrain (1997) to identify six basic steps in conflict resolution: (1) clarifying the issue; (2) finding out what each person wants; (3) identifying various alternatives; (4) deciding how to negotiate; (5) solidifying the agreements; and (6) reviewing and renegotiating. Other approaches suggest that there are three principal dimensions to the resolution process: the degree of activity (decision taking, investment of ad hoc resources, evaluation of the effects); cognitive elaboration (definition of the stressor, communicating its purpose, gathering pertinent information); and the extent of relational concern (attention given to cohesion, to mutual support, and to relational re equilibrium) (Widmer et al. 2003). These authors show that a propensity to over invest in one of the terms (action, cognition, or relation) is a frequent reaction to the anxiety engendered by the conflict. Equilibrium between the three dimensions can be expected more commonly in families with good levels of cohesion and flexibility.

family demography

Lynne M. Casper

Family demography is a subfield of demography and is the study of the changing nature of intergenerational and gender ties that bind

individuals into households and family units. The core of family demography uses basic demographic information collected about household members, including the numbers of members, their relationships to each other, and each person's sex, age, and marital status, to describe the composition of families and households. *Composition* describes the *structure* of families and households: the set of statuses and associated roles that are important for the functioning of society. American families and households have diverse and complex structures. For example, households can contain married couples, cohabiting couples, single mothers, children, grandparents, other relatives (e.g., brothers, sisters, or in laws), roommates, or simply one person living alone. Family composition is the result of demographic *processes* or family related events such as marriage, divorce, and fertility or childbearing. Changes in the timing, number, and sequences of these events transform family and household composition. Family demographers aggregate the composition and processes of individual families into larger units (e.g., nations, states, counties, neighborhoods) to examine family change in societies and other units. They aggregate them separately by other social and economic groups (e.g., racial and ethnic groups, poor families, immigrants) and by countries to examine family variation. Thus, family demographers study family change and variation to understand both individual and societal behavior.

Several theoretical strands are influential in interpreting family change and variation in family demographic research. They include (second) demographic transition theory, the life course perspective, household and family decision making theories, biodemographic interactions, and the focus on culture and context.

The bedrock of demographic data analysis on family change is descriptive cross sectional and trend analysis of family structures and processes, most often with census or survey data, although increasingly qualitative methods are also used. The field of demography has its own toolkit full of measures and methods that are suited to studying family change. Measures of age and age related processes are fundamental. Change is understood as reflecting age, period, or cohort processes or effects; explanations of change emphasize the aging of

the population (or life course change of individuals), broad, sweeping societal or time period effects, and/or the replacement of older cohorts by successively younger ones with different life experiences. An indispensable measure in family demography is the rate: the number of people experiencing the event out of the population "at risk" of experiencing that event. Another important tool for examining family change is decomposition, in which family change is empirically separated into two components: the proportion of change attributable to shifts in population composition versus that part that is due to change in the likelihood that some family event occurs. However, family demography has increasingly moved toward explaining family change and variation. In the last three decades, a number of panel surveys and various labor force and educational cohort studies have been developed. These studies include many more "explanatory" variables and provide prospective sequencing data that are better suited to inferring causality.

COMMON DEFINITIONS

The core of family demography continues to be based on concepts developed by the US Census Bureau. A household, as defined by the US Census Bureau, consists of one or more people who occupy a house, apartment, or other residential unit (but not "group quarters" such as dormitories). One of the people who owns or rents the residence is designated the *householder*. The householder is said to *maintain* the household. For the purposes of examining family and household composition using census data, two types of households have been defined: family and non family. A *family household* has at least two members related by blood, marriage, or adoption, one of whom is the householder. *Families* consist of all related people in a family household. Families can be maintained by married couples with or without children or by a man or woman with children and no spouse in the home. A *non family household* can either be a person living alone or a householder living only with non relatives. Family units within family or non family households that do not include the householder are *subfamilies*. Subfamilies include either a

married couple, with or without children, or a parent-child pair. A *related subfamily* is related to the householder, whereas an *unrelated subfamily* is not. *Family groups* are family households plus all related and unrelated subfamilies. For example, a family household that is maintained by a grandmother and contains her daughter and her daughter's daughter has two family groups. *Children* include sons and daughters by birth, stepchildren, and adopted children of the householder regardless of the child's age or marital status. *Own children* are a subset of *children* and identify the householder or family reference person as a parent in the household, family, or subgroup – they are usually defined as never married children under the age of 18.

FAMILY AND HOUSEHOLD COMPOSITION AND LIVING ARRANGEMENTS

Changes in the number and types of households depend on population growth, shifts in the age composition of the population, and decisions individuals make about their living arrangements. Demographic trends in marriage, cohabitation, divorce, fertility, and mortality also influence family and household composition. Economic shifts and improvements in the health of the elderly over time can also have an impact.

In the US, families have traditionally accounted for a large majority of all households – as recently as 1940, nine out of ten households were family households. This proportion decreased steadily to 81 percent in 1970 and by 2003 family households made up only 68 percent of all households, with the remaining 32 percent accounted for by non family living arrangements. Part of the increase in non family households was due to the growth in one person households – people living alone. The proportion of households containing one person increased from 17 percent in 1970 to 26 percent in 2003.

The increase in non family households resulted from many social, economic, and demographic shifts. A postponement of marriage took place after 1960 leading to a substantial increase in the percentage of young, never married adults and to greater diversity and fluidity in living

arrangements in young adulthood. In 1970, 6 percent of women and 9 percent of men aged 30–34 had never married. By 2003, these figures increased to 23 percent and 33 percent, respectively. The delay of marriage means that young adults in 2003 were less likely to be living with their spouses and more likely to be living alone, in a parent's home, or with roommates, than they were in the past. Thirty one percent of men aged 18–24 lived with their spouses in 1970, for example, while only 9 percent lived with a spouse in 2003. A similar drop occurred for women: from 45 percent in 1970 to 16 percent in 2003. As a declining share of young adults chose married life, a greater share lived on their own, with roommates, or cohabited with an unmarried partner. In 1970, 15 percent of women and 13 percent of men were living in these arrangements compared with 38 percent and 37 percent, respectively, in 2003.

The delay in marriage coincided with an increase in cohabitation and these trends also decreased the proportion of married couple families and increased the proportion of non family households. Unmarried couple (cohabiting) households have grown dramatically since 1970 and in 2003 numbered 4.6 million, or over 4 percent of households. Cohabitation historically has been most likely to occur before a first marriage, but, more recently, cohabitation has been replacing remarriage after divorce occurs. Researchers have offered several explanations for the rapid increase in cohabitation, including increased uncertainty about the stability of marriage, the erosion of norms against cohabitation and sexual relations outside of marriage, the wider availability of reliable birth control, and increased individualism and secularization. Some have argued that cohabitation allows a couple to experience the benefits of an intimate relationship without committing to marriage. If a cohabiting relationship isn't successful, one can simply move out; if a marriage is not successful, one suffers through a sometimes lengthy and messy divorce.

Significant improvements in the health and economic well being of the elderly over the period have increased the life expectancy and the quality of life of both men and women. This means that elderly men and women are increasingly able to maintain their own homes.

Not only has this augmented the number of households, but also the fact that women continue to outlive men by a significant number of years has led to a greater number and proportion of one person non family households. The proportion of women 65 years and over who live alone grew from 34 percent in 1970 to 40 percent in 2003.

Households and families have become smaller over time, with the most profound changes occurring at the extremes – the largest and smallest households. Between 1970 and 2003 the share of households with five or more people decreased from 21 percent to 10 percent. During the same period, the share of households with only one or two people increased from 46 percent to 60 percent. Another measure of household size is the average number of members in the household. Between 1970 and 2003 the average number of people per household declined from 3.1 to 2.6.

Changes in fertility, marriage, divorce, and mortality all contributed to the shrinkage of American families and households. Between 1970 and 2003, births to married women declined sharply while births to unmarried women increased. These two trends decreased the proportion of two parent families and increased the proportion of one parent families, which also tend to have fewer children. The cumulative effect of these trends was to shrink family and household size. Increases in divorce also reduced the size of households and families; divorce generally separates one household into two smaller households. Meanwhile, the proportion of divorced people increased about fourfold from 2 percent to 8 percent for men and from 3 percent to 11 percent for women from 1970 to 2003.

The delay in marriage and improvements in the mortality and health of the elderly increased one person households, thereby decreasing the average family and household size.

Other aspects of the composition of families changed as well. The number of families maintained by people with no spouse at home increased rapidly from 1970 to 2003. Single mother families grew by 147 percent from 5.5 million in 1970 to 13.6 million in 2003. Single father families grew even more over the same period, tripling from 1.2 million to 4.7 million. By contrast, married couple families grew from

44.1 million to 50.7 million over the same period – only a 15 percent increase. These differential increases shifted the composition of family households from married couple to single mother and single father families. In 1970, married couples maintained 89 percent of family households, but by 2003 this proportion had declined to 72 percent.

Several demographic trends have affected the shift from two parent to one parent families. A larger proportion of births occurred to unmarried women in 1990 compared with 1970, increasing the proportion of never married parents. The delay of marriage also augmented the risk of a nonmarital birth, because adults were single for more years. In addition, the growth in divorce among couples with children increased the proportion of unmarried parents.

Most of the decline in family households reflects the decrease in the share of married couple households with children. In 2003, 48 percent of families contained own children compared with 56 percent in 1970. These changes reflect several demographic trends, including the delay of childbearing, the decline in the number of children people have, the delay of marriage, and the aging of the population. Due to the trend toward delayed marriage and childbearing, younger families were more likely to be childless in 2003 than in 1970. For example, in 1970, 94 percent of women aged 30–34 had been married at least once; of them, only 12 percent were childless. In 2002–3, only 77 percent of women aged 30–34 had ever been married; of them, 19 percent were childless. Thus, fewer women in these prime childbearing ages had ever been married in 1990 and nearly twice as many of them were childless (reflecting primarily a delay in childbearing, but also a delay in marriage).

Change in family and household structure began slowly in the 1960s, just as society was embarking on some of the most radical social changes in US history, and the leading edge of the huge baby boom generation was reaching adulthood. The steepest decline in the share of family households was in the 1970s when the first baby boomers entered their twenties. By the 1980s, change was still occurring, but at a much less rapid pace. By the mid 1990s, household composition reached relative equilibrium, where it has been since.

FAMILY CHANGE IN OTHER INDUSTRIALIZED COUNTRIES

The changes in family that occurred in the US have also occurred throughout most industrialized countries, for many of the same reasons. In most European countries marriage rates have been declining since the late 1960s and early 1970s. Since the 1980s, marriage rates have continued to decline, but at a slower pace. Europeans are also postponing marriage. For example, the median age at first marriage in Sweden was 25 in 1975, but increased to 29 by 1995. The increase was even greater in Denmark: from 23 in 1975 to 29 in 1995. Although women tend to marry earlier in most other Northern and Central European countries, the average age of marriage increased from 1975 to 1995 and now stands at 26 or above in these countries.

As in the US, a rise in cohabitation has contributed to the decline and postponement of marriage. In the 1960s in Sweden and Denmark, cohabitation as a prelude to or an alternative to marriage began to rise. By the 1970s, this type of cohabitation began to rise in other countries. Postmarital cohabitation has also increased.

Women in other industrialized countries are postponing births and having more nonmarital births. For example, in most European countries, the age specific fertility rates declined for women under 25 and rose substantially for women aged 30 and over in the 1980s. Nonmarital births in Scandinavia grew about 20 percent between 1975 to 1988. In Northern Europe, Australia, and New Zealand the growth rate was not as large – in the single digits for all countries except for the United Kingdom (16 percent) and France (18 percent).

SOCIAL DEMOGRAPHY OF THE FAMILY

Early family demographic studies documented change and variation in fertility, marriage, households and families, and living arrangements, with each of these areas typically studied in isolation. Growing diversity in the timing, number, and sequencing of family events led researchers in the US and other

industrialized countries to study the interaction of these events (e.g., nonmarital childbearing) and to incorporate other events (e.g., cohabitation) into family demography to provide a more accurate accounting of family change and variation. Family demography has also expanded to examine the causes and consequences of family change and variation, including the social and economic context in which it occurs. This change has led many demographers who study the family to refer to the field as *social demography of the family*. It has also increased the number of disciplines that have adopted the demographic perspective. Historically, the majority of family demographers had training in sociology and a substantial minority had training in economics. More researchers in the fields of anthropology, child development, family studies, genetics, geography, medicine, psychology, and public health have come to employ the concepts and tools of family demography.

Several key changes in the family occurring in developed countries in the second half of the twentieth century have expanded the borders of family demography beyond the traditional measures of family composition, processes, and living arrangements. Historically, family demography only included the study of marriage, remarriage, and divorce. However, changing union (marriage and cohabitation) formation and dissolution, low fertility, increases in nonmarital fertility and a growing diversity of family structures, changing intergenerational relations, and increases in women's paid work have made it necessary for family demographers to study a broad set of processes to adequately characterize and explain family change and variation and to explore the consequences of these changes.

The rise of cohabitation and the delay and decline in marriage have prompted family demographers to examine cohabitation. Cohabitation, marriage, divorce, and childbearing are entwined in complicated ways. Cohabitation increasingly precedes marriage, is often an alternative to remarriage after separation and divorce, and, in several European countries, has become a long term substitute for marriage. Intimate Union Formation and Dissolution Tracking and explaining the increase in cohabiting couples, both heterosexual and

same sex, and examining the consequences of cohabitation for adults and children require not only a better understanding of cohabitation, but also a better understanding of marriage; the meaning, value, and nature of both of these relationships are poorly understood in contemporary developed economies.

A second area of family change of increasing interest is explaining low fertility in industrialized economies. Fertility is a core focus of family demography, but until relatively recently most research focused on high fertility in developing regions of the world. The rapid decline in fertility in all parts of the developing world has shifted attention away from high fertility and toward the very low fertility levels of Southern and Eastern Europe and Japan. Most of these countries have fertility levels far below the 2.1 children per woman needed to replace the population. Explanations for these low levels of fertility include changing normative, social, and economic contexts, particularly women's changing work and family roles.

Third, recent increases in childrearing within cohabiting and other nonmarital unions have also heightened the awareness that trends in childbearing and childrearing cannot be studied independently of union (marriage and cohabitation) formation and dissolution. Whereas timing of entry into marriage, parenthood, and, to a much lesser extent, cohabitation can be distinguished empirically, conceptually and analytically they are intertwined. In the US, where fertility levels remain close to replacement (around two births per woman, on average), the questions of greatest interest are about two distinct fertility behaviors that characterize US fertility trends. On the one hand, both marriage and children are being postponed to older ages among the better educated segments of the population. On the other hand, there seems to be increased willingness to disassociate childbearing from marriage altogether, particularly among less educated, minority groups – to have children relatively early, outside of marriage, and to raise them in environments that will not include two co-residential biological parents. Policymakers and researchers seek to better understand the underlying causes of these different behaviors. They are also interested in the consequences for children and men and women of the separation of marriage and

childbearing, on the one hand, and the postponement of both, on the other, and how the consequences vary for different groups within the population.

Fourth, the intergenerational family is changing in form – from a *pyramid* structure with few living grandparents and many children and grandchildren to the *beanpole family* with more grandparents than parents and, increasingly, more parents than children. Demographically, these changes occur when mortality is low, life expectancy is high, and fertility is relatively low, as in most industrialized countries. Changes in marriage, divorce, and childbearing complicate the intergenerational picture, as financial and care obligations are no longer necessarily dependent on biological or marital ties. In groups where marriage is increasingly fragile, intergenerational ties may supersede nuclear ties in the rearing of children. Researchers are interested in the economic and social consequences of these changes.

Fifth, the steady increase in women's labor force participation in the US and most other industrialized countries, especially among married women, in the second half of the twentieth century, and the accompanying decline in the one wage earner, two parent family, provides a greatly altered context for understanding and interpreting family demographic trends. The interrelationship between increased female employment and changes in union formation, fertility, cross generation caregiving and the gender division of labor in non market spheres is receiving increased attention in the family demographic literature of both developed and developing economies.

including longer life expectancy, postponed marriage and childbearing, dramatic increases in both childbearing and childrearing outside of marriage, and substantial growth of singlehood, cohabitation, divorce, and remarriage (Teachman et al. 2000). As a result, there has been a sharp increase in the visibility of diverse family forms such as single parent (mostly single mother) families, stepfamilies, households headed by gays and lesbians, and families living in poverty (Rank 2000). These changes have stirred considerable debate surrounding the definition of family. For example, do two cohabiting adults and their dependent children constitute a family? Are they still a family without the presence of children in the household? What if the two adults are gay or lesbian?

Beginning in the middle of the twentieth century, a strong value was attached to a "benchmark" family type in the United States, or what is commonly termed the "traditional" nuclear family. Following World War II, rapid social changes including men returning to the labor force, a post war economic boom, an increasing standard of living, increases in marriage and birth rates, and a decline in the divorce rate supported a set of values and beliefs that privileged the two biological parent, male breadwinner, female homemaker family. Although families of the 1950s often are viewed with nostalgia, evidence shows that many traditional families were characterized by severe inequities, male dominance, men's overinvolvement in work and underinvolvement in family activities, wife abuse, and alcoholism (Coontz 1992). Since then, changing historical contexts and powerful social movements (e.g., civil rights, women's rights, gay and lesbian liberation, and men's movements) have been associated with the establishment of a wide variety of family forms, making the diversity of families more visible and normative, and sparking debates over the future of marriage and whether there is one best type of family.

There are many issues and complexities inherent in studying and defining families. Our purpose here is to provide an overview of family diversity by (1) defining the study of family diversity and its historical context; (2) defining family; (3) discussing the major structural dimensions of diversity (e.g., ethnicity, socioeconomic status, sexual orientation); and

family diversity

Brad van Eeden Moorefield and David H. Demo

Family living arrangements in the US and throughout much of the world are considerably more diverse, pluralistic, and fluid than they were just a few decades ago. We have witnessed profound demographic changes,

(4) illustrating the diversity characterizing family processes.

DEFINING FAMILY DIVERSITY AS A FIELD OF STUDY

Historically, the term family diversity referred to variations from a traditional family. This implied that there was one best type of family, and that all other family types were dysfunctional and deviant. In a more contemporary view, family diversity refers to a broad range of characteristics or dimensions on which families vary, along with a recognition that there are a multitude of different family types that function effectively. Family diversity thus refers to variations along structural or demographic dimensions (e.g., race/ethnicity, socioeconomic status), as well as in family processes (e.g., communication and parenting behaviors).

We caution readers to be particularly mindful of comparisons in which one family is upheld as a "better" family than that to which it is compared. In this, we do not take a purely relativistic view by assuming that all families function effectively, nor do we believe there is one best type of family. Our view is that families are diverse and there are many ways that families can function effectively regardless of family type. As stated earlier, historical accounts of family diversity were concerned with pathological views that perpetuated marginalization of many family types. However, social movements and demographic changes have increased the visibility of diverse families, thus facilitating a shift away from pathological views to a recognition of family strengths and resilience (Walsh 1998). Thus, the study of family diversity is embedded within historical and social contexts, as is the intensifying debate over how to define family.

DEFINING FAMILY

Families are characterized by a rich variety of compositions that mix gender, ethnicity, sexuality, and marital history. Families also vary widely in their dynamics, or how family members interact with and relate to one another. As a result, family researchers have invested considerable energy in designing and conducting

studies that examine the flexibility and creativity with which individuals create and sustain a sense of family. To be sure, there are myriad ways that individuals experience and define family. However, there is a need to define family in a way that is useful, meaningful, and inclusive, yet not devoid of theoretical or empirical meaning. It also is important to recognize the difficulty in establishing an appropriate and inclusive definition of family that is flexible over time, i.e., a definition that reflects historical, demographic, social, and family change. No definition of family applies universally across cultures and historical periods (Coontz 2000).

The US Census Bureau defines a family as two or more individuals related by birth, marriage, or adoption. While practical, this definition excludes many groups who consider themselves to be families, such as couples who cohabit (with or without children), foster parents residing with their children, and gay and lesbian couples. Further complicating this debate and its implications for families is the disparity in family policies and laws across local, state, and federal levels. For example, the state of Massachusetts now recognizes same sex marriages, but such marriages are not recognized by other states or by federal law. A second example is a woman who adopts a child and lives with her lesbian partner. According to the US Census Bureau definition, the lesbian partner is considered a member of the household, but not a member of the family.

For our purposes, family is defined more broadly and involves consideration of both family structure and family process. Structurally, a family is defined as two or more persons related by birth, marriage, adoption, or choice (Allen et al. 2000). Adding the element of choice recognizes that individuals have human agency, or the ability to choose those whom they consider family, such as individuals who might be close friends. An inclusive definition of family also recognizes that family members do not need to be physically present or live in the same household. To illustrate, non residential fathers are family members even though they typically live apart from their children much of the year. Similarly, individuals may consider a deceased parent or other relative to be part of their family.

Typically, families also provide emotional and financial support, recreational opportunities, nurturance, discipline, and affection (Allen et al. 2000). As such, family also needs to be defined by process. Again, we do not take a purely relativistic view and assume all families function adequately, but we do believe that we need to be explicit about the definitions we use. Taken together, incorporating choice and process allows for a broader, more inclusive, and more meaningful definition of family.

DIMENSIONS OF FAMILY DIVERSITY

Race/Ethnicity

In the early twenty first century, racial/ethnic families represent a growing proportion of society, including substantial numbers of interracial couples and transnational families. Understanding the diversity of intersecting cultures and the influence of diversity on society and family life is important, particularly when developing public policy. Given that the proportion of Hispanic families is growing faster than any other family groups, we are witnessing an increased research emphasis on Hispanic family life, including examination of the effects of immigration and acculturation (see Zinn & Wells 2000). According to the most recent Current Population Survey (Fields 2004), 71 percent of all family groups in the US are white, with 12 percent black, 4 percent Asian, and 13 percent Hispanic. (It is worth noting that many of those categorized as Hispanic may have reported as being both white and Hispanic.)

Socioeconomic Status

Socioeconomic status (SES) is defined in terms of a family's combined index of income, education, occupational prestige, and the number of related adults and dependent children in the household (Rank 2000). Research consistently shows that economic hardship and stress adversely affect individual and family well being (White & Rogers 2000). Unemployment, underemployment, and low family income are associated with poor mental and physical

health, lower marital quality, diminished parenting effectiveness, and child maladjustment (Fox & Bartholomae 2000). Currently in the US, 12.4 percent of the total population lives below the poverty level, and 10.8 percent of all people living in families and 16.1 percent of families with children under age 18 live below the poverty level. A disproportionate number of black (24.9 percent) and Hispanic (22.6 percent) families live in poverty compared with white (9.1 percent) and Asian (12.8 percent) families. Interestingly, 15.8 percent of single fathers live below the poverty level compared to 32.2 percent of single mothers. As troubling as these statistics are, they do not include millions of children and adults in the US who live in severe economic hardship but have family income that falls just above the official poverty threshold (Rank 2000).

Gender

Gender refers to social meanings regarding masculinity and femininity that are produced through social processes and interactions (West & Zimmerman 1987), whereas sex refers to biological distinctions between a man and a woman. Each individual, whether male or female, is the product of complex configurations of both masculine and feminine characteristics that influence daily interactions (Thompson & Walker 1995). As a dimension of family diversity, gender is an ever present and powerful force in family relationships. For example, one family might divide labor on the basis of traditional gender beliefs and values such that the woman "stays home" to care for children and the man is the sole or primary earner. In this instance, gender is related to power in families because the man makes all or most of the family's income and controls the family's financial decision making. With each choice families make, such as how mothers and fathers parent, how they divide household labor, and how they provide care for aging parents, they are doing gender (West & Zimmerman 1987). Patterns unfold with enormous implications for family life and future generations because families exert a primary influence on gender socialization. Gender is

thus a critical axis of both social stratification and family diversity.

Sexual Orientation

One of the influential social movements of the twentieth century was the gay and lesbian liberation movement, which continues to draw attention to issues of civil and family rights. Sexual orientation refers to an individual's beliefs, attractions, and behaviors toward members of the opposite and same sex. From a family diversity perspective, families do not have a sexual orientation, but are comprised of individuals with varying sexual orientations. Consider, for example, a family in which one parent identifies as heterosexual, the other as gay, an aunt as bisexual, and a child as transsexual. These variations are of increasing importance as more families are faced with how to accept, or whether to accept, a family member whose sexual orientation differs. Due to the difficulties involved in collecting sensitive information regarding sexual orientation, available statistical evidence regarding the prevalence and types of gay and lesbian headed households is likely to be conservative. Using data from the 2000 Census, Gates and Ost (2004) suggested that approximately 5 percent of the US population over age 18 are gay or lesbian. Of those who were identified as gay or lesbian and in couple relationships, 27.5 percent had children present in the household. Other estimates suggest anywhere between 9 and 11 million children are being reared by a gay or lesbian parent (Patterson 2000). Studies of sexual orientation often compare the adjustment of children who live with gay or lesbian parents with that of children who live with heterosexual parents (Patterson 2000). This area of research is of great concern given current policy debates concerning same sex marriage, adoption, and foster care. Collectively, research in this area suggests no negative differences in child outcomes based on parental sexual orientation (Patterson 2000). Studies also suggest that relationship quality and relationship outcomes are similar for families of gays and lesbians compared with families of heterosexuals (Kurdek 2004). Unfortunately, we know little about the important topics of

bisexuality, transgenderism, transexualism, and family life.

Family Structure

Recent demographic changes, notably including high rates of non marital childbearing, divorce, and remarriage, have changed the face of American families. Less than half of American children now live in traditional nuclear families, defined as families consisting of two biological parents married to each other, full siblings only, and no other household members (Brandon & Bumpass 2001). Variations in family structure and the consequences for individual well being have been widely studied. Most of the research has focused on the impact of different family forms (e.g., first married families, divorced families, and remarried families) on children's development and well being. In general, when compared with children in first married families, children in single parent families and remarried families are slightly disadvantaged on measures of academic performance, psychological adjustment, conduct, social competence, and physical health (Amato 2000; Demo et al. 2004). However, for most children the effects of family disruption are temporary. Studies suggest that 80 percent of children who have experienced parental divorce function within normal ranges of adjustment within one to two years of the divorce (Barber & Demo 2006). Similarly, divorced adults report more negative life events, more difficulties in parenting, and lower psychological well being during the separation process, but most are resilient and function normally within a couple of years post divorce. Although family composition and family transitions are important to understand, the evidence suggests that family processes exert stronger effects on the well being of family members.

Family Process

Family process refers to the interpersonal dynamics (e.g., support, communication, decision making, conflict resolution, violence) between family members (e.g., parent-child, husband-wife, partner interactions). Given

societal concerns related to couples who divorce or dissolve their relationships, examination of family process is especially important and has the potential to provide valuable insight. For example, once a conflict between partners starts, the discussion that follows and the rate at which the conflict escalates is related to the prediction of divorce/dissolution. Gottman et al. (2003) examined communication among heterosexual, gay, and lesbian couples and found that gay and lesbian couples used humor more effectively during initial stages of conflict discussions, leading to lower escalation rates compared to heterosexual couples. Attending to the diversity of family process provides a better understanding of family dynamics and has potential to guide prevention and intervention efforts for practitioners.

CONCLUSION

Contemporary families are remarkably diverse both in structure and process, and the social and demographic changes propelling family diversity are likely to accelerate (Stacey 2000). Unfortunately, much of the extant research relies on samples of predominantly white, middle class, heterosexual families and their children, limiting our ability to generalize to increasingly pluralistic family forms. Students, scholars, practitioners, and policymakers need to be more inclusive and explicit with their definitions of families and attend more fully to the rich, fluid, and multidimensional diversity of family experiences.

family, history of

Mark Hutter

European societies during the nineteenth century underwent massive changes. The old social order anchored in kinship, the village, the community, religion, and old regimes was attacked and fell to the twin forces of industrialism and revolutionary democracy. The sweeping changes had particular effect on the family. There was a dramatic increase in such conditions as poverty, child labor, desertions, prostitution, illegitimacy, and the abuse of women and children. These conditions were particularly evident in the newly emerging industrial cities. The vivid writings of a novelist such as Charles Dickens in *Oliver Twist* and *Hard Times* provide startling portraits of a harsh new way of life.

The industrial revolution dramatically changed the nature of economic and social life. The factory system developed, and, with its development, there was a transformation from home industries in rural areas to factories in towns and cities of Europe and America. Rural people were lured by the novelty of city life and the

prospects of greater economic opportunity. The domestic economy of the pre industrial family disappeared. The rural and village based family system no longer served as a productive unit. The domestic economy had enabled the family to combine economic activities with the supervision and training of its children; the development of the factory system led to a major change in the division of labor in family roles.

Patriarchal authority was weakened with urbanization. Previously, in rural and village families, fathers reigned supreme; they were knowledgeable in economic skills and were able to train their children. The great diversity of city life rendered this socialization function relatively useless. The rapid change in industrial technology and the innumerable forms of work necessitated a more formal institutional setting – the school – to help raise the children. Partially, in response to the changing family situation, the British passed legislation to aid children. Separated from parental supervision, working children were highly exploited. Laws came into existence to regulate the amount of time children were allowed to work and their working conditions. The law also required that children attend school. These legal changes reflected the change in the family situation in the urban setting; families were no longer available or able to watch constantly over their children.

The separation of work from the home had important implications for family members. Increasingly, the man became the sole provider for the family and the women and children developed a life comprised solely of concerns centered on the family, the home, and the school. Their contacts with the outside world diminished and they were removed from community involvements. The family's withdrawal from the community was tinged by its hostile attitude toward the surrounding city. The city was depicted as a sprawling and planless development bereft of meaningful community and neighborhood relationships. The tremendous movement of a large population into the industrial centers provided little opportunity for the family to form deep or lasting ties with neighbors. Instead, the family viewed neighbors with suspicion and weariness. Exaggerated beliefs developed on the prevalence of urban poverty, crime, and disorganization.

This entry deals with the different approaches taken by social scientists in their analysis of the family in the wake of the industrial revolution. Throughout the nineteenth and early twentieth centuries they voiced concern about the excesses of industrial urban society and the calamitous changes in the family system. Social Darwinists and Marxists tried to make sense of these changes through utilization of evolutionary theories. Radicals, conservatives, and social reformers called for fundamental changes in the society and in the family and its new way of life. However, by the mid twentieth century, the dominant perspective in sociology, structural functionalism, proclaimed that the family was alive, well, and functioning in modern industrial society.

EVOLUTIONARY THEORIES

Sociological interest in the study of the history of the family was very strong in the mid nineteenth century in Western Europe. Prior to the nineteenth century, western thought generally held to a biblical belief in the origins of the family stemming from God's creation of the world, including Adam and Eve. Although there was recognition of relatively minor familial changes over time, the biblical family form and its underlying patriarchal ideological precepts were seen as continuing intact into the nineteenth century. Western thought clung to uniformity throughout the world in terms of family structures, processes, and underlying familial beliefs and values. These governed the behavior of men, women, and children in families. The belief in universal family uniformity led to ramifications on the nature and place of the human species and affected the traditional institutions of the church, the state, and the family. Coinciding with the doctrine of evolutionism was the development of individualism and democracy.

There are a number of important factors to help account for the historical study of the family. First, the fabric of Western European and American society was undergoing major changes. Societies were rapidly industrializing and urbanizing. The old social class systems were being reworked and a new class structure was developing. Family relationships were also

undergoing radical changes. The individual's rights, duties, and obligations to the family and, in turn, to the larger community were being questioned and challenged. Second, western colonial expansionism and imperialism were developed fully. Unknown and hitherto unsuspected cultural systems with strange and diverse ways of life were discovered and analyzed. Family systems were found to have differences almost beyond imagination. Third, an intellectual revolution was occurring. The controversy surrounding evolutionary theory was sweeping Western Europe and America. Developing out of this social and intellectual ferment was the application of evolutionary thought to the analysis and understanding of the social origins of the human species. This discussion is concerned with the resultant theories of social change and their applicability to the study of the history of the family and to family change.

The theory of evolutionary change developed by Charles Darwin in his *Origin of the Species* in 1859 was the culmination of an intellectual revolution begun much earlier that promoted the idea of progressive development. Progressive development believed that the human species evolved from stages of savagery to civilization. As the theory of evolution became the dominant form in explaining biological principles, social scientists of the nineteenth century developed the belief that there was a link between biological and cultural evolution. The basic argument was that since biological evolution proceeded by a series of stages (from the simple to the complex), the same process would hold for cultures. Thus, the Social Darwinists shared in the basic assumption of unilinear evolution (the idea that all civilizations pass through the same stages of development in the same order). They then sought to apply the ideas of progressive development to social forms and institutions – a primary concern being the development of explanatory schema on the evolution of marriage and family systems.

Social Darwinism was associated with, among others, Herbert Spencer (*The Principles of Sociology*, 1897), J. J. Bachofen (*Das Mutterrecht* [The Mother Right], 1861/1948), Henry Sumner Maine (*Ancient Law*, 1861/1960), and Lewis Henry Morgan (*Ancient Society*, 1877/

1963). Social Darwinists seemingly dealt with such non immediate concerns as the origins and historical development of the family, yet their theories had social and political implications. Social Darwinism provided "scientific" legitimation for western colonization and exploitation of "primitive" peoples through the erroneous belief that western culture represented "civilization" and non western cultures (particularly among nonliterate, low technology societies) represented a primeval state of savagery or barbarity. And through its advocacy of evolutionary progress, Social Darwinism provided laissez faire guidelines that supported neglect of the poorer classes of American and Western European societies.

The Social Darwinists differed concerning specific lines of development. Some argued that there was a historical stage of matriarchy in which women ruled the society, whereas most others argued that a patriarchal stage of social evolution never existed. This controversy had implications for the roles of men and women in nineteenth century family systems. The prevalent view was for a patriarchal evolutionary theory of male supremacy and dominance over females. Thus, Social Darwinists gave implicit support to the Victorian notions of male supremacy and female dependency.

In summary, the evolutionary theory of the Social Darwinists ostensibly dealt with such non immediate concerns as the origins and historical development of the family, but underlying their theorizing were implications for the roles of men and women in contemporary nineteenth century family systems. Indeed, their twentieth century evolutionary theory counter parts continued to put forth these same arguments over a century later. The initiative for this rebirth of interest in the evolutionary reconstruction of family forms has been the development of arguments and counter arguments stemming from the concern of the women's movement with the origins of patriarchy and male sexual dominance.

An important rebuttal to Social Darwinism that in part developed out of evolutionary theory was made by the nineteenth century founders of communist thought, Marx and Engels. They made gender role relationships a central and dominating concern of evolutionary theory. Engels (1972) used it to address his primary

concern: the social condition of the poor and working classes and the exploitation of men, women, and children. Concern for gender role egalitarianism, as opposed to patriarchy and male sexual dominance, achieved their fullest evolutionary theory expression in this work. Engels's evolutionary theory saw economic factors as the primary determinants of social change and linked particular technological forms with particular family forms. Echoing Lewis Henry Morgan, Engels depicted a stage of savagery as one with no economic inequalities and no private ownership of property. The family form was group marriage based on matriarchy. During the stage of barbarism, men gained economic control over the means of production. In civilization, the last stage, women became subjugated to the male dominated economic system and monogamy. This stage, in Engels's view, rather than representing the apex of marital and familial forms, represented the victory of private property over common ownership and group marriage. Engels speculated that the coming of socialist revolution would usher in a new evolutionary stage marked by gender equality and by common ownership of property. Engels's main achievement was in defining the family as an economic unit. This has become a major focus in much of the subsequent historical research on the family and is of great theoretical importance in the sociology of the family. But, insofar as Engels's Marxist view constituted a branch of evolutionary thought, it was subject to many of the same objections raised against other evolutionary theories.

By the end of the nineteenth century the popularity of Social Darwinism was rapidly declining. Contributing to this decline were the methodological weaknesses of the approach (data obtained by untrained, impressionistic, and biased travelers and missionaries) and a growing rejection of both its explicit value assumptions on the superiority of western family forms and its belief in unilinear evolutionary development of the family. This belief was replaced by multilinear evolutionary theory that recognizes that there are many evolutionary tracks that societies can follow. It rejects the unilinear evolutionary view that all cultures advance toward a model represented by western culture as ultimately ethnocentric and often racist.

Social Darwinism also made the fatal error of equating contemporary nonliterate cultures with the hypothetical primeval savage society. It failed to understand that *all* contemporary peoples have had a prolonged and evolved past. The failure of many of them to have a written record of the past led the Social Darwinists to assume erroneously that they had none. Further, they did not understand that many nonliterate societies deemphasize changes in the past to stress their continuity with it. This is especially true in cultures that glorify traditions and reify their sameness with their ancestors. Social Darwinists made ethnocentric and subjective pronouncements. They viewed their own society's art, religion, morals, and values according to their notions of what was good and correct, explaining such "barbaric" practices as polygamy and sexual promiscuity based on their own national and individual norms. They biased their analysis with their own moral feelings on such customs and practices.

Another factor in the decline of evolutionary theory was that it was involved with an irrelevant set of questions. For instance, what difference does it make which society represents the apex of civilization and which the nadir if it does not aid in understanding contemporary marriage and family systems? This is especially the case in a world undergoing revolutionary changes and one in which formally isolated cultures are becoming more and more involved with western civilization as a result of colonization. Social scientists felt that attempts to theorize about the historical evolutionary process were not as important as examining the influences which cultures had on each other. Societies did not evolve in isolation, but continually interacted and influenced each other. One final factor in the decline of evolutionary theory was the shift in focus of the sociology of the family. This shift was in part precipitated by the sweeping changes in American and European societies during the nineteenth century. Social scientists were appalled by the excesses of industrial urban society and the calamitous changes in the family system. The precipitating factor seen in this change in the family were the sweeping changes in American and European societies during the nineteenth century brought about by the industrial revolution.

SOCIAL POLICY AND REFORM

Toward the end of the nineteenth century and through the early twentieth century social scientists concerned about the abuses arising from rapid urbanization and industrialization began to see the decline in the importance of kinship and community participation and the changes in the makeup of the nuclear family as more important areas of investigation than the study of the evolutionary transformations of the family. Their research and theories focused on the causal connections relating family change to the larger industrial and urban developments occurring in the last two centuries. Much attention was given to theoretical analyses of the effects these changes had on the individual, on women, men, and children, on the family, on kinship structures, and on the larger community and the society.

Sociology in the US shifted its emphasis away from the study of social evolution to the study of social problems and the advocacy of social reform. The paramount concern was the study of the family in the context of the abuses of rapid industrialization and urbanization. The emphasis switched from the development of theories of family systems to the more urgent concerns of individual families and their members. Illegitimacy, prostitution, child abuse, and other resultant abuses were seen as arising from non governmental supervision of industrial and urban institutions. This underlying assumption about the causes of social problems was held by the social reform movement's major advocate, the Chicago School of Sociology, which was composed of such important sociologists as Robert E. Park, Ernest W. Burgess, Louis Wirth, E. Franklin Frazier, W. I. Thomas, and Florian Znaniecki. They contributed much to the development of family sociology and urban sociology. The Chicago School developed a distinct contrast between urban and rural life. They saw traditional patterns of life being broken down by debilitating urban forces, resulting in social disorganization within the family. An underlying theme was the loss of family functions as a result of urbanization and industrialization.

In traditional societies, the family (following the argument of Chicago School sociologists William Ogburn and Ernest Burgess) performed

economic, educational, recreational, religious, and protective functions. In modern society most of these functions have been taken over as a consequence of the increased participation of government, economic enterprises, and education. The cornerstone of family life was its companionship and emotional functions. This shift in family functions led to Burgess's famous classification of family types as moving from "institution to companionship." According to Burgess, the institutional family is sustained by external community pressures and involvements; the companionate family, on the other hand, is sustained by the emotional attachments among its members.

Beginning in the late 1930s and accelerating after World War II, many of the views of the Chicago School either merged with or influenced newer perspectives. By the 1950s the dominant school was structural functionalism, under the intellectual leadership of Talcott Parsons, who was one of the most predominant and influential sociologists of the twentieth century. According to Parsons (1943), the isolation of the nuclear family "is the most distinctive feature of the American kinship system and underlies most of its peculiar functional and dynamic problems." The typical American household consisted of a husband, wife, and children economically independent of their extended family and frequently located at considerable geographical distance from it. Parsons viewed American society as having been greatly changed by industrialization and urbanization. In particular, he believed it had become highly "differentiated," with the family system's previous educational, religious, political, and economic functions being taken over by other institutions in the society. By differentiation, Parsons meant that functions performed earlier by one institution in the society are now distributed among several institutions. Thus, schools, churches, peer groups, political parties, voluntary associations, and occupational groups have assumed functions once reserved for the family. Rather than viewing industrialization and urbanization negatively, Parsons saw the family as becoming a more specialized group. It concentrates its functions on the socialization of children and providing emotional support and affection for family members.

Parsons further suggested that the isolated nuclear family may be ideally suited to meet the demands of occupational and geographical mobility inherent in industrial urban society. Unencumbered by obligatory extended kinship bonds, the nuclear family is best able to move where the jobs are and better able to take advantage of occupational opportunities. In contrast, the traditional extended family system of extensive, obligatory economic and residential rights and duties is seen to be dysfunctional for industrial society.

Arguing against the social disorganization thesis on the breakdown of the contemporary family, Parsons (1955) found support for the importance of the nuclear family in the high rates of marriage and remarriage after divorce, the increase in the birthrate after World War II, and the increase in the building of single family homes (particularly in suburbia) during this period. All these trends provided evidence of the continuing visibility, *not* social disorganization, of the family and of the *increased* vitality of the nuclear family bond. Thus, a specialized family system functionally meets the affectional and personality needs of its members. Further, it may be admirably fitted to a family system that is a relatively isolated and self-sustaining economic unit of mother, father, and children, living without other relatives in the home and without close obligations and ties to relatives who live nearby.

In summary, Parsons emphasized the importance of the nuclear family – in the absence of extended kinship ties – in that it meets two major societal needs: the socialization of children and the satisfaction of the affectional and emotional demands of husbands, wives, and their children. Further, the isolated nuclear family, which is not handicapped by conflicting obligations to extended relatives, can best take advantage of occupational opportunities and is best able to cope with the demands of modern industrial urban life.

MODERNIZATION THEORY

Modernization theory combines conceptual orientations from both Social Darwinism and structural functionalism to elaborate the theoretical relationship between societal

development and family change. The concept of modernization, derived from structural functionalism, and the theories stemming from it have been the dominating perspective in the analysis of global social change and the family since the last quarter of the twentieth century. Modernization is usually used as a term in reference to processes of change in societies that are characterized by advanced industrial technology. Science and technology are seen to guide societies from traditional, preindustrial social institutions to complex, internally differentiated ones.

Modernization is often linked with a wide range of changes in the political, economic, social, and individual spheres. For example, there is a movement from tribal or village authority to political parties and civil service bureaucracies; from illiteracy to education that would increase economically productive skills; from traditionalistic religions to secularized belief systems; and from ascriptive hierarchical systems to greater social and geographical mobility resulting in a more achievement based stratification system. Likewise the extended family kinship ties are seen to lose their pervasiveness and nuclear families gain in importance.

Modernization theory, while it recognized to some extent that cultural values of non western societies might have an impact on the pace of industrialization, argued that they would not affect its inevitability. Diffusion theory and the convergence hypothesis, offshoots of modernization theory, predicted that cultural differences would diminish as less developed countries industrialized and urbanized. The held belief was that as societies modernized, they would come to resemble one another more and more over time. These societies would lose their cultural uniqueness as they began to act and think more like one another and more like the more developed countries. Accompanying modernization would be a shift to "modern" attitudes and beliefs and a change in the family and kinship system. The family change would see the diminishing control and power of extended kinship systems and emergence of affectional ties and obligations with the nuclear family.

The classic statement of modernization theory, centering on the family and change, is

William J. Goode's *World Revolution and Family Patterns* (1963). This work has had a profound impact on the comparative study of social change and the family. Goode's major contribution is the comprehensive and systematic gathering and analyses of cross cultural and historical data to attack the notion that industrial and economic development was the principal reason that the family is changing. Goode concluded that changes in industrialization and the family are parallel processes, both being influenced by changing social and personal ideologies – the ideologies of economic progress, the conjugal family, and egalitarianism. Finally, Goode proposes that in the "world revolution" toward industrialization and urbanization there is a convergence of diverse types of extended family forms to some type of conjugal family system.

DEPENDENCY THEORIES

Dependency theories take strong exception to these predictions articulated by modernization theory's hypotheses. Further, and more importantly, proponents of dependency theories have changed the focus of the analysis of the impact of industrialization and globalized economy. Rather than focus on whether or not there is a convergence to western models of modernity and family structure, they have focused on the impact of the globalization of the economy on the poor, not only in third world societies but in industrial ones as well. Dependency theories are of particular relevance in their analysis of global inequality on those who are most economically vulnerable: women, children, elderly people, and families living in poverty.

Women are particularly impacted by global poverty. Modernization theory often does not examine the experiences or structural location of women in their own right as societies undergo change. The belief that women's status improves with economic development does not fully realize that widespread structures of patriarchy often keep women in subordinate positions. Patriarchy is the ideology of masculine supremacy that emphasizes the dominance of males over females in virtually all spheres of life, including politics, economics, education, religion, and the family. Its worldwide

pervasiveness is particularly acute in the third world, where women have relatively little political power. Economically, when women's work is not solely relegated to the household they are often found in lower echelon jobs where they work longer hours for less pay than men. Land, the principal source of wealth in most third world countries, continues to be controlled by men. Education is often seen as a male prerogative, and lacking education they have fewer economic options. Women's role in religion often is of secondary or of little religious importance. Modernization, rather than significantly increasing women's independence, often results in and perpetuates their dependency and subordination.

GLOBALIZATION THEORY

Globalization theory has become another perspective in examining family change. Here the emphasis is on an examination of the transnational processes that have an impact on families. Rather than focusing solely on families in the modernized countries or on families in third world societies, of paramount importance are relationships that exist and are experienced by individuals who have family members living in both rich and poor countries. For example, one concern is the impact of globalization on generational relationships among family members, particularly as a consequence of differential socialization experiences in different cultural settings. Also of much interest (Ehrenreich & Hochschild 2002) is the broad scale transfer of domestic service associated with female migration of women whose traditional roles result in their employment as child and elderly caretakers or as domestics in affluent countries while their families in their home countries suffer the absence of their services. The problems associated with international sex tourism are also of great concern. Another area of interest is the involvement of men who have migrated from poorer countries to wealthier ones primarily for economic motives. Not only do they maintain their contacts with their families in their home countries through financial support, but they develop trader communities that are transnational and which link them to their families and to economic networks (Stoller 2001).

Essentially, in evaluating contemporary perspectives on family change, we become cognizant of a twentieth/twenty first century replay of the ideological positions and arguments put forth by the Social Darwinists in the nineteenth century and underlining moral valuations inherent in these orientations. Modernization theory, through its utilization of structural functionalism, can be seen as the twentieth century counterpart of Social Darwinism. Likewise, developmental theory can be seen as a twentieth century counterpart that shares many of the assumptions put forth by nineteenth century radicals such as Marx and Engels.

family, men's involvement in

Sandra L. Hofferth

Father involvement refers to involvement by fathers in the daily responsibilities of parenthood. According to data from the early 1990s, only 12.6 percent of men 45 to 64 years of age report never having had children (Bachu 1996). Thus, although not all men are fathers, most eventually father a child and have, therefore, the opportunity to act as a father to their own children. Men without their own biological children have the opportunity to be a father to their partners' children through marriage or cohabitation. Sixty-four percent of children live with their biological or adoptive mother and father, 6.7 percent live with a biological parent and a stepparent, 21 percent live with a single mother, another 2 percent live with their single mother and the mother's cohabiting partner, 2.5 percent live with their single biological father, and 4 percent do not live with a parent (Hofferth et al. 2002).

SOCIAL AND DEMOGRAPHIC CHANGES AFFECTING FATHERS AND FATHERING

Adjustments in the roles of fathers and mothers have resulted from social changes over the past decades. Such changes include women's increased labor force participation, the absence

of many men from families, the increased involvement of other types of fathers in children's lives, and increased cultural diversity in the US (Cabrera et al. 2000). A concern about the well-being of children raised in low-income families is linked to these same changes. Although many of the same concerns are recognized in developed countries across the globe, this discussion is limited to the US context.

In the recent past much of the focus on fathers was occasioned by their absence. The focus on father absence sprang from large increases in divorce and separation beginning in the 1970s that resulted in fathers substantially reducing their financial and other commitments to family and children. Early research focused upon the effects of the absence of the father on the financial condition of the family. Since the mid 1990s, research has focused on the involvement of non-residential fathers with children, not just on the father's financial contribution. Research from the Fragile Families and Child Wellbeing study suggests that unmarried fathers are more involved with their families than popularly believed. At birth 82 percent were romantically involved with the baby's mother and 44 percent were living together (Fragile Families and Child Wellbeing 2000).

The other major change is the increased labor force participation of married mothers. Women have always worked; however, the increase in employment of married mothers with young children in the 1970s and 1980s, and in the 1990s of single mothers, was remarkably rapid. Maternal labor force participation, which has increased maternal financial support for the family and removed financial support as fathers' primary responsibility, has led to the focus on paternal responsibility for non-financial involvement and care of children.

CONCEPTUAL FRAMEWORK

The most frequently used framework conceptualizes father involvement as having three major components: (1) the time fathers are engaged with or accessible to children overall or in specific activities; (2) the responsibility they take for them; and (3) the quality or nature of the relationship (Lamb 2004).

Research has found that fathers in intact families spend about 1 hour and 13 minutes on a weekday and about 3.3 hours on a weekend day with children under age 13 (Yeung et al. 2001). Because both parents' time with children may vary, relative levels of involvement may provide a better sense of father involvement. Based upon data from the 1980s and 1990s, fathers' time engaged in activities with their children is about two fifths of mothers' time. Fathers are accessible to their children about two thirds as often as mothers. These figures are higher than in the 1970s and early 1980s. A recent study from the mid 1990s shows that fathers' time engaged with children on a weekday is about two thirds of mothers' time, and on a weekend day almost 90 percent of mothers' time, additional evidence for increased father involvement. In these more recent data, the ratio of fathers' to mothers' time accessible to their children is about the same as that of engaged time. As children get older and the absolute amount of parental time declines, fathers' time rises as a proportion of mothers' time with children.

Of course, the increasing ratio of fathers' to mothers' time since the 1970s could be due to either a decline in mothers' or an increase in fathers' time. However, one comparison between 1965 and 1997 suggests that mothers' time with children has remained fairly constant, and, hence, the rise in the ratio of fathers' to mothers' time with children is not due to a decline in mothers' time, at least in two parent families. Other research also suggests that fathers' time with children has risen in two parent families where the average amount of time children spent with fathers rose about 3 hours per week between 1981 and 1997 and time with mothers rose as well. The time children spent with fathers did not rise significantly over all families because of the offsetting increased number of single parent families and because non residential fathers are less involved with their children (Sandberg & Hofferth 2001).

Although the overall amount of time may be important to child development, developmental psychologists are concerned about the nature of those activities. As has been found in several studies, play and companionship account for the largest fraction of time children spend with

their fathers. About 39 percent of children's engaged time with fathers is spent in play and companionship on a weekday or weekend day. Learning, household work, and social activities comprise a relatively small fraction of children's time with their fathers, about 31 percent. The time children spend in learning and educational activities with their fathers is quite small, averaging only 3 to 5 percent of engaged time.

A second important category is personal care received by the child from the father, about 25 percent of the father's engaged time on a weekend day and 35 percent on a weekday. Childcare by fathers when mothers are working is an important aspect of caregiving. In the US a substantial minority of dual earner parents keep their use of non parental care to a minimum by adjusting their work schedules so that a parent can care for their children when needed. About one third of working parents in two parent families with a preschool child work different schedules and can share child care responsibilities. The proportion of fathers who care for children during the hours when mothers work rises to three quarters as the number of non overlapping hours increases. Other evidence that fathers' time in childcare is responsive to available time is that, during the 1991 recession in which more men were presumably out of work or working fewer hours, the proportion of men who provided childcare as primary or secondary provider while their wives were working rose by one third. It declined again following the end of the recessionary period.

Much of what parents do for children demands time indirectly, through management of their lives and activities – the extent of responsibility fathers take is a key variable across families. Fathers can participate in a wide variety of managerial and supervisory activities, including selecting doctors and child care programs, managing appointments, arranging transportation, coordinating with schools, and monitoring children's activities (Cabrera et al. 2000). Although fathers take less responsibility than mothers, and few fathers take sole responsibility for any parenting tasks, fathers are likely to share direct care, to transport children to activities, and to participate in choosing activities and selecting a childcare

program, preschool, or school (Hofferth et al. 2002). They are less likely to be involved in purchasing clothing, and in selecting and making appointments for doctor visits.

An additional aspect of fathering considered here is the quality of the father-child relationship. Most developmental psychologists argue that the quality of parenting and of the parent-child relationship is crucial to developing competent children. A combination of responsiveness with control has been shown by research to be linked to optimal child development. Fathers who were affectionate, sensitive, spent time with their child, and had more positive attitudes had securely attached infants at 9 months. Positive father involvement has also been linked to greater social skills, cognitive ability, school performance, self esteem, and social confidence in children (Lamb 2004).

WHAT FACTORS MOTIVATE FATHERS TO BE INVOLVED WITH THEIR CHILDREN?

Family structural variables are expected to be associated with paternal involvement because they may influence fathers' motivation to participate. Particularly important are the relationships of the male to the child (biological/other) and to the mother (married/cohabiting). From the point of view of evolutionary psychology, genetic benefits arise from fathering and investing in one's own natural offspring. Such "parenting investment" increases the reproductive fitness of the next generation. Stepfathers gain little genetic benefit by investing in the care of stepchildren, and such investment detracts from time they might otherwise spend ensuring their own biological progeny. However, many examples of caring behavior by stepparents exist, suggesting that paternal investment is not restricted only to biological offspring. One of the mechanisms behind such investment is "relationship investment." By investing in their spouse's children from a prior union, remarried men increase the prospect of further childbearing as well as continuation of supportive exchanges with their partner. Thus investment in one's partner's children may have payoffs. However, there is also less normative support for involvement by stepfathers than biological

fathers, consistent with findings that stepfathers are behaviorally less involved (Hofferth & Anderson 2003). It is likely that cohabiting (especially non biological cohabiting) fathers also receive less normative support for being involved. In addition, both stepfathers and cohabiting fathers may receive less support than married biological fathers for involvement from the child's mother.

Fathers are likely to differ on a variety of social and demographic factors that could also be linked to father involvement. For example, fathers' motivation for involvement with older children may be greater because interaction with them is more gratifying. On the other hand, adolescent children may become less interested and motivated to spend time with their father. Cultural variation also exists. Recent research found African American and Hispanic fathers taking more responsibility for managerial tasks than white fathers, even after adjusting for differences in socioeconomic and demographic characteristics (Hofferth 2003). African American fathers have been found to be less warm and more controlling than white fathers and Hispanic fathers equally warm but less controlling than white fathers. Better educated fathers may have more positive fathering attitudes and more equitable gender role attitudes, which may relate to greater engagement with children. Their expectations may also be higher. On the other hand, fathers with longer work hours will be constrained from spending more time with children. Fathers' income could be positively or negatively related to engagement with children, depending upon whether the level of income is a function more of education or of work hours.

CURRENT RESEARCH ON FATHER INVOLVEMENT

Much of the current research focuses on effects of father involvement on child development (Lamb 2004). One of the major issues in examining outcomes of father involvement is to identify unique effects of fathers separate from mothers. There are three basic ways it is thought that fathers affect their children's development. The first is by direct interaction and involvement with the child, including

teaching, helping, playing, etc. A second is by taking responsibility for aspects of the child's life, such as making appointments, talking with teachers, arranging care, and monitoring the child's activities. The third is through interaction with the mother, including supporting the mother in childrearing, both emotionally and financially. All avenues are likely to be important, but only the first has been widely researched.

Research has failed to find a strong association between amount of time spent doing things with children and their well being and development. Rather, research tends to find significant links between the warmth of the father and mother and child development. It has been extremely difficult to show links between specific parenting behaviors, such as helping with homework, and child achievement. Parental involvement in children's schooling, for example, has been found to be associated with greater school achievement. Thus it is likely that the quality and type of parenting matters more to child development than the total amount of father involvement. It is possible, of course, that the types of involvement measures used to date are not specific enough to capture these linkages.

There is substantial support for the hypothesis that a positive relationship between mother and father is good for children. Parents who have a good relationship feel better about themselves, are better parents, and their children are better adjusted, whereas conflict leads to maladjustment.

Most of the above research has been conducted on residential parents. Increasing research on amount and quality of involvement has focused on non residential fathers (Hofferth et al. 2002). Research has found greater frequency of contact with the non resident father to be associated with better child outcomes (Amato & Gilbreth 1999).

METHODOLOGICAL ISSUES IN STUDYING MEN AS FATHERS

Fathers are difficult to study. A report that summarized some of the methodological issues in studying fathers was produced in the 1990s by the Forum on Child and Family Statistics

(Federal Interagency Forum on Child and Family Statistics 1998). Obtaining the cooperation of fathers in order to obtain the best information about their involvement is not the easiest task. To begin with, men are undercounted in surveys. Many men are loosely connected to households and are simply not included in our enumeration of households. Low income fathers, in particular, may be living in several places, on the street, or be in jail or in the military. Even if they are identified, men's fertility is usually underestimated. Fathers are accessed mainly through the mothers of their children. Married fathers can be located; however, fathers are much less likely to agree to participate than mothers. They work full time more often, are at home less frequently, and are less likely to agree to be interviewed. Thus much of the information on fathers that is used today is reported by the mother. That is unlikely to provide the best information about father involvement as it may depend upon the mother's attitude toward the father. This has always been a problem for non residential fathers, because many mothers do not want to provide access to these fathers or do not know their whereabouts. The Child Development Supplement to the Panel Study of Income Dynamics (PSID CDS) was able to interview only about 25 percent of the non residential fathers of the children in the study. Most of the contact problem was due to failure to obtain contact information from the mother. Mothers refused in one third of the cases and one third could not be located. Upon contacting the father, cooperation was reasonably high, about 64 percent. In the Early Head Start Study, 60 percent of mothers gave information that could be used to identify the father of the child, and of these 60 percent participated.

Interviewing residential fathers is also problematic. Obtaining an interview with a second family member is expensive and time consuming because it takes additional contact and interview time. The use of a self administered questionnaire in the PSID CDS resulted in a response rate of only about 60 percent of fathers.

An alternative way to obtain information about fathers is by starting with the man as the study respondent and following him as he becomes an adult. The problem here is in obtaining accurate reports of having fathered a

child. Men who were without a high school degree, who were black, who fathered a child at a young age, and who did not consistently live with the child from birth were less likely to be verifiable as children's fathers in the National Longitudinal Survey of Youth 79 (NLSY79). Besides reports that may not be accurate, male fertility reports are often missing. In the Survey of Income and Program Participation (SIPP), 8 percent of men did not report on the number of children ever born (Bachu 1996). An alternative strategy that has worked well is to start with the birth of a baby and get the couple at this "magic moment." In the Study of Fragile Families and Child Wellbeing, which took this approach in studying unmarried couples, response rates for mothers were 87 percent and for fathers were 75 percent (Fragile Families and Child Wellbeing 2000).

FUTURE DIRECTIONS

The research on fathers' involvement in the family increasingly focuses on two areas: (1) examining the relationship between father involvement and child development in special types of families, such as minority families, low income and "fragile" families, and stepfamilies; and (2) conducting qualitative interviews with fathers to examine such topics as the meaning of fatherhood in men's lives and how men become fathers to children they did not sire. These qualitative studies should be helpful in designing a new generation of studies that examines the process of becoming a father and how becoming a father links to men's later involvement with children.

family migration

Darren P. Smith

Since the late 1970s the topic of family migration has increasingly been examined by sociologists, geographers, economists, and demographers. Studies of family migration have clearly become a wide ranging, interdisciplinary endeavor, with discussions cross cutting the social sciences. Although family migration occurs at many geographic scales, from the neighborhood to the global, academic discourses within the developed world have

tended to focus on the movement of family units over long distances at a subnational level. Kofman (2004) and Smith and Bailey (2006) argue, for example, that the “family” has been lost from accounts of population movements between European states, or across wider international boundaries, respectively. In addition, there is limited interchange between accounts of family movements within the developed and developing world, with the latter often being absorbed within wider development studies.

North American and European studies of family migration have generally focused on the *outcomes* of family migration (Halfacree 1995). More specifically, there has been an emphasis on pinning down the *socioeconomic* effects, which are often measured by the post migration employment or occupational status of family migrants. There has been less concern with the non economic outcomes of family migration (e.g., quality of life, caring, family forming, marriage). At the same time, there have been limited empirical explorations of *how* and *why* family migration unfolds, or the subjective dimensions which underpin the decision to move the family unit.

This longstanding perspective is tied to an epistemological and methodological engagement, with many scholars of family migration drawing upon the tenets of positivism. As a result, researchers of family migration have tended to adopt quantitative research methods, particularly statistical modeling, and utilize large scale aggregated data sets to test hypotheses about the general patterns and trends of family migration (Smith 2004). Indeed, during the 1970s and 1980s there were a number of defining hallmarks associated with studies of family migration. First, one of the major conventions was to view labor motivations as the primary stimulus of family migration. To investigate this dimension hypotheses were often constructed from the theoretical models of neoclassical economics, and the *a priori* behavior of economic rational actors (see Bailey & Boyle 2004). Second, there was an underlying assumption that family migration is triggered when the movement of the family unit yields an increase in total family income, irrespective of the impacts on the employment earnings or career aspirations of individuals

within the family. Third, family migration was often viewed as being induced by the male partner, in order to enhance his career development. This normalization of family life and behavior is clearly influenced by the taken for granted model of the traditional “male breadwinner/female homemaker” couple. Many early studies therefore asserted that the employment aspirations of female partners are often “sacrificed” (i.e., unemployment or economic inactivity) or “satisfied” (i.e., part time employment) following the movement of the family. Such a disenfranchisement of female partners within the labor market is borne out by the widely used terms “female tied migrant” and the “trailing spouse.” Importantly, since the early 1990s this treatment of family migration has been widely critiqued, and theorizations and conceptualizations of family migration have shifted in three important, and interconnected, directions.

First, within quantitative studies of family migration there has been a more critical thinking to the ways in which family migrants are conceptualized and categorized. Traditionally, and tied to the limitations of data sets, analyses of family migration were predominantly based on aggregations of family migrants, with family migrants generally treated as “homogeneous lumps.” With this in mind, some recent studies have constructed more nuanced categorizations of family migrants, which are more sensitive to intra familial differences and diversity. One example is Boyle et al.’s (2002) use of microdata from the 1990 US and 1991 UK Census to reconstruct family units by linking together male and female partners. This technique allows an examination of the relational characteristics between migrant partners, and a consideration of the effects of different family and household arrangements and relations. In addition, early studies of family migration tended to focus on wholly moving family units (i.e., male and female partners moving together), which implicitly treats family migration as a simplistic “neat” event.

Understandings of the links between family migration and processes of family and household formation were therefore, until recently, extremely limited (Smith 2004). This point is integral to Smith and Bailey’s (2006) manipulation of UK Census microdata to explore how

migrant families use different strategies which involves partners joining or moving together, and how these different strategies influence the post migration labor market status of both partners. Moreover, the above studies clearly adhere to Halfacree's (2001) call for scholars to be more reflexive when establishing taxonomic classifications of family migrants.

Second, ideas from social theory are now more fully embraced by scholars of family migration. One fruitful development has been a more critical perspective of the gendered dimensions of family migration, linked to critiques of the substantive relevance of human capital hypotheses to explain tied migration. A pioneering work here is Halfacree's (1995) commentary of how and why female tied migrants are, in part, reproduced through the "structuration of patriarchy." This structurationist reading of family migration explicitly draws upon the writings of Anthony Giddens and Sylvia Walby, and demonstrates how the orientations of family migration can be usefully informed by wider social theories. In a similar vein, other recent studies have provided insights of the ways in which diverse familial arrangements and relations mediate family migration. Important accounts include Cooke's (2001) investigation of the effects of the onset of parenting and childrearing, and the presence and different numbers of dependent children; Bailey et al.'s (2004) assessment of how childcare and the care of elderly family members allow and constrain family migration; and Bonney et al.'s (1999) examination of the implications of marriage events and the rise of cohabitation on family migration. All of these studies incorporate a deeper level analysis of the impacts of gendered power relations, and gender role ideology and task allocation on family migration decision making and behavior.

A third development, and linked to the above, has been the implementation of post positivist, inductive approaches within studies of family migration. Recent theory building endeavors have involved the use of in depth, qualitative research methods and the gathering of rich qualitative data to tease out the decision making processes and behavior of family migrants. In the British context, for example, Hardill et al. (1997) and Green (1997) utilize

biographical methods to explore the complex intra familial negotiations, compromises, and tradeoffs which take place between male and female partners within dual career couples. These studies draw attention to the importance of non economic and cultural concerns (e.g., locational and residential preferences) within family migration decision making processes, particularly quality of life aspirations, and stress that family migration is not always motivated by labor related issues. In doing so, recent qualitative studies also reveal that family migration is not a straightforward, neat event. Rather, family migration is identified as a complex and experiential process, which involves many compromises, stresses, and anxieties for family members. One particular benefit of such qualitative research is that it is possible to more accurately assess changes in the pre and post migration status of family migrants, therefore providing a precise understanding of the effects of family migration when compared to quantitative studies using cross sectional data sets (e.g., US and UK Censuses).

The above three interconnected developments have undoubtedly enabled scholars to capture the diversity of the processes and effects of family migration. However, one general commonality between recent findings is that family migration often has a negative impact on women's labor market status. On the whole, the female tied migrant thesis is reaffirmed by recent studies; although it is important to note that many of the interpretations are based on short term measures (i.e., within one year of move) of post migration labor market participation. Indeed, in a cross national study of the effects of subnational family migration on the labor market status of female partners in the US and UK, Boyle et al. (2002) reveal that the socioeconomic effects are remarkably similar for women in both contexts, despite major institutional and ideological differences. Likewise, studies in the Netherlands and Sweden point to family migration having a negative effect on women's labor market status. It would appear, therefore, that despite rising levels of female employment in Europe and North America, family migration continues to be detrimental to women's labor market participation.

Nevertheless, some recent studies disrupt the tied migrant thesis, and have demonstrated that geographical contingencies (e.g., labor market opportunities, childcare support, public transportation) have a major impact on post migration labor market status of male and female partners. For example, Cooke and Bailey (1996) show that long distance migration can have a positive effect on female labor market status in some contexts within the US. It is contended that this positive effect is tied to family migrants moving into economic growth areas. Importantly, this interpretation overlaps with other migration studies which have examined links between rising female occupational status and movement into specific locations, such as Fielding's (1992) conceptualization of London and the southeast of England as an "escalator" region. In essence, these studies beg questions of the wider geographic pertinence of the tied migrant thesis.

Overall, the shifting treatment of family migration since the early 1990s has stimulated a vibrant interdisciplinary research agenda, with scholars now posing a broader range of research questions to investigate the diversity of family migration. This includes a richer appreciation of the influence of sociospatial contingencies on processes and outcomes of family migration. Tied to this is a growing interest with the ways in which family formations, ethnicity, race, age, life course, sexuality, class, and culture cross cut with different expressions of family migration. Another useful entry point for future research is the inclusion of other types of family structure, such as lone parent, single adult, multi person, and same sex couples within analyses of family migration, and the need to transcend the considerable focus on heterosexual nuclear families.

family planning, abortion, and reproductive health

Ann E. Biddlecom

Many societies have made the transition from high mortality and large family sizes to settings where most children survive, small families are desired, and most people control their fertility. In the early 1960s, the average woman could expect to have almost five children over her life, but now she can expect to have fewer than three children. The conscious use of contraception and abortion to control fertility thus assumes paramount importance in explaining basic aspects of contemporary human society. However, substantial differences exist in fertility and contraceptive levels and access to services between developed and developing regions of the world. For example, while in more developed regions women now have fewer than two children on average and nearly 7 in 10 women in marital or consensual unions use contraceptives (mainly sterilization, the pill, or the male condom), women in Africa have about five children on average and fewer than 3 in 10 women in marital or consensual unions use contraceptives (mainly the pill, injectables, and implants) (United Nations 2004). Other factors such as social structure, culture, gender relations, and economic opportunities also contribute to these regional differences.

The area of sexual and reproductive health is broad and encompasses *sexual behavior* (as it relates to marriage, pregnancy, and fertility; adolescents' sexual activity; and risky sexual behaviors that can lead to unintended pregnancy, sexually transmitted infections (STIs) and the human immunodeficiency virus (HIV)); *STIs and other reproductive tract infections* (the prevention, diagnosis, and treatment of these infections); *contraceptive use* (measuring the demand for and effective use of contraceptive methods, reasons for non use, and method choice and discontinuation); *abortion* (levels of and access to abortion, unsafe abortion and its consequences, and post abortion care); *reproductive morbidities* (e.g., infertility and

reproductive cancers, obstetric fistula, and consequences of female genital cutting); *contraceptive and abortion technology* (the feasibility, acceptability, and demand for new methods such as medical abortion, female condoms, microbicides, and various male contraceptive methods); *family planning related information and education* (including sex education in schools and condom promotion); and *reproductive health care* (e.g., financing, access to, and quality of reproductive health care and its effects on reproductive outcomes). Studies tend to have close ties to health policies and programs and focus on levels, determinants, and consequences of family planning, abortion, and sexual and reproductive health related problems. Sources of evidence have changed immensely over time, moving from a heavy reliance on indirect estimates based on census data to population based surveys (from the 1970s onward) and clinic based studies to the use of qualitative evidence (from the 1990s onward), mainly from focus group discussions, in depth interviews, and ethnographies.

Research and public policy emphases up until the early 1990s were grounded in arguments for reducing population growth, and the areas of abortion and reproductive health were not very visible. The 1994 International Conference on Population and Development (ICPD) in Cairo, Egypt, and its final document, the Program of Action, shifted the focus from overpopulation concerns and demographic targets to an emphasis on reproductive rights. An example of this shift is reflected in the increasing use of the concept of "unmet need for family planning," which includes both contraceptive behavior and fertility preferences and reflects the situation of individuals who want to avoid or delay a birth but who are not using any method of contraception, as a justification for and indicator of family planning program efforts and needs (Casterline & Sinding 2000). Understanding why people are in this apparently paradoxical situation and how best to meet their contraceptive needs adheres to the overall approach of satisfying individual reproductive choice rather than meeting national targets. Recent studies point to lack of knowledge about contraceptive methods, social opposition to contraceptive use, and concerns about health side effects as important reasons for why

women and men do not use contraceptives though they want to delay or avoid pregnancy (Casterline & Sinding 2000).

The ICPD conference also expanded sexual and reproductive health to encompass a broad set of issues beyond family planning, such as women's rights to control their sexuality. Subsequent policymaking, advocacy, and scholarship turned to gender inequities that affect key determinants of sexual and reproductive health. The often unstated assumption that women hold full decision making power over their health has been supplanted by research on the influence of spouses, parents, and peers, gender based power and violence in sexual relationships, women's status and access to resources, and neighborhood and community level characteristics. For example, while a community based family planning program in Ghana led to increased contraceptive use, there were related strains in gender relations in the communities and fears among women of beatings by their husbands if they used contraceptives (Bawah et al. 1999). There is also increased attention to how voluntary sexual intercourse is, especially for young women, and the implications of these findings for women's rights as well as sexual and reproductive health. Several studies in developed and developing countries show evidence that women who experience sexual or physical abuse (in childhood or in relationships as adults) are also more likely to experience STIs, pelvic inflammatory disease, and unwanted fertility (Jejeebhoy & Koenig 2003).

Broadening the interpretation of reproductive health to include more than family planning has been supported by the dramatic spread of HIV/AIDS since the 1980s. The epidemic has spurred research on male condom use for HIV and STI prevention, including investigations of the barriers to consistent and correct use of condoms and women's difficulties in negotiating condom use, and has legitimated the study of sexual behavior as it relates to sexual and reproductive health. Issues that continue to plague researchers and program planners alike include the difficulty of increasing condom use (especially within marriage), how protection from disease is reconciled with planning births, and how the nature of reproductive decision making has changed in the

context of HIV/AIDS, especially for people who are HIV positive.

Historically, women's experiences dominated research studies and data on family planning, abortion, and reproductive health, since women were deemed more accurate reporters of reproductive events and perceived as the people "at risk." Many data collection efforts in the 1960s were limited to married women and then expanded in the 1970s, and later in some regions, to include unmarried women. Evidence on men's sexual and reproductive health is mainly from the 1990s and 2000s. A recent worldwide study documented that men are involved in family planning decisions – many have discussed family planning with their partners and used methods to space or limit births – and many men who have an STI say they have informed their partners of the infection or have sought treatment (Alan Guttmacher Institute 2003). Nevertheless, established family planning and reproductive health care services are much better developed for women in most countries (though there are still subgroups of women who are underserved) than for men.

Recent research incorporates men's views and experiences by studying couples and their reproductive behaviors. Studies of couples reflect the broader social context in which decisions like contraceptive use are made, and evidence shows that partners have significant influence over one another's contraceptive behavior via their individual fertility preferences and approval of and communication about family planning. Couple studies have tended to focus on contraceptive use (including condom use for preventing STIs), and much less on abortion or other sexual and reproductive health outcomes. One methodological challenge which arises is when partners have different reports of the same behavior. For example, men have been shown to report much higher levels of condom use than do women, both in the aggregate and within couples.

Abortion remains one of the more difficult topics to study despite its widespread practice – estimates suggest that about one quarter of pregnancies worldwide end in abortion – because of the moral arguments surrounding abortion, the criminalization of the practice in many countries, and the clandestine nature of abortion for many women and abortion

providers. Measuring the extent of abortion and abortion related complications, particularly in countries where abortion is illegal and records are not maintained at health facilities, is critical to understanding the magnitude of the public health impact of abortion. Methods to measure the prevalence of abortion include records from registration systems (based on reports from hospitals, clinics, and private doctors), surveys of abortion providers, and surveys of women in the community. Other techniques, such as third party reports, where women report on abortions they know other women in the community or in their social networks have had, have also been used. Most evidence is on the level of abortion and much less on reasons why women obtain abortions and the social, health, and economic consequences of unsafe abortion. Monitoring changes in public opinion toward abortion, especially the conditions under which it should be legal, is also important given links between popular acceptance of abortion and the politics of its legal status. Yet even abortion attitudes are difficult to measure; for example, more people in the United States agree that abortion should be legal for any reason when a survey question specifies a first trimester pregnancy than when no pregnancy gestation is stated (Bumpass 1999).

With the continued decline of fertility world wide, persistent inequities in sexual and reproductive health (including access to services), and the spread of HIV/AIDS, questions about the ways that women and men – as individuals and as partners in sexual relationships – can better achieve their childbearing desires and protect their sexual and reproductive health become increasingly important to address. Future directions for social research will include a focus on the contextual factors that shape individuals' use of contraception, abortion, and reproductive health services; the continued inclusion of men in analyses of sexual and reproductive health; understanding the barriers to effective contraceptive use; ways to increase the dual use of contraceptive methods for pregnancy and STI prevention; the conditions under which risky or coercive sex occurs; greater attention to sexual and reproductive decision making; and new techniques to improve reporting of sexual behavior and abortion.

family poverty

Mark R. Rank

Family poverty generally refers to households lacking a minimum amount of income. However, specific definitions and measurements of poverty vary widely across countries. In the US, family poverty is officially measured in terms of whether various sized households fall below specific annual income levels. In Europe, poverty is frequently defined as residing in a household that falls below one half of the national median income. In developing countries the standard is often that of living in a family earning less than a dollar a day. The underlying concept behind all of these approaches is that there is a basic minimum amount of income necessary in order for families to carry on their day to day activities adequately. Families that fail to acquire such income are considered poor.

The social scientific study of family poverty dates back to the turn of the twentieth century with Seeborn Rowntree's study of 11,560 working class families in the English city of York. Rowntree's research indicated that working class families were more likely to experience poverty at certain stages in the family life cycle during which they were particularly economically vulnerable (e.g., the period of starting a new family and during retirement). Since that time, social scientists have been interested in family poverty for at least three major reasons. First, there has been a longstanding concern regarding the role that families play in the intergenerational transmission of poverty. Second, there is considerable interest in the importance of family structure as a causal factor leading to poverty, and in particular, understanding the relationship between single parent families and the risk of poverty. A third line of research has examined the detrimental effects

that poverty exerts upon family functioning and development. In each case, much of the social scientific research on poverty has taken place in the developed world, particularly within the US.

Early work addressing family poverty frequently assumed that poverty was chronic and handed down from generation to generation. One longstanding argument to explain this pattern was that it resulted from the larger economic reproduction of social class. Families with few resources are unable to provide their offspring with the types of advantages necessary for getting ahead economically, resulting in a perpetuation of poverty from one generation to the next. Recent economic and sociological work in this area has shown a strong correlation between parents' and children's socioeconomic status.

An important variation of this perspective was the culture of poverty framework derived from the ethnographic work of Oscar Lewis in the 1950s and 1960s. Lewis studied lower class Mexican and Puerto Rican families residing in slum communities in both New York and Puerto Rico. He argued that chronic high unemployment and underemployment, coupled with little opportunity for upward mobility, led to what he called a culture of poverty. Such a culture was most likely to arise in economically depressed and isolated areas such as urban inner cities or remote rural areas. The culture provided families with a means for coping with their poverty. Traits include a present time orientation, strong networks of kinship ties, and an unwillingness to delay gratification. These traits were then passed on from parents to children, contributing to an intergenerational transmission of poverty. Lewis wrote: "it is both an adaptation and a reaction of the poor to their marginal position in a class stratified, highly individuated capitalistic society . . . Once the culture of poverty has come into existence it tends to perpetuate itself" (Lewis 1966: 22). While such a culture allows families to better cope with their environment, it also makes it more difficult for them and their children to break out of poverty.

Although Lewis stressed that only approximately 20 percent of US poor families fell into such a culture of poverty, those who utilized this perspective during the 1960s and 1970s

often linked the majority of families in poverty with a culture of poverty. In particular, it was closely associated with poverty among African American families. The culture of poverty perspective also exerted a significant effect on the social policy of the US in the 1960s. Policy initiatives and programs arising out of the War on Poverty such as the Moynihan report, Head Start, and community action were all influenced by this perspective. In addition, popular books such as Michael Harrington's *The Other America* (1962) were strongly influenced by the culture of poverty framework.

With the advent of several large, longitudinal data sets such as the Panel Study of Income Dynamics (PSID) and the National Longitudinal Survey of Youth (NLSY) in the late 1960s and 1970s, the assumption that family poverty was chronic, longlasting, and intergenerational could be empirically examined. Of particular significance was the 1984 book by Greg Duncan entitled *Years of Poverty, Years of Plenty*. Using 10 years of the PSID data, Duncan demonstrated that family poverty was to a large extent episodic rather than chronic. The typical pattern was that households were impoverished for one or two years and then managed to get above the poverty line, perhaps experiencing an additional spell of poverty at some later point in their lives. This and other longitudinal work showed a much more fluid and dynamic picture of family poverty than had frequently been assumed. Duncan and others also demonstrated that one of the critical factors leading households into poverty was family dissolution and the formation of single parent (generally female headed) families.

The rise of female headed families with children during the last third of the twentieth century (fueled by the high rate of divorce and an increasing number of out of wedlock births) became a major area of research among US sociologists and social scientists studying the patterns and causes of poverty. The popularity of the term *the feminization of poverty*, coined by Diana Pierce, illustrated the emphasis in the 1980s and 1990s of looking at gender and family structure as important factors leading to poverty. A large volume of research demonstrated that female headed families with children were at a significant risk of encountering poverty and economic destitution. Various

studies showed that following a divorce, the standard of living for women and their children declined sharply. Many women worked at lower paying jobs and lacked child support payments. The result was that female headed families with children had a substantially higher rate of poverty than other types of families, and experienced poverty for longer periods of time.

Of particular importance to the area of single parent families and poverty has been the work of William Julius Wilson. In both of his two major books, *The Truly Disadvantaged* (1987) and *When Work Disappears* (1996), Wilson focused on the deteriorating conditions of inner city minority families in Chicago. Somewhat along the lines of Oscar Lewis, he argued that declining economic opportunities in central cities have led to the breakdown of the family and to the rise of poverty. In particular, Wilson notes there has been a decreasing number of employable men in central cities, resulting in greater numbers of female headed families with children. Such families, in turn, are at a heightened risk of long term poverty.

These and other research findings spotlighting the significance of family structure have led to an academic and political debate regarding the importance of encouraging marriage as a strategy for alleviating family poverty. Recent welfare reform legislation in the US has placed a strong emphasis on policies and programs to encourage marriage and to discourage out of wedlock births. Others have argued that a more reasonable and effective policy approach is to provide the supports necessary for all families and children to succeed, not just those in married couple families.

A third research emphasis within the area of family poverty has been to examine the independent effect that poverty has upon family development and functioning. This body of research has shown that poverty influences family functioning in a variety of ways. Poverty exerts a profound influence upon the health and development of family members. Poverty is associated with a host of health risks, including elevated rates of heart disease, diabetes, hypertension, cancer, infant mortality, malnutrition, mental illness, and a variety of other diseases. The result is that family members living in poverty have significantly higher

mortality rates and shorter life expectancies than the non poor. Furthermore, poor infants and young children are likely to have far lower levels of physical and mental growth (as measured in a variety of ways) than their non poor counterparts. Both the duration and the depth of poverty intensify these negative outcomes. The result is that poverty can have longlasting physical and mental consequences as children become adults.

Research has also demonstrated that poverty affects family structure and functioning. First, the likelihood of marriage is substantially reduced among the poverty stricken. Second, women at lower income and educational levels tend to have children at earlier ages and are more likely to bear children out of wedlock. Third, several ethnographic studies have indicated that the poor are more likely to use a larger network of kinship than the non poor to exchange resources and services. Fourth, poverty and lower income are associated with greater levels of marital stress, dissatisfaction, and dissolution. Fifth, higher levels of domestic violence tend to be found within poverty stricken households. In each of these cases, the economic stress caused by poverty is hypothesized as an important factor behind these associations.

In addition to the direct effects on the family, researchers have also examined the effect that high rates of neighborhood poverty have on the viability of the community, which in turn influences the viability of the family. Major research areas include the relationships between neighborhood poverty and elevated rates of crime, neighborhood poverty and declining social capital, and neighborhood poverty and the increasing risk of environmental pollution and hazards. Each of these in turn have been shown to have a detrimental effect on the health and functioning of low income families residing in impoverished neighborhoods.

Finally, recent work has examined the wider effects of family poverty upon society at large. Mark Robert Rank's book *One Nation, Underprivileged* (2004) illustrates the connections between family poverty and a host of societal problems and issues. This body of work has also documented the widespread risk of family poverty and economic vulnerability for the population as a whole. Between the ages of

20 and 75, approximately three quarters of Americans will reside in a household that experiences poverty or near poverty for at least one year. Research in European countries has also begun to demonstrate the prevalent nature of families experiencing poverty at some point during the life course.

family, sociology of

Joel Powell and Karen Branden

Sociology of family is the area devoted to the study of family as an institution central to social life. The basic assumptions of the area include

the universality of family, the inevitable variation of family forms, and the necessity of family for integrating individuals into social worlds. Family sociology is generally concerned with the formation, maintenance, growth, and dissolution of kinship ties and is commonly expressed in research on courtship and marriage, childrearing, marital adjustment, and divorce. These areas of research expanded in the twentieth century to encompass an endless diversity of topics related to gender, sexuality, intimacy, affection, and anything that can be considered to be family related.

A recognizable, modern sociology of family emerged from several different family studies efforts of the nineteenth century. Early anthropologists speculated that family was a necessary step from savagery to civilization in human evolution. Concentrating on marital regulation of sexual encounters, and debating matriarchy versus patriarchy as the first enduring family forms, these explanations framed family studies in terms of kinship and defined comprehensive categories of family relations. In consideration of endogamy, exogamy, polygamy, polyandry, and monogamy, these efforts also fostered discussion of the best or most evolved family forms, with most commentators settling on patriarchy and monogamy as the high points of family evolution.

Nineteenth century sociologists such as Herbert Spencer and William Sumner adopted evolutionary views of family and made use of anthropological terms, but discussions of best family types gave way to considering the customs, conventions, and traditions of family life. The evolutionary view of family pushed sociology toward the pragmatic vision of the family as adaptable to surrounding social conditions. And sociology's emphases on populations, societies, and the institutions embedded within them allowed the observation that American and European families were rapidly changing in response to the challenges of modern society.

Another important development in early family sociology resulted from the growing distinction of sociology from religion, charity, and activism. Commentaries of the middle and late nineteenth century warned urgently of the social problems of divorce and abandonment – citing individualism, easy morals, and lax divorce laws for a breakdown of family. Family

advocates saw such decline as a sure cause of more social calamities and sought reliable social data and solutions. While sociologists of the day were concerned with social pathologies, they were also working to establish sociology as an objective, scientific discipline. Scientific work on family issues specifically had already been completed. Shortly after the US Census Bureau published a report on marriage and divorce statistics in 1889, Walter Willcox completed *The Divorce Problem: A Study in Statistics* (1891). This study presented the family as a strong, flexible institution, and linked divorce to social conditions. Casting family change as a dependent variable and subjecting divorce to demographic analysis were two strong indicators of an emerging science of family that would be relatively independent from moral concerns. This type of analysis also satisfied scientific urges to predict and explain.

Interest in the properties of family as an institution, and the incidental necessity of describing family for other sociological work, contributed to the development of scientific, sociological approaches as well. This was shown in the breadth and scope of Thomas and Znaniecki's *The Polish Peasant in Europe and America* (1929). The family as a socializing agency, the pressures of urbanization and industrialization on family, the effects of immigration, and the problems of migration from rural to urban life were all addressed in *The Polish Peasant*. Thomas and Znaniecki cast the Polish immigrant family as an object for neutral sociological analysis and examined the effects of rapid change and disorganization on the integrity of the family. In these ways the family was revealed as an institution situated in society and subject to social influences.

During the first two decades of the twentieth century, sociological study was seldom devoted exclusively to family. The family as a topic in its own right was still most often the province of social workers concerned with social problems and therapeutic issues. Still, these interests overlapped with sociological concerns about social pathologies and helped to maintain general, academic interest in a scientific sociology of family. In the 1920s the landmark accomplishments for sociology of family included the first American Sociological Association sessions on family and the development

of a section on family in the journal *Social Forces*. At the University of Chicago, Ernest Burgess elaborated the properties of family as a collection of interacting individuals, and encouraged a commitment to prediction and explanation in all of sociology including the area of family. This further distinguished sociological family research from the concerns of activists and social workers, and by the end of the decade a fully formed, scientific sociology of family was visible in textbooks, classrooms, and scholarly journals.

During the institution building phase (Maines 2001) of sociology up to World War II, sociology was empirical, quantitative, and theoretical. Family sociology was compatible with abiding, understandable variables in sociology such as race, class, and religion, and topics associated with family sociology multiplied rapidly in the 1930s, 1940s, and 1950s. Sociological research on family investigated rural, urban, and black families, explored the impact of the Depression, observed the migration of families from the country to the city, and described the characteristics of single parent families. Much of this work presented families in structure and process (as in the roles of grandparents and the process of grand parenting), types of families (like military families), internal dynamics such as decision making or emotional conflict, or basic life processes such as housing and employment. Many more topics were developing, of course, and research continued on the topics that had come to represent family sociology – courtship, marriage, socialization, and divorce. Family sociology grew to be among the largest specialty areas of the discipline during the middle decades of the twentieth century. It was a robust and diverse area. Family sociology also became historical in its orientation to changes, trends, and patterns over time. For example, researchers noted a constant increase in the percentage of marriages ending in divorce and linked the increases to changes in economy, law, and the changing roles of women who were entering the workforce in increasing numbers. Family sociology was comparative within and between cultures. It compared families by race, geography, income, and occupation in the United States, and as the sociological community became more global, American sociologists

conducted more international family comparisons and American journals published significant international work. As was much of American sociology at mid century, family was relentlessly empirical, demographic, and quantitative. The known and understood areas of family such as marriage, fertility, and divorce were particularly amenable to statistical analysis.

Although the popularity of family sociology was represented in a large body of empirical research, the theoretical contributions of family sociologists were relatively narrow. The commitment to an explanatory and predictive family sociology first expressed by Burgess came to be represented by a sociology of straightforward, testable propositions and quantitative descriptions of phenomena. For example, family sociologists might be interested in measuring the effects of divorce on the school performance of children, determining the influence of birth order on personality, or collecting the personal traits of the ideal mate. Family theory aimed at phenomena no more general than family roles, organization, life cycles, and the like. While theoretical work tended to be topic specific, and did not offer refinements to established sociological perspectives, it was also evident that family sociology was relatively free of the intellectual directives of major schools. Attempts to show how family sociology should be framed by theory were rare; so much so that a 1979 collection by Burr and his associates is still considered particularly noteworthy. Family sociology rather kept pace with advances in descriptive and inferential statistics. Researchers produced thousands of journal articles from the 1950s through the 1980s that were increasingly data driven and quantitative. Half of all articles in the *Journal of Marriage and Family* were empirical by the end of the 1970s. By the end of the 1980s, 90 percent of *Journal of Marriage and the Family* articles were empirical (Adams 1988).

Because research and commentary in family sociology are guided more often by topical interests than by gaps in theory, family has been one of the most fluid and open areas of sociology. The open quality of family sociology has widened the array of staple topics to include cohabitation, childlessness, and extra marital sex, to name only a few, and family is clearly among the most responsive specialties to

popular and political issues. In the 1980s this was already apparent in the frequency of research enterprises related to policy. Responding to conservative shifts in fiscal politics, family sociologists in the US conducted extensive research on the impact of changes in welfare, Medicaid and Medicare, and Aid to Families with Dependent Children (AFDC). Family planning, contraception, and abortion policies also received attention during the 1980s in a time of a perceived reactionary cultural climate. This attention has persisted as private sector funding sources reevaluate their support for family planning agencies, state legislatures tighten abortion restrictions, and contraceptive technologies advance. Real and proposed changes in social security in the late twentieth century have pushed policy research on aging families. Government and business practices associated with a globalizing economy have been scrutinized in recent years. In these and other areas, family sociologists have explored reciprocal effects of family and family policy, considering how changes in family behavior have influenced policies, and how policy changes have affected different types of families.

The large balance of sociological research on family is still as insulated as most professional intellectual activity, and concentrates on issues primarily of interest to scholars. But the policy and issue discussions of the 1980s reflected deeper cultural and political divides that did become important to public presentations of contemporary family sociology. In the most accessible venues of classrooms, texts, trade books, periodicals, and weblogs, family sociologists have slipped into debunking roles in responding to popular social criticism or common myths and misunderstandings. Typically this involves minor factual correctives that address sensational but accepted media narratives – there is not an epidemic of teen pregnancy (rates continue to decrease), there is no precipitous decline in US households with children, but slow changes related to delayed marriage, low unemployment, and an aging population. More often family sociologists address diffuse, popular anxiety about the family in “decline,” in “crisis,” or the “breakdown” of the family. The common view of divorce rates as an indicator of family decline

can be addressed by historical analysis of changing divorce laws, the relative marital satisfaction of modern couples, the desire for marriage expressed by the overwhelming majority of young people, the blending of families after divorce, or the abiding interest in their children shared by divorced parents. Common concerns about the negative effects on children and marriage of two career families are countered by an examination of the benefits – more income, less stress, healthier and happier women, and men more engaged with their children. What is brought to the public from family sociology is the established and unified view that the family is a tough, flexible institution that is constantly in transition, and that decline and crisis are critical evaluations rather than scientific conclusions.

In recent years family sociologists seem especially sensitive to national discussions of family issues. Family research and commentary often amplify political rhetoric, and scientific findings are obscured by political debate. Moreover, well funded moral entrepreneurs (Becker 1973) have adopted nomenclatures and trapings that ape the process of peer reviewed science. Clinicians and academics from a variety of disciplines founded the Council on Contemporary Families in 1996 specifically to bring accurate information about family research to the public. The foundational assumption of the Council is that shifts in family life are best met with investigations of underlying causes rather than moralizing discourse. Though a decidedly progressive organization, its stance against the framework of families in decline because of selfishness and immorality is within the mainstream of sociological thought.

If family sociology were more visible to the lay public, its basic assumptions would be recognized as politically liberal and culturally progressive. This is nowhere more apparent than in the passionate inclusiveness of sociological definitions of family. Having established the perspective that family is plastic and resilient, rather than fixed and vulnerable, sociology necessarily accounts for families in all of their emergent forms. This standpoint was manageable for a twentieth century sociology that had variations of the two parent household as its units of analysis. Now, along with single parent families, extended families, stepfamilies,

and blended families, contemporary family sociology accounts for gay and lesbian families. That gay and lesbian relationships are accorded the family label attests to the non judgmental attitude popularly associated with liberal thinking. Invocations of family in political debate reveal the deep understanding that most people belong to families and hold cherished values associated with family life. And family sociologists commonly observe that everyone who has been in a family is somewhat expert in family sociology. However, in its refusal to find an ideal family form and the causes of family decline, family sociology departs from this commonsense expertise. This is the scientific quality of family sociology. It will remain topical, comparative, and empirical, but the politics and rhetoric of family will increasingly frame its issues.

family structure

Graham Allan

Within any society there are more or less common ways of “doing” family relationships. That is, there are ways of organizing family relationships which are broadly accepted as appropriate and given legitimacy in that society. This does not mean that all family relationships are similar or that all follow the same societally imposed “rules.” There are always variations, exceptions, and alternative practices. Moreover, the more complex and diverse the society, the more variation there will be in the family practices given legitimacy by different social groupings within it. Indeed, one aspect of different family systems is the social tolerance given to divergent patterns of family relationships. Nonetheless, it is useful, at least heuristically, to ask questions about the dominant family structures existing in different societies, in part to facilitate comparison and understand the variations that arise. The types of questions posed by sociologists concerned with family structures involve such issues as the distribution of power and authority within families; the patterns of solidarity and obligation that arise between different family members; and the differential access to resources that different family members have. A key prior question concerns the boundaries of family membership and belonging: Who is considered “family,” when, and for what purposes?

In examining family structure it is important to distinguish “family” from “household,”

though the two are frequently elided, a tendency which itself is indicative of contemporary understandings of family structure. Household structure refers to the demography of households, domestic living arrangements, and domestic economies. Family structure, on the other hand, is concerned with the organization of kin relationships, though part of this also concerns how domestic life is framed and the different roles and responsibilities that different family members have within this. Indeed, historically, many of the key debates in the early years of family sociology were integrally concerned with the types of household structure that predominated in different societies. In particular, debates about the transformations that industrial capitalism generated in family structures often reflected the changed household composition found in developing industrial urban areas, legitimately so as these demographic changes reflected different familial obligations and solidarities. Nonetheless, analytically it is important to recognize that family structure reflects more than just household structure.

This becomes of consequence in examining some of the key theoretical developments in family sociology in the mid part of the twentieth century. In these, the dominant model of change, expressed with greater or lesser subtlety, was one that highlighted the movement from an "extended family" system to a "nuclear family" – one of parents and dependent children. The most compelling and sophisticated account of this shift was produced by Parsons (1943), who argued the "structural isolation" of the nuclear (or in Parsons's terms, "conjugal") family was a dominant aspect of mid twentieth century American kinship. Parsons's starting point was that industrialization involved increased functional specialization. The family as a social institution was affected by this as much as any other institution. It too became more specialized, with its prime roles becoming the socialization of the young and the stabilization of adult personalities. The family structure that Parsons saw as most compatible with this was a nuclear family structure in which husbands and wives also had differentiated roles – employment for husbands and domestic responsibilities for wives. Parsons's argument was that within this family structure,

each individual's primary kinship responsibility was to the other members of his or her nuclear family. An advantage of this family structure for industrialized societies was that it facilitated geographical mobility, seen as essential for meeting the dynamic workforce requirements of a developed economy.

Parsons did not argue that other kinship responsibilities were of no consequence. Rather, he claimed these were secondary to the responsibilities individuals had to nuclear family members (Harris 1983). Nonetheless, other writers took issue with Parsons's work, arguing that kin outside the nuclear family remained significant in people's lives, especially parents, siblings, and (adult) children. This is undoubtedly so. Many studies in different developed societies have shown that kin outside the household are routinely drawn on to provide support, assistance, and companionship. At this level, it is evident that nuclear families are not *socially* isolated from other kin. However, this does not of itself contradict the argument that nuclear families are *structurally* isolated within economically developed societies. As noted, structural isolation refers to primacy of obligation rather than level of social contact, though clearly the two are not entirely discrete.

Other tendencies within contemporary family patterns also indicate the structural priority given to nuclear families. In particular, the increased emphasis placed on "the couple" reflects the centrality of nuclear families over wider kinship ties. The trend towards higher rates of marriage, and more youthful marriage, across much of the twentieth century is one indication of this, as is the growth in the number and variety of different experts and guides offering advice on how couples should best maintain and organize their relationships. At a cultural level, this clearly reflects the continuing shift from marriage as an institution to marriage as a relationship. Similarly, the emphasis placed on the rights and needs of children, the increased responsibilities of care, and the growth of child and adolescent centered markets highlights the level of priority given to dependent children within contemporary family systems. While recognizing the emotional and practical significance of some kin relationships outside the household, it is evident that in terms

of structural properties, the conjugal family continues to be prioritized.

However, recognizing this does not imply that family structure has been unaltered since the mid twentieth century when Parsons was writing. It very clearly has, throughout the developed world. Two aspects of this are particularly significant. First, the family structure characteristic of the mid twentieth century involved a very marked division of labor between spouses. Each spouse had their own sphere of responsibility and obligation: employment for husbands, childcare and domestic servicing for wives. While this gendered division of labor is still evident, it is not now as powerful as it previously was. Wives usually continue to carry primary responsibility for domestic organization and care within the family, but changes in employment patterns as well as the cultural impact of second wave feminism have reduced the level of their financial and social dependence on husbands. In this regard, while the distribution of responsibilities and obligations within families remains gendered, there is now somewhat less rigidity about this than there was throughout most of the twentieth century.

And just as there is now greater flexibility in the division of familial responsibilities, so too there is greater acceptance of diversity in other family practices. Patterns that were previously understood to be in some sense problematic, if not pathological, are now accepted as legitimate alternative family forms. The most obvious example here is lone parent families, which have increased dramatically since the early 1970s, but other examples include stepfamilies, cohabitation, and gay partnerships. Moreover, life course trajectories are now far more diverse than they were. With new forms of partnership, increasing levels of separation and divorce, and what can be termed "serial commitment" (i.e., committed relationships which may or may not involve marriage), the patterning of people's family lives over time has become increasingly variable. Indeed, there is now greater cultural uncertainty about who counts as "family." Think here of stepparents who may be household members but not necessarily regarded by stepchildren as family members; cohabiting heterosexual and gay partners where the commitment is comparatively recent; or even non custodial fathers where there has been no

relationship. In addition, with globalization, in most developed societies there is now also increased ethnic variation, which frequently entails diverse beliefs about the legitimacy of different family practices.

This greater diversity within the familial relationships people construct is a key characteristic of contemporary family structure in developed societies. It is linked to both the growth of individualization and an increasing recognition that sexual and domestic arrangements are matters of choice, and thus legitimately located within the private rather than the public sphere. However, it also makes the specification of family structure within contemporary developed societies more problematic. No single form of family organization or pattern of constructing familial relationships holds normatively or experientially in the way Parsons's nuclear family model did in the mid twentieth century. Yet accepting this diversity as a feature of contemporary family life, it is also clear that there are continuities and consistencies patterning the ways family members usually construct and negotiate their relationships. Three warrant highlighting. First, as noted above, gender remains a primary organizational principle within most families, in part as a consequence of gendered labor market realities. Second, in the main, people prioritize their commitment to their partner and dependent children above those to other family members, though this does not imply that relationships with these latter are necessarily inconsequential. Many studies have shown the reverse is true, with ties to parents and siblings in adulthood continuing to be significant in people's lives. And third, albeit with some ethnic diversity, love as a personal and emotional commitment is generally understood as the prime basis for contemporary partnership, whether or not this involves marriage. Conversely, the evident absence of emotional commitment within a partnership is accepted legally and culturally (in most instances) as a *prima facie* reason for ending the partnership.

family structure and child outcomes

Susan M. Jekielek and Kristin A. Moore

The implications of family structure for child well being have been a central topic of research for several decades. In its simplest form, it is the comparison between two parent and one parent families that is the root of concern for child well being. Children who live with two married parents are defined in most government statistics as living in two parent families, whereas children who live with just one biological parent due to death, divorce, or having never married have been considered to live in single parent families. However, the issue is much more complex, and trends in family structure among American children over recent decades make it increasingly necessary to specify the biological and social relationships between children and the adults in their lives in order to understand the implications for child well being.

The most highly researched areas of child well being in the context of family structure

include socioemotional well being, such as aggressive behavior problems and emotional distress; academic outcomes, such as math and reading scores; economic well being, such as family poverty; and life course and intergenerational outcomes, such as low weight at birth, educational achievement, and offspring's own marital stability and quality in adulthood.

This entry focuses primarily on family structure and child well being in industrialized countries, and particularly in the US. The implications of family structure for children in other countries may differ to the extent that family and child policies also differ, cultural definitions of family differ, and the patterns of family structure differ, among other factors.

SOCIAL CONTEXT

Since the family is a primary setting for the care and socialization of children, it is of interest to both scholars and the general public that an increasing proportion of children have been growing up with a single parent, although this trend may be leveling off. In 1960, about 9 percent of all children lived in a single parent family in the US; this percentage was up to 28 percent in 2003, with 68 percent living in married parent families. Both estimates have remained within 2 percentage points in each year since 1994.

In the 1970s, divorce replaced parental death as the primary cause of single parent families. It is estimated that about four in ten children will eventually experience their parents' divorce. However, divorce is only one factor contributing to estimates that about half of all children are expected to reside with a single parent at some point during their childhood. More recently, the increased proportion of births to unmarried women has also contributed. In 1970, 11 percent of children were born to unmarried couples. By 2002, about one in three births occurred outside of marriage. Contrary to popular perceptions, teenagers account for less than three in ten nonmarital births, with women in their twenties accounting for more than half.

Of recent interest are nonmarital births of second or higher order parity. Only about half of all nonmarital births were first births in 1998. Between 1992 and 1995, more than one

in three nonmarital births to women aged 20 or older were preceded by a teenage birth. There is a growing recognition that multiple births to the same woman may not be births by the same father.

An unmarried parent is not necessarily a parent without a partner. In the early 1990s, 39 percent of all nonmarital births occurred to cohabiting couples, up from 29 percent ten years earlier. A national study places this at 51 percent, based on a survey of mothers who gave birth in large cities between 1998 and 2000. According to this survey (the Fragile Families Study), the majority of nonmarital births (82 percent) are to parents who are romantically involved at the time of birth, either in a cohabiting or a visiting relationship. All in all, about 40 percent of all children are expected to spend some portion of their childhoods living with cohabiting parents, and cohabitation has become an increasingly recognized family form.

Living in a stepfamily is also a common experience. About half of current marriages are actually a second or higher marriage for at least one of the spouses. About one in three children will spend some of their childhood living in a remarried or cohabiting stepfamily.

These social changes are also apparent in people's attitudes. Acceptance of cohabitation and nonmarital childbearing, as measured in public opinion surveys, has increased since the 1960s–1970s, although having a birth out of wedlock is still not viewed as a positive goal. This pattern is consistent with research that examines how single parent families are depicted in popular magazines. Portrayals of single parent families as unacceptable or negative for children have declined over time.

After decades of increase, accepting attitudes toward divorce have stabilized, although the plateau of acceptance is quite high. About four of every five young people believe that divorce is acceptable even if children are involved. At the same time, “having a good marriage and family life” was rated as extremely important to 81 percent of females and 72 percent of males who were high school seniors in 1997 and 1998.

A child's family structure is often viewed in terms of the child's connections to the parent figures in the household. It is notable, however, that 8 percent of all children resided with a

grandparent in 2002, most of whom were the heads of households.

IMPLICATIONS OF FAMILY STRUCTURE

For some, having children within marriage and preserving the sanctity of marriage are essential societal functions. Others argue for the importance of marriage based on research indicating that married adults tend to be wealthier, healthier, live longer, and have more social support than unmarried adults. Others argue that changes in family structure are inevitable and represent “new” family forms that are not necessarily inferior family forms for raising children. Still others take a policy perspective, arguing that reducing the number of single parent families would reduce the economic burden on the taxpayer, and this is a goal of current welfare reform law. Despite this disagreement, at the heart of these concerns, and cutting across many different perspectives, is the well being of children.

Research on family structure is consistent: the majority of children who are not raised by both biological parents manage to grow up without serious problems. Yet, on average, children in single parent families, children who experience divorce, and children who live in stepfamilies all experience worse outcomes, on average, compared with children who are brought up with both biological parents.

There are many possible explanations for these patterns. A stressful life events perspective posits that family structure transitions cause instability in family routines and therefore are detrimental to both parental and child well being. Indeed, multiple family transitions themselves increase a child's risk of negative outcomes. A parental absence perspective suggests that biological parents are the most likely to provide social and economic resources to their own children, and therefore the absence of a parent puts children at risk of diminished well being. A selection perspective suggests that the characteristics that predate family transitions are actually responsible for negative effects. An economic resources perspective would posit that children are at a greater risk of living in poverty and having poor outcomes

when they do not have access to two parents – in part due to the economies of scale involved in maintaining one household as compared to two.

Indeed, compared to children who live with two married parents, those whose parents divorce are more prone to academic and behavior problems, including depression, anti social behavior, impulsive/hyperactive behavior, academic achievement, and school behavior problems. Mental health problems linked to marital disruption have also been identified among young adults. These findings are consistent across many outcomes and many studies; however, there are also many caveats.

Advances in data collection, namely longitudinal surveys that collect data on the same children over multiple time points, have shown that many of the problems that are observed in children post divorce can actually be attributed to pre divorce factors – this is often referred to as selection bias. For example, parents with anti social personalities are more likely to both administer poor parenting and also divorce, and therefore the observed relationship between divorce and child well being is due, in part, to parental characteristics. Using longitudinal, national survey data, Andrew Cherlin and colleagues (1991) demonstrated that much of the difference in well being scores between children of divorced and intact families is apparent prior to the date of divorce.

Numerous studies indicate that parental conflict is detrimental to child well being, and a handful of studies measuring both divorce and marital quality have shown that children from high conflict families are better off on a number of outcomes when their parents divorce rather than remain married. However, it has been estimated that fewer divorces are preceded by high conflict than are preceded by low conflict. It is also noteworthy that the differences between children of divorced and intact couples, although arguably small at about one fifth of a standard deviation, tend to remain significant, even after accounting for important pre divorce factors. Further, due to the variability in the capacity of children and families to cope with divorce, this average “small” effect likely masks larger effects among certain subgroups of children.

An additional advance in research on children of divorce is the investigation of outcomes

that might occur later over the life course when they are adults. For example, research has shown that children whose parents divorce are more likely to experience divorce themselves as adults, to have increased marital problems and lower socioeconomic achievement, and to report poorer subjective well being.

Stepchildren also do not do as well, on average, as children living with both biological parents. A review of the literature suggests that, on average, stepchildren have lower grades and scores on achievement tests, and have greater internalizing and externalizing behavior problems. They fare worse in terms of dropout rates, school attendance, and high school or GED completion. Similar to explanations for the effects of divorce on children, researchers often posit that the stress of reorganizing as a stepfamily is an important reason for these differences. Children often move to new cities and possibly lower quality schools; children in stepfamilies have likely experienced a number of other family changes; and conflict might still exist between the child’s original two parents. In addition, children in stepfamilies are found to have less access to parental involvement than children living with two biological parents. Not only might a child’s biological parent be distracted and focus attention on her/his new spouse, but stepparents tend to spend less time with stepchildren than biological children, and relationships with absent biological parents, namely fathers, tend to diminish with time.

Children in single parent families are about twice as likely to have problems as children who live in intact families headed by two biological parents. Children born to unmarried mothers are more likely to be poor, to grow up in a single parent family, and to experience multiple living arrangements during childhood. These factors, in turn, are associated with lower educational attainment and a higher risk of teen and nonmarital childbearing.

It is important to note that the implications of single parent family structure can differ for children in other countries. For example, single parenthood has been found to be less detrimental for children’s academic achievement in countries where family policies equalize resources between single and two parent families.

CHANGES OVER TIME AND CONTEMPORARY RESEARCH ISSUES

The study of family structure and child outcomes has paralleled the changing demographic trends in children's families. Research has shifted from a focus on the effects of divorce on children to an increasing focus on the diversity of family structures, especially those other than the biological two parent family as a setting for bearing and raising children.

As described above, the majority of nonmarital births are to couples who are romantically involved at the time of the birth. While most unmarried couples have plans to stay together and get married around the time of the birth of their child, one year later only 9 percent were actually found to marry, while another 49 percent of parents continued to be romantically involved. In general, cohabiting relationships are more likely to break up than marriages. Parents of children in cohabiting unions typically have lower earnings, lower levels of education, higher rates of poverty, and elevated rates of incarceration, substance use, and domestic violence, compared with parents of children in married couple families. In addition, their children may not have full legal access to paternal resources. We would expect that these characteristics would undermine child well being compared with married parent families. On the other hand, cohabitation might incur greater economic resources for children than single parent families, but there is as yet little documentation of whether and how cohabitators share their resources. Overall, we know very little about actual child outcomes in relation to cohabitation, although a recent study documents significantly fewer behavior problems and greater school engagement among school age children living with two biological married parents compared to children living with two biological cohabiting parents.

As divorce has become more common, so has the study of how custody after divorce affects children. It is not clear whether joint physical custody of children is beneficial, and frequency of father visitation is not consistently linked with better child well being. While more work is needed, some research suggests that contact with a non resident father is beneficial when

conflict between parents is low or when the non resident father is warm but sets limits in his parenting.

Gay marriage and family life has received much attention, but research on gay families is still in development. Census questions in 1990 and 2000 included categories that made it possible for researchers to identify same and different sex couples in "marriage like" relationships, but even these are not direct measures, and the census data do not include child outcome assessments. It is rare for any national data set to collect information on gay couples, let alone match it to children in the household. Nonetheless, in the 2000 Census, approximately one third of female householders with same sex partners were living with their own children, and about one fifth of male householders with same sex partners were living with their own children. Marriage between same sex partners gained particular relevance in 2004 and attempts were made to confine marriage to heterosexual couples as a constitutional amendment. In terms of child development, rigorous research on representative samples is lacking.

METHODOLOGICAL ISSUES

There are at least three clear methodological issues in the study of how family structure affects child outcomes. First, addressing selection bias is perhaps the most critical issue. Longitudinal data are critical here.

A second critical methodological element is that when children experience one family structure outside of the traditional married two parent family, they typically experience multiple changes. Therefore, it becomes difficult to disentangle the effects of previous family transitions, such as divorce, from the effects of current family structure, such as a stepfamily.

Third, data quality has not "caught up" with the many different types of family structures in which children live. Knowing a mother's marital status is not enough information to determine whether she is living with her child's father, or whether all children in the household share the same father. It has become increasingly critical to understand the biological

connection of that child to the people in the household, as well as the marital status of that child's parents, and also the timing of parental marital/cohabiting/dating transitions. While this seems straightforward, there are very few data sets that collect such information (for an exception, see the Survey of Income and Program Participation), and it is even more of a rarity for child outcomes to be assessed in the same data source.

Further development is also necessary to accurately measure parental cohabitation. For example, couples who are living together do not necessarily identify with the terms "cohabiting" or "unmarried partner" on questionnaires.

FUTURE DIRECTIONS

The family context for childrearing in the US is changing. Significant proportions of children will spend time living in single parent families, families headed by cohabiting biological parents, or families headed by their biological parent and a cohabiting or married stepparent, and will experience transitions in their family structure in general.

With regard to child well being, it will be important to examine how cohabiting biological parents rear their children and how children in cohabiting families fare relative to others. A point of departure for this inquiry is to assume that cohabiting biological parents provide the same home environments for their children as married biological parents, but empirical evidence is not definitive with regard to this assumption. Empirical evidence is also lacking in regards to children whose parents may not reside together but remain romantically involved.

The past two decades of research have shown that there is diversity in how children adjust to divorce. Understanding the conditions under which children adjust poorly or successfully to divorce, and disruption in general, is an important next step. In the same vein, most research on the effects of family disruption examine potential *negative* effects. Qualitative research suggests that there also may be *positive* implications of divorce transitions. Systematically

testing this possibility could help inform the knowledge base of the conditions under which children might adjust well to family disruption.

While children in one parent families typically have fewer economic and social resources at their disposal than do children in two parent families, accumulating evidence warns that socioeconomic inequality for children in these two family structures is growing. This is due in part to the rise in dual earner families. For the sake of child well being, it will be important to monitor this trend.

Child outcomes with regard to the structure of siblings in the household are also likely to be a topic of continued research interest. Some research suggests that paternal investments in children may depend upon whether the children in his household are his own, his wife's, or a combination of both.

With federal funding targeted at experimental evaluations of interventions to improve the marital quality and stability of low income couples, a much anticipated topic of future research is whether an intervention can improve marital stability and quality among low income families. If such an intervention is successful at improving child well being, this would be a significant milestone. However, low income couples face many challenges to marital stability, such as inadequate employment and economic hardship. Further, most research showing evidence that couple interventions can affect relationship stability has been targeted towards white, middle class samples. The same is true for the development of marital quality measures. Therefore, a great deal of research is needed to answer the question of whether an intervention can improve marital stability and quality and enhance child well being in low income families.

Pregnancy intentions have been monitored for decades as indicators of control over fertility and the need for reproductive health services. Moreover, the implications for children of being mistimed or unwanted has received increased attention; but more work is needed. In addition, the effect of having unintended or unwanted pregnancies on marriage and family formation more generally, as well as on marital disruption or family disruption, needs further examination with data from males as well as

females. What are the implications of different levels of intendedness for each partner? How does pregnancy intendedness affect male commitment to their partner and investments in the child? Under what circumstances do unintended pregnancies undermine couple stability? Finally, there is a need for research on the implications of infertility and new fertility technologies for family formation and stability.

Long overlooked is systematic investigation of family processes and child well being in non white families. Studies in the past decade have made strides towards describing fathering and gender roles, particularly in African American and Hispanic families, and also describing how parenting is shaped by grandparents and neighborhood context. Further high quality longitudinal studies are needed, not only for high risk families of color, but also for families of color in general. Further highlighting the need to pay attention to race and ethnicity is the fact that immigrant children are the fastest growing segment of the child population, up by over 50 percent in the last decade.

family structure and poverty

Daniel T. Lichter

Family structure and poverty are inextricably linked. Different types of families have much different risk profiles for poverty and welfare dependence. Family structure typically refers to the myriad organizational and compositional parts that make up the family. Among others, these include headship patterns (e.g., female headed families), the marital histories of family members (e.g., single or married or cohabiting), the presence of multiple generations, family size, and the presence of co residential children. These structural features of families (hence, family structure) reflect individual choices that are shaped by cultural values and norms, economic constraints, and demographic events, such as childbearing or death.

Data from the US Census Bureau highlight the strong statistical relationship between family structure and poverty in the United States. The poverty rate of female headed families with children was 35.5 percent in 2003, compared with 7.0 percent among their married couple counterparts. The Census Bureau defines poverty on the basis of absolute money income of all family members, i.e., whether annual family income falls below a specific poverty income threshold. Poverty thresholds vary by family size and other structural features of the family, such as the number of adults or children. In 2003, for example, the official poverty threshold for a three person family of one adult and two children was \$14,824. Family structure is also linked to other manifestations of low

income – inadequate housing, food insecurity, lack of access to health care, and poor physical and mental health.

In most other western industrial societies, the relationship between family structure and poverty is much weaker. Lee Rainwater and Timothy Smeeding report in *Poor Kids in a Rich Country* (2003) that about 20 percent of children in the United States and Sweden live in single mother families. Yet, data from the Luxembourg Income Study show the child poverty rate for these children is over 50 percent in the United States, compared with only 7 percent in Sweden. Moreover, the poverty rate of children living in single mother families increases sharply as family size increases. This is much less true in other countries, where income transfers help offset the tendency for single mother families and larger families to be less well off economically.

In the United States, the strong statistical relationship between family structure and poverty is rarely questioned. Instead, debates center on the appropriate interpretation of this relationship and on the alternative policy solutions they imply. At the heart of the debate is whether poverty is a *cause* or a *consequence* of changing family structure. This debate is not new. Indeed, the key issues were probably encapsulated first in scholarly reactions to Daniel Patrick Moynihan's controversial 1965 report entitled *The Negro Family: The Case for National Action*. An excerpt from the so called Moynihan Report states: "The fundamental problem [of blacks] . . . is that of family structure. The evidence – not final, but powerfully persuasive – is that the Negro family in the urban ghettos is crumbling. . . . So long as this situation persists, the cycle of poverty and disadvantage will continue to repeat itself."

Moynihan's views were seemingly straight forward: (1) "crumbling" black families were typically poor families; (2) changes in black family structure contributed to growth in poverty and its many manifestations (e.g., welfare dependency, crime, alienation, unwed child bearing); and (3) changes in black family structure exacerbated black-white inequality in poverty and welfare. The policy implications followed accordingly. In Moynihan's view, a concerted national effort was needed to strengthen the family, which had created a

"tangle of pathology" in the black community. Many scholars today view Moynihan's conclusions as prescient. In 1965, the percentage of black women raising children alone exceeded in 2000 the percentage of white unmarried mothers.

At the time, however, Moynihan's critics charged him with "blaming the victim." They questioned whether changes in family structure caused poverty among blacks or instead reflected the effects of poverty. His critics argued that chronic poverty or welfare dependence undermined marriage, contributed to more marital dissolution, and led to out of wedlock childbearing – the underlying components of changing family structure. Some also believed that poverty and family structure simply reflect the effects of other conditions in the black community, such as low education or too few job opportunities. In other words, the relationship between family structure and poverty was spurious rather than causal.

Establishing causality is difficult in the absence of experimental data. Instead, most non experimental studies are based on survey data that compare the economic circumstances of married and unmarried women, while controlling for other observed variables associated with both (e.g., education). The problem is that other unobserved variables may cause a spurious association between family structure and poverty. More generally, we do not know what the poverty rate would be for currently single or unmarried women if they actually married. And we do not know the poverty rate of currently married women if they divorced or became widowed. Simply, the counterfactual situation is not observed.

Much of the recent research on racial differences or trends in poverty has employed a demographic accounting framework that avoids issues of causality altogether. These descriptive studies estimate the share of racial or temporal change in poverty that is accounted for by shifts in family structure, such as the rise in single parent families. These analyses are often based on methods of demographic standardization or shift share analyses. Researchers ask what percentage of individuals would be poor today if (1) the distribution of family types had not changed over time or if the distribution was identical to a comparison

group (e.g., whites), and (2) they experienced current family specific poverty rates. Differences between the observed and expected poverty uncovers the effects of changing family structure. Using such an approach, Eggebeen and Lichter (1991) reported that roughly one half of the upward rise in child poverty in the 1980s was accounted for by increases in the percentage of US children in "high risk" families (e.g., female headed). More recent studies have shown that changes in poverty during the 1990s were largely unrelated to changes in family structure; changes in maternal employment matter more (Iceland 2003; Lichter & Crowley 2004).

As with Moynihan's report, it remains controversial to claim that poverty differences across racial groups are due to racial differences in family structure. The debate pivots on the usual canard: are individuals (in this case blacks) to blame for making economically self destructive decisions about unwed childbearing, marriage, and divorce? Or are larger structural forces (e.g., economic restructuring and high unemployment) responsible for high poverty rates? Eggebeen and Lichter (1991), for example, reported that about two thirds of the black-white difference in family structure is responsible for black-white differences in child poverty. At the same time, even if blacks had the same family structure as whites, their poverty rates would remain high. Family structure is only part of the explanation, and such analyses cannot assign causality. Demographic studies typically do not address the question of why family structure changes, although a large literature suggests that economics – the availability of good jobs and good incomes – is fundamental.

These demographic approaches contrast sharply with behavioral models that emphasize individual decision making. Such analyses typically link out of wedlock childbearing, divorce, or marriage changes or other factors to individual changes in poverty or economic deprivation (Bianchi 1999). Perhaps the largest body of work is on the economic consequences of divorce. These studies show that divorce is strongly associated with subsequent declines in women's economic well being. One recent study showed that poor women were more likely than non poor women to subsequently

divorce (Smock et al. 1999). More significantly, this study attempted to estimate the counterfactual situation. If these poor women had not divorced they would be much better off economically, but not as well off as other women who had remained married. This study illustrates the potential inferential problems – common to most previous studies – with statistical comparisons of the economic well being of currently divorced and married women.

Studies of divorce disagree most often about the magnitude of economic declines and on the specific economic and demographic pathways that shape income trajectories. Lenore Weitzman, in *The Divorce Revolution* (1985), for example, reported a 73 percent decline in women's standard of living after divorce and a 42 percent increase in men's standard of living. Other work shows much smaller negative effects on women's economic well being. Peterson (1996) estimates a 27 percent decline in women's standard of living after divorce and only a small increase (10 percent) in men's standard of living. Studies show that the loss of husband's income, even after several years, cannot fully offset increases in cash assistance from the government, earnings from more work, or financial assistance from friends or relatives. Moreover, the best route to economic recovery seems to be remarriage (Morrison & Ritualo 2000).

Indeed, scholars have increasingly emphasized the link between marriage and economic well being. Transitions to marriage are associated with declines in poverty and reductions in welfare dependency (Lichter et al. 2003). The improvement reflects the addition of another potential source of family income (i.e., the spouse). Marriage also seems to make men more productive in the workplace, if measured by hours worked and earnings. The counter argument is that marriage selects on those with the greatest earnings potential. Earnings growth is reinforced by marriage itself, which strengthens the underlying economic foundation of marriage, while reducing the likelihood of divorce and poverty. This is a mutually reinforcing process. Drawing strong causal arguments, however, is difficult. Individuals who marry or divorce may be different from single people on a number of observed and unobserved characteristics. This is the

fundamental problem in drawing strong causal inferences about links between family structure and poverty.

More recently, efforts to establish causality have made use of natural experiments. In the early 1990s, Geronimus and Korenman (1992) claimed that out of wedlock childbearing was not responsible for the negative outcomes experienced by disadvantaged unwed mothers (e.g., low schooling, higher poverty, etc.). Despite sharing genes and family background, adolescents who became unwed mothers were no different on a variety of adult outcomes than their sisters who did not bear children. Other studies have drawn similar conclusions by comparing women who miscarried a pregnancy with those whose pregnancies ended in live births. Any differences between women who miscarry and women who become mothers arguably must be due to unwed childbearing if miscarriages are randomly drawn from the same population of unmarried women. No differences suggest that out of wedlock childbearing is a symptom of poverty and family disadvantage rather than a cause. Such studies have spawned many subsequent studies that have critically evaluated the putative causal effects of teenage childbearing on later life outcomes (Hoffman 1998).

Conceptual and technical debates in the scholarly community about causality have not prevented lawmakers and the public policy community from addressing the issue of changing family structure and its potential deleterious relationship with poverty. This willingness to act on behalf of American families is new. For example, the 1996 welfare reform bill, the Personal Responsibility and Work Opportunity Reconciliation Act, has "encouraging the formation and maintenance of two parent families" as a way to increase economic self sufficiency. States have developed and implemented experimental marriage initiatives aimed at encouraging marriage or reducing divorce. These have taken the form of public announcement campaigns about the value of marriage, counseling programs that develop conflict resolution techniques or promote relationship skills, and new efforts to change the tax code or welfare system to eliminate any economic disincentives to marriage or out of wedlock childbearing.

Whether such programs will work to reduce poverty and promote economic self sufficiency is unclear a priori. This is a social experiment on an unprecedented scale in American history. As state program evaluations are completed, however, scholars will have a much stronger basis in evidence concerning whether manipulating family structure (i.e., promoting stable two parent families) will have the intended salutary effects on poverty and welfare dependency.

family theory

David Cheal

Family theory consists of sets of propositions that attempt to explain some aspect of family life. Theorizing involves making general statements about some phenomenon, and an important characteristic of family theory, therefore, is that it involves a degree of abstraction from reality. Theoretical statements are abstract statements employing concepts that refer to things in the real world. Theories differ in the concepts that they use, and in the statements that are made about them. There are many different theories in family theory, and the relationships between them range from complementary borrowing of ideas, through mutual indifference, to antagonism.

INTELLECTUAL AND SOCIAL CONTEXT

The history of family theory varies according to the national context of family theorists. For example, in the 1970s and early 1980s Marxism had a significant influence on family theorizing in Britain and, especially, in Canada, but it was rarely mentioned in the United States. On the other hand, British and other European theorists have not paid much attention to exchange theory, which has been popular in the United States.

Family theory has changed from a consensus on the value of nuclear family living in the period immediately after World War II to the current situation of theoretical pluralism. In the post war period the standard theory of family life held that the nuclear family was an adaptive unit that mediates between the individual and society. An early, and very influential, version of standard sociological theory was structural functionalism. This approach held that families perform essential functions for family members and for society. Talcott Parsons, for example, argued that the nuclear family household has two main functions in modern industrial society. It socializes children and manages tensions for adults.

Influenced by the prestige of grand theory in structural functionalism, the period of the late

1960s and 1970s saw a move in family studies toward theory construction combined with the theory integration. The phrase that was most often used to describe the goal of creating a unified body of family theory was theory systematization. By the early 1970s the sociology of the family had entered a phase of systematic theory building and theory unification. However, this phase did not last long.

Beginning with the impact of feminism on family studies, the sociology of the family went through a Big Bang in the mid 1970s. There was a rush of theorizing about family issues, but only a portion of this growth resulted from the application of theory construction techniques. By the mid 1970s it was clear that the move toward theoretical convergence had omitted issues and theories which did not fit the image of the family favored in standard sociological theory. New types of theory were developed that asked new kinds of questions. This was especially true of feminism.

From the 1980s onwards family studies has been characterized by the acceptance of theoretical pluralism. One way of looking at this theoretical pluralism is presented next.

MAJOR DIMENSIONS

In North America, James White and David Klein (2002) have identified seven major dimensions of family theory. These are theoretical frameworks from which specific theories are derived. The seven theoretical frameworks are: (1) the social exchange and choice framework; (2) the symbolic interaction framework; (3) the family life course development framework; (4) the systems framework; (5) the conflict framework; (6) the feminist framework; and (7) the ecological framework.

Exchange Theory

The individual is the unit of analysis in exchange theory. Individuals are seen as making rational choices about behavior based on the balance of rewards and costs that the behavior has for them. The relationship between rewards and costs defines the profit that is derived from behavior, and individuals are assumed to try to maximize their profits. Actors rationally

calculate their expected profits for all possible choices in a situation and then choose the action that they calculate will bring the greatest rewards for the least costs. A theory of choice is at the heart of the exchange approach to family interaction. Behavior becomes exchange when the actions of one individual enter into the rewards and costs of another individual, and each individual modifies the behavior of the other.

Applications of exchange theory include the study of the choice of marriage partner, the quality of the marriage relationship, marriage bargaining, and separation and divorce. One of the advantages of exchange theory is that it enables the investigator to think about rewards provided within the family, and rewards provided by sources outside the family, as alternatives between which individuals choose. Marriages are seen as breaking down when one or both partners no longer find them profitable by comparison with the alternatives. The probability of divorce is thought to be a result of two comparisons that individuals make. First, individuals compare the profits they derive from their own marriage with the profits that others derive from their marriages. If the sense of relative deprivation is high then the motive to divorce is enhanced. Second, individuals compare the rewards and costs associated with the alternatives to the existing marriage, including being divorced or remarrying. Rewards might include finding a more compatible partner, and costs might include social disapproval for divorce.

Symbolic Interactionism

Symbolic interactionism rests on three simple premises. First, human beings act toward things on the basis of the meanings that things have for them. Symbolic interactionists therefore believe that to understand social behavior, the researcher must understand the meanings that actors assign to the situation and action. Second, the meanings that people assign to the objects in their environment are drawn from the social interactions in which they engage. That is to say, we do not simply form our meanings as a result of psychological elements in our personalities, but other people's actions

define the meanings for us. Third, the meanings of things are handled in, and modified through, an interpretive process. There is a process of interaction that goes on within the individual, as people engage in an internal conversation about what things mean and how they should respond.

The emphasis in symbolic interactionism is on the family as a unity of interacting personalities. Whatever unity exists in family life can only be the result of interactions between family members. One of the most basic concepts in symbolic interactionism is that of role. Roles are the rules of behavior for positions in a family, and as such they are taken into account by individual members as they construct their lines of action. Symbolic interactionists have therefore often believed that individual behavior can only be understood within the context of the family role that an individual occupies. Interactionist work on patterns of family life includes studies of the ways in which behavior is negotiated and renegotiated among family members. It is through negotiations that members adjust their individual claims to produce joint actions.

Family Life Course Development

The family life course development framework is a dynamic approach that looks at family life as a process that unfolds over time. It focuses on the systematic and patterned changes experienced by families as they move through stages and events of their family life course. This approach has gone through several phases itself. The first phase consisted of an approach that studied families as moving through deterministic, invariant stages of the family life cycle. This approach was heavily criticized. The principal difficulty has been the impossibility of fitting all of the many different living arrangements that exist into a universal set of stages. Accordingly, this approach was replaced by an emphasis on family careers. More recently, it has been followed by an approach stressing patterns of the life courses of individuals. The focus here is upon the individual life course, and on how it affects and is affected by the life courses of other individuals.

Systems Theory

A system is a set of interconnected parts that exhibits some boundary between itself and the surrounding environment. Families may be considered as systems, as they are in the systems framework. Assumptions of the systems framework include the idea that all parts of the system are interconnected; the idea that understanding is only possible by viewing the whole; and the idea that a system's behavior affects its environment, and in turn the environment affects the system. It is also commonly held that systems exhibit equilibrium, that is to say, they tend to maintain a steady state in the face of environmental changes.

Family processes are understood as the product of the entire system. Family systems theory therefore shifts the primary focus away from the individual family member toward relationships among the members of the family system. The systems approach to the family has therefore been welcomed by some scholars and practitioners as a way to understand family problems and intervene in family processes without blaming any one family member. For example, the eating disorders of bulimia and anorexia nervosa can be conceptualized as disorders involving the entire family system rather than the identified patient alone.

The concept of boundary is an essential one in systems thinking. Systems theorists have therefore been interested in the issue of boundary redefinition when spouses divorce and remarry. Boundaries are defined by rules that identify who participates in a family, and how they do so. Blended families require drawing new boundaries and establishing a consensus on those boundaries. Confusion over boundaries, in other words boundary ambiguity, is thought to create a variety of interpersonal problems. It is held that boundary confusion in remarried families leads to confusion in the rights and duties associated with different positions in the family.

Conflict Theory

Conflict theory maintains that conflict is a normal part of social life, and it therefore deserves to be a focus of explicit attention. Sources of

conflict include the competition for scarce resources, and incompatible goals, such as the tension between privacy and jointness. Most conflict theorists accept the assumption that individuals act out of self interest, and that interests are often contradictory. There are many dimensions of conflict, such as class conflict, age based conflict, and gender conflict. Conflict can occur between groups or within groups.

The concept of power is as central to many versions of conflict theory as is the concept of conflict itself. The resources that are available within families are not only the subject of competition, they are also the means by which one individual may gain power over others. The unequal distribution of power can be seen as important in several respects. First, the distribution of legitimate power can be seen as a structural mechanism of conflict management that operates to suppress overt conflict. Second, power differentials can themselves become a source of conflict. And third, power inequalities influence the outcomes of conflict, including who wins and who loses.

Applications of conflict theory include the study of family violence. One of the major issues here is the fact that most family violence is violence against women. Because of the interest in gender divisions, there is some overlap here between conflict theory and feminist theory.

Feminist Theory

Feminist theory is concerned with the position of women in society, and specifically with the disadvantages that women face in a society that is dominated by men. It is a diverse approach, but three premises can be identified as it is applied to the study of family life. First, family life is envisaged as an arena within which individuals who pursue different economic and social interests meet and struggle. That struggle is not equal. There is thought to be an internal stratification of family life, in which men receive more benefits than do women. The allocation of tasks among family members is seen as taking the form of a gendered division of labor. Although this division of labor has the appearance of an equal exchange, feminists

maintain that women contribute more than they receive in return. Second, processes of control and domination are thought to come into play whenever men and women interact. Relations between husbands and wives are identified as power relations, in which men dominate over women. Feminist theories of marriage and family therefore devote much attention to analyzing structures of patriarchy, or the oppression of women by men. Third, ideological legitimations of gender inequality are held to be responsible for the acceptance by women of their own subjection. It is claimed that there exists an ideology of familism, or familialism, that supports traditional family norms, including traditional gender norms. Feminist theory considers familism to be a restrictive ideology that is a barrier to women's liberation. For example, there is the domestic ideology which encourages girls to think that putting family responsibilities first is the normal pattern for women.

Viewed from the perspective of feminist theory, the family is a concept which has been created and distributed by those whose interests it serves (mainly men). Scholars working in the feminist tradition therefore argue that existing concepts of the family must be deconstructed, or decomposed. As a result, the social scientific concept of the family as a system is replaced by the concept of the family as an ideology. That is to say, "the family" is thought to be a set of ideas which obscures more fundamental relations, such as the sex/gender system.

One of the most obvious applications for feminist theory has been the study of the division of household labor between husbands and wives. For example, feminists have been interested in time use studies which have examined the contrasting amounts of time that men and women devote to housework.

Family Ecology

A concern with individuals and their environment is at the heart of the ecological approach. A person's behavior is seen as a function of the interaction between the person's traits and abilities and their environment. One of the most popular ways of thinking about this is to

conceive of the nested ecosystems in which the individual human being develops. First, there is the microsystem of connections between persons who are present in the immediate setting directly affecting the developing person. Second, there is the mesosystem consisting of linkages between settings in which the developing person actually participates. Third, there is the exosystem that consists of linkages between settings that do not involve the developing person as an active participant, but in which events occur that affect, or are affected by, what happens in the setting. And finally, there is the macrosystem consisting of overarching patterns of ideology and organization of the social institutions common to a particular culture or subculture. Individuals develop within the family microsystem, and families are situated within society. The relations between a family and the larger society are meso, exo, and macrosystem issues.

An ecological approach can be taken to family decision making. Here the family is viewed as a system interacting with its environment. The embeddedness of the family system in the larger ecosystem is emphasized, and the interchanges that take place between the various levels are described.

CURRENT EMPHASES

The main current emphasis in family theorizing does not fit into any of the theoretical frameworks identified above. Perhaps it deserves to be identified as a distinctive theoretical approach. This approach is concerned with the deinstitutionalization of family life. It is associated with the work of Ulrich Beck and Elisabeth Beck Gernsheim as well as the work of Anthony Giddens.

Beck and Beck Gernsheim have advanced individualization theory. This states that many of the changes occurring in families are the result of a long term trend in modern societies to accord more autonomy to individuals. Individualization involves liberation from traditional commitments and personal emancipation. Individuals construct their own lives, and they therefore make decisions about whether and whom they shall marry, whether or not to have children, what sort of sexual preference

they will have, and so on. As a result, the traditional family, which consisted of a lifelong officially legitimated community of father–mother–child, is being replaced by a diverse array of ways of living.

Giddens argues that traditional family ties have been replaced by the pure relationship as the foundation of personal life. A pure relationship is one based upon emotional communication, where the rewards derived from such communication are the main basis for the relationship to continue. It is not maintained by external forces, but it is constructed by the participants out of their own unaided efforts. Interpersonal trust is, therefore, no longer based on customary obligations between the occupants of well defined roles. In a pure relationship trust can only be gained through the mutual disclosure of feelings and beliefs. There is therefore a great demand for intimacy in pure relationships. Intimacy is found within marriage, but it is also found outside marriage, in cohabitation for example. The focus of attention today is the relationship between a couple, not the institution of marriage.

family therapy

Leigh A. Leslie

Family therapy is a clinical approach to treating mental health and relationship problems based on the assumption that dysfunction can best be understood and treated by examining the social context in which it exists. Emerging as an identifiable “field” in the 1950s, family therapy was, and continues to be, characterized by attention to the interaction and communication patterns existing within couples and families. Several precursors set the stage for what, at the time, was thought to be a dramatic and controversial shift in clinical treatment from a focus on individuals to families.

First, the profession of social work emphasized the need to treat families as units. Recognizing that treatment of one family member would both impact and be impacted by other family members led to the practice of family casework in the early 1900s. Second, the early 1900s also saw the child guidance field begin in Europe and move to the United States. Psychiatrists working with children gradually came to acknowledge and write about the significance of the family in understanding the child. Nonetheless, this new orthopsychiatry movement continued to promote individual psychoanalytic treatment with children. Third, the 1920s and 1930s gave rise to the marriage counseling movement in the US. Made up largely of physicians, clergy, and social workers, this group began working with spouses together.

While writings and practice from the fields of social work, child guidance, and marriage counseling readied the larger mental health field for a paradigm shift, it was changes in psychiatry that are generally seen as the major

impetus in the development of family therapy. Frustrated by the limited effectiveness of psychoanalysis for mental illness, particularly schizophrenia, and influenced by the writing emanating from social psychiatry, most notably the work of Harry Stack Sullivan, several individuals and teams began to study and develop new treatment modalities with families of schizophrenic patients. Although the treatment models developed throughout the late 1940s and 1950s varied on many dimensions, it was their similarities and their contrast to the prevailing psychoanalytic thought of the time that led ultimately to a unified field. The primary theme that ran throughout the models was the concept of wholeness; families were more than the sum of their members and the emergent relational and interactional components were the focus of the therapist's intervention. Common characteristics of what came to be called "family systems" models of therapy included circular causation, function of symptoms, boundaries and organization, and communication patterns.

Multidirectional/circular causation is the notion that change in any part of the family impacts all other parts and that any given behavior cannot be understood linearly by what preceded or followed it. Instead, behavior must be considered by looking more broadly at the interactional field in which it is located.

Function/purpose of symptoms refers to the assumptions that symptoms exist for reasons in families. Although the purpose a symptom served may not be obvious to family members and be counter to stated family goals, early family therapy maintained that the symptom was currently or had been functional at some point in a family's history. For example, while the young adult child who cannot successfully separate from parents and lead an independent life may seem like a problem to parents, the continuation of this behavior may serve to keep the parents united by their joint focus on a troubled child.

Boundaries and organization refer to structural characteristics of families. Organization addresses how the family has structured roles and relationships to meet its tasks or goals. Boundaries, on the other hand, address the degree of fluidity and adaptability in family organization. While boundaries need to be

flexible enough to respond to changes in family needs and environmental demands, they should not be so malleable that family members and subsystems lose their sense of distinctiveness. For example, parents who allow children to become involved in their arguments, or share marital discontents with their children, would be said to have weak boundaries around the marital subsystem. Conversely, families who could not adapt and take on different tasks when a mother becomes ill, or families that could not respond effectively to age appropriate changes in children's needs for guidance and affection, might be thought of as rigid in their boundaries and organization.

Communication patterns refer to the messages that family members send one another. The emphasis here is not simply on the words spoken but on both the multiple levels of messages sent and the metacommunications about how messages are to be interpreted in the context of this relationship. Thus, the statement, "tell me how you feel," will be interpreted and responded to very differently in a family that has low tolerance for anger and dissension than in a family that respects differences of opinion.

Throughout the 1960s and 1970s family therapy increased in prominence in the mental health field as publications and training programs proliferated. However, the late 1970s and 1980s saw several critiques of the field. The field's singular focus on the system and lack of attention to individual biology, psychology, and responsibility were criticized from two primary quarters. Families of the mentally ill challenged family therapy for blaming them for their children's illnesses by focusing on the function of a symptom in the family and using language (such as "schizophrenic family" or "alcoholic family") that held the entire system accountable for a problem. Likewise, feminist scholars criticized the circular systemic thinking and language that held both victim and abuser responsible for the violence. Additionally, feminists criticized the field for promoting traditional family structure and failing to incorporate the larger cultural system into therapists' understanding of how gender and race impact family dynamics.

Both in response to these criticisms and as part of the movement toward integration in the

mental health field in general, family therapy is continuing to evolve.

The last decade has seen a refocusing on the individual within the family system, and increased attention to issues of race/ethnicity, gender, and sexual orientation in treatment. Further, the strict division between models is eroding as integrative models emerge, and non systemic postmodernist models – such as narrative and social constructionist models – grow in prominence in the field. An additional change is the integration of family therapy with other systems of service delivery, most notably family medicine.

The primary challenge currently facing family therapy is the challenge facing all mental health fields. The increased demand by insurers for evidence based treatment has led to an increase in research assessing the effectiveness of specific treatment protocols with specific populations.

Fanon, Frantz (1925–61)

Alan Bairner

Born in Martinique and a psychiatrist by training, Frantz Fanon's sociological legacy lies mainly in the study of "race" and, above all, in the development of postcolonial studies. Having fought for the Free French Army during World War II, Fanon studied medicine and psychiatry in Lyon. In 1952 he began to practice psychiatry in Algeria and thereafter he became associated, particularly in the minds of the political left for whom he became an iconic figure during the 1960s, with the cause of Algerian independence. In arguably his most famous work, *The Wretched of the Earth* (1961), Fanon sought to combine traditional Marxist revolutionary theory with ideas more appropriate to struggles in the developing world.

For some, he was an unattractive thinker who romanticized killing and whose rhetoric was typical of a strain of politics which glorifies violence in pursuit of an imagined future. Others, however, saw in his forensic analysis of the dehumanizing impact of the colonized condition, as evidenced in his first book, *Black Skin, White Masks* (1952), an honest and compelling justification for the use of political violence. Only through acts of violence could the subjugated individual destroy not only the colonial oppressor but also his or her former self.

It could be argued that national liberation struggles of the type for which Fanon proved to be a source of inspiration have been superseded by new challenges centered on globalization. On the other hand, there is an equally strong case for asserting that questions about "race" and about the extended repercussions of colonialism which Fanon sought to answer are as relevant today as when he was writing.

In many respects, for example, it is possible to situate the events of 9/11 or the war in Iraq as the direct consequences of the kind of trauma that Fanon explored both as a physician and as a political activist. Ironically, however, despite Fanon's undoubted contribution to postcolonial studies, his own theoretical approach, like that of C. L. R. James, owes almost everything to the western tradition of social and political thought. To that extent, therefore, while he would most certainly have understood the reasons that lie behind the violence of some Islamic fundamentalists, he would have been ill at ease with the theocratic ambitions of men such as Osama bin Laden. Regardless of the deep seated psychological need for third world revolution, the concrete objective of revolutionary movements, as understood by Fanon, consisted of material goals, including an equitable distribution of wealth and technology. At no time did he advocate a return to precolonial conditions or, indeed, a requirement to view the world from a perspective that was wholly distanced from western Enlightenment thought.

Having resigned from his position as director of the psychiatric department at Blida Joinville's hospital, Fanon became more directly involved in the struggle of the National Liberation Front (FLN) to free Algeria from French rule and in 1959 was seriously wounded. He served briefly as the provisional Algerian government's ambassador to Ghana. In 1960 he became seriously ill and died of leukemia in Washington, DC, on December 12, 1961. He was buried in Algeria.

Fanon's other major works were *A Dying Colonialism* (1959) and *Toward the African Revolution* (1964).

fans and fan culture

Matthew Hills

Fans have become important to work in media sociology and cultural studies for a variety of reasons: they can be taken to represent a dedicated, active audience; they are consumers who are often also (unofficial, but sometimes official) media producers (Jenkins 1992; McKee 2002); and they can be analyzed as a significant part of contemporary consumer culture. Fandom – the state of being a fan – is usually linked to popular culture rather than high culture. People who appreciate high culture, often being as passionately partisan as pop culture's "fans," are described as "connoisseurs" or "aficionados" rather than as fans (Jensen 1992). Whilst connoisseurship is typically deemed culturally legitimate, fandom has been analyzed as rather more problematic: the stereotype of "the fan" has been one of geeky, excessive, and unhealthy obsession with (supposedly) culturally trivial objects such as TV shows. Henry Jenkins has highlighted and opposed this negative fan stereotype, arguing that such portrayals of fandom should be critiqued, and that fans should instead be viewed more positively as building their own culture out of media products, and as selectively "poaching" meanings and interpretations from favored media texts. Jenkins, whose seminal work *Textual Poachers* (1992) helped to make fandom a viable object of academic study, suggests that the creativity of fans is downplayed in cultural common sense in favor of viewing fans as "cultural dupes" who are perfect consumers, always accepting what the culture industry produces for them. Against

this narrative, depicted as belonging to the Frankfurt School of Marxist theorists such as Theodor Adorno as much as to forms of cultural common sense, Jenkins argues that fans discriminate keenly between and within their objects of fandom, developing an aesthetic sense of what counts as a “good” episode of television series such as *Star Trek* or *Doctor Who* (see Tulloch & Jenkins 1995).

Fans develop extensive knowledge and expertise about their shows or sports teams, also characteristically feeling a sense of ownership over “their” object of fandom. They also “tend to seek intimacy with the object of their attention – a personality, a program, a genre, a team” (Kelly 2004: 9). This “intimacy” could involve meeting a celebrity, getting a sports woman’s autograph, seeing an actor give a talk onstage at a convention, chatting with him or her in the bar afterwards, or even visiting real locations used in the filming of a TV series (see Hills 2002). Fans thus seek to break down barriers between themselves as subjects and their objects of fandom, their fan identity becoming a meaningful aspect of cultural and self identity. Indeed, Tulloch and Jenkins (1995: 23) distinguish between “fans,” who claim a cultural identity on the basis of their fandom, and “followers,” who despite following pop cultural texts, pop groups, TV series, and so on more than casually, do not make such an identity claim.

As can be seen from this, fandom is generally discussed in relation to media consumption and media texts, sometimes being referred to specifically as “media fandom” (Jenkins 1992: 1), although this prefix is often assumed. Scholars have tended to isolate out and focus on specific fandoms such as fans of science fiction film and TV (Bacon Smith 1992; Jenkins 1992); fans of soap operas (Harrington & Bielby 1995; Baym 2000); fans of the *Star Wars* films (Brooker 2002); fans of particular TV series and radio shows (Thomas 2002); and sports fans (Crawford 2004).

Fans and fan culture are, however, not quite the same thing. By using the term “fans” we can refer to individuals who have a particular liking or affection for a range of popular cultural texts, celebrities, sports (teams), or artifacts. These individuals – typically displaying an affective relationship with their fan object;

that is, they are passionately interested in and committed to following their beloved pop group, sports team, or soap opera – may nevertheless *not* take part in socially organized fan activities. They may not attend fan conventions, be part of fan clubs, post to online fan message boards, or even attend live sporting events – instead perhaps supporting a baseball or football team by reading about games or watching them on television.

By contrast, collective activities such as convention going or fan club membership are very much indicative of what is meant by “fan culture.” Nicholas Abercrombie and Brian Longhurst (1998: 138) mark this distinction by contrasting “fans” with what they term “cultists”: the former display their fandom privately or personally rather than communally, whilst the latter are participants in communal fan cultures and activities. However, many writers simply use the term “fans” when referring to members of a fan culture (Bacon Smith 1992; Jenkins 1992; Hills 2002).

Here, fans are socialized within affective communities of fandom, and engage in subculturally distinctive fan practices such as writing their own fan fiction (“fanfic”) based on characters and situations from official films and TV shows, producing their own fan magazines (“fanzines”), writing their own lyrics to popular songs or standards (“filking”), and engaging in costuming at fan conventions by making replicas of costumes worn onscreen by film or TV actors (Jenkins 1992; Joseph Witham 1996; Hills 2002). “Fans” in the first, socially atomized, sense have been far less studied than “fan culture,” probably in part because the latter is more sociologically and culturally visible to researchers, and because such socially organized communities and practices have provided a rich terrain for media ethnographers such as Camille Bacon Smith (1992) and scholars such as Henry Jenkins (1992). Despite this partial focus in fan studies to date, scholars and students of media fandom should take care not to replay fan debates over “authenticity,” where socially atomized fans are considered to be somehow not “true” or “authentic” fans in comparison with those organizing or attending conventions, or regularly attending live sports matches (see Crawford 2004). Furthermore, we should take care not to always explore specific

fan cultures as singular objects of study: many soap fans may also be fans of particular celebrities or popular music, and many science fiction TV fans may also be fans of horror movies, and so on. Repertoires of media fandom are thus also important, as fans move between different fan objects and navigate through intertextual networks of TV shows and films (Jenkins 1992; Hills 2002, 2004).

Although it would be fair to say that there is no singular body of work that can be counted as the “sociology of media fandom,” the work of French sociologist Pierre Bourdieu has nevertheless been key to studies of fan cultures. John Fiske (1992) has drawn on Bourdieu’s theorization of cultural distinction to illuminate how fans, meaning participants in fan cultures, distinguish themselves from non fan audiences. Fiske emphasizes how such fans work to accumulate “fan cultural capital” or “popular cultural capital,” namely, knowledge about, and literacy in relation to, their object of fandom. In this instance, Fiske applies and develops Bourdieu’s (1984) take on “cultural capital,” by which is broadly meant the level of education and “training” in legitimate culture and its appreciation that a cultural agent holds. Sarah Thornton and Mark Jancovich have also applied Bourdieuan theories to fandom, with Thornton (1995: 11) coining the term “subcultural capital” to describe that form of capital which is not common across an entire culture, but is, instead, specific to a subculture or fan culture. Hills (2002: 57) has further related Bourdieuan concepts to media fandom, discussing “fan social capital” (the network of contacts that a fan has within his or her fan culture) as well as fan cultural capital. This sociological focus has led to fan cultures being thought of as hierarchical rather than romanticized as anti capitalist, “resistant” communities magically free of power differentials and struggles over status. Many media fandoms and sports fandoms can also be analyzed as male dominated cultural groups as well as middle class dominated elective affinities, meaning that Bourdieu’s emphasis on structural inequality in the distribution of forms of capital, beyond economic capital (money) alone, remains important here.

Nick Couldry (2003) has suggested that Bourdieu’s work is somewhat weakened by its

lack of focus on the operation of the media in relation to “symbolic capital” (prestige), arguing that sociologists should consider the “media’s meta capital” (p. 672), through which “what counts as symbolic capital in particular fields” is altered (p. 668). Thus, fans who become regular sources for the media – or who run popular message boards or websites/Internet news sites – may not merely be reflecting their already acquired fan cultural capital. Rather, by virtue of their own role within mass or niche mediation, these fans, people such as cinephile Harry Knowles (founder of aintitcoolnews.com) or *Doctor Who* fan Shaun Lyon (founder of gallifreyone.com), may be accruing and exercising “media meta capital.” Such fans can even become “subcultural celebrities” in their own right (Hills 2003), being recognized and respected by many others in their subculture or fan culture, while being largely unknown outside this subculture.

Alongside the importance of Pierre Bourdieu’s (1984) work on forms of capital, other key theories within recent work on fandom have been those of performance (Abercrombie & Longhurst 1998; Lancaster 2001) and performativity (Hills 2002; Thomas 2002; Crawford 2004). In particular, and drawing on Judith Butler’s work, Matt Hills (2002) has suggested that fans should not be thought of either as “consummate consumers” (Kelly 2004: 7) or as “cultural dupes” in thrall to the culture industry. Rather, Hills (2002: 159) suggests that fans display “performative consumption,” performing their identities as fans in ways that are simultaneously highly self reflexive or self aware *and* non reflexive or self absent, given that they cannot always account for why they became fans in the first place (Harrington & Bielby 1995). Crawford (2004: 122) applies Hills’s concept to sports fans, finding it to be of use here. The notion of “performative consumption” indicates that we should not treat fandom via a sociological either/or, where fans are either agents whose fan cultural practices can be celebrated, or they are subjects whose fan cultural practices can be accounted for, and critiqued, as effects of structural/capitalist forces. It also suggests that depth psychology or psychoanalytic theories may be useful in exploring aspects of fan identities that operate below the level of discursive consciousness (and

a number of writers have pursued post Freudian and sociologically contextualized discussions of this: see Harrington & Bielby 1995; Hills 2002).

In short, media fandom acutely poses problems of “structure” versus “agency” that have dogged contemporary sociological debate, and although Bourdieu’s work has been influential in work on fan cultures, surprisingly little attention has yet been paid to utilizing other competing theories of structuration such as those of, for example, Anthony Giddens and Margaret Archer, although J. B. Thompson and Sean McCloud have sociologically analyzed fandom as a “late modern project of the self” (McCloud 2003: 199), using the Giddens of *Modernity and Self Identity* (1991) rather than *The Constitution of Society* (1984).

As the sociology of media fandom moves toward maturity, we might therefore expect further work on structuration theory, as well as further applications of post Marxist work on commodification and post Durkheimian work on ritual and the “collective effervescence” of contemporary neotribes (Hills 2002). Work to date has either tended to push toward the status of a general theory of media fandom (Hills 2002), or it has taken specific (and limited) fan cultures as objects of study (see McKee 2002). These maneuvers have left a range of comparative questions open: are all fan cultures similarly structured through issues of “fan cultural capital” and “fan social capital”? And are fan cultures in Japan, say, structurally and affectively similar to those in the US? Indeed, what of transnational fan cultures? A research agenda relating fandom to matters of globalization has yet to be fully pursued, although one major research project under way at the University of Aberystwyth, and headed up by Martin Barker, promises to deal with the transnational consumption and meanings of *The Lord of the Rings* trilogy of films. Fans and fan cultures have offered one test case for theories of audience “activity” (Fiske 1992) and “performance” (Abercrombie & Longhurst 1998), as well as allowing for the ethnographic exploration of fan communities (Bacon Smith 1992), but the study of fandom continues to face many challenges and new opportunities.

fantasy city

John Hannigan

"Fantasy City" refers to a new urban form located at the intersection of leisure, consumption, tourism, and real estate development. In *Fantasy City: Pleasure and Profit in the Postmodern Metropolis* (1998), Canadian sociologist John Hannigan points to six defining features: fantasy cities are characteristically thematic (scripted), aggressively branded, active day and night, modular (mixing a standard array of retail and entertainment components), solipsistic (isolated physically and economically from the neighborhoods that surround them), and postmodern (in their reliance on simulation and spectacle). This set of phenomena is empirically manifested in an infrastructure of themed restaurants, nightclubs, shopping malls, multiplex cinemas, virtual reality arcades, casino hotels, book and record megastores, sports stadiums and arenas, and other urban entertainment destinations. While the only urban centers that currently qualify as full scale fantasy cities are Las Vegas and Orlando, Florida, most cities today have some commercial neighborhoods and developments that display these characteristics to a greater or lesser extent. Furthermore, fantasy city development has spread aggressively beyond the borders of North America, with large scale projects currently operating or under construction in such

countries as Australia, Singapore, Malaysia, China, Saudi Arabia, and Dubai.

The contemporary trend toward saleable leisure spaces in the city has its roots in the past. During the "golden age" of popular urban entertainment (1890–1930) in North America, an extensive array of amusements emerged, from the "Trip to the Moon" ride at Coney Island to the elaborately themed vaudeville theaters and motion picture palaces of the 1920s and 1930s. Despite claims by leisure merchants of the day that they were front and center in the movement toward the democratization of leisure, most urban leisure spaces were, in fact, effectively segregated by social class, race, and gender.

The contemporary fantasy city differs from its earlier predecessor in several key aspects. First, it is more pervasive and portable, the cornerstone of urban economic development efforts in North America, Europe, Asia, and the Middle East. Second, fantasy city construction has been undertaken on an unprecedented scale, encompassing not only single venues but also entire neighborhoods and districts. Third, fantasy city development has spread beyond its traditional base in the central city to exurban malls, sports complexes, and lifestyle centers, as well as port lands and other reclaimed waterfront locations. Fourth, these new urban spaces are conceived, branded, and managed by a new set of corporate players – multinational retail, media, and entertainment conglomerates such as Disney, Nike, and Sony – in partnership with the local and regional real estate developers and construction firms that previously shaped the commercial landscapes of the city.

Fantasy cities appeal especially to tourists and suburban visitors because they satisfy a bourgeois preference for sanitized environments of "riskless risk." That is, they are the end products of a longstanding cultural contradiction between the American middle class desire for experience and their equally strong parallel reluctance to take risks, especially those that involve face to face contact with the "lower orders" in big cities. In this regard, the technologies of simulation and virtual reality that characterize the theme park city at one and the same time both dazzle and reassure. Excitement is divorced from actual experience and made safe. The sanitized consumption that is

characteristic of the fantasy city is realized by three central, strategic processes: theming, branding, and experiential storytelling.

Theming invites consumers to participate in structured fantasies derived from an exotic geographical locale (a tropical rainforest, a Moroccan bazaar), a distinctive historical period (pioneer days, medieval times), a popular motion picture or television show (Star Trek, the Flintstones), or a sports, music, fashion, or film celebrity (Wayne Gretsky, Dolly Parton, Cindy Crawford). As such, theming serves both to unify and market leisure sites, rendering them entertaining, easy to read visually, and controllable through a centrally directed corporate script. Theming has become pervasive, George Ritzer (1999) suggests, because it is a unique means of "re enchanting" a world that has become excessively dull and practical. Ritzer refers to such themed venues as "cathedrals of consumption" to indicate their quasi religious appeal for postmodern consumers in search of enchantment and identity.

Branding has three interrelated dimensions, each of which relates to the production and marketing of fantasy cities. Insofar as it invites instant consumer recognition, branding encourages "synergies" with global sports and entertainment conglomerates such as Nike, Disney, and Sony with their rosters of widely publicized and recognized celebrities. Furthermore, successful branded leisure spaces play on our desire for comfort and certainty, key attributes of postmodern theme parks. Third, branding provides a ready made point of identification for consumers in an increasingly crowded commercial marketplace.

Finally, fantasy cities are constructed around the creation of guest centered experiences. This is a testament to the power of narrative to imbue leisure environments, products, and services with an added dimension of interest and meaning. Urban entertainment destinations and attractions are increasingly outfitted with a "back story" that purports to link them with a historical (or mythical) repertoire of iconic events, personalities, and milestones.

Consumption in the fantasy city is further characterized by a dedifferentiation of the spheres of education, shopping, dining, and entertainment. This results in the growth of synergistic, hybridized consumer activities, as

described by the terms "shopertainment, entertainment, and edutainment." This further extends the urban entertainment economy into such community institutions as museums, hospitals, churches, and schools.

Promoted by civic boosters as the panacea of urban revival, fantasy cities nevertheless bring with them a host of social, political, and economic liabilities.

As Mike Davis demonstrates in *City of Quartz* (1990), his apocalyptic vision of contemporary Los Angeles, fantasy city style development aggressively colonizes public space, limiting access to a select leisure class. It is an environment constructed out of fear, uncertainty, and the desire for exclusion, just the opposite of the traditional city park or market. In order to guarantee a sense of security, these spaces are regulated through a battery of surveillance and control techniques. Chief among these are CCTV (closed circuit television) and privately operated BIDs (business improvement districts). The latter routinely utilize private security guards and street clean up crews and lack any direct public accountability. This infrastructure of surveillance and control is especially evident in urban settings in which the pleasure seeking, entertainment economy operates at night and where bars, nightclubs, and the like are suspected of fostering a higher degree of lawlessness and disorder. The current proliferation of entertainment development endangers what Sharon Zukin (1995) calls "the dream of a public culture." That is, the ideal of a diverse metropolis where residents of varied ethnic, racial, and socioeconomic backgrounds mingle freely and work together to build a civil society is undercut by the operation of pre packaged urban entertainment destinations that furnish safe, random encounters within the confines of a "tourist bubble." This contributes to the growth of what Sorkin (1992) has termed "ageographical cities," urban spaces that are stripped of any identifiable sense of place and sealed off from the surrounding environment.

Furthermore, the argument that fantasy city development functions as an economic multiplier more often than not turns out to be deeply flawed. The "urban growth machines" that control municipal business and politics justify sports and entertainment projects on the

grounds that they act as catalysts, generating increased trade for the local small businesses such as bars, restaurants, and corner stores that dot local neighborhood streets. Alas, in this context the oft cited saying that “a rising tide lifts all ships” is faulty. Rather, these are more likely to be cannibalized by entertainment megaprojects than to be catalyzed by them. In Baltimore, Maryland, after nearly a quarter century of festival marketplace development around the Inner Harbor, much of it publicly financed, prosperity has scarcely spilled over to the surrounding inner city. Visitors rarely venture far from the waterfront. This further erodes an inner city landscape of vacant storefronts, dilapidated residential buildings, and escalating poverty. Most jobs in the tourism and entertainment industry are of dubious quality: part time, minimum wage, few fringe benefits or career ladders (Levine 2000).

Finally, fantasy cities are problematic insofar as they exhibit marked undemocratic qualities. Poster children for the “new entrepreneurial city,” they are designed, built, and managed by “public-private partnerships” in which the latter holds the upper hand. As such, they stand apart from everyday municipal governance. Key decisions are increasingly made by public/private institutions rather than by elected representatives. Grassroots input is minimal. What has paved the way for this is the widespread deindustrialization and movement of manufacturing offshore encountered by North American urban economies in recent decades. In the face of this downward spiral, local government has embraced a promotional and marketing role, encouraging the privatization of urban development and culture.

Since the term was introduced in the late 1990s, fantasy city has proven to be a useful construct in a variety of different theoretical and empirical contexts. Bauman (2003: 25) locates its “magic blend of security and adventure – of supervision and freedom, of routine and surprise, of sameness and variety” as central to the contradictory desires and expectations of urban residents. This reflects, he says, the combination of globalizing pressures and territorially oriented identity search that shapes the structural development of the contemporary city. Atkinson and Flint (1995) link the idea with “gated communities.” The key imperative

of the fantasy city for city center development, they observe, is the desire for experience without danger leading to the desire for “urbanoid spaces” (spaces that resemble “real” streets but are devoid of the diversity that they formerly supported). This provides the means for people to exercise control over where, how, and when social encounters are made. Chatterton and Hollands (2003) focus on the production, regulation, and consumption of “urban nightscapes,” most notably those that provide branded, themed, and stylized experiences to young adults in search of hedonism and cool. In the brew pubs, themed “super clubs” (combined bar, restaurant, and club) and sports bars that are proliferating in urban entertainment districts, they encountered many of the same elements of “Disneyfication” and global corporate ownership that are characteristic of the fantasy city, as described by Hannigan (1998). Hubbard (2003) situates fantasy city development in the exurban fringe of the metropolis, where urban dwellers “increasingly seek distraction in spectacular, peripheral landscapes located away from the ‘inner city.’” He empirically illustrates this with survey data describing patterns of cinema going among the population of Leeds (UK). McGuire (2003) writes that Sony’s PlayStation 2 gaming environment not only exhibits all of the features that characterize the fantasy city, but also builds on its central attraction – amplifying the thrill of the spectacle without any exposure to the personal risks found that physical presence entails. As is the case with other 3D virtual communities, players are guaranteed freedom from the confines of the physical body, freedom from the constraints of geographical space, freedom from strangers, and freedom from control.

fascism

Mabel Berezin

Fascism as a historical entity began in 1922 when Mussolini came to power in Italy. As a political ideology, fascism defines many of the movements that were present in post World War I Europe from the British Union of Fascists to the Romanian Iron Guard. Fascism could have remained simply a characteristic of a group of historically specific political formations, but the term rather quickly developed a life of its own. Today, it serves as what Alexander (2003) has described as a bridging metaphor, that is, a term that one uses independently of historical or definitional context

when confronted with acts of arbitrary violence or authoritarianism in political and, in some instances, social life.

The entries in the 1931 and 1968 editions of the *Encyclopedia of the Social Sciences* discuss fascism exclusively in terms of the regime in Italy. The authors make some effort to distinguish Italian Fascism from German National Socialism. The 2002 edition of the *Encyclopedia* 1990s, scholars viewed fascism as a descriptor of events in post World War I Europe or as an ideology with only historical interest. Precise conceptualization has eluded past, as well as current, exegeses of historical fascism. Attempts to theorize fascism have mined specific historical instances for generalities and yielded catalogs of characteristics. Even a cursory reading of this scholarship suggests that it is difficult to generalize across cases and leaves the impression that Benedetto Croce was correct when he described fascism as a “parenthesis” in European history.

The historian Gilbert Allardyce (1979) wrote a frequently cited analysis that claimed to have closed the question of “generic” fascism. He asserted fascism had no meaning outside of Italy and that it was neither an ideology nor a mental category. Comparing fascism to romanticism (and curiously obtuse to fascism’s other ideological kin, modernism), he stated that both terms “mean virtually nothing.” Resigned to the fact that “fascism [as a political term] is probably with us for good,” Allardyce asserts the proper analytic task is to “limit the damage.” Allardyce argues that fascism should be considered as descriptive of a historical period within a single nation state. The historicity of fascism renders it imprecise as an analytic frame.

The death knell of fascism has not sounded either in the real world of political practice or in the relatively cloistered world of the academy. For example, Griffin (1991: 26) begins where earlier studies left off. He argues that the term fascism has undergone an “unacceptable loss of precision” and proposes a new “ideal type” of fascism based on the following definition: “Fascism is a genus of political ideology whose mythic core in its various permutations is a palingenetic form of populist ultra nationalism.” The collapse of communism in 1989, the electoral success of European

right wing populist parties that began in the early 1990s coupled with a resurgence of neo Nazi violence, and the more recent rise of Islamic fundamentalism have reawakened social science interest in historical fascism. Three basic approaches to fascism have emerged over the last 50 years.

Existing studies of fascism fall into two schools that may be broadly categorized as follows. The first tries to answer the "what" or definitional question. Frequently, this is articulated in a discussion of whether or not fascism is a "generic" concept or a national variation of historically specific political instances. Of those who try to define fascism, the central theme is the impossibility of definition. The second approach bypasses definition and tries to establish the characteristics of regimes and constituencies. Lipset's (1981) classic account of the class composition of fascist movements attributes fascism's success to the political disaffection of the middle classes. Linz's (1976) approach to constituency formation starts from the premise that an independent "phenomenon" of fascism existed and defines it as "hyper nationalist, often pan nationalist, anti parliamentary, anti liberal, anti communist, populist and therefore anti proletarian, partly anti capitalist and anti bourgeois." Linz emphasizes that European fascists (he uses the term for a range of cases while recognizing national differences) combined paramilitary tactics with standard electoral procedures to gain legitimate power. Fascism, for Linz, was a peculiar combination of law and violence.

Linz's definition rests on his assumption that fascism occupies a residual political field. As a "late comer" to the political scene, fascism had to capture whatever "political space," in the form of ideological doctrine and political constituencies, was available to it. His argument is dependent upon analyzing the social bases of fascism's political competitors (Linz 1980). Linz recognizes the importance of national case studies and the characteristics that he outlines are applicable in various combinations to a broad range of fascist movements and regimes. In general, studies of institutions and constituencies display greater degrees of analytic precision than those that wrestle with definition.

A central weakness in much of the writing on fascism, past and present, has been a failure to

draw a sharp distinction between fascist movements and regimes, between fascism as ideology and fascism as state, between political impulse and political institution. In general, analysts elide the question of culture and ideology or simply deal with it in a descriptive manner. The forces that enable a political movement to assume state power are different from, but not unconnected to, the forces that define a new regime. During the 1920s and 1930s virtually every country in Europe had a fascist movement, or political movements that displayed the characteristics of the fascist impulse, but relatively few of these movements progressed to political regimes, that is, took control of the state. Culture and ideology figure differently at both stages. In the movement phase, culture and ideology act as a powerful mobilizing device that frames the political beliefs of committed cadres of supporters. In the regime phase, culture and ideology serve as conversion mechanisms to ensure the consent of a broad public constituency.

Totalitarian states are not necessary outcomes and historical evidence suggests that they are as much fascist fictions as political realities. Mussolini declared that his regime was the first totalitarian state. Although recent historiography has shown that the fascist cultural project was highly fissured, the intention (if not the reality) of coherence was a goal. Arendt (1973) built terror into the definition of totalitarianism. Her quasi psychoanalytic approach to fascism paints a portrait of mass societies, mobs, and atomized individuals responding to the congeries of a police state and evokes contemporary neo Nazis and images of an Orwellian 1984. Terror and violence as analytic frames may capture the political realities of Stalinist Russia and Holocaust horrors, but terror did not represent the quotidian experience of Italian Fascism and distracts from historical and theoretical understanding. In contrast to Nazi Germany and Stalinist Russia, the Italian Fascist regime was relatively non repressive.

Scholars have argued that it should be possible to establish a "fascist minimum," by which they mean a set of criteria without which fascism could not exist. Yet they have been reluctant to ascribe greater or lesser degrees of importance to the variables that they view as

characteristic of fascism. For example, Italian Fascism was anti Socialist and anti clerical, despite its conciliation with the Catholic Church, but above all it was anti liberal as liberalism was understood in early twentieth century Italy.

Discussions of Marxism have confounded discussions of fascism. Positing that fascism is not Marxism, or is a form of "anti Marxism," fails to address the salient features of both ideologies. Many Fascists – including Mussolini himself – began their political careers as socialists. What were the differences and points of confluence between Fascism and Marxism which made the transition from one to the other possible?

The beginning of an answer lies in Sternhell's (1994) analysis of fascism as an "independent cultural and political phenomenon" representing a "revision" of Marxism. According to Sternhell, fascism was a political hybrid that rejected, first, the liberal ideals of rationalism, individualism, and utilitarianism, and second, the materialistic dimensions of Marxism. From Marxism, fascism borrowed a concept of communitarianism embodied in a new form of revolutionary syndicalism; and from liberalism, it borrowed a commitment to free markets. Sternhell's contention that market economies are compatible with fascist ideology and regimes forecloses purely economic interpretations of fascism. Sternhell's analysis lends support to fascism's disavowal of liberal political culture, but it is overly dependent upon the writings of national, and sometimes obscure, avant garde intellectuals to serve as a fulcrum for generating new theories of fascism.

Fascism refuses to go away. There are four identifiable stages in the career of fascism as a concept: first, the post World War II period when the classic analyses were written, spanning roughly from 1950 to the early 1970s (much of these writings have been discussed above); second, the social interpretations phase; third, the cultural institutional turn; and fourth, the return to political explanations.

Social interpretations of fascism began to reemerge in the 1980s. Heirs of Lipset's mode of analysis, these studies were less deterministic and grounded in a nuanced notion of class and political action. De Grazia's (1981) study of the

Fascist leisure organization the *Dopolavoro* examines how Fascism coopted the Italian working classes through the regime's colonization of its leisure time. De Grazia focuses on how workers pursued political projects that on the face of it were against their interests instead of locating the charisma of Fascism in the collective psychology of class groupings.

Social interpretations have occupied more historians of Nazi Germany than of Fascist Italy. Two central and contrasting works in this genre are Browning's (1992) history of a German police battalion in Poland and Goldhagen's (1996) study of how ordinary Germans were not only complicit but actively engaged in the murder of the Jews. Browning provides a measured analysis of how ordinary citizens became involved in the Nazi genocide. Goldhagen argues "ordinary Germans" became killers because they were inherently anti Semitic and enjoyed hunting down their Jewish neighbors and engaging in acts of violence against them. Brustein (1996) argues membership in the Nazi Party was a rational and not an emotional decision. Career advancement demanded party membership and German citizens who wanted to feed and clothe their families fell in line.

In the mid 1990s the social approach to the study of fascism shaded into an approach that focused on political culture. Gentile (1993) studied the symbols of Italian Fascism and concluded that it was a form of political religion that sacralized politics. Another thread of the cultural analysis was the focus upon how cultural institutions intersected with political regimes. Berezin's (1997) study of public political events links the study of fascist ritual to comparative political analysis.

The millennium has seen a resurgence of interest in fascism within the social sciences. Paxton (2004) begins where earlier generations of studies left off. Paxton sets himself the task of trying to define the parameters of fascism as a political phenomenon and he astutely chooses the term "anatomy" to characterize his project. As his title *Fascists* suggests, Mann (2004) rein vigorates the class approach to fascism. Mann analyzes six cases of inter war European fascism and identifies the presence of paramilitarism combined with the usual array of

anti statism and nationalist ideology as a distinguishing feature of fascism. Despite the vast array of new scholarship at their disposal, Mann and Paxton more or less conclude that fascism was an inter war European phenomenon that is not likely to repeat itself in its early twentieth century form.

Political scientist Nancy Bermeo's *Ordinary People in Extraordinary Times* (2003) is not exclusively a study of fascism and it has the advantage of including Latin America in the analysis. Bermeo views transitions to and from democracy as a series of choices that ordinary people make as they try to get on with their lives. This book taps into the attraction of individuals to political groups who offer solutions to practical problems. The attraction is based on potential efficacy rather than any prior moral assessment of ideology – whether that ideology is democratic or not. Bermeo offers a first step in demarcating the experience of the varieties of popular political choice.

A striking feature of various approaches, past and present, to fascism is lack of specificity. For example, violence is constitutive of political ideologies that are not fascist as well as those that have been labeled fascist. Berezin (1997) reviews an array of available theories. She argues that if one examines fascism in the historical moment in which it occurs, the early twentieth century, then its ideological opposite was socialism and communism. Indeed, many prominent fascists such as Mussolini himself began their careers as socialists and then became fascists. She concludes that the defining characteristic of fascism was that it was political disposition that conflated the public and private dimension of the self. The fascist self was a political self submerged in the nation. As such, fascism privileged public life over private life and demanded a perpetually mobilized citizenry. This conception of fascism has the advantage that it dehistoricizes fascism and creates an analytic frame that can be applied to other ideologies and historical instances. Examining other movements, regimes, and ideologies that demand the fusion of public and private self has the potential to lead to a more precise and conceptually refined definition of fascism.

fatherhood

Esther Dermott

Fatherhood is a social institution and includes the rights, duties, responsibilities, and statuses associated with being a father. A useful

distinction is made between the terms father, fathering, and fatherhood. The first refers to the connection made between a particular child and a particular man (whether biological or social). The second refers to behavior; the actual practices of "doing" parenting. The third refers to more general ideologies and public meanings associated with being a father.

Fatherhood research is conducted in a number of academic disciplines and commentaries on fatherhood have also become commonplace outside academia in literature and non fiction. Within the social sciences, researchers working from a developmental perspective use quantitative techniques to explore the effect of paternal influence and father-child relationships on the well being of children and fathers. Statistical techniques, applied to survey material, are also used to develop cause and effect linkages between men's structural positions and their fathering behavior. Qualitative approaches, often associated with a symbolic interactionist perspective, are adopted by scholars interested in exploring individuals' perceptions and experiences of diverse forms of fatherhood. Discourses of fatherhood are examined by poststructuralists using images of fatherhood in policy documents and the popular media. Apparent discrepancies between representations of fatherhood and fathering behavior mean that exploring the alleged gulf between the "culture" and "conduct" of fatherhood (La Rossa 1988) has become a major focus for scholarly attention.

The breadth and depth of research on fatherhood have developed exponentially since the 1970s. Debates about women's role in society that emerged at this time stimulated a complementary interest in exploring masculinity. Women's increasing participation in the labor market intensified discussion about the construction of motherhood and led to an awareness of the relative lack of comment about men's roles in the family. Thus fatherhood research gained attention to provide balance to family research that was dominated by analyses of motherhood. Justification for the significance of fatherhood as a research topic in its own right drew on psychological evidence, which emphasized the importance of fathers for the successful emotional and educational development of children (Lamb 2003).

The changing nature of fatherhood is a consistent theme in research. The stereotypical image of Victorian fatherhood as strict and detached has been frequently adopted as a basis for comparison with contemporary ideas, and the emergence of scholarship on fatherhood in the 1970s sometimes led to an impression that a fundamentally different kind of fatherhood began during this period. The absence of a "usable past" (La Rossa 1997) may explain the tendency towards making overly neat distinctions between old/traditional and new fatherhood. A simplistic historical pattern describes the father as moving from moral guardian, disciplinarian, and educator, to the single role of financial provider, to the modern version of nurturing involvement (Pleck & Pleck 1997). However, more nuanced accounts have challenged this narrative by drawing attention, for example, to the presence of emotional responses to parenthood in men's lives in earlier periods. It is now widely accepted that a linear progression does not easily fit onto historical reality or adequately indicate the complexity of fatherhood.

While there is general agreement that the meanings of fatherhood have altered, there is less consensus over the extent of change and the meaning of modern fatherhood. A key question is the degree to which being the financial provider remains a significant aspect of fatherhood. Those who claim the ideology of breadwinner/ricewinner has been replaced with the nurturing father model suggest it is the quality of the father-child relationship and childcare that is increasingly prioritized by men. Given women's higher levels of participation in the labor market throughout the life course and the rise of dual income households, providing money to support family life can no longer be described as the preserve of the male parent. On the other hand, in two parent households men continue to contribute a larger proportion of the family income than women and the continuing expectation that men will provide for their family is exemplified in the common legal requirement that a father continues to be financially responsible for his children after divorce or separation.

Another focus is describing the components of "new" fatherhood. One characteristic is the development of an emotional relationship between father and child, but there is an

increased emphasis on “caring for” in addition to “caring about.” The words “nurturing” and “involved” are frequently invoked in order to capture this aspect of modern fatherhood. Nurturing is often applied to mothers and can be conceptualized as encompassing day to day care within the private sphere and focused on child development. Its application to men suggests a growing similarity between the roles of mothers and fathers. Involvement is a broad term that has been the subject of further qualification. In terms of childcare, three aspects have been demarcated: engagement, accessibility, and responsibility (Lamb et al. 1987). These refer respectively to interaction with a child through care or play; availability for interaction; and taking on the planning and forward thinking around children. Some authors have commented that providing money should be recognized as a form of involvement, although this suggests that involved fatherhood is a counter to negligent or absent fatherhood rather than to “traditional” fatherhood.

There is an awareness of fatherhood in political and policy arenas, which both reflects and encourages academic discussion. Concern over deadbeat dads (US) or feckless fathers (UK) is mainly associated with the absence of financial support for families, but also the potential impact of the lack of male role models and paternal influence over children's lives. This has been characterized as the problem of “fatherless families” and has prompted right wing authors to support a return to traditional family values and the male breadwinner model. An alternative explanation for fathers' absence from families is because they are undervalued and discriminated against in society. Many of the expanding fathers' rights groups focus on the legal position of fathers with respect to issues such as the right of fathers to insist on or veto abortions and, perhaps most notably, custody access post divorce. Structural, especially workplace, constraints have also been noted as influential in men's frustrated attempts to be “good dads.” Authors interested in this position concentrate on the extension of parental rights to fathers, such as paternity leave and access to reduced working hours. From a feminist perspective an increased role for men in relation to childcare seems essential in order to move towards gender equality, but

there is skepticism over whether an extension of rights by employers and states will lead to wholesale transformation.

Recognition of the heterogeneity of fathers' social situation and relationship to their children has been an important development in fatherhood studies. Until recently, fatherhood, unlike motherhood, has not been a proven biological fact. Instead, fatherhood was confirmed indirectly through a man's relationship to the mother of a child. The significance of biological fatherhood has increased with the arrival of DNA testing and the possibility of identifying the genetic parent. Perhaps paradoxically, social fatherhood without any biological tie is also gaining more attention. Increasing divorce and remarriage rates have led to more men entering fatherhood through either formal or informal adoptive and step relationships. Variations in the experiences and ideals of fatherhood due to differences in residency, age, class, sexuality, and ethnicity are also increasingly the subject of study. Further research can be expected to explore these terrains in order to develop a fuller picture of fatherhood. The future aim will be to establish the sociology of fatherhood as a *sui generis* area of study within the social sciences, albeit one which draws strongly on interdisciplinary perspectives.

fear

Jackie Eller and Andrea Eller

How do sociologists theoretically and empirically study fear? A simple answer is that the literature can be divided into two rather broad and overlapping areas of emphasis: fear as an emotion and fear as a consequence of or motivation for social relations.

While fear has its traditional roots in psychology, the sociological study of emotions draws on a rich heritage from theorists such as Durkheim, Mead, Cooley, Freud, Homans, and Goffman. It has been over the past 30 years that the sociology of emotions has emerged, emphasizing emotion as a crucial aspect of both micro and macrosociological examinations of social reality. Although there is general agreement among sociologists that emotions (fear included) are socially constructed and made meaningful within sociohistorical contexts, there is also some disagreement as to the importance of including certain elements such as biological and cognitive processes in the sociological examination of emotions (Barbalet 1998, 2002; Turner & Stets 2005; Turner 2006).

When sociologists examine fear as an emotion, they are in general consensus that it varies in interpretation and expression. But fear is also considered to be universal to the human experience, along with happiness, anger, and sadness. As a primary emotion, then, fear contributes to the experience of such secondary emotions as anxiety, shame, repulsion, and regret (Kemper 1987; Scheff 2000). However, as Tudor (2003: 244) notes, a sociology of fear "must examine the cultural matrix within which fear is realized and attend to the patterns of social activity routinely associated with it."

In the conceptualization of fear as a consequence of or motivation for social relations, the concern is less with the examination of the emotion per se and more with the relationship of fear to anxiety, panic, risk, victimization, and social control. Of particular interest for researchers and apparently the public in general is fear of crime and victimization, especially as it relates to children, women, the elderly, drugs, terrorism, and the media (Glassner 1999; Altheide 2002, 2004; Elchardus et al. 2005).

The study of fear as an emotion has emerged alongside the 30 year development of a sociology of emotions in general. Of particular relevance for theorizing fear is the work of Kemper (power status model), who argues that loss of power and status leads to fear and that fear can be meaningfully conceptualized as an emotion that differentiates people. Drawing on Kemper's work, Barbalet's macrostructural theory of emotion argues not only that fear is potentially incapacitating, but also that it can motivate groups either to increase power in order to enhance interests or to work to maintain current power levels.

Although crime and concerns with security dominate the "fear of" literature, it is of significance to mention the emergence of an ever expanding list of that which is feared, by whom, and with what consequences for social control: falling from the middle class, gaining or losing weight, growing old, "different others," impotency, disasters, and even knowledge. Most relevant is the growing body of literature that seeks to understand the relationship of fear and the media.

In addition to Turner and Stets, who work toward an integrated theory of the sociology of

emotions, current and future work on fear can be separated into three main areas: a (macro) sociology of fear, fear of crime, and media consumption and the discourse/politics of fear.

Tudor frames the social construction of fear in terms of six interlocking but distinct parameters: environments, cultures, and social structures (the modes of institutional fearfulness) and bodies, personalities, and social subjects (the modes of individual fearfulness). He then argues that this model may be used to test and further develop our understanding of a "culture of fear."

Elchardus et al. argue that the empirical literature addressing the relationships between victimization and media consumption can be used to test the two most frequently appearing, although not necessarily identified, paradigms of fear: a rationalistic paradigm of fear of crime (consequence of risk and vulnerability) or a symbolic paradigm (consequence of a "collective malaise"). Ditton et al. (2004) add to this discussion by emphasizing that the weak relationships found between the counting of fear of crime and media consumption are less important than the consumers' interpretation of the relevance of media content to their lives.

Despite the many "fear of" approaches, Altheide, among others, argues that a more useful approach is to study fear as "a perspective or an orientation to the world" (2002: 178) that emerges through a mass mediated discourse of fear – "the pervasive communication, symbolic awareness, and expectation that danger and risk are a central feature of the effective environment" (p. 41). He convincingly explains this discourse through the analysis of framing strategies, topics of fear, and the expanding list of victims and victimization. As Weigert (2003: 95) notes, fear and anxiety sow "dis ease," the "social pathology of interaction" which threatens public order and personal identity. Altheide concludes that this discourse of fear has implications for the possible realization of a just society. Fear becomes the framework for constructing the social world but not necessarily a *safer* or more humane one.

federalism

Brian Galligan

Federalism consists of two spheres of government, national and state, operating in the one political entity according to defined arrangements for sharing powers so that neither is sovereign over the other. According to William

Riker (1964), the activities of government must be divided in such a way that each government has some activities on which it makes final decisions. Daniel Elazar (1987) summed up federalism as a system of “self rule plus shared rule” – self rule in regional communities and shared rule at the national level. The older notion of federalism was an association of associations, or a league or confederation of independent member states whose delegates managed central institutions. This was the institutional form of the American Articles of Confederation that provided a weak form of national government during the War of Independence. In the 1789 Constitution, as explained in the Federalist Papers, the American founders created modern federalism by strengthening the powers of national government and making its key offices directly responsible to the people. Modern federalism was a significant innovation in both institutional design and popular sovereignty: the people became dual citizens, or members of the new national union while remaining members of the smaller state unions. Federalism was also a key feature of republican government, with powers controlled and limited through being divided between governments and constitutionally specified. The federal constitution was based upon popular sovereignty, with the leading institutions either directly elected or indirectly accountable to the people.

Federalism is a popular form of government adopted by quite heterogeneous countries. A survey by Ronald Watts (1999) lists 24 countries – 23 since the collapse of Yugoslavia – that account for about 40 percent of the world’s population, although the bulk of these are in India. The list includes quasi federations and federations that retain some overriding national powers that are more typical of unitary government. Examples are India, Pakistan, and Malaysia that have central emergency powers, while South Africa retains elements of its pre 1996 unitary system. Because of their diversity in political culture and stage of development, federations are usually grouped in clusters of more similar countries by scholars. The well established Anglo and European federations, Australia, Canada, and the United States, together with Austria, Germany, and Switzerland, are often assumed to be the core federal

systems. Other groupings in comparative studies are Latin American federations, to which Spain is now added, and less developed countries, of which Nigeria is a leading example. India tends to be studied separately because of its vast size and complexity. Federalism is also used as a paradigm for articulating federal tendencies in unitary countries, for example fiscal decentralization in China, or describing aspects of groupings of countries such as the European Union, which is more a confederation of nation states.

Federalism’s popularity is due to its flexibility as a form of government that can serve diverse and multiple purposes. It has proved resilient in the enduring older federations of Switzerland, the United States, Canada, and Australia, all of which have their origins in smaller established states coming together to form new national unions, and have prospered for more than a century. Federalism has been successfully reestablished in Germany and Austria, countries with long federal traditions, after World War II and periods of centralist rule. Federalism has become an attractive way for enabling unitary states like Belgium, Spain, and South Africa to decentralize. Federalism can be adopted primarily for any or all of a variety of purposes: to decentralize government and serve regional communities in large and diverse countries, to control government powers in order to safeguard individual rights and preserve market economies, to serve ethnically diverse societies that are regionally based, or to accommodate regions that are geographically distinct or at different stages of economic development. The United States and Australian federations have mainly decentralist and liberal purposes; Switzerland and Canada have a more fundamental ethnic purpose, as does Ethiopia, which allows a right of succession; Russia and the Latin American federations, Argentina, Brazil, Venezuela, and Mexico, have a combination of purposes including accommodating different stages of economic development among regions; while India has elements of all purposes.

While federalism is embodied in a variety of ways in federal countries, there is a set of institutions commonly identified as typical by federalism scholars. These are (1) a written constitution that specifies the division of

powers between national and state governments and is hard to amend; (2) a bicameral legislature with a strong federal chamber to represent the states; (3) a supreme court to protect the constitution through exercising the power of judicial review; and (4) a system of intergovernmental institutions to facilitate collaboration in areas of shared or overlapping jurisdiction. None of these features is exclusively federal, and each one can be found in varying forms in non federal countries. Taken together, they are considered to constitute the core federal institutions. Additional institutions that have been proposed as essential for federalism are a political party system that channels elites' behavior to support federalism; and well established state institutions that are sufficiently robust to withstand the tendency toward centralist power. Whether federalism suits a particular country and how well it works depends as much on political culture, traditions, and politics as it does on institutional design. For example, state governance that serves ethnically distinct regions can facilitate national integration or fragmentation.

While some have advocated a coordinate model of federalism – having separate and distinct powers for each sphere of government – concurrent or shared jurisdiction is the norm. Both levels of government are usually present in most major policy areas, so that intergovernmental arrangements and management are required to keep the systems working. Federal policymaking can be “interstate,” with varying degrees of competition between national and state governments, as tends to be the case in Anglo federations, or “intrastate,” as in the German and Austrian cases where the states, or *Länder*, are incorporated into national policymaking. Federalism has been variously criticized in the past as a weak, obsolete, or obstructive form of government, but its survival and recent flourishing belie those claims. The ways in which federalism affects policy innovation and development are complex, variable over time, and contingent upon political and cultural developments. Federalism provides both multiple veto points for blocking new policies and multiple entry points and sites for innovators. Federalism seems more compatible with the paradigm shift from a world of sovereign nation states to one of increased

interstate linkages and international rule making and standard setting. Even so, the effects of globalization, for better or worse, will be mediated through national institutions including federalism, and depend to a considerable extent upon national attributes, including heritage, ethnocultural composition, and political economy.

female genital mutilation

Susan Hagood Lee

Female genital mutilation (FGM) is the ancient cultural practice of removing portions of a girl's genitalia. It occurs extensively in northern Africa on girls from infancy to puberty, with significant negative medical consequences. Many Muslims believe that it is a religious duty. The procedure reduces sexual desire and the patriarchal groups which practice FGM consider it necessary to maintain a girl's good reputation for marriage. Uncircumcised girls are believed to be unclean and promiscuous. In response to political pressure from African women's organizations, 14 countries have banned the procedure. Nonetheless, it continues to be practiced and has become increasingly medicalized. Grassroots change efforts working within cultural norms have been the most successful.

The World Health Organization defined FGM in 1995 as follows: “Female genital mutilation comprises all procedures that involve

partial or total removal of female external genitalia and/or injury to the female genital organs for cultural or any other non therapeutic reasons." The practice is also known as female circumcision (FC) or female genital cutting (FGC). The term FGM is used by international agencies, led by the World Health Organization. Some see the term as culturally judgmental and prefer the terms used by practitioners, namely circumcision (English speaking areas), excision (French speaking areas), or cutting. In Arabic, the language of many proponents of female circumcision, the practice is known as *tahara*, cleanliness or purification.

FGM occurs in four patterns or types. In Type I, the prepuce or hood over the clitoris is removed, sometimes together with part or all of the clitoris itself. This type is known by some as Sunnah circumcision, meaning in accordance with Muslim law. In Type II, the most common form with 80 percent of cases, the clitoris is removed (clitoridectomy), together with parts or all of the labia minora. Type III excision involves removal of all external genitalia, including clitoris, labia minora, and labia majora, and stitching together of the remaining tissue with a small opening for the passage of urine and menstrual blood. This type is called infibulation, Pharaonic circumcision, or Sudanese circumcision, and comprises 15 percent of cases. Type IV refers to other sorts of female genital mutilation, such as pricking, piercing, stretching or incision of the clitoris or labia, cauterization of the clitoris, cutting of the vagina, and introduction of corrosive substances or herbs into the vagina.

The practice occurs most frequently in northern Africa. In Somalia, Egypt, and Djibouti, 97 percent to 98 percent of all adult women have been circumcised. In the Sudan, 90 percent of adult women have been circumcised. Infibulation, the most severe type of FGM, is the traditional practice in these countries, though clitoridectomy has become more common in Egypt. Female circumcision is practiced in 28 African countries in all, including the East African countries of Ethiopia and Eritrea as well as the West African nations of Mali, Sierra Leone, Gambia, Guinea, Burkina Faso, and Nigeria. The prevalence within these countries sometimes varies dramatically by ethnic group. Education and urban residence reduce

the incidence of FGM somewhat. However, as many as 90 percent of Egyptian women with a secondary degree have been circumcised. Arabian countries near eastern Africa, such as Yemen, Oman, and the United Arab Emirates, also practice female circumcision. Muslim communities in other parts of the world, such as Indonesia and Malaysia, practice a less severe form of female circumcision, where a single drop of blood is drawn from the prepuce or clitoris. The practice of FGM has been carried to Europe and North America by African immigrants. It is estimated that in the US, 10,000 girls are at risk of being circumcised. Worldwide, around 140 million women or about 5 percent of the world's female population have been subjected to FGM. Two million additional girls are circumcised annually, around 6,000 girls per day.

The age at which girls undergo FGM varies according to the customs of their local village and region. The most common age is from 4 to 8 years. In some areas, infant girls are circumcised, while in other places, circumcision takes place upon the onset of menstruation or when a girl reaches the marriageable age of 14 to 16 years. In Egypt, girls are circumcised between the ages of 8 and 14 years. Typically, the procedure is performed in unsanitary conditions with ordinary cutting utensils such as razor blades, scissors, kitchen knives, or broken pieces of glass. The same cutting utensils are often used on several girls in succession without cleaning. Anesthesia is rarely used in village settings. In most areas, circumcision is carried out by older women, known in eastern Africa as *dayas*, who derive a substantial portion of their income from the ritual. In Sierra Leone, circumcisers are highly respected women viewed as priestesses by their followers. They head the traditional secret societies for excised girls in West Africa.

In a typical circumcision, according to Kathleen Kilday (1990), the girl lies down or sits on a low stool while her female relatives hold her head and arms tightly and stretch her legs apart. The women shout chants of encouragement to the girl, sometimes accompanied by loud drumming, as she struggles and cries out under the pain of cutting. After the excision, the relatives inspect the wound to verify that enough has been removed and the girl is sewn

up with catgut or silk. In Somalia, thorns are used. The open wound is covered with herbs to stem the bleeding and promote healing. The girl's legs are often bound together for a period of time during recovery and urination is particularly painful. According to Nawal El Saadawi (1980), who worked as a physician in rural Egypt, girls remember their circumcision as a searing pain, "like a burning flame" (p. 34). They feel betrayed by the people they trusted the most, their mother and other female relatives. Most come to accept the cultural explanation that the procedure is necessary to be a clean and pure woman prepared for marriage. When they become mothers of girls, they perpetuate the practice. Ellen Gruenbaum (2001) notes that women interviewed about their own circumcision remembered it vividly as a pivotal event of their childhood. Some laughed off the memories of the pain while others attributed it to the inevitable fate of women. A few work for cultural change.

Health consequences of FGM vary according to the conditions under which the procedure is conducted and the extent of the excision. In the typical village setting, the immediate health consequences for all types of FGM are infection from the use of unsanitary instruments, including HIV transmission. In some cases, girls die due to shock, hemorrhage, or septicemia. With infibulation, the urethral opening may be inadvertently blocked, preventing the girl from urinating, and she must be taken to a hospital for surgical intervention. Over the long term, women who have undergone FGM are more likely than non circumcised women to have urinary tract infections and pelvic inflammatory disease, sometimes resulting in infertility. Women who have experienced clitoridectomy and infibulation may have problematic abscesses and scarring as well as delayed menarche and difficulty reaching orgasm. Upon marriage, infibulated women must be opened for intercourse. In some areas, the husband is expected to open his wife with his penis or face dishonor. To avoid the humiliation of calling in the midwife if he is unable, a husband may cut his wife open himself with a razor or piece of glass. In other areas, the groom is expected to open his wife with a dagger on their wedding night.

Childbirth poses special risks for women with extensive excisions. Since scar tissue does

not stretch, labor is more likely to be prolonged and difficult and may involve additional cutting to permit delivery. Infibulated women may endure obstructed labor, resulting in a ruptured perineum for the mother and brain damage or death for the infant. Newborns of infibulated women are more vulnerable to infection. Infibulated women are almost always reinfibulated after delivery, and each subsequent delivery becomes more difficult as the amount of scar tissue in the area increases. Concomitant with these physical consequences of FGM, women may experience psychological repercussions such as depression, anxiety, and fear of sexual intercourse.

Female circumcision is a meaningful cultural event for practitioners. Among Muslim groups, it is widely believed to be a religious duty stipulated in the Qur'an. In reality, the Qur'an does not mention circumcision at all, for either females or males. Muslim references to circumcision occur in the secondary writings called the hadith or sayings of Mohammed where, in a conversation with an exciser called Um 'Atiyyah, the Prophet confirmed that female circumcision was allowed within limits. Some Muslim commentators have challenged the validity of this hadith. Many Muslim leaders have supported the practice of female circumcision, with one imam ruling that while it is not obligatory, it is an honorable deed and recommended for Muslims. A few Muslim leaders have strongly condemned the practice and have led efforts to abolish it in places such as Senegal. They point out that the practice predates Islam and it is not observed in Saudi Arabia, the birthplace of Mohammed. Not only Muslims but also other religions engage in female circumcision in East Africa, including Protestants, Catholics, Coptic Christians, and Ethiopian Jews.

Practitioners give many non religious reasons for FGM. Concerns about virginity and marriage are paramount. Female circumcision reduces sexual desire and increases the likelihood that the girl will remain a virgin. A girl is considered unclean and promiscuous if she is not circumcised and so is a less attractive marriage choice. Marriage is the predominant occupation for women in these traditional low income societies. Parents who do not circumcise their daughters are seen as inexcusably

neglectful of their daughter's future. Infibulation, the most severe sort of circumcision, increases a girl's marriage value since the very small opening ensures the girl's virginity. Infibulation is thought to increase male pleasure in sexual intercourse and so to contribute to a stable marriage. In the Sudan, infibulation confers higher class status on the girl and her family than more mild types of FGM. Parents consider these cultural benefits for their daughters and their families when deciding about circumcision.

FGM takes place in patriarchal cultures where women's status or even survival is dependent on pleasing men. Women take drastic steps to change their bodies in ways which improve their appeal to a male audience. Mothers arrange the circumcision of their daughters, midwives perform the operation, and female relatives serve as the cheering squad. One may compare the practice to cosmetic surgery in the West, another case where cultural notions of female beauty move women to engage in drastic medical interventions to increase their appeal to men. The significant difference is the lack of anesthesia or sanitary conditions in female genital mutilation.

FGM reveals the ancient patriarchal concern with control of female sexuality, key to maintaining the male dominated social structure. In regions which practice FGM, female sexuality is believed to be wild, aggressive, and threatening to the social order. Without preventive restraints, girls will be promiscuous and wives will wander. The West has also resorted to genital surgery to control female sexuality. In nineteenth century Britain and the United States, surgical removal of the clitoris was an accepted way to cure hysteria, masturbation, and other alleged female illnesses.

In colonial Africa, the British opposed the practice of FGM in their colonies, especially Sudan and Kenya, despite popular protests. Legal efforts to abolish FGM today are hampered by identification with colonialism. Some African leaders believe that to ban the practice is to undermine both African culture and Islam. They fear repercussions on other aspects of African culture, such as the West African female secret societies. Other African leaders have led the fight against FGM. The president of Burkina Faso, Thomas Sankara, strongly

opposed FGM before his assassination in 1987. Awa Thiam of Senegal was a pioneer in organizing female opposition and bringing political pressure on her country to abolish FGM. Fourteen African countries have passed laws banning FGM. The laws are not enforced, however. Low income countries do not have effective law enforcement even in urban areas, much less in rural villages. Progressive central governments, influenced by modern ideas, may pass laws that rural areas never hear of, much less obey. Even in urban areas, the cultural forces setting the stage for FGM require more than legislation to change.

In 1984, African women's non governmental organizations working on FGM met in Dakar, Senegal and formed the Inter African Committee on Traditional Practices Affecting the Health of Women and Children (IAC). The Committee has affiliates in 26 African countries and coordinates abolition efforts. The IAC opposes the growing medicalization of FGM in countries such as Egypt, which passed laws to restrict the procedure to medical settings with anesthesia. In Kenya, hospitals perform FGM despite a total legal ban. Medical professionals argue that the practice is better done in a hospital than in unsanitary conditions, while women's groups lobby the government to enforce the ban.

Successful efforts to change the prevalence of FGM have featured comprehensive action by government, the medical community, communities of faith, and public education. The most effective efforts have worked within the cultural context at the grassroots level. One such approach has been to replace FGM with another initiation ritual, such as a one week program in Kenya called "Circumcision through words." It teaches girls about self esteem, health issues, and problem solving and culminates in a coming of age ceremony with certificates, gifts, and feasting. In some areas, traditional midwives are trained to become salaried community health care workers who educate villagers on the dangers of FGM as well as other women's health issues. Some efforts have looked at the need for girls' education and economic development to lessen women's dependence on men. The most successful eradication efforts have been in Senegal with the Tostan project. Organized

by local women working with village religious leaders and supported by the national government, entire villages have taken a public pledge to refrain from circumcising their girls or marrying their sons to circumcised women.

female masculinity

Silvia Posocco

Female masculinity refers to a range of masculine inflected identities and identifications. Debates over the status and meaning of female masculinity and the bodies and selves to whom the terms may be ascribed emerge in the context of analyses of sex, gender, and sexuality.

Research in social and cultural history has documented the lives of individual women who

defied gendered conventions, adopted masculine clothing, and/or engaged in gendered nonconformist behavior in Anglo American and European contexts from the eighteenth to the early twentieth centuries (Wheelwright 1989). The case of Colonel Victor Barker, for instance, caused notable controversy in England in the early twentieth century, as this military man was exposed to be female bodied and deserv-ing a perjury trial (Wheelwright 1989). Scholarly approaches to archival material have tended to challenge transhistorical claims of stable forms of female masculinity across time (Halberstam 1998; Doan 2001). Assumed relations of equivalence and translatability between and across culturally specific practices relating to female masculinity have also appeared suspect (Blackwood 1998).

Key to the development of innovative conceptual trajectories on female masculinity in interdisciplinary academic gender studies are the numerous critical readings of Radclyffe Hall's novel *The Well of Loneliness* (1928) and related analyses of its cultural, social, and historical context. In her pioneering essay on the subject, anthropologist Esther Newton (2000 [1984]) notes that Hall's novel constitutes a central reference for paradigmatic imaginings of female masculinity in the twentieth century, and the ground for the entrenchment and popularization of a relation between female masculinity and lesbianism. Newton (2000 [1984]: 177) shows how, since the obscenity trial that took place in London in 1928, the novel's protagonist Stephen Gordon has acquired "mythic" archetypal status as a "mannish lesbian," that is, "a figure who is defined as lesbian because her behavior or dress (and usually both) manifests elements designated as exclusively masculine." Further analysis reveals that the subject matter of the novel exemplifies the cultural salience of discourses of sexology in early twentieth century England, the social significance of the medicalized category of "the invert," and the ways in which these discourses played out in the public domain (Prosser 1998; Doan 2001). A different reading is offered by de Lauretis (1994), who highlights the relevance of psychoanalysis to an understanding of the relation between masculine identification and lesbianism in *The Well of Loneliness*. It is de Lauretis's contention that

the Freudian "masculinity/virility complex," with the female subject's longing for a masculine identification, should be reinterpreted and not entirely dismissed. De Lauretis (1994: 211–12) argues that Stephen Gordon's subjectivity comes into being through a fantasy of "bodily dispossession," as the melancholic subject mourns a feminine embodiment that she can desire but does not fully embody, and a masculinity that she does embody but that is never maleness. In short, an original fantasy of castration underpins Stephen Gordon's bodily dispossession, with her muscular body standing for the paternal phallus which ultimately places the female body beyond reach.

Halberstam (1998) challenges this psychoanalytic reading and instead proceeds from the premise that unhinging the relation between masculinity and men can yield important insights into the social and cultural production of masculinity. This theoretical move reveals a spectrum of female masculine inflected subject positions, identities, and identifications that in the nineteenth century included the androgyne, the tribade, and the female husband. In mid to late twentieth century Anglo American contexts, female masculinity comprises soft butch, butch, stone butch, and transbutch identities and identifications, the youthful exuberance of tomboys and the parodic performances of drag kings. Building on Rubin's (1992: 467) classic definition of butch as "a category of lesbian gender that is constituted through the deployment and manipulation of masculine gender codes and symbols," Halberstam (1998) aligns her spectrum of female masculinities, including the figure of the stone butch, firmly with lesbianism. However, in his analysis of transsexual autobiographies, Prosser (1998) contests this point and speaks of butch and stone butch identities as "propellers" toward transgender and transsexual identifications. Butch and stone butch thus become entangled in "border wars" (Hale 1998) that are as much about subjectivities as they are about the intellectual strategies at our disposal for understanding the articulation and experience of sex, gender, and sexuality.

In view of this, future research should aim to clarify the relation between female masculinity and queer theory. Whilst the emphasis on masculinity may correspond to a generalized rejection of the feminine and a specific form

of misogyny associated with queer theory (Martin 1994), previous analyses should be complemented by a sustained focus on the psychic and performative processes of production of masculine inflected identities and how these may be implicated in processes of identification and disidentification with, for instance, femme and feminine identities. Second, a response to Newton's call (2000 [1984]: 66) for analyses that address the ways in which aesthetic, social, and cultural categories may function ethnographically is long overdue. This confirms the importance of investigating social taxonomies of female virility and masculine experience, their contexts and meanings in everyday life.

female sex work as deviance

Ronald Weitzer

Sex work (in this case, involving female workers) refers to sexual services or performances provided in return for material compensation. Examples include pornography, prostitution, stripping, and telephone sex. The most common forms of sex work involve female workers and male customers – which reflects larger, traditional gender relations between men and women. Objectification of women is taken to the extreme in sex work, where the workers are valued almost exclusively for sexual purposes. The existence of commercial sex also provides men with an avenue for reaffirming their masculinity, by satisfying their “need” for sexual stimulation and fantasy or their desire for a certain type of sex with a certain type of woman. The gendered character of the sex industry is also evident in its power structure: most managers are men who exercise control over female workers and reap much of the profit. In general, power is largely concentrated in the hands of pimps, traffickers, and those who run brothels, strip clubs, and companies that produce and distribute.

Many people view sex work as deviant behavior. The opinion polls presented in Table 1 reveal that the majority of Americans see both prostitution and pornography as immoral;

three quarters believe that we need “stricter laws” to control pornography; and a substantial number want prostitution to remain illegal, strip clubs and massage parlors closed, and pornographic magazines/videos banned.

Over the past three decades some cities and suburbs have indeed banned or restricted massage parlors, strip clubs, and X rated video stores. During the Reagan administration the Justice Department launched a massive campaign against distributors of adult pornography, prosecuting them for obscenity in conservative areas of the country (“obscenity” is determined by local “community standards” as determined by a jury). The campaign was successful in putting a significant number of distributors out of business. Under President Clinton the Justice Department shifted its attention away from adult pornography and intensified enforcement against child pornography (Weitzer 2000: 11–12). Prostitution is illegal throughout the US, with the exception of rural counties in Nevada, where legal brothels have existed since 1971.

Americans are less tolerant of the sex industry than citizens in several other western societies. Certain types of prostitution, for example, are legal or tolerated in some European nations (e.g., the Netherlands, Germany), and opinion polls indicate that a majority of the population in Britain, Canada, France, and Portugal favor legalizing prostitution (Weitzer 2000: 166).

Some types of sex work are more heavily stigmatized than others. As Table 1 shows, stripping is less widely condemned than work

Table 1 Public opinion on sex work

	<i>% Agreeing</i>
Pornography leads to a “breakdown of morals”	62
Internet porn is a “major cause of the decline in moral values” in US	62
Looking at pornographic magazines is morally wrong	58
Pornography “degrades women because it portrays them as sex objects”	72
Need “stricter laws” to control pornography	77
Telephone-sex numbers should be illegal	76
Strip clubs should be illegal	46
Morally wrong for a “man to spend an evening with a prostitute”	61
Prostitution should be illegal	70
Media should publish names and photos of men convicted of soliciting prostitutes	50
Close massage parlors and porn shops that “might permit casual sex”	70

Sources: Opinion polls of Americans conducted between 1977 and 1996 (Weitzer 2000).

that involves direct sexual contact (prostitution, pornography). In general, sex workers are more stigmatized than their customers. This is because, first, the former engage in disreputable activity more regularly, whereas the customers typically participate occasionally and, second, a cultural double standard exists, whereby the sexual behavior of female sex workers is more circumscribed than the sexual behavior of their male clients. One reason for this disparity is that female sex workers break gender norms for women – by being sexually aggressive and promiscuous – whereas male customers' behavior is consistent with traditional male sexual socialization, which puts a premium on sexual titillation and valorizes sexual conquest as evidence of masculinity. Many men are willing to pay for sexual titillation in the form of pornography, exotic dancing, and Internet and telephone sex, and a minority has had contact with a prostitute. One third of American men report that they have watched an X rated video in the past year, 11 percent have been to a strip club in the past year, and 18 percent admit to having paid for sex at some time in their lives (Weitzer 2000: 1–2).

Because they are stigmatized, female sex workers typically attempt to deflect the stigma. They compartmentalize or separate their deviant work persona from their “real identity”; conceal their work from family and friends; describe their work in neutral or professional terms (“dancer” or “entertainer” instead of “stripper”; “actress” instead of “porn star”); and they may see themselves as performing a useful service (keeping marriages intact, engaging in sex therapy, providing emotional support to customers).

There are some major differences between street prostitution and indoor sex work (escorts, call girls, strippers, telephone sex workers, workers in brothels and massage parlors). First, street prostitutes are more heavily stigmatized than indoor workers. Some popular cultural depictions romanticize call girls while denigrating women who work the streets. Second, risk of exposure to sexually transmitted diseases varies between street and indoor workers. HIV infection rates vary markedly among street prostitutes (with the highest incidence among street workers who inject drugs or smoke crack cocaine), but HIV infection is rare among call

girls and other indoor workers. Third, indoor workers, and especially call girls and escorts, generally exercise more control over working conditions, express greater job satisfaction, and have higher self esteem than do street workers (Weitzer 2005). Fourth, street prostitutes are much more likely to be victimized. Street workers are more vulnerable to being assaulted, robbed, and raped by customers, pimps, and other men, and some have been kidnapped and killed. Indoor workers are much less vulnerable to such victimization, as several comparative studies show (Weitzer 2005). There is one important exception: women and girls who are recruited by force or fraud and trafficked to work in indoor venues (brothels, massage parlors, etc.) in another country (Kempadoo 2005). Such individuals are victimized from the very outset, and they differ dramatically from other types of indoor workers who make a conscious choice to enter the trade and have more control over their working conditions.

In sum, workers in different sectors of the sex trade have different kinds of work experiences – that is, varying degrees of stigma, victimization, exploitation, and freedom. The type of sex work makes a significant difference, and grand generalizations about “sex work” should be avoided.

Traditionally, the authorities in the US and elsewhere paid fairly little attention to customers involved in the purchase of illegal sex services or products. Until recently the criminal justice system targeted workers almost exclusively, all but ignoring the customers of prostitutes (or “johns”). Laws in the US and other societies continue to punish patronizing less severely than prostitution, and in most jurisdictions arrests of prostitutes far exceed those of customers. Customers who are prosecuted and convicted typically receive lower fines and are less likely to receive custodial sentences than prostitutes. This, despite the fact that arrested johns are much less likely to recidivate than arrested prostitutes. Only recently have the authorities in some cities begun to arrest customers in substantial numbers, but this is exceptional. But a substantial number of Americans want customers sanctioned: in a representative poll conducted in 1995 for *Newsweek*, half the population favored

a policy of displaying in the media the names and photos of men convicted of soliciting a prostitute (see also Table 1). The one area where law enforcement has intensified the most is against those who possess child pornography. This development is a fairly recent trend in the social control of persons involved in sexual exploitation of minors.

Customers have attracted far less research than sex workers, but some recent studies do focus on the clients. Many johns are middle aged, middle class, and married, but we are only beginning to understand their motivations, attitudes, and behavior patterns. A few studies suggest that customers patronize prostitutes for the following reasons: they desire certain types of sexual experiences (e.g., oral sex); they desire sex with a person with a certain image (e.g., sexy, raunchy, etc.) or with specific physical attributes (e.g., racial, transgender); they find this illicit and risky conduct thrilling; they wish to avoid the obligations or emotional attachment involved in a conventional relationship; they have difficulty finding someone for a conventional relationship (Jordan 1997; Monto 2000).

In the largest study yet conducted, 43 percent of customers reported that they "want a different kind of sex than my regular partner" provides; 47 percent said that they were "excited by the idea of approaching a prostitute"; 33 percent said they did not have the time for a conventional relationship; and 30 percent said they did not want the responsibilities of a conventional relationship (Monto 2000). Men who patronize call girls or escorts are often looking for companionship and emotional support, in addition to sex. Lever and Dolnick's (2000) comparison of call girls and street prostitutes in Los Angeles found that customers expected and received much more emotional support from the call girls, and Prince (1986) found that 89 percent of call girls in California and 74 percent of Nevada's brothel workers believed that "the average customer wants affection or love as well as sex" – the view of only one third of streetwalkers.

Some other studies examine customers of legal sectors of the sex industry, such as men who watch pornography, who call telephone sex lines, and who visit strip clubs. Flowers (1998) found that some telephone sex callers

want to fulfill ordinary sexual scenarios while others fantasized about incest, rape, pedophilia, bestiality, and mutilation. (Some phone sex operators refuse to take part in these fantasies and even try to curb some of the more extreme interests of the caller.) Customers of strip clubs, as Frank (2002) found, seek not only sexual stimulation and fantasy, but also want the company of attractive women. They enjoy talking, flirting, and sharing details of their lives with the women, and regular customers try to become friends with the dancers. Frank's book is the only study to focus on the customers rather than the strippers.

A largely unexplored area is that of female customers of male prostitutes – a small but important fraction of the market. Some women tourists in the Caribbean and other vacation spots buy sex from young male prostitutes, whom they meet on the beaches and at clubs. Taylor's (2001) study of 75 female tourists in Jamaica and the Dominican Republic who reported that they had had sexual encounters with local men found that 60 percent of the women had paid the men with money, gifts, and/or meals. There are some basic similarities between female sex tourism and male sex tourism (e.g., economic inequality between buyer and seller), as well as some differences (e.g., female sex tourists rarely assault or rob male prostitutes).

The sex industry has grown in the past two decades and has spread into new markets. This trend began with the creation of video recorders, followed by the advent of pornography on cable television, the rise of telephone sex operations, the growth of escort agencies, and the opportunities afforded by the Internet. The Internet offers unprecedented access to every kind of pornography imaginable, and also facilitates cyber exchanges, information sharing, and subsequent face to face encounters between clients and strippers, escorts, and other female sex workers. Furthermore, Internet message boards and chat rooms allow customers and others to discuss personal experiences with providers and share more general opinions of the sex industry. Participants discuss where to locate certain kinds of workers or a massage parlor; what to expect in terms of prices and services; "reviews" of a specific worker's appearance and behavior; and warnings on

recent law enforcement activity in a particular city. The sites also provide unique insight into customer beliefs, expectations, justifications, and behavioral norms. Review of these sites confirms that many customers are looking for more than sex; they place a premium on the provider being friendly, conversational, kissing, cuddling, and providing what they call a “girlfriend experience” with a semblance of romance and intimacy (Weitzer 2005). Many of the cyber exchanges discuss appropriate and inappropriate client behavior toward sex workers, and errant individuals are chided for violating this emergent code of ethics. This normative order is a byproduct of discourse on Internet sites, something that did not exist previously.

Despite the proliferation of commercial sex over the past two decades, sex workers and their customers continue to be seen by many Americans as involved in disreputable, deviant behavior. In other words, it would be premature to say that any part of the sex industry has become “mainstream.” Both the workers and their clients remain stigmatized.

femininities/ masculinities

Amy Lind

Femininities and masculinities are acquired social identities: as individuals become socialized they develop a gender identity, an understanding of what it means to be a “man” or a “woman” (Laurie et al. 1999). How individuals develop an understanding of their gender identity, including whether or not they fit into these prescribed gender roles, depends upon the context within which they are socialized and how they view themselves in relation to societal gender norms. Class, racial, ethnic, and national factors play heavily into how individuals construct their gender identities and how they are perceived externally (hooks 2004). Gender identities are often naturalized; that is, they rely on a notion of biological difference, “so that ‘natural’ femininity [in a white, European, middle class context] encompasses, for example, motherhood, being nurturing, a desire for pretty clothes and the exhibition of emotions” (Laurie et al. 1999: 3). “Natural” masculinity, in contrast, may encompass fatherhood, acting “tough,” a desire for sports and competition, and hiding emotions (Connell

1997; Thompson 2000). In both cases, these constructions of gender identity are based on stereotypes that fall within the range of normative femininities and masculinities. Yet, as many sociologists have pointed out, not all individuals fit within these prescribed norms and as such, masculinities and femininities must be recognized as socially constituted, fluid, wide ranging, and historically and geographically differentiated (Connell 1997; Halberstam 1998; Laurie et al. 1999).

Feminist scholars have long addressed the social construction of femininities, particularly in the context of gender inequality and power (Lorber 1994). Early second wave feminist scholars such as Simone de Beauvoir (1980) argued that women's subordinated status in western societies was due to socialization rather than to any essential biological gender difference, as evidenced in her often cited phrase, "One is not born, but rather becomes, a woman." Many feminist scholars in Anglo Saxon and European countries have emphasized social construction over biological difference as an explanation for women's ways of being, acting, and knowing in the world and for their related gender subordination (Gilligan 1993). Some feminist scholars have addressed the social construction of femininities as a way to explain wage inequality, the global "feminization of poverty," and women's relegation to "feminine" labor markets (e.g., secretarial labor, garment industry, caring labor) and to the so called private realm of the household and family (Folbre 2001). Because feminists were primarily concerned with the question of women's subordination, masculinities themselves were rarely analyzed except in cases where scholars sought an explanation for male aggression or power. Likewise, hegemonic femininity was emphasized over alternative femininities such that the experiences of women who did not fit into socially prescribed gender roles were either left unexamined or viewed through the normative lens of gender dualisms (Halberstam 1998).

Particularly since the 1980s, at least three areas of research on gender identity have helped shift the debate on femininities and masculinities: (1) masculinity studies, which emerged primarily in the 1980s and 1990s; (2) queer studies and lesbian, gay, bisexual,

and transgender (LGBT) studies, including the pivotal research of Butler (1990); and (3) gender, race, ethnic, and postcolonial studies, a trajectory of scholarship in which researchers have long critiqued hegemonic forms of masculinity and femininity on the basis that these racialized constructions helped reinforce the criminalization and subordination of racial/ethnic minorities in industrialized societies and the colonization of both men and women in poor and/or non western regions.

In contrast to feminist scholarship that focused primarily on women's experiences with femininity, Connell's (1987) research on "hegemonic masculinity and emphasized femininity" was among the first to systematically analyze both sets of constructions as they contribute to global gender inequality. Connell argues "hegemonic masculinity," a type of masculinity oriented toward accommodating the interests and desires of men, forms the basis of patriarchal social orders. Similarly, "emphasized femininity," a hegemonic form of femininity, is "defined around compliance with [female] subordination and is oriented to accommodating the interests and desires of men" (p. 23). Borrowing from Gramsci's analysis of class hegemony and struggle, Connell develops a framework for understanding multiple competing masculinities and femininities. He argues that hegemonic masculinity is always constructed in relation to various subordinated masculinities as well as in relation to women. Thus, for example, non European, poor, non white, and/or gay men tend to experience subordinated masculinities, whereas men of middle class European, white, and/or heterosexual backgrounds tend to benefit from the privileges of hegemonic masculinity.

Especially since the 1980s, scholars of masculinity studies have produced innovative research on various aspects of men's lives and experiences. Messner (1992), for example, examines men's identifications with sports as an example of how masculinities are constructed and maintained. Messner analyzes the "male viewer" of today's most popular spectator sports in terms of the mythology and symbolism of masculine identification: common themes he encounters in his research include patriotism, militarism, violence, and meritocracy. Scholars of gay masculinities have

addressed how gay men of various ethnic, racial, class, and national backgrounds have negotiated hegemonic masculinity, sometimes in contradictory ways, and constructed alternative masculinities through their everyday lives (Messner 1997).

Importantly, research on hegemonic masculinities sheds light on how and why masculinity has been largely “invisible” in the lives of men who benefit from hegemonic masculinity and in the field of women’s/gender studies, which tends to focus on the experiences of women. Although there are obvious reasons why the field of women’s/gender studies has focused primarily on women, since women experience gender inequalities more than men, scholars increasingly have pointed out that male socialization processes and identities, as well as masculinist institutions and theories, should be examined as a way to rethink gender inequality. As Kimmel (2002) notes: “The ‘invisibility’ of masculinity in discussions of [gender] has political dimensions. The processes that confer privilege on one group and not another group are often invisible to those upon whom that privilege is conferred. Thus, not having to think about race is one of the luxuries of being white, just as not having to think about gender is one of the ‘patriarchal dividends’ of gender inequality.”

Judith Butler’s research on gender performativity has opened space for discussion about the naturalized linking of gender identity, the body, and sexual desire. Butler (1990) argues feminism has made a mistake by trying to assert that “women” are a group with common characteristics and interests. Like sociobiologists, feminists who rely exclusively on a sociocultural explanation of gender identity construction also fall prey to essentialism. Many individuals, especially those who define as “queer” or as lesbian, gay, bisexual, or transgendered, do not experience gender identity, embodiment, and sexual desire through the dominant norms of gender and heterosexuality. Influenced by Foucault, Butler suggests, like Connell, that certain cultural configurations of gender have seized a hegemonic hold. She calls for subversive action in the present: “gender trouble,” the mobilization, subversive confusion, and proliferation of genders, and therefore identity. This idea of identity as free floating

and not connected to an “essence” is one of the key ideas expressed in queer theory (EGS 2005).

Butler and other queer theorists have addressed how normative femininities and masculinities play a role in disciplining the lives of LGBT individuals. Halberstam’s (1998) research addresses constructions of “female masculinity” and argues that scholars must separate discussions of gender identity (e.g., masculinities, femininities) from discussions of the body. Women can “act masculine” just as men can “act feminine”; how individuals identify in terms of their gender is not and should not be linked to their biological anatomies, however defined. Halberstam’s own research addresses how masculine identified women experience gender, the stratification of masculinities (e.g., “heroic” vs. alternative masculinities), and the public emergence of other genders. Other scholars have examined how medical and scientific institutions have managed normative gender (and sexual) identities through psychological protocols and surgical intervention (Fausto Sterling 2000). This type of research points toward a broader understanding of gender that places dualistic conceptions of “masculine” vs. “feminine” and “male” vs. “female” into question.

Scholars of race, ethnic, and postcolonial studies have addressed how normative femininities and masculinities, which tend to benefit those with racial/ethnic privilege, help reinforce a racialized social order in which subordinated groups are demasculinized or feminized in ways that maintain their racial/ethnic subordination in society. One example involves the stereotyping of African American men as unruly and hypersexual. The “myth of the male rapist,” as Davis (2001) has discussed, has played a highly destructive role in black men’s lives and has influenced legal, political, and social actions toward them, including their disproportionate criminalization for rape, often based on fraudulent charges. Another example concerns immigrant men racialized as minorities in the US. Thai (2002) illustrates how working class Vietnamese American men have developed innovative strategies to achieve higher status in their communities by marrying middle to upper class Vietnamese women and bringing them to the US. Faced with few

marriage options and low paying jobs in the US, working class Vietnamese American men who experience a form of subordinated masculinity seek upward mobility through these transnational marriage networks.

Women of color in the US and working class women in developing countries also face unequal access to hegemonic femininity, as defined in western terms. Hill Collins (2004) addresses how African American women have been hypersexualized in US popular culture, thereby placing them outside the realm of normative femininity according to hegemonic white, western standards. Postcolonial studies scholars have demonstrated how poor women in developing regions (particularly non white women) have been sexualized by male tourists from industrialized countries and sometimes also by local men (Freeman 2001). More broadly, scholars of masculinities and/or femininities have pointed out how constructions of masculinities and femininities are embedded in social institutions (e.g., the state, economy, nation, educational system) and processes (e.g., social welfare policy, globalization, colonization, political campaigns, popular culture, everyday life) and shape individuals' everyday experiences and gendered self perceptions (Connell 1987, 1997; Laurie et al. 1999; Freeman 2001; Hill Collins 2004).

Critics have defended normative femininity and masculinity on religious, moral, and/or biological grounds. Some, for example, have argued that these social norms (what Connell would call hegemonic masculinity and emphasized femininity) are "naturally" aligned with men's and women's assumed biological roles in reproduction and/or with their assumed heterosexual desire (see Lorber 1994; Messner 1997). On all sides of the ideological spectrum, individuals have participated in interesting political responses and social movements that either embrace or challenge dominant societal constructions of masculinity and femininity. Some women have joined feminist movements and challenged traditional notions of femininity; whereas other women have joined right wing women's movements that embrace traditional gender roles and identities (e.g., Concerned Women for America). Men have formed feminist men's movements, based largely on the principles of women's feminist

movements, as well as movements to embrace traditional notions of fatherhood, as in the divergent examples of the Christian based (and largely white, middle class) Promise Keepers and the Million Man Marches, first organized in 1995 by Nation of Islam leader Louis Farrakhan and attended by over 800,000 African American men as part of a movement to reclaim black masculinity (Messner 1997).

Future research on femininities and masculinities will likely be influenced by the recent scholarship in the fields of masculinity studies, queer theory and LGBT studies, and race, ethnic, and postcolonial studies. Although scholars vary in their disciplinary backgrounds and methodological approaches to the study of femininities and masculinities, most would agree that femininities and masculinities can be seen as sets of rules or norms that govern female and male behavior, appearance, and self image.

feminism

Patricia Lengermann and Gillian Niebrugge

Feminism is the system of ideas and political practices based on the principle that women are human beings equal to men. Feminism may be the most wide ranging social movement in history, effecting change in the institutions, stratificational practices, and culture of nearly all societies. Its impact on sociology is the focus here. A study of this impact shows that sociology as an intellectual discipline and as a professional organization is itself deeply gendered, located in and affected by the society it attempts to study, and that its gendered

character changes only in response to changes in the gender dynamics within society – changes in part produced by the action of feminist sociologists.

As a system of ideas, feminism includes alternative discourses: liberal, cultural, materialist or socialist, radical, psychoanalytic, womanist, and postmodernist. Among these, liberal feminism and materialist feminism have been most important to sociology. Liberal feminism argues that equality with men means equal rights for women; it has focused on achieving those rights through political action, enlisting the state to prohibit practices of discrimination against women; while basically accepting the capitalist organization of society, it works for a more level playing field for women in that society. Materialist feminism attempts to incorporate Marxist or socialist ideas and focuses on social production as the key social process wherein equality must be achieved. Radical feminism has helped sociology define violence – domestic violence, spouse abuse, rape – as central to gender dynamics. Psychoanalytic feminism has effected a reworking of socialization theory. Womanist feminism challenges the concept of a unitary standpoint of “woman,” making intersectionality a key idea in feminist analysis. Postmodernist feminism has, as post modernism has done everywhere, challenged some of the basic conceptual categories of feminist analysis, such as woman and gender.

As political practice, feminism is understood as a social movement with several periods of high mobilization, called “Waves.” First wave feminism is the period from about either 1792 (the date of Mary Wollstonecraft’s *Vindication of the Rights of Women*) or 1848 (the date of the first Women’s Rights Convention in Seneca Falls, New York) to 1920 (the date that US women got the vote). Second wave feminism is the period of activism that began in the 1960s – starting events were President Kennedy’s 1961 Commission on the Status of Women headed by Esther Peterson and Betty Friedan’s *The Feminine Mystique* (1963). Third wave feminism refers to the ideas and actions of women and men who will spend the majority of their lives in the twenty first century. Between first and second wave feminism there was a period of relative quiet, a seeming hiatus (though this is debated among scholars).

The relationship between feminism and sociology has existed from the beginning of the discipline. Women have been contributors to the enterprise of sociology as creators of professional organizations, sociological theory, sociological methods, and empirical research; they have made these contributions in the discipline's founding, classic, modern, and contemporary generations – and the majority of these women have been feminists, attracted to sociology's promise that social life can be studied as a human creation, that as such it can be controlled and changed in directions that are more just. It is possible to trace four generations of feminist sociologists. First wave feminism spanned two generations of sociology: the founding (1830–80) and classic (1890–1930) generations. The primary message of first wave feminist sociologists was that women could claim a right to participate in the discipline, to do sociology – theory, method, practice. Second wave feminism began at the midpoint of modern sociology (1930–90) and continues to influence the momentum of feminist sociologists in the contemporary generation (1990–). The primary message of second wave feminist sociologists has been that women have a right to participate equally with men in the enterprise of sociology and that sociology itself is not free of the sexism that shapes the societies it studies. Despite this long continuity, the history of women's sociology has followed the rule of women's history generally – it is lost and recovered, lost again, and rediscovered generation by generation. One work of second wave feminist sociologists has been the recovery of the founding and classic generations of women in sociology. Third wave feminism will presumably pattern the dynamics of the profession in the twenty first century – a prediction that draws its strength from the fact that women increasingly constitute the majority of students at all levels in sociology programs.

FEMINISM AND THE CONCEPTUAL PRACTICES OF SOCIOLOGY

Despite the gap in historical memory between the founding and classical generations and the modern generation of feminist sociologists, it is possible to generalize about themes that mark feminist sociology across all four generations.

These themes constitute feminism's contribution to the conceptual practices of sociology. But the presence and effect of these themes in sociology turn in part on their validity as descriptors of social reality and in part on the influence of feminism as a political movement.

The major contribution of feminism to sociological practice has probably been the concept of gender, which feminism has both centralized and refined. The first attempt at identifying gender as a sociological variable was made by Gilman (1898) when she described human society as distorted by "excessive sex distinction"; by "excessive" she means any distinction between men and women beyond the biologically necessary differentiation for reproduction. But Gilman's insight, while widely hailed by women, was not followed up in sociology. The term gender was used only infrequently in sociological publications until the 1970s – and only as a synonym for sex. A sample run of a computerized database shows that between 1895 and 1969 only 69 sociology articles used the concept and in none is it a major variable or title feature; but in the decade 1970 to 1979, over 500 articles are recorded as using gender, with many featuring it in the title.

In the modern usage of gender, feminist scholars worked to distinguish it from sex and sexuality. Three main understandings of gender have emerged from the engagement of feminism and sociology: gender has been understood as a part of role performance across institutions – and most recently as an institution in its own right (Martin 2004); as a product of ongoing individual activities in which social actors consciously and unconsciously "do gender" (West & Zimmerman 1987); as a stratificational category (Acker 1973) – including the concept of "gender class" (MacKinnon 1989). Whichever of these definitions a sociologist may work out of, the key feminist achievement has been to separate gender from sex as an analytic category and to define gender as a social construction imposed on perceived biological differences. The most radical claim urged by some feminist sociologists is that "gender" can and should be dismantled, that it is a dysfunctional social structure (Lorber 1994).

Central to all these approaches to gender is the process of gender socialization: the question

of how people learn to conduct themselves and to configure their identities around the socially constructed categories of masculine and feminine. Gender socialization is seen as occurring through a variety of social experiences – parent–child interaction, peer group experiences, children’s play, media representations. An important addition to this analysis is R. W. Connell’s discussion of “hegemonic masculinity,” a cultural construct that presents the exaggerated and idealized traits of manhood as a goal for all men; as idealizations, no individual can fully realize these traits, but they serve as an instrument of social control as individuals try to do so. Hegemonic masculinity legitimizes both male dominance over women and the dominance within patriarchy by some men – the most hegemonically masculine – over other men. The cultural complement to hegemonic masculinity is emphasized femininity.

The standpoint of women is the epistemological claim made by feminist sociologists that the social world can and should be analyzed from the perspective of women and that a complete sociological knowledge requires such an analysis. From Harriet Martineau’s *Introduction to Society in America* in 1836 to Charlotte Perkins Gilman’s analysis of food production in *Women and Economics* (1898) to Dorothy E. Smith’s landmark 1979 essay “A Sociology for Women,” feminist sociology has been shaped by the assertion that women’s standpoint offers an essential lens for discovering the organization of society and that the organization they discover is different from that of sociology based in male experience. The idea of a standpoint of women rests on three main claims in feminist epistemology: (1) that understanding of the world is created by embodied actors situated in groups that are variously located in social structure; (2) this understanding, therefore, is always partial and interest based; and (3) this understanding is shaped by the individual’s and the group’s experience of power or disempowerment in relation to others. There can be, feminists argue, a standpoint of women because women constitute a definable group, recognizable in part by their embodiedness, who share a common interest in terms of their assignment to specific tasks in social production and a common relation to power as it is exercised in patriarchy.

The idea of the standpoint of women has been limited and refined by Donna Haraway and Patricia Hill Collins (1998) to capture the fact of what Collins has termed “intersectionality” – the lived experience in an individual biography of the daily workings of social power as multifaceted and involving besides inequalities of gender, inequalities of race, class, geosocial location, age, and sexuality. This intersection produces what Haraway calls “situated vantage points” or shifting under standings of the world arising out of the relevant structures of a particular context at a particular moment.

Feminist epistemology charts the dynamic interplay between a standpoint of women and the experiences of intersectionality and situated vantage point. But in all forms, feminist epistemology challenges the universalizing voice of traditional and androcentric social theory.

MODEL OF SOCIETY

Feminist sociology’s model of society turns on a reworking of the traditional concept of social production. In this reworking feminists expand the concept of social production, critique the concept of “public and private spheres,” show how gender stratification permeates all of production, and offer a distinctive model of the way in which power and production in interaction organize the social world. From the standpoint of women, social production is seen as encompassing all the activities necessary to maintain human life – paid work in the economy, unpaid work in the home, the production of material goods – but also the production of emotional goods such as security, kindness, love, acceptance, etc., of order in time and space through coordination of schedules, waiting, cleaning, replenishing; and the reproduction of the worker both biologically in birth and childrearing and daily in all the activities of maintenance, including care of the sick.

This production is gendered. A gender ideology divides it into public and private spheres, and patriarchy as an organizing principle of social production means that women of every class find themselves responsible in some way for the private sphere. From the standpoint of women these spheres overlap so that

an individual's position in one sphere affects their position in the other. The public sphere is organized around the unacknowledged assumption of ongoing, uncompensated private sphere labor by women; a woman's work in the private sphere hinders her participation in the public sphere; her gender role in the private sphere patterns expectations of her in the public sphere; where public sphere participation for women intensifies the difficulty of private sphere performance, public sphere participation for men gives privileges in the private sphere; the sexual harassment of women is part of a battle between men and women over spheres and domains; for women who work as domestics, private sphere work is their public sphere participation; and for all women private sphere work is undervalued by the society. Feminist studies of the gendering of work have produced a vocabulary that has entered the everyday world: "women's double day or second shift," "sexual harassment," "equal pay," "pay equity," "comparable worth," "municipal housekeeping," "the glass ceiling," "domestic violence," "his marriage and hers," "the ideal worker norm," "juggling work and family."

Perhaps the most large scale generalization from this line of thought is Dorothy E. Smith's division of the social world into the local actualities of lived experience, where the world's production is done, and the relations of ruling, the interconnections of power which control and appropriate that production. In Smith's model all women are part of the local actualities of lived experience – as are most men; the domain of the relations of ruling is a masculine one, fulfilling what one might see as the ethic of hegemonic masculinity – control. This control is exercised through anonymous, impersonal, generalized texts – documents created by the apparatus of ruling that determine who can legitimately do what.

From the beginnings of their engagement with the discipline, feminist sociologists have been concerned with methodology, inventing many of sociology's most characteristic and innovative strategies for collecting and presenting data. They pioneered the survey, the interview, the questionnaire, personal budget keeping, participant observation, key informants, and secondary data analysis (census, legislation, memoirs and diaries, wage and cost

of living records, court reports, social worker reports, tax rolls, nursery rhymes, industrial accident reports). They were equally pioneering in methods of presentation, using photographs, detailed colored maps of neighborhoods, tables, bar charts, graphs, statistical analyses, narrative accounts, and extended quotation from subjects (Reinharz 1992; Lengermann & Niebrugge Brantley 1998).

Growing out of the lived experience of asserting the validity of women's standpoint in the world, feminist sociology has made as the cornerstone of its research ethic respect for the subject. It has argued from its beginnings (Holbrooke 1895) that the researcher is not at liberty ethically to "use" the subject as a source of information and then forget about him or her. Hallmarks of feminist research methodology are the practices of selecting research topics that may contribute to bettering the lives of women, taking the research back to the subject for comment, and active and helpful engagement in the life of the research subject as it is lived in the local actualities. Feminist method also emphasizes keeping alive the voice of the subject in the final report of the research.

FEMINISM AND THE ORGANIZATIONAL DEVELOPMENT OF SOCIOLOGY

The presence of these conceptual achievements of feminist practice in sociology rests ultimately on feminism as a political movement. Although the history of sociology is often told as a history of its great ideas transmitted from Europe to America, sociology in the US and Europe did not spring full grown as a set of ideas; its development turned equally on the establishment in the nineteenth and early twentieth centuries of organizational bases for professional practice. Of these, the academy was only one of many and in the establishment of these various bases feminists played an important but, until the 1990s, underappreciated role.

In the middle of the nineteenth century women spurred by first wave feminism were among the first adherents of the new social science movement (Bernard & Bernard 1943). The social science movement began as volunteer activity by concerned citizens who believed

that scientific inquiry could be used to address the social problems produced by the expansion of capitalism and industrialism. In Britain, feminist sociologist Harriet Martineau was an early supporter of the National Association for the Promotion of Social Science established in 1856. In the US, feminist Caroline Healey Dall corresponded with the British association and was one of the founding members of the American Social Science Association (1865) (ASSA). ASSA spawned and affiliated with many progressive organizations in which feminists played significant roles, including the National Conference of Charities and Corrections (NCCC) begun in 1874 and the Association for the Advancement of Women (which had begun as the Ladies' Social Science Association in 1873). State and local chapters of ASSA provided a base in which local feminists could play an important role. As sociologists began to establish an academic presence in the latter part of the nineteenth century, sexism in the academy meant that men became the professional face of sociology in that setting; women were welcome as students but not as professors. But between 1885 and 1910 sociology was also being practiced intelligently, innovatively, and self consciously outside the academy in the social settlements that grew up in America's major cities. For many citizens, settlement sociology was the face of the discipline and in that location women were the primary actors, particularly Jane Addams, consistently voted among the most admired Americans, in part for her sociological practice (Lengermann & Niebrugge Brantley 1998).

In the new American Sociological Society (ASS) formed in 1905, an indirect offshoot of ASSA, women were a very small minority; in the first year, women constituted about 12 percent of the society's membership – 15 out of a membership of 116. That percentage of professional activity within the association remained fairly constant down to about 1969. Though women maintained membership, presented papers at meetings, and wrote for the society's official publication the *American Journal of Sociology* (and had so done since its inaugural issue in 1895), they only occasionally were elected to national offices. Between 1932 and 1969 – a hiatus in the waves of women's activism – only 7 women reached the office of vice

president. Only one woman was elected president: Dorothy Swaine Thomas in 1952. Women in unknown numbers entered the profession indirectly as faculty wives, of whom the most influential for the profession was Helen McGill Hughes, who served the *AJS* as *de facto* and then acknowledged managing editor from 1944 to 1961, establishing practices for editing manuscripts and affecting the review process itself. In the years 1949 to 1958, while women represented slightly more than half of all bachelor's degrees in sociology in the US, they constituted only about one third of master's degrees, and only about 12 percent of all doctorates, authored only slightly more than 5 percent of journal articles in *AJS* and the *American Sociological Review*, and made up less than 10 percent of the attendance at annual meetings.

However, with the beginnings of second wave feminism, feminist sociologists began to organize – a move symbolized by Alice Rossi's 1964 declaration "An Immodest Proposal" that argued that society was free of "antifeminism" not because of an absence of sexism but because of an absence of feminist consciousness, that women had to "reassert the claim to sex equality." The reassertion of this claim within sociology had its first major impact on professional sociology at the 1969 ASA annual meeting in San Francisco, when the Women's Caucus produced a series of 10 resolutions voted on and accepted at the ASA Business Meeting, calling for equity in ASA organization, departmental hiring, training of graduate students, and in sociological curricula, for the promotion of women's history and for sociological study of sex inequality. In February 1971 some 20 members of the Women's Caucus met at Yale and formed Sociologists for Women in Society (SWS). Representative of the success of this effort is the 1973 *AJS* issue on "changing women in a changing society" in which Jessie Bernard (1973) described the four revolutions she had lived through in professional sociology, with feminism becoming the fourth.

But by the 1980s, while research on gender and women was certainly more present in journal discourse than in the past, what were considered the leading journals – *AJS*, *ASR*, and *Social Forces* – still published less on gender

and women than other journals. Responding to what Stacey and Thorne (1985) called the "missing feminist revolution in sociology," the SWS in 1987 founded its own journal *Gender and Society*, which today has the largest readership of any SAGE sponsored journal. The SWS helped establish an ASA section on Sex and Gender which was in 2005 the largest section in the ASA. Since 1970 there have been 8 women presidents of ASA and 21 women vice presidents.

The 1990s represented a high water mark of feminist activism in professional sociology: 1993 marked the beginning of a period in which women have consistently received more doctorates than men; in 1994 women constituted 75 percent of the ASA Governing Council; by 1995 women were almost 50 percent of assistant professors and were approaching 40 percent of the associate professors; in 1996 they were 40 percent of the editors of ASA sponsored journals. Since then, there has been a leveling off of women's participation in professional policymaking in the association. While from 2001 women constituted over 50 percent of all members of the ASA, this figure reflects the growth of female student membership – and also the general decline across the social sciences of male graduate students. The 2004 Report of the ASA Committee on the Status of Women in Sociology showed that women were still underrepresented in significant ways – on editorial boards, as editors, as recipients of major awards – and that women tend to leave the ranks of assistant professors in significantly greater numbers than men. One challenge for third wave feminist sociologists is to address equity issues in a situation where, while much has been achieved, much remains to be done.

feminism, first, second, and third waves

Jo Reger

The women's movement in the United States is generally broken into waves of protest, each set in different time periods with diverse tactics, ideologies, and goals. The waves are divided into a first wave, starting in the 1840s; a second wave, beginning in the late 1960s; and the third wave, emerging in the mid 1990s. Although most scholars and historians use the analytical device of waves to discuss the movement, a variety of debates have arisen around the concept, with some arguing that the wave model ignores some forms of collective action and groups.

Despite debates on the occurrence of waves within the movement, it is clear that in the United States, the women's movement shaped society, politically and culturally. As the result of campaigns addressing citizenship, suffrage, civil rights, and reproductive rights, US citizens live in a society where women are free to vote, own property, retain custody of their children, divorce and marry at will, work in traditionally male occupations, and obtain legal abortions. Beyond changes to the legislative and economic systems, feminist ideas have been incorporated into the mainstream. Ideas of feminine/female strength, independence, and free will are now a part of the cultural norms about women.

THE WAVE MODEL OF WOMEN'S MOVEMENTS

To understand why US women's activism is considered a movement, it is important to consider its characteristics. The US women's movement is enduring, having its roots in the abolition movement of the 1800s and continuing into contemporary times. It is organized, drawing on networks of activists and organizations from the first attempts at suffrage to current redefinitions of femininity and sexuality. Finally, it is dynamic, constantly changing and "spilling over" into other movements.

To describe this organized, shifting yet continuous movement, scholars break the movement into a series of waves that influence, yet differ from, each other. Each wave is characterized by a period of mass mobilization when women of different backgrounds united on common issues, followed by periods of fragmentation, when women searched for ways to acknowledge their differences and to work on a variety of issues, including those pertaining to race/ethnicity, class, and sexual identity. For example, in the first wave of feminism, women united over the goal of suffrage (among others) but experienced fragmentation when that goal was achieved and no consensus of future courses of action was identified. In addition, in the second wave of feminism, many disparate groups of feminists came together to fight for reproductive, occupational, and legal rights but experienced divisions as lesbian, working class and women of color began to articulate how their issues and identities have been left out of feminist activism and ideology.

Studies of the first wave tend to focus on the structural and organizational aspects of the movement. Therefore scholarship on the first wave investigates the organizations that emerged, activists' and organizations' relations with the political environment, and the larger social climate (e.g., demographic shifts). While these aspects continue to define the second and third wave of the movement, scholars also incorporate more cultural analyses to capture how individuals act politically, the role of identity and community, and multiplicity of oppression.

THE FIRST WAVE

The first wave of the US women's movement emerged in a time of great social change due to industrialization, national expansion, and a public discussion on individuals' rights. As the world that they knew began to change (i.e., growing rates of urban poverty, changes in workplace and family), women were drawn to social reform with the goal of helping the "unfortunate" in society. The issue of slavery drew many women into the public sphere and in the early 1800s, women were instrumental in organizing and participating in the Abolition

Movement. In 1837, women organized the first Anti Slavery Convention of American Women, without the assistance of men. Women were also active in the Temperance Movement struggles of the 1830s and 1840s. When denied the right to speak and visibly participate at anti slavery and temperance conventions, women reformers organized the first women's rights convention. The Seneca Falls Women's Rights Convention, held July 14, 1848, was organized by abolitionists Lucretia Mott and Elizabeth Cady Stanton and focused on multiple issues, including education rights, property reforms, and women's restrictive roles within the family. The convention attendees drew up a Declaration of Sentiments, modeled after the Declaration of Independence, which detailed how men had denied women their rights. It was only after much deliberation that the 300 attendees decided also to address the controversial issue of women's suffrage. The Seneca Falls convention sparked women's rights activism and spawned a decade of women's rights meetings and conventions throughout small towns in Ohio, New York, Pennsylvania, Massachusetts, and Indiana in the 1850s.

In addition to this focus on the politics and the state, first wave activists and organizations also worked for cultural change. From 1851 to 1854, there was a campaign to change women's dress. Dress reform activists argued that to change women's costumes would also work to change their lives. Women who adopted the "Bloomer" outfit of a loose tunic and pantaloons found it liberating. However, the dress reform movement brought a hostile backlash and consequently, activists advocated dropping the issue, fearing it was detracting from their other points of reform.

Race/ethnicity also became a divisive issue when some activists, such as Stanton, argued that white women should be given the vote to offset the votes of African, Chinese, and "ignorant" immigrant men. Although generally a popular speaker, Sojourner Truth, a former slave and women's rights reformer, often faced hostility as she spoke at women's rights conventions. The tendency for some suffragists to place gender disadvantage over other sources of discrimination served to drive a wedge between blacks and whites who were organizing together to win the vote. It is this history of racial

divisiveness, along with the later experiences of second wave feminists, that led feminists to reconceptualize oppressions as intertwined and intersecting instead of arguing over which oppression was the most relevant.

Scholars of the first wave have focused in particular on two organizations, each pursuing different strategies for winning women the vote. The National Woman Suffrage Association (NWSA), founded in 1868 by well known leaders Stanton and Susan B. Anthony, pursued a broad range of issues and endorsed more radical tactics. Stanton and Anthony believed that the courts were the fastest avenue to suffrage and eventually took their case to the Supreme Court. Adopting a different strategy was the American Woman Suffrage Association (AWSA), founded by Lucy Stone. Stone and her followers focused solely on suffrage issues and believed that working state by state was the most feasible strategy for winning national suffrage. The AWSA had success working with western states, and Wyoming (before it became a state) was the first to grant women suffrage.

By 1890, the focus of both groups had narrowed to suffrage so the two organizations merged, creating the National American Woman Suffrage Association (NAWSA). In 1913 the movement was again fragmented when a militant group called the Congressional Union formed. Led by Alice Paul, Congressional Union members engaged in dramatic tactics to draw public attention, such as marches, picketing, and hunger strikes. The Union, later renamed the National Woman's Party (NWP), brought new attention to suffrage and, in coalition with the NAWSA, the groups finally achieved their goal. Feminists had introduced the 19th Amendment every year since 1848 before it finally passed on August 26, 1920.

Along with the suffragist organizations, other women's groups emerged in the first wave. These organizations focused on a variety of concerns from child custody laws to lobbying for equal pay. The Women's Christian Temperance Union (WCTU) from 1874 to 1898 was one of the most visible and drew women into the public sphere as anti alcohol reformers and activists. Other organizations, perceived as less radical and scandalous than the suffrage groups, also mobilized women at a time when educational and career opportunities were

expanding for women but traditional ideas and practices constrained them. Through lobbying for suffrage and other issues and repeatedly presenting women's claims to legislators and other political actors, the first wave of the women's movement had left an important mark on American interest group politics.

In sum, the first wave of the movement has been characterized as seeking national level policy and legislative change, populated mostly by white upper and middle class women within organizational contexts, and subject to factions, divisiveness, and dwindling mobilization after the suffrage victory. This focus on organizational visibility led to the common belief that the women's movement ceased to exist in the 1920s. Starting in the late 1980s, feminist scholars began to examine the ways in which the women's movement was sustained but not visible to the public. The term "abeyance" was coined by social movement scholar Verta Taylor to illustrate how the movement had not disappeared but instead continued to exist in a period of dormancy, sheltered in organizations such as the NWP. Dialogues on women's equality also continued after suffrage in networks and communities such as the Communist Party in the 1940s, 1950s, and early 1960s. By the 1950s, despite the traditional images of women, more and more middle class white women were entering the labor force, and single motherhood and divorce rates were beginning to rise. The strain between societal expectations of domesticity and women's experiences in education and the workforce, along with other factors such as the rise of the cycle of new social movements that swept the United States and Western Europe, led to the reemergence of the movement in the 1960s and 1970s.

THE SECOND WAVE

While the structural changes that created opportunities for women to attain skills and establish networks through the workplace may have set the stage for the rise of the first wave, it was the actual lived experiences of women and the construction of a shared feminist identity among groups of women that led to the second wave. The emergence of the second

wave drew on activist networks from the first wave as well as other movements, particularly the New Left and the Civil Rights Movement. In addition, the publication of books such as Simone de Beauvoir's *The Second Sex* in 1952 and Betty Friedan's *The Feminine Mystique* in 1962 sparked primarily white middle class women's dissatisfaction with the roles of men and women.

Two events mark the reemergence of the second wave. First was the break from the New Left and Civil Rights movements by politically educated younger women dissatisfied with these movements' failure to address gender issues. Women in the New Left and Civil Rights movements participated in a variety of protests, gaining important political organizing skills. For example, Jo Freeman and Vivian Rothstein, who later became women's liberation movement organizers, participated in the Free Speech Movement's sit in and strike at Berkeley. However, by 1964, women were beginning to articulate their issues with the patriarchal structure and culture of the movements. In 1965, Casey Hayden and Mary King circulated a memo on sexism in the Civil Rights Movement and the "woman question" was raised at a Students for Democratic Society meeting that same year.

Second was the formation of the National Organization for Women (NOW) by a group of women enmeshed in government networks and upset at the lack of attention to workplace discrimination against women by the Equal Employment Opportunity Commission (EEOC). NOW formed October 29, 1966 during a luncheon of women at the National Conference of State Commissions in Washington, DC. NOW was created when conference participants were blocked from passing a resolution pressing the EEOC to use greater force in investigating sex discrimination cases. Founding members include Friedan, lawyer and Civil Rights activist Pauli Murray, and Kay Clarenbach, head of the Wisconsin Commission on the Status of Women. Modeled after the National Association for the Advancement of Colored People (NAACP), NOW's original goal was to expand women's economic rights and responsibilities by fighting sex discrimination in the workforce. In one of its first actions, NOW pressured the EEOC to end the

practice of sex segregated help wanted advertisements in newspapers. Along with employment and economic issues, NOW formed task forces to deal with areas of discrimination in education and religion; family rights; women's image in the mass media; political rights and responsibilities; and problems facing poor women.

These two events, the split from contemporary movements and the formation of NOW, served as the seeds of two different branches of the movement. These branches are described in a variety of ways, including "small group sector" versus "mass movement," "collectivist" versus "bureaucratic," "younger women" versus "older women," "liberal" versus "radical," and "women's rights" versus "women's liberation." The two branches were connected through interpersonal and organizational networks, had overlapping memberships, and cooperated on some goals.

Drawing on younger, college age students, the women's liberation branch encompassed different ideologies and organizational structures. Women's liberation groups tended to be collectivist versus hierarchical in structure, and without established leaders and organizational positions.

The women's liberation branch endorsed a more radical feminist ideology, influenced by socialist, radical, and lesbian feminist theory, and participants believed that change came through personal and systematic transformation. For example, to accomplish personal transformation, The Redstockings, a radical feminist group, began to organize consciousness raising groups. Consciousness raising (CR) is a process by which women share personal experiences and beliefs as a means to illuminate patriarchal control and oppression. In CR groups, women discussed a variety of issues from sexuality to housework, connecting them to gender inequality. CR, as a form of a politicized personal strategy, spread into the dominant culture and into women's rights organizations, such as NOW, that recognized it for its recruitment potential.

The membership of the women's rights branch of the movement was predominantly older, middle class professional women concerned with legislative and policy issues. The women's rights branch of feminism focused on

change through legislation and placement of women in positions of power as the vehicle to equality. The ideas of liberal feminism, that men and women will become equal when they are in comparable positions in society, are reflected in the overall strategies of the women's rights branch.

Actions from both branches brought media attention and drew large numbers of women into feminism. From the years 1972 to 1982, the second wave was in what has been characterized as its heyday. Women's liberation groups continued to recruit women to feminism and caused cultural shock waves with their critiques of femininity, gender roles, and heterosexuality. During this period, the American culture was shaped by the creation of cultural institutions such as *Ms. Magazine* and Naiad Press, a lesbian book publisher, and the growth of women's music through such companies as Olivia Records. It was also during this time that women's studies programs began appearing on college campuses. In the meantime, women's rights groups won legislative victories with the 1972 passage of Title IX directed at ending sex discrimination in publicly funded education and the 1973 *Roe v. Wade* decision by the Supreme Court legalizing abortion. One result of this heightened activity in the United States and abroad was that in 1975 the United Nations sponsored the First International Conference on Women in Mexico City.

Although these years were times of success for feminists, it was also a period of conflict, fragmentation, and growing discord in the movement. Lesbians, working class women, and women of color critiqued white middle class women's control of both branches of the movement. NOW suffered from dissension over the presence of lesbians in the organization. Some lesbian feminists began to organize separately in the 1970s and, in 1973, held a national conference. NOW eventually changed its position and endorsed lesbian rights. Working class women also struggled with the movement, believing that their work and family lives were not being addressed, and created separate organizations. For example, the Coalition of Labor Union Women was formed in 1974, when 3,000 women met to address sexism in the unions and also women's inequality in society. Women of color also worked with and

separated from the second wave. Black women, along with Chicana and Asian American women, often had their racial, ethnic, and class based experiences of discrimination ignored, so they created organizations – including the National Black Feminist Organization, the Mexican American Women's National Association, and the Pan Asian American Women – specifically designed to address their issues. Informed by the discord in the first and second waves, feminists and feminist scholars, such as the Combahee River Collective and, later, Patricia Hill Collins, conceptualized an intersectional feminist paradigm that views race/ethnicity, class, gender, and sexuality as interlocking systems of oppression, forming a “matrix of domination.”

As the second wave experienced fragmentation and dissension from within, it also faced growing countermovements, particularly opposing the Equal Rights Amendment (ERA) and abortion rights. By the late 1970s, the two branches had largely united in an effort to pass the ERA, an amendment originally introduced in the 1920s by the NWP to the Constitution that would guarantee women equal rights under the law; however, the amendment was defeated in 1982. The ERA's demise and the election of conservative president Ronald Reagan instigated a period of backlash. Many of the gains of the past decade were eroded, and media pundits labeled the 1980s the “post feminist era.” Among the setbacks was a lack of compliance with Title IX, increased cases of work related sexual harassment, increasing state restrictions on abortion and related services, escalating anti abortion violence, and attacks on affirmative action. However, the movement survived with activists drawing on established organizations, networks, and women's communities for stability and support. In sum, the second wave of the women's movement brought about a resurgence, differentiation, and expansion of feminist activism and ideologies, along with shifting strategies and tactics from the confrontational strategy in the 1960s, to the organizational strategy in the 1970s, and the electoral strategy in the 1980s. In its two branches, movement activists influenced national policy as well as addressed personal experience and cultural norms.

Evident in these historical accounts is the continuity of feminist organizing in the United

States. Influenced by structural and political shifts and maintained by organizations, networks, and communities, the movement has undergone different levels of mobilization, but it has not died. In fact, feminism continues to shape political society. For example, political sociologists have shown how feminist ideas continue to shape the polity. Women identifying as feminists account for a large portion of the gender gap on specific issues, in particular domestic issues involving social service spending. For example, in the 1992 US presidential election, feminist consciousness emerged as a significant factor in shaping women's voting behavior.

THE THIRD WAVE

The popular media and some political pundits have repeatedly declared feminism dead or in decline. Scholars and activists respond to these obituaries in different ways. Some argue that these “premature” death notices serve a larger goal, preserving the status quo by erasing women's activism. Others argue that feminism is still alive, yet suffering from a backlash and is carried on through the efforts of “older” feminists and their organizations, institutions, and policies put in place in the 1960s and 1970s. Some argue that feminism diffused into the larger culture, bringing about a “post feminist” era where feminist goals and ideology are alive but submerged into the broader culture. Others see the movement in a state of abeyance, awaiting external impetus for remobilization. Others view the movement as fragmented, particularly because of issues of homophobia, classism, and racism, yet insist that it still remains active and vital. Related to this view, others argue that feminism has changed form and is now done in a different way by a new generation of activists.

Adopting the view that the movement has changed form and tactics, some scholars and participants refer to this phase of the women's movement as “the third wave.” The idea of a third wave comes from the concept of a political generation, a period when common historical experiences form a political frame of reference for a group. Young women and men in the twenty first century enter into feminism

in a society dramatically shaped by the movement's first two waves. Through the efforts of second wave activists, a variety of feminist cultural events exist – ranging from feminist theater, cruises, and music and comedy festivals to camps, day care programs, and workshops on feminist spirituality. Young girls and boys can read non gendered children's books, listen to feminist music, and attend summer camps organized around gender equity. In addition, feminism is embedded in the institutions in which third wave feminists spend their lives. Their families, schools, health care providers, and political representatives have been influenced by the beliefs and values of first and second wave feminism.

While scholars of the first and second wave trace the emergence of feminist activism to specific organizational events (i.e., the Seneca Falls Convention or the formation of NOW), the third wave's emergence is less obvious. A variety of explanations for the origin of the third wave exist. In 1991, Lynn Chancer called for a "third wave" feminism to signify a turn from the defensive posture of the 1980s feminism and its backlash. Some credit its emergence to Rebecca Walker when, in 1995, she called herself "third wave" in the introduction of her anthology, *To Be Real*. For others, the Riot Grrrl movement in the Northwest United States in the 1990s signaled the conceptualization of a new, punk infused, generationally defined form of feminism. Finally, many credit the rise of the third wave as having its origins in the challenges made by women of color to the second wave for its lack of racial ethnic inclusivity. In all of these origins, third wave feminism is seen as drawing on the political, cultural, and institutional accomplishments of the second wave, while finding new forms of protest and working to undo norms of racism, classism, and homophobia that marred early waves of feminism.

The third wave has organizational roots, similar to the first and second waves, along with more subcultural and submerged roots. For example, the Third Wave Foundation was formed as a social justice organization addressing a variety of gender, racial, ethnic, and sexuality related concerns in 1997 for women aged 15 to 30. The Riot Grrrl movement shifted from being musically oriented to politically

oriented with a 1992 convention and saw several chapters form in the early to mid 1990s. In addition, second wave organizations such as *Ms. Magazine* also serve as a point of origin for several voices of contemporary feminism such as Jennifer Baumgardner, co author of *Manifesta*, and Rebecca Walker, editor of *To Be Real*. NOW has also launched several initiatives to involve young feminists in the organization.

Despite these groups, many view the third wave as cultural and submerged into broader subcultures of music, social justice activism, and art. In the early 1990s, several cultural events contributed to a growing sense of a generational change from second to third wave feminism. Singer Ani DiFranco launched her record company, Righteous Babe, in 1990 and became for many young activists the voice of contemporary feminism along with other performers such as Alix Olson and the Indigo Girls. Magazines such as *Bitch* and *Bust* emerged, expanding from their do it yourself 'zine inceptions.

Incorporated in these cultural vehicles are familiar political issues such as sexual harassment, occupational discrimination, violence, sexual abuse, and body image that continue to concern third wave feminists. Just as the first and second wave did with protests against restrictive dress, third wave feminists attack cultural norms of femininity. However, these protests have a new twist. Using the body as a site of protest, Lesbian Avengers, a group visible in the early to mid 1990s, "ate fire" to symbolize their strength and boldness. Other young feminists engage in disparaged feminine activities such as crafting, knitting, and embracing the color pink as a way to reclaim and redefine femininity. For example, a regular column in *Bust* magazine provides readers with how to instructions on a variety of crafts. This reclaiming of the feminine is not solely in the province of individuals. Political organizations also draw upon both traditional political strategies and inventive protests to reclaim the feminine. Code Pink, a grassroots peace and social justice movement, protested at the 2004 Republican National Convention, using the color pink as an antidote to the Bush administration state of emergency color coding system, and as a way to give President Bush the "pink slip."

Both collectively and individually, third wave feminists use the performance of identity to redefine femininity and make political statements. For example, some twenty first century young feminists play with gender by wearing short skirts with combat boots and masculine looking haircuts. In this case, feminists take cultural norms and, using the body, reinvent them as a display of feminine power. Along with playing with appearance, third wave writers and activists also talk of reinventing sexuality and gender norms. Young feminist scholars argue that activists need to fight against societally defined norms of feminine sexuality as well as second wave conceptions of sexual appropriateness, reclaiming pleasure through the use of sexual play and sex toys.

The culturally focused tactics of the third wave also emerge from institutional settings, such as education. Women's studies plays an important role in the continuity and continued mobilization of feminism. Young women come to feminism through transmission from their mothers and from women's studies courses that link the theoretical with the political. Much of contemporary feminist activism by young women is being done in college or university contexts in conjunction with women's studies departments and/or women's centers.

Along with shifts in issues, contemporary feminists are also turning to new ways to mobilize and communicate. Third wave feminists are increasingly turning to the Internet as the site of protest and the source of community. Cyberfeminism, a movement started in the 1990s, uses technology to redefine femininity and address a masculinist approach to technology that can alienate women. At a 1997 international conference in Kassel, Germany, cyberfeminists refused to define themselves and instead created a list of "100 Antitheses" of what the movement is not. Those antitheses include "cyberfeminism is not a fragrance," "cyberfeminism is not an ideology," and "cyberfeminism is not a structure" (Old Boys Network 1997). The Internet is also home to a multitude of sites dedicated to feminist organizations and to communities of activists who mobilize, support, and inform each other within web pages, or through blogs (i.e., Internet diaries) or ongoing journals.

One challenge facing the third wave is the sense of generational discord that pervades both

this wave and the second wave. Young feminists (i.e., third wave) often feel that older (i.e., second wave) feminists malign their more individual and performance oriented protests and would prefer to see more traditional, organizationally focused activism. Older feminists report that their histories and efforts are often oversimplified and that the complexity of earlier feminisms is ignored. These sentiments have led to serious dissension between the two groups. For example, at the 2002 Veteran Feminists of America meeting, a group of predominantly second wave feminists bemoaned the lack of clear activism by young women, while third wave feminists reported feeling patronized and ignored. Because of this, second and third wave feminists often have difficulties in working cooperatively with each other. One area in which the generations have different views is on the issue of racial ethnic inclusion. A major emphasis of third wave feminist ideology is acknowledging the differences between women and working to incorporate all women into feminist activism. This view is founded on the idea that first and second wave feminists failed to build inclusive organizations and networks. While many second wave feminists admit this is true, they also argue that the history presented by third wavers ignores the efforts of women who tried and sometimes successfully integrated feminist groups and worked to meet all women's needs, not just those of white middle class women.

In sum, contemporary feminism continues to shift and change, drawing on the ideas, strategies, and institutional gains of past waves of the women's movement, at the same time as it appropriates modern technologies, the media, gender codes, and the fabric of everyday life as sources of resistance. Simply stated, feminism in the twenty first century is the same but different. It draws on the first two waves of the women's movement, yet functions in a fundamentally different world that demands scholars' continued innovation in order to capture the complexity and dynamics of that world.

DEBATES ABOUT THE WAVE MODEL

Some scholars have argued that the wave model, although conceptually neat, ignores

forms of protest activity. Scholars, such as Mary Katzenstein, argue that one reason much feminist protest in modern society goes unnoticed is because it takes place inside mainstream institutions, such as medicine, education, religion, and the workplace, rather than in the streets, in what she labels "unobtrusive mobilization." For example, the creation of sub merged networks within societal institutions such as the Catholic Church and the US military has sustained the women's movement. Unobtrusive mobilization is also evident in the feminist activism inspired by cultural events such as women's movement festivals, institutionalized organizations with feminist origins, and work oriented organizations such as unions. Within these organizations and institutions, feminism is carried out through an identity that activists use to make sense of their lives and is spread through networks promoting movement goals.

Outside of the institutional contexts, sub merged networks (i.e., those not readily evident to others such as scholars, media, and politicians) may also be left out of the conceptual framework of the "wave." Scholar Nancy Naples documents the networks that emerged in neighborhood communities as a result of the 1960s War against Poverty. Activists, drawing on feminist ideologies and strategies, turned their attention from national level policy to focus on community work. While many of the low income urban women involved did not identify as feminists or label their work as "political," they organize in their neighborhoods drawing on the rhetoric of "activist mothering." In addition, although less visible than it was in the movement's heyday, feminism in the late 1980s and 1990s established roots in other social movements of the period. Scholars argue that the women's movement, through the creation of networks, heavily influenced the peace and anti nuclear movements of the 1980s by spreading feminist ideological frames, tactical repertoires, and conceptions of organizational structure and leadership. In sum, scholars argue that the women's movement trained a large number of feminist activists in the 1970s who, through their networks, have participated in new social movements and integrated feminism into them. This spillover is evident in the ways in which contemporary

feminists engage in a variety of global concerns. For example, the New York City Radical Cheerleaders is a grassroots organization that subverts the traditionally feminine activity of cheerleading by protesting issues such as globalization, the war in Iraq, the occupation of Palestine, and sweatshops as well as sexual harassment, homophobia, and fat bias (New York Radical Cheerleaders 2005).

Along with the criticism that the wave model leaves out some contexts of protests is the argument that the wave model excludes movements of groups marginalized in society, such as women of color, lesbians, and working class women, and focuses more on the activities of white, middle class, heterosexual women. Scholars adopting this view argue that the second wave was in reality one of *feminisms*, with women of color and white women working on similar issues in organizationally distinct movements. This focus on the most visible groups creates a history shaped by hegemonic (i.e., dominant) feminism and ignores a justice based perspective toward feminism. By tracing the activism of women of color and anti racist white women, an understanding of multiracial feminism as a movement emerges, complicating the first, second, and third wave history and the overall use of the wave metaphor.

Perhaps one of the biggest challenges to the notion of feminist waves of activism is the carryover of strategies and tactics from one wave to the next, making the waves less distinct from each other. For example, both second and third wave feminists use sexuality as an everyday political statement against hegemonic heterosexuality. Works by second wave authors such as Andrea Dworkin and Adrienne Rich are catalysts changing the way many women viewed sexual relationships and desire, along with third wave writers such as Inga Muscio, the author of *Cunt: A Declaration of Independence*. In addition, like third wave activists, first and second wave feminists challenged clothing and appearance norms, from the introduction of bloomers to the emergence of norms violating traditional femininity such as not shaving one's legs or going without a bra. In sum, instead of embracing a set of distinct historical waves, some argue that our understanding of the feminism of the day should incorporate the ambiguity and contradiction that has been

present in all the “waves.” Along these lines, Ednie Garrison argues that we change the conceptual model from discrete “ocean” waves to the more fluid, overlapping, and competing structure of radio waves, allowing for multiple movements and interpretation of women’s activism to exist.

CONCLUSION

As we have seen, women’s movement activism has flourished and receded at different times in US history and has been conceptualized as a series of waves. While first and second wave feminism were viewed through a structural and organizational lens, contemporary or third wave feminism persists in a new, more loosely structured form that seeks changes in the realms of culture, identity, and everyday life, as well as through direct engagement with the state. The overall continuity of the women’s movement throughout each of these waves is sustained by distinctive feminist cultures, fostered in social networks and social movement communities, when mass political action declines. Although scholars agree that the US women’s movement has a long and dynamic history, some question the viability of the wave metaphor and seek to reintroduce forms of protests and social groups left out of its history, making a more complex and richer history of women’s activism.

feminism and science, feminist epistemology

Anne Kerr

Feminist scholars systematically began to focus upon the gender values in the biological and medical sciences in the 1970s, drawing upon and developing a radical social constructivism where facts were treated as social products rather than objective value free entities and knowers were seen to be part of communities rather than lone scholars. This work ran alongside other developments in social studies of science, but was shaped by political commitments to women's rights, in contrast to the intellectual agnosticism of the mainstream, predominantly male scholars of sociology of scientific knowledge.

A great deal of the focus of feminist studies of sciences has been on the ways in which gender seeps into scientific theories, and the very "discovery" of natural objects. For example, Oudshoorn (1994) showed how sex hormones were categorized during the 1920s as sexually specific: female hormones were said to make females more female and male hormones to make males more male. Scientists then went on to use these gendered molecules to explain wider biological processes such as development of gender and sexuality in embryos. However, as Oudshoorn and others have argued, sex hormones are very complex. Men and women both have so called male and female hormones; hormones are not only produced in the ovaries or testes, but also from the adrenal glands; hormones can also be converted. Gendered categories fail to account for such complexity. Feminists have also pointed out that there is a considerable overlap between what are considered to be male and female bodies on most physiological measurements. This complexity and overlap still tends to be overlooked in popular accounts of the differences between men and women, and scientific research has traditionally perpetuated the duality. The rise of molecular biology has involved a reinterpretation of biological sex which is no less determinist. As Fausto Sterling (2000) notes, Sry – the so called testes determining factor – privileges masculinity against a feminine "default" because Sry is cast as a "master switch" which makes a fetus male. The induction of testicular tissue is presented as active, while induction of ovarian tissue is presented as passive, so that male is represented as presence, female as absence. In these ways scientific studies of sex and gender often reinforce a fixed duality between male and female and overemphasize difference at the expense of an appreciation of diversity and change. Masculinity and heterosexuality are privileged, and femininity is seen as "lacking" or a "default position."

In the 1980s feminists also moved beyond criticizing the gender biases in science to advocate new ways of doing science based upon feminist epistemology. This took place against a backdrop of considerable intellectual interest, in philosophy and the social sciences, in developing a middle ground between postmodernism

and empiricism, where the social construction of knowledge was recognized, but relativism did not become a barrier to better knowledge. Once again feminists' commitment to tackling social problems, including inequalities, gave their inquiries an explicit political dimension. Three main types of feminist epistemologies of science which sought to bridge the gulf between traditional feminist theories and post modernism emerged: Harding's (1986, 1991) feminist standpoint theory developed from the work of Hartsock (1983) and Rose (1983), among others; Haraway's (1991) "situated knowledge"; and Longino (1990) and Nelson's (1990) versions of feminist empiricism.

Harding's main argument is that science would be better if scientists developed the ability to *think from women's lives*. She combines the work of Rose (1983), Hartsock (1983), Ruddick (1990) (who developed maternal thinking theory), and Gilligan (1984) (who developed theories on moral reasoning) to argue that women have a privileged standpoint because their caring labor gives them a better understanding of the world. For Harding, scientists need to learn to see the world from the perspective of the marginalized and the oppressed, with the assistance of critical social theories generated by the emancipatory movements. This type of critical reflection requires *strong* objectivity: it is essential for feminists to remain able to judge between the validity of different knowledge claims by looking to the social conditions of the knowledge production.

Haraway and others have criticized Harding's notion of a feminist standpoint, because people have a multitude of different standpoints, based on differences in class, race, and sexuality, as well as gender. This is said to undermine Harding's notion of "seeing from below" as a means of judging the validity of knowledge claims when there are so many different standpoints that one could adopt. Instead, Haraway (1991) prefers to emphasize "situated knowledge" where people do not hold one perspective on the world, but many, some of which are contradictory. This also means that people can see from other people's perspectives, the result of which is a constantly shifting set of alliances. With a sufficiently diverse group of scientists, Haraway suggests these coalitions could form the basis for

scientists' critical reflection about what influences their knowledge claims.

Longino favors a similar reinterpretation of objectivity, which she argues comes from a robust version of empiricism. This involves critical evaluation of knowledge claims based on the available evidence. She argues, as does Haraway, that it is important to focus on building a diverse community of knowers. Longino argues in favor of contextual empiricism where she says that scientists should allow their political commitments to guide their choice of particular models in science and not simply aim to uncover sexist bias. For Longino, explicit value commitments can underpin good science. Nelson advocates a similar model, drawing on the work of Quine, to argue that knowledge and values form a unified web of meaning and must therefore be explored and developed together. Both Longino and Nelson are more focused than Harding or Haraway upon change from within science.

Many scholars have engaged with these various versions of feminist epistemology of science from a range of disciplinary and political perspectives, not just feminism. Several common themes characterize their writings. The first is the issue of determinism and, more broadly, the uniqueness and value of women's perspective (and that of other marginalized groups) in guiding critical inquiry in science. The second is the precise nature of values and their relationships to scientific practice. The third is the operationalization of feminist epistemology, particularly in the physical as opposed to the social sciences.

Turning first to essentialism, despite her emphasis on women's diverse experiences and her rejection of biological determinism, Harding's feminist standpoint is often said to be problematic because of its implied gender essentialism. This is in part because she draws on Hartsock and Rose's analyses, which both incorporate a weak version of the radical feminist emphasis upon women's bodies within their broad materialism. Poststructuralist feminists' deconstruction of the sex/gender divide, and insistence on the constructedness of the biological as well as the social dimensions of womanhood, have also undermined Harding's and other feminist standpoint theorists' emphasis upon the commonality in women's

experience, biologically and socially. Other critics have noted that when white, middle class, western feminists homogenize women's experiences they perpetuate racist and imperialist erasure of black women's standpoint. Although scholars such as Hill Collins (1999) have developed feminist standpoint theory from the perspective of black women, the danger of feminist standpoint theory fracturing to represent ever smaller groups of knowers is well recognized.

Harding has defended her theory against these criticisms on the basis that her emphasis upon social location and political struggle has stimulated debate and further reflection. This, she argues, is a benefit to critical inquiry in itself, because it entails the active negotiation of modern and postmodern projects, objectivity and subjectivity, by diverse groups of knowers. Harding implies that the hostility that has been shown towards standpoint theory is a sign of resistance to the oppressed studying the oppressors and in so doing reversing the usual power relations between researchers and their subjects. Others, such as New (1998), have also defended feminist standpoint theory on the basis that it sets out a program for change – an exploration of commonality and a means of building links and shared agendas. Here the feminist standpoint is the end point rather than the starting point of critical inquiry. This means that the category of women is always open to revision and contestation rather than commonality being simply assumed.

However, many questions remain about the detailed relationships between values, knowledge, and scientific practice in feminist standpoint theory. Haraway's situated knowledge is also vague about the relationships between values, knowledge, and practice in science, stressing instead the importance of partiality and difference in perspective. Nelson's web of meaning is also difficult to unpack, given that empirical and social/political values form a "seamless web" of scientific knowledge. On an abstract level tensions between realism and constructivism can be productive. As feminist empiricists and standpoint theorists have argued, it is possible to be epistemic relativists, recognizing the social production of knowledge, without becoming judgmental relativists – all beliefs are not equally valid. Yet the problem

remains of how to adjudicate between values. In particular, the danger has been raised that values will drive inquiry so that scholars will simply find what they are looking for and use their values to insulate themselves from criticism.

The details of how values shape knowledge and how one decides between legitimate and illegitimate influences have been recently taken up by other scholars in a more rigorous fashion, more usually through the development of various types of feminist empiricism rather than standpoint theory *per se*. As Anderson (2004) has argued, all research design is biased in some sense because it opens some lines of inquiry while closing others. For Anderson, so long as this is acknowledged it is legitimate. However, bias in relation to hypotheses is illegitimate when it means that experiments are deliberately "rigged" so that researchers find what they are looking for. As she argues, good research involves unwelcome, surprising, and null results, for feminists as well as non feminists. She argues there is a range of methodological tools available to researchers to guard against these types of illegitimate values, or errors. Clough (2004) makes a similar point when she distinguishes between the deadlock of global skepticism about the values and the value of all knowledge and the necessity of fallibilistic worries about the empirical accuracy of knowledge claims which are an important part of robust scholarly inquiry. Yet, for others, these types of detailed accounts of legitimacy are not very different from standard empiricism, and therefore still unable to grasp the thoroughgoing social situatedness of knowledge and inquiry. Judgments about legitimacy remain just that, and are always shaped by the convictions of the research team and the community of scholars of which they are a part. This means that gender bias might remain "legitimate" despite feminist scholars' best efforts to the contrary.

On a more general level, operationalizing feminist epistemology has also proved to be difficult, especially in the physical sciences where bodies and behaviors are not the focus of inquiry. Starting from the perspective of women's lives, feminists have successfully theorized and offered alternatives to gender biases within biomedicine. In the US in particular, in

the 1980s feminists began to challenge mainstream medicine's omission of women from trials, and to put women's health on the agenda. This was taken up by the federal government and reflected in the National Institute of Health's policy on research funding. These changes were not only produced by outsiders, but also by insiders in science, and by women like Evelyn Fox Keller, who choose to locate themselves between inclusion and exclusion. Feminists have uncovered the ways in which gender structures science at the level of theory, taxonomy, research priorities, and subjects of study. They have asked questions about who stands to benefit from large scale projects like the Human Genome Project and looked critically at the ways new genetic technologies shape women's lives, crucially, in the arena of pregnancy and reproduction.

This development of feminist epistemology has been more difficult in the so called "hard sciences" of physics and maths. As Schiebinger (1999) has argued, questions of meaning are not typical fare for the physical sciences and are seen as matters of ethics or history. Their model of inquiry is of the individual knower rather than the collective. However, feminists have analyzed the gendered nature of the hierarchy of hard and soft science – in particular the Cartesian dualism between the practice and critical reflection about science, or objectivity and subjectivity. As such feminist epistemologies perform a valuable role in making us think more deeply about what a feminist science might mean, and of problematizing taken for granted paradigms and hierarchies of "soft" and "hard" sciences. Problems of essentialism are still present in the popular cultural representations of women's way of doing science, but the move towards a more grounded understanding of feminist transformations of science avoids this because it generates many different understandings of women's practice, emphasizing the local and incremental process of moving towards a feminist science, and the importance of "building bridges" between scientific and local communities.

feminist activism in Latin America

Julie Shayne

Feminism has a variety of meanings. According to Nikki Craske, despite the often heated debates about the meaning of feminism, most would likely concur with Rosalind Delmar's assessment that feminism attempts to transform women from object to subject, specifically with respect to knowledge. In other words, feminism and by extension feminist activism is about centering the lives of women. Sonia Alvarez (1990), another leading scholar of Latin American feminisms, defines an act as feminist if it strives to transform social roles assigned to women while simultaneously challenging gender power arrangements, and advancing claims for women's rights to equality and personal autonomy.

From Julie Shayne's research about the relationship between revolutionary and feminist mobilization she argues that in Latin America feminism is most accurately defined as "revolutionary feminism." For Shayne, a revolutionary feminist movement is one born of revolutionary mobilization. Ideologically revolutionary feminists are committed to challenging sexism as inseparable from larger political institutions not explicitly perceived as patriarchal but entirely bound to the oppression of women. Or in the words of Salvadoran feminist activist Gloria Guzman, feminism is:

a political struggle for the eradication ... of women's subordination. It is a proposal for a change in the relations of power between people, men over women, and the relations of power expressed in the different realms of life. We [Salvadoran feminists] believe that it is a

political struggle that will take us specifically to new kinds of relations, economic as well as relationships of power between men and women. (Shayne 2004: 53)

HISTORY OF FEMINISM

One of the most thorough historical overviews of women, politics, and feminism in Latin America is Francesca Miller's *Latin American Women and the Search for Social Justice* (1991). Miller (and countless others) argues that, contrary to what many male leftists purport, feminism is not a western import into the region, but rather, an ideology that has emerged over the last century.

In the latter half of the nineteenth century, feminists were concerned with three specific issues: gaining women's suffrage, protective labor laws, and access to education. By the early twentieth century, the organization of International Feminist Congresses began with its first meeting in Argentina in 1910. Many of the attendees were members of women's groups and political parties, namely socialist or anarchist parties. Central to the congress was the theme of equality between men and women. A second congress then happened in Mexico in 1916, with several national ones following throughout the next 20 years addressing issues specific to women of different countries (e.g., the issue of race was quite important to Peruvian women).

Miller argues that the typical division of first and second wave feminism as applied to the US context does not entirely fit in Latin America. She suggests that the main reason for this is due to the fact that while first wave feminists in the US were successful in their campaigns to secure the right to vote (as evidenced in the passage of the 19th Amendment in 1920), parallel goals of Latin American and Caribbean women were not, thus necessitating ongoing mobilization. While women in some countries in the region earned the right to vote not long after women in the US (e.g., Ecuador in 1929), others would not obtain it until the mid 1960s (Belize 1964). In other words, if the end of first wave feminism is marked by women gaining the right to vote, then in Latin America first wave feminism did not end until the 1960s. However, even prior to the region's women

gaining collective suffrage, feminist mobilization was percolating in the context of non gendered liberation struggles.

WHAT CAUSES THE EMERGENCE OF FEMINIST MOVEMENTS?

Beyond understanding the meaning of feminism, scholars have also spent time analyzing how feminism has emerged in the region. In the 1970s and 1980s both violent and non violent revolutionary upheaval consumed the region. Despite many obstacles, women participated in these revolutionary movements in varying capacities (Jaquette 1973; Lobao 1990; Randall 1994; Kampwirth 2002; Shayne 2004). There is a fairly solid consensus among academics and activists that women's participation in leftist movements has been one of the central reasons for the development of Latin American feminisms. Recently, Kampwirth (2004) and Shayne (2004) have expanded the discussion through their combined analyses of Chiapas, Mexico, Chile, El Salvador, and Nicaragua.

Shayne (2004) proposes a model for the development of feminist organizations in the region. Drawing on the positive cases of El Salvador and Chile, she argues that five factors need to converge during and after a revolutionary struggle to lead to the emergence of what she calls "revolutionary feminism." First, women's experiences in revolutionary movements need to have presented permanent challenges to status quo understandings of gendered behavior and roles, or, gender bending. Second, women need to have acquired logistical training vis à vis their experiences in revolutionary movements. Third, a political opening of some sort needs to be available in the aftermath of a revolutionary struggle to provide the opportunity for feminists to organize. Fourth, women revolutionaries need to find themselves with many of their basic needs unmet by their revolutionary movements. Fifth, a collective feminist consciousness needs to emerge in order for feminists to have the will to organize.

WHAT ISSUES ARE IMPORTANT TO FEMINISTS?

Once such movements arise, upon what sorts of issues do women focus their collective

attention? According to Peruvian feminist Virginia Vargas (1992), post suffrage feminism in Latin America was organized around three streams: the feminist stream, the stream of women in political parties, and the stream of women from the popular classes. Some of the issues of greatest concern to feminist organizations are voluntary maternity/responsible paternity, divorce law reform, equal pay, personal autonomy, and challenging the consistently negative and sexist portrayal of women in the media. For some women, the primary agenda lies in the goal of increasing women's access to formal political representation, where as women of the popular classes tend to focus their agendas on issues of economic survival and racial and ethnic justice. In other words, just as women in the region are a diverse group, so too are their feminist goals.

Though many organizations had only short lifespans, attention to the issues did not necessarily fade away with the dissolution of organizations. The Salvadoran women's *Asociación de Madres Demandantes* (Association of Mothers Seeking Child Support) and Cuban women's *Colectivo Magín* are two such examples (*Magín* means intelligence, inspiration, and imagination in Castilian). The *Madres Demandantes* was a grassroots feminist organization in El Salvador in the mid to late 1990s. It worked with feminists inside the Legislative Assembly to pass a series of laws, which mandated that politicians would be unable to assume office if they could not verify that they were up to date on their child support payments. Though the organization eventually disbanded, the laws themselves remain on the books and the issue of responsible paternity, voluntary motherhood, and (implicitly) legal access to safe abortion have influenced the direction of feminism in that country.

Another very challenging issue that Latin American feminists have sought to organize around is the negative portrayal of women in various media outlets, including television, school textbooks, and the like. The Cuban organization *Colectivo Magín* took as its primary goal to challenge this negative portrayal. The organization was rather short lived (1993–96), as the Cuban Communist Party eventually decided its efforts needed to be thwarted. Despite its deactivation, the conversation about

the negative portrayal of women in the media as related to the subsequent negative self image internalized by Cuban women has remained a topic of feminist conversations, isolated though they may be.

ARE ALL POLITICALLY AND SOCIALLY ACTIVE WOMEN FEMINISTS?

Related to the emergence of post suffrage feminist activism in the region are political and social organizations of women, which have non feminist agendas, sometimes quite explicitly. Examples include the Federation of Cuban Women (FMC), the various committees of the Mothers of the Disappeared that continue to exist throughout the region, collective soup kitchens, and women's commissions of labor unions and leftist political parties. Such organizations have focused on issues like those listed above. However, more often than not, their actions are articulated in very non feminist terms.

Because women have played roles in various social and political organizations the tendency is to assume that all politically active women are feminists. However, in Latin America this is not always the case. Though there are many examples of this, perhaps the most illustrative are the Committees of the Mothers of the Disappeared that spread throughout the region during the dictatorships of the 1970s and 1980s. The women who organized their committees did so as mothers, wives, grand mothers, sisters, daughters, etc. of the "disappeared" men in their lives; they were in no way making a feminist statement. Rather, their efforts lay firmly in a human rights agenda which called for the end of dictatorships and their tactics of summary torture, kidnapping, and incarceration. In most cases the women demonstrated a political strength for midable enough to in part be responsible for the dissolution of the dictatorships in the region. Regardless of their strength, their goals were entirely separate from feminism. However, despite their lack of attention to feminist agendas, the women in these organizations did offer a model for women's mobilization that in some cases was mimicked by feminist organizations.

The distinction between women's activism and feminist activism is not necessarily articulated, but rather implicit. Maxine Molyneux coined this distinction "practical" (feminine) versus "strategic" (feminist) demands. Molyneux's (1985) classic article argues that a distinction exists between women organizing to meet basic needs which are the result of a patriarchal division of labor and those explicitly organizing to counter systems of patriarchy responsible for such a division. For example, a practical need would be a daycare center. The patriarchal division of labor mandates that women are the caretakers of children and thus institutionalized assistance with childcare would ease this burden. On the other hand, a strategic demand would be that of voluntary motherhood, or access to free and safe abortion. Implicit in this demand is a challenge to the patriarchal division of labor that positions women as caretakers of children and reframes it to argue that women should first be able to decide if they want to be mothers. This later political statement, from Molyneux's perspective, is feminist, whereas the former is not.

HOW HAVE WOMEN COORDINATED THEIR EFFORTS?

In addition to the national developments in Latin American countries that played a part in the evolution of feminism, regional and transnational events have also proved central to the emergence of the ideologies and movements. The most concrete example of regional and transnational influences are the Latin American and Caribbean feminist *Encuentros* (Encounters), which began in 1981 in response to the United Nations declaring 1975–85 the Decade of the Woman. The five meetings of the first decade of the *Encuentros* (1981–90) addressed questions related to the relationship between feminist movements and male leftists, and eventually between feminists and non feminist women activists. Central to these debates was the issue of feminist autonomy. It was during this period that revolutionary upheaval was fundamental to the political backdrop in the region, as was evidenced by the debates occurring among the feminists.

As the violence in the region subsided and the transitions to democracy began, the debates

that faced feminists changed significantly. Of central concern to the delegates at the 1993, 1996, and 1999 meetings were issues regarding local grassroots feminist efforts versus the increased institutionalization of feminist organizations resultant from what some have identified as hegemonic relationships between international non governmental organizations and local feminist organizations. The final meeting in 2002 centered on feminist interpretations of globalization and its impact on the lives of women.

The meetings have varied in size, with the first and smallest one in Colombia with only 200 women in attendance, in contrast to the fifth meeting in Argentina where over 3,200 women were present. By now, nearly every country in the region has sent delegates at one point or another, but the demographic makeup still favors the wealthier, whiter, and Spanish speaking segments of Latin America and the Caribbean.

HOW HAS THE RETURN OF CIVIL SOCIETY AFFECTED FEMINIST MOVEMENTS?

With the completion of the so called transition to democracy in the region, feminist movements have changed significantly. Because military regimes and conflicts have more or less become a thing of the past, the place of civil society and formal politics are the social venues in which feminist battles are now played out. Furthermore, with the intensification of globalization, national and international non governmental organizations are a permanent fixture in all aspects of politics. As a result, one manifestation of post transition feminism is what Alvarez (1998) has dubbed the NGOization of feminist organizations.

Many feminist theorists argue that the transition to democracy in the region has virtually led to the demobilization of grassroots feminist organizations and their absorption by state centered feminist entities (Waylen 1994; Friedman 1998). On the other hand, some scholars argue that feminist organizations have not demobilized, but taken on different forms to run parallel with the overall political and economic transformation in the region: neoliberalism.

For example, Franceschet (2003) (speaking to the case of Chile) argues that such institutionalization is not in and of itself the problem. She suggests that the National Women's Service in Chile (SERNAM), which basically functions as a ministry of women within the government, has provided an axis for the women's movement with respect to discourse and resources. She argues that the women's movement in Chile is indeed fragmented and heterogeneous, and SERNAM is fraught with problems. However, she maintains that its existence contributes to the strengthening of the movement by providing crucial resources, not the least of which is a discourse of women's rights that organizations can employ to mobilize their members. Though her research and findings speak specifically to the case of Chile, parallels certainly exist in other countries in the region, as so many had strong women's and feminist movements during the dictatorships that have since morphed with the onset of democracy.

CONCLUSIONS

The evolution of feminist mobilization in Latin America and the Caribbean is largely connected to national, regional, and global changes. When the region was consumed with militaristic regimes and civil wars, feminists and non feminist women activists had a whole different set of issues to confront (e.g., revolutionary struggles for national liberation and the ongoing search for disappeared loved ones). As the struggles subsided (some more successful than others), women have found themselves in a variety of positions. A common trend has been the virtual dismissal of women's political contributions to their various leftist social movements that consumed the region in the 1970s and 1980s. This often blatant ignoring of women's participation in many cases served to push women out of formal politics and to start their own autonomous feminist organizations. In other cases, women seized the opportunity provided by the emergence of civil society and new democratic structures to insert themselves into formal political structures that in many cases simply had never existed before. Some have argued that such shifts have resulted in the dissolution of previously vibrant feminist

movements, while others interpret such changes in structure as inevitable and even empowering.

feminist anthropology

Helen Johnson

Feminism refers to the awareness of women's oppression and exploitation at work, in the home, and in society, as well as the conscious political action taken by women for progressive social and economic change toward equality and recognition of women's difference. Social anthropology has evolved from a dominant western discourse in which it explores cultural difference and uniqueness, while simultaneously seeking the similarities in human lived experiences. Feminist theoretical critiques entered social anthropology in the 1970s and are vital to ongoing theoretical and methodological developments. Feminist social anthropologists question many of the discipline's basic assumptions and have documented scholars' failure to fully explore the human experience due to the neglect of the organizing categories of "women" and "gender" as significant dimensions of social life.

The first wave of studies in the 1970s assumed universal sexual asymmetry through an assessment of the "global" subordination of women and thence tried to explain the situation

from various theoretical perspectives. Critical archeologists also joined with feminist social anthropologists to charge that the role of women in human evolution had been ignored due to inherent male bias in scholarly work that privileged hunting over gathering. And, although social anthropology had included women in its empirical studies due to anthropology's traditional concern with kinship and marriage, it had not problematized the representation of women. Thus the new "anthropology of women" that began in the 1970s confronted the thorny difficulties of how women were represented in anthropological writings. The preliminary issue of male bias was seen as having three tiers: the bias imported by the anthropologist to the culture being studied; the subordination of women in most societies which is then communicated to the anthropologist, predominantly by men; and the bias in favor of men inherent in western culture (Moore 1988). Simply adding women to traditional social anthropology would not resolve the obstacle of the invisibility of women, as male bias would not simply disappear. In turn, the assumption that women could effectively study women via the "anthropology of women" was also erroneous because, while successful in making women visible and as the precursor to feminist social anthropology, "the anthropology of women" was more remedial than radical. Furthermore, female scholars could easily become marginalized within mainstream academic studies (Moore 1988). Indeed, fears of the marginalization of female scholars and of the anthropology of women were linked to the sociological category "the universal woman" that was in favor at that time. The category did not recognize that because images, attributes, activities, and appropriate behaviors are always culturally and historically specific, both the categories of "woman" and "man" need to be investigated in their given context, not assumed.

The second wave in the 1980s saw feminist social anthropologists move away from totalizing assumptions of gender asymmetry to present analyses of women's oppression from neo Marxist perspectives. These argued that in societies prior to western invasion, gender relations were typically egalitarian because women

and men participated equally in the processes of production. As a consequence, European subjugation of societies and the imposition of capitalist forms of production *created* women's inequality in formerly egalitarian societies.

Feminist social anthropology in the 1990s and onwards introduced poststructural analytical frameworks that considered how women in contemporary communities actively construct and encounter globalization through their lived experiences as consumer purchasers, users of technology, controllers of land, and negotiators of its produce. As a consequence, feminist critique in social anthropology will continue to be central to theoretical and methodological developments within the discipline. The contemporary basis for the feminist critique of social anthropology, which grew out of a specific concern with the neglect of women in the discipline, is no longer the study of "women," but the analysis of gender relations, and of gender as a structuring principle in all human societies (Moore 1988).

Hence, feminist social anthropology now studies gender, the interrelations between women and men, and the role of gender in structuring human societies, their histories, ideologies, economic systems, political structures, and development projects. It is currently accepted that it is impossible to pursue valuable social science without incorporating analyses of gender.

A key problem relating to the theoretical and political complexities of women concerns the issues of race and ethnocentric bias in favor of one's own culture. Social anthropology has a critical involvement with its colonial past and the power relationships that characterized the encounter between the researcher and the researched. While edited collections such as Buckley's (1997) presented the "voices" of Japanese feminism, the often ethnocentric bias of feminist social anthropology provided a springboard for critiques by scholars from "Asian" nation states who questioned why they should establish further universals (re)presented through western experiences of modernity. Karim (1995) offered a critique of western concepts of power and their construction of gender hierarchies in Southeast Asian civilizations. She contended Southeast Asian civilizations derive theory and knowledge from

concepts of bilateralism, that is, the need to maintain social relationships through rules of complementarity, similarity, and the application of mutual responsibility and cooperation, rather than western concepts of hierarchy, opposition, oppression, and force (Karim 1995: 16).

From a predominance of western viewpoints about women's lived experience yet anchored in subaltern social analyses, examinations of what may best encompass many Asian societies' gender relations were made, especially through their attempts to centralize the informal and private and to provide clearer insights into daily activities which concern gendered actors in culture. Karim argued that many women enact their human agency in "Asian" societies via the use of informal structures. She contends this practice is considered to be "proper" behavior. Hence, she proposes that women operate as strategic agents within socially accepted notions of custom, by non cooperation, the strategic use of silence, leaving the household due to "overdue" visits to family, and discouraging open confrontation yet pressuring non compliant peers and superiors through the use of "hostile harmony" (1995: 18). While similar strategies and informal structures can be found in western cultures, Karim argues that "proper" behavior in terms of discouraging open confrontation forms part of South east Asian people's behavior in public as well as domestic arenas and social interactions, whereas open confrontation in public arenas is more acceptable in the West and, between men, is condoned as strong minded and/or purposive behavior (1995: 30).

Karim's (1981) early work on the belief system expressed by the Ma'Betisék of Selangor, Malaysia, in their relationship to plants and animals is concerned with the way in which ideas contained within a particular culture change from one situation to another. While drawing on Lévi Strauss's structuralism in terms of "culture" being the product of/constituted by real and abstract phonemic differences, Karim formulates her own concept of structure by focusing on the underlying rules which guide changes in the contents of the ideology of a particular culture. Her analysis of women, culture, and the entwining of Malay

custom with Islam (Karim 1992), and her co editing of a work that critiqued women, men, and the practice of ethnography, facilitated her work on the public social visibility of women in Southeast Asia (Karim 1995). She examined how their invisibility in formal politics or the great religions endorsed by the state has led to a questioning of the different valuations of power and prestige between women and men and the way that social intangibles such as patience, spirituality, and transference become sources of resistance and strength. She has also sought to examine the relationship between social sentiment and culture and society, and the relationship between individual emotions and social realities derived from collective sentiments, using Malay society as a basis for her research (Karim 1990). Her 1993 work is significant for its contributions to debates about how knowledge is made. She argued that it is no longer possible to separate clearly the researcher and the native into two neat categories as reflexive anthropology, generated by significant feminist social anthropology, has highlighted the ambiguous position of native scholars in anthropology and has promoted interest in western anthropologists doing research in their own societies. Further, the acquisition of knowledge about non western cultures in a reflexive mode can help generate perspectives on humankind that are more balanced and humanitarian and can overcome generalizations that are implicitly racist. Karim, in particular, highlights the challenges of doing anthropology as a non western anthropologist in cultures other than her own, but situated within her natal country.

Other female anthropologists have contributed to the discipline in similar yet varied ways. While Ong (1990) has examined the dynamic historical transformations of gender symbolism and gender relations wrought by massive changes in the political economy of the Southeast Asian region, Puri (1999) investigated the tensions of female bodies, desire, womanhood, and social class and the hegemonic codes that regulate the experiences and self definitions of middle class women's lives in the postcolonial nation state of India. Her work links with that of Sunder Rajan (1993, 2001, 2003), who reconceptualizes the stereotyped subjectivity of

"third world women" in essays that explore the representation of *sati*, wife murder, and the gender issues surrounding the construction of the "new woman" stereotype in postcolonial India. Moreover, while appreciating Tharu and Lalitha's (1991) work as one of stupendous research, scholarship, and critical energy, Sunder Rajan notes they do not adequately theorize the category of "experience" within and across cultures, the legitimacy of the role of the subaltern/feminist historian and critic, nor the role of the "invention of tradition" in contemporary Indian society and politics.

Trinh (1989) incorporates postcolonial theory and modes of writing into her examinations of diaspora and displacement to question the normative stance of "male" as literary and theoretical producer of knowledge. Her work links to Mohanty's (Mohanty et al. 1991; Alexander & Mohanty 1997; Mohanty 2003) theories of how knowledge is made about women across cultures, particularly under the umbrella of "development," with Yoon's (1998) focus on women's potential roles in sustainable development, and Sen's (1998) critique of the stereotypic Asian working woman as a laborer on the multinational factory floor. The work of a range of feminist anthropologists in Japan also complicates debates about the diverse roles of women in the varied cultures in the region and critiques western standpoints that too simplistically categorize these as "Asian." Kondo's (1990) exceptional field research and subsequent theorizations about how Japanese women's subjectivity and identity are constructed in a work environment enduring the changes wrought by modernity are foundational to Iawo's (1994) research and to Fujimura Fanselow and Kameda's (1995) edited collection, which analyses how the notion of "the Japanese woman" has changed across and through time.

Nagata (1984) has built on her work that analyzed the revitalization of Islam in Malaysia, its impact on the tightening of ethnic boundaries, and the definition of personal identity. She has examined the potential for ethnic, political, and institutional pluralism in Malaysia (Nagata 1975), and has lately focused on the process of nation building in Malaysia, the role of Islam, and how it shapes the ways in which Malaysia is establishing a presence and image in

the international community (Nagata 1997). In analyzing Malay women's veiling practices to explain how a symbol of dress takes on a local and global metaphor of anti modernism among the educated classes, Nagata (1995) contends that conformity to symbols of resistance in economic, political, and ritual life does not necessarily denote powerlessness or domestication but an active reconstruction of the image of the person amidst a world where modernity is equated with progress and virtue, and government control of social change. She has criticized Karim's (1995) emphasis on the dress code of women in Malay Muslim sects as a metaphor of women's oppression in Muslim societies, which Karim has countered with her view that the imitation of "Arab" dress styles is alien to Malay culture.

The contributions of feminist anthropological scholars from a range of non western cultures have been critical to the development of the discipline in the past decade. Throughout the 1990s feminist social anthropology confronted criticisms by indigenous and non western scholars that it was defined by the concerns of white, middle class western women who lacked understandings of race, class, and ethnicities in the constitution of social hierarchies. Contemporary feminist social anthropology acknowledged the validity of, and now works with, these challenges by paying attention to issues of international concern to women, experimenting in writing reflexive anthropology, and incorporating studies by non western scholars into the intersections of gender and other relations of power. Nonetheless, non western women's work is still marginalized or ignored within many western anthropological arenas, as are non western scholars themselves. Cross cultural research teams are potential ways forward, as the edited collections of the 1990s demonstrated in terms of bringing a range of viewpoints together from different cultural bases.

feminist criminology

Angela M. Moe

Feminist criminology represents an effort by social scientists to center research, teaching, and activism around issues of gender and justice. Feminist criminology as a whole stands as a critique of the sexist nature of theorizing within the discipline of criminology. The history of this movement extends back to the 1960s when scholars began testing the application of traditional criminological theories and applying the philosophical tenets of the women's liberation movement (also known as the second wave feminist movement) to female criminal offenders. Up until this time very little attention was given to women or girls in the justice system. Over the last four decades, feminist criminology has come to represent a conglomeration of conscientious efforts that focus on women and girls (and, to some extent, men and boys) in the justice system. The focus has extended beyond criminality to include the victimization of women and girls as

well as women who work in criminal justice occupations. The intersections of race, ethnicity, social class, and sexual orientation with gender have also become significant to feminist criminological inquiries. A central tenet of such work, beyond theory development and empirical research, is activism (within both academe and the larger community).

The scant attention given to female offending prior to the 1960s produced distorted images premised largely on biological determinism. Genetic defects, stunted evolutionary development, chemical imbalances, particularly those arising from menstruation or menopause, and personality traits were all believed to play roles in causing women and girls to be predisposed to criminality. Such perspectives equated women's temperament and ability to control themselves strictly with their own bodily functions, excusing any need to consider social and structural components to their criminality.

Women and girls involved in the criminal justice system were necessarily deemed pathological or mentally ill, and their treatment in the justice system reflected such beliefs with heavy use of psychiatric hospitals and therapy, particularly for white women and women of middle to upper class standing. Because the belief was that proper social control and socialization could prevent them from yielding to their biological drives, the use of stereotypical gendered programming (e.g., sewing, cosmetology, childrearing) within correctional settings was also popular. The exception included poorer women, immigrant women, and women of color who were more often excluded from rehabilitative programming.

Even with the development of sociologically driven theories of crime during the early to mid 1900s, the social and structural components of female offending remained largely unexamined. The sociologically driven theories were predominantly created by scholars interested in the illegalities of men and boys; hence, theoretical development and empirical research were skewed toward explaining male criminality.

Beginning in the 1960s and correlating with the second wave feminist movement as well as the influx of women in graduate education, social scientists, primarily but not exclusively women, began formally and openly critiquing the state of criminological theory, research, and

practice. Several of the individuals who led this charge came out of the critical criminological tradition, where they had critiqued the role of class and criminal justice operations. These individuals, who became known as the first feminist criminologists, recognized the gaps within the critical criminological framework when gender was excluded from analysis. Most theories at this time, while sociologically driven, still neglected women or girls. They were often assumed to apply equally to males and females despite being based almost solely on men's or male adolescents' behavior. This was especially problematic in light of the fact that gender as a variable holds enormous power to predict who is most likely to commit crime. Throughout the subsequent decades, attempts were made to apply these theories to women and girls. Overall, the findings suggested that such theories needed to be altered or disregarded as explanations of female criminality.

In the 1970s, scholars, particularly in the United States, started developing theories to explain female criminality specifically. Freda Adler's *Sisters in Crime* (1975) and Rita Simon's *Women and Crime* (1975) were not aimed explicitly at critiquing earlier individual based theories or at applying previously developed sociologically based theories. Instead, both attempted to explain female criminality through an application of liberal feminism, arguing that greater emancipation for women would bring changes in the nature and frequency of female offending. While both works have been heavily critiqued, they did mark the first criminological studies explicitly focused on women, as well as the blending of feminism and criminology. Criminologists interested in either women's and girls' experiences in crime, or gender disparities in offending, began relying on various tenets of feminism (e.g., liberal, socialist, Marxist, radical, and later postmodernist) to understand these phenomena.

A plethora of feminist criminological research has been produced over the past four decades. Traditional criminological theories continue to be tested by feminist scholars as to their applicability to women and girls. Most of this research, termed feminist empiricism, continues to rely on the scientific (deductive) method, utilizing quantitative analyses on large datasets. A more recent trend has been the use

of feminist epistemology and methodology as a foundation for research. Much of this type of work is done qualitatively within a grounded or exploratory framework. Of particular relevance is standpoint epistemology wherein the contributions to research inquiries by members of socially, historically, or economically marginalized groups are privileged above the contributions of members of more privileged groups. The study of women and girls has fit well within this framework given their marginalization in society, as well as within criminological research.

Most recently, feminist criminologists have employed postmodern perspectives in their work in order to address the essentialism that has plagued earlier research that attempted to develop succinct and generalizable explanations for all women's and girls' illegality. By questioning the ability of social research to find an absolute and objective truth, postmodernist feminist criminology has served as a reminder of the importance of producing scholarship that is mindful of the nuanced complexities of women's lives. Postmodernist feminist criminology has also informed masculinities research wherein the hegemonic notions of sexuality and gender performance have been analyzed within the context of male criminality.

Of particular relevance to both postmodernism and standpoint perspectives is the intersectionality within women's lives, without which it is assumed a researcher could only hope to understand a small aspect of an individual's decision making and behavior. Attention to prior life experiences such as child maltreatment and intimate partner victimization, as well as to racism, ethnicity, culture, poverty, sexual orientation, age, and (dis)ability, have all become focal points in feminist theorizing about female criminality.

Feminist criminology has had an impact on victimology as well. The second wave feminist movement is credited with focusing greater attention on female victimization, particularly rape and intimate partner assault. Feminist criminologists have addressed the power dynamics involved with (mostly male) violence against women and girls, as well as the structural components of such violence. For instance, by examining law enforcement and court responses to domestic violence, institutional inaction,

erroneous action, or complacency have been formally documented. Feminist criminologists have extended their academic work into social activism by becoming advocates for victims, serving, for example, as expert witnesses in rape cases. A focus on victimization has also helped lead to one of the current themes within feminist criminological research – that is, the link between victimization and criminal offending. Often termed pathways research, this line of inquiry has produced several new insights on the ways in which women's and girls' criminality is often linked to, if not a direct result of, prior victimization, often in the form of child abuse, sexual assault, and partner battering.

Finally, feminist criminology has addressed gender and the workplace, specifically women workers in criminal justice occupations. Studies have examined the working conditions and environment for women in criminal justice occupations within law enforcement, the court system, and the correctional system, all of which have been predominantly male occupations. Harassment, victimization, and discrimination have been documented throughout the hiring practices, training, and promotional practices of these occupations. Specific attention has focused on the enhanced discrimination and hostility encountered by women of color and lesbians within these working environments. Such work has also focused on women's positions in academe within departments of criminal justice, criminology, and sociology where women, particularly those who identify as feminists, have historically faced isolation, devaluation, and sometimes direct harassment and discrimination. Many of the first criminologists were also the first women in their departments; hence, the struggle to center criminological inquiry on women and girls has coincided with efforts to gain legitimacy within the workplace.

Feminist criminology will continue to have a significant presence within criminology. As more women and girls become involved in the criminal justice system and as greater interest abounds as to the nature of their offending, it is probable that existing and perhaps newly developed academic journals will seek feminist criminological research. Debate currently ensues as to the future of feminist criminology in relation to the discipline of criminology, however. Some

scholars argue that feminist criminology ought to remain on the fringes of the discipline, where it can be given specific and concerted attention by researchers who are committed to blending academic inquiry with social justice and activism. Proponents of this perspective believe that specialized courses on gender and justice, and violence against women, are necessary in order to give the respective topics the amount of attention they deserve. They also argue that specialized journals provide critical forums for the highest quality feminist work and that professional legitimization will come as feminist scholars and practitioners reach positions of authority. Others assert that purposely keeping feminist criminology on the fringe of the discipline only contributes to its relative isolation and devaluation within academe. Advocates of this perspective argue that legitimacy of feminist criminological work within the larger discipline of criminology will come only when it has been incorporated entirely into mainstream criminology such that all types of journals accept feminist based work, all university and college courses include discussions of gender and feminist material, and feminist academics are as well recognized within the discipline as traditional criminologists.

feminist disability studies

Monica J. Casper and Heather Laine Talley

Feminist disability studies is an emergent interdisciplinary field of inquiry shaped by a productive yet tense dialogue between feminist studies and disability studies. It is framed as a collaborative enterprise between feminist studies, which highlights vectors through which social relations and bodies are gendered and sexed, and disability studies, which focuses on

the ways socio medico legal discourses and practices construct impaired bodies as disabled (Thomson 2002). Both feminist studies and disability studies emerged out of twentieth century political projects emphasizing social justice and collective action. Intellectually, both fields address questions about subject formation, power, bodies, subjugated knowledges, and normalization. Feminist disability studies is kin to and stands alongside other critical, identity based scholarship aimed at social justice, including queer theory, critical race theory, gender studies, and ethnic studies.

Disability studies scholar Rosemarie Garland Thomson (1994) cites a 1986 essay by Nancy Mairs, "On Being a Cripple," as one possible inauguration of feminist disability studies, in that Mairs attends both to her disability and to her gender in critiquing "normal" culture and society. Yet delineating an origin story for this field is complicated, as a number of scholars studying the relationship among gender, bodies, illness, medicalization, body image, and deviance can also be read as having pursued versions of feminist disability studies without directly naming their work as such. For example, Susan Bordo's *Unbearable Weight* topic, methodology, and cultural critique, could certainly count as feminist disability studies, as could Anne Finger's *Past Due: A Story of Disability, Pregnancy, and Birth* (1990). Indeed, a current project of feminist disability studies is articulating the field's roots, theoretical concepts, methodologies, political aims, and topics (Thomson 2002; Rohrer 2005). Locating the history of the field and its intersections with other fields of inquiry is a vital component of implementing feminist disability studies as both scholarly endeavor and activist project.

Thomson (2002) criticizes disability studies scholars for either ignoring or failing to draw upon feminist studies, suggesting that there is a great deal of "wheel reinventing" going on. On the other hand, disability studies scholars, including many feminists, have criticized women's and gender studies for ignoring or excluding disability from research projects and syllabuses (DePauw 1996). Feminist disability studies attempts to bridge these gaps and elisions, bringing the insights of feminist scholarship to the study of disability and vice versa. This means that the ability/disability system

(Thomson 2002) is included among gender, race, sexuality, class, and other systems of power as a category of analysis. Like feminist theory, disability studies offers a more complex history and political analysis of bodies and embodiment than can be gained through less self conscious sociological approaches. Feminist disability studies recognizes that disability, like gender, is a pervasive concept constructed by and embedded in all aspects of culture, including institutions, identities, practices, politics, and communities (Thomson 2002). Feminist disability studies deepens our understanding of intersectionality and the ways in which multiple systems and identities are mutually created and performed.

The fit between feminist and disability studies is a seemingly logical one, in that a gender aware disability studies is transformed by and activates ongoing feminist conversations about body image, weight, beauty, embodiment, medicalization, illness, prenatal diagnosis, reproduction, pregnancy, sexuality, sport, mothering, and a host of other topics. Indeed, a major strategy of feminist theory and gender studies has been to frame women's bodies as "disabled," that is, as non normative. Feminist theory has long attended to questions of normalcy and normalization and the troubling ways in which women's bodies are sculpted physically and conceptually in and through institutions and cultural practices. Gender is constructed and performed in large part through a repositioning of female bodies as the deviant opposite of the standard male. While men and male bodies are framed as normal, women are perceived always to be "throwing like a girl" (Young 1990) and subjugated accordingly. The female body, like the disabled body, never quite measures up and must be continually refashioned to fit social norms of beauty, fitness, and appropriate behavior. In its attention to normalization practices, feminist disability studies can be woven into extant theories of gender, culture, and disability.

The interjection of feminist approaches into disability studies opens up spaces for considering the uniquely gendered experiences of disability, specifically the lived experiences of disabled women and the experiences of women caregivers. This does not mean that feminist disability studies is about only disabled women.

But it does mean that if women's bodies are always framed as "monstrous," as feminist scholars have argued, then disabled women's bodies are doubly excluded from cultural conceptions of normalcy. By focusing on cultural representations and experiences of disabled women, feminist disability studies reaffirms that the normative assumptions surrounding the body are, in fact, deeply and consequentially gendered. While feminist disability studies need not erase or devalue the experiences of disabled men, it does acknowledge that disabled men are privileged in spite of their disabilities because of their status as gendered persons. Race and class further complicate hierarchies of illness and disability experiences and of informal health care.

While there are now many scholars working in the area of feminist disability studies, few have been more central to the self-conscious development of the field than Thomson (1994, 1997, 2002). As a scholar in feminist studies and disability studies, her integration and linkage of both fields provides a model for intersectional analysis in practice. It is widely acknowledged that we can no longer speak in monolithic terms, yet Thomson challenges scholars interested in gender and disability to consider specificity by distinguishing *feminist disability studies* from a generic feminist studies or disability studies approach. In doing so, she posits a legitimate insider's critique of each intellectual progenitor while also laying important groundwork for learning to speak across these fields.

Specifically, she argues that disability studies has failed to produce a gendered analysis of disability and that feminist studies has failed to take into account real experiences of disabled women despite a stated value of intersectional analyses. For example, Thomson contends that certain strains of feminism have posited a romantic version of the female body that emphasizes reproduction and motherhood in such a way that neglects or infantilizes disabled women. Thomson (2002) identifies four key trajectories and objects of analysis for feminist disability studies: representation, the body, identity, and activism. In outlining these disciplinary concepts for future work in feminist disability studies, Thomson's articulation of the field establishes feminist disability studies within the realm of the humanities.

Thomson's project and the work of other scholars illustrates that feminist disability studies is an emerging field. While few have explicitly identified their work as part of a feminist disability studies project, much work located in feminist studies and disability studies is compatible with the vision of feminist disability studies offered by Thomson. For example, feminist disability studies inherits from disability studies skepticism toward definitions of disability anchored in "deviant" bodies. Rather, the focus is on cultural narratives that define some bodies as non normative, thereby subjugating and devaluing particular embodiments. Feminist disability studies is a critical enterprise in that the underlying project is to illustrate how gender and disability function to privilege certain bodies over others, resulting in differential social access and recognition by and within human communities. Scholarship that may be identified as feminist disability studies has relied largely on ethnographic methods. Yet, as an emergent field, the full range of methodological possibilities has yet to be identified.

Some examples of feminist disability studies in practice highlight both emergent contributions of the field and ongoing tensions between the field and its intellectual kin. A particularly compelling example is Gelya Frank's (2000) account of the life of Diane DeVries. The book, a cultural biography, offers Frank's personal narrative about her friend DeVries, a woman born without arms and legs. The women met at UCLA when Frank was 28 and DeVries 26, one a graduate student and the other a funny, irreverent undergraduate. *Venus on Wheels* presents DeVries as a quintessential American woman of the second half of the twentieth century, in personal language that never erases DeVries's identity at the expense of Frank's academic voice and methodological aims. DeVries, a disabled woman with guts and a sex life, is positioned as an exemplar for feminist and disability rights politics, challenging boundaries of gender and embodiment. Yet locating DeVries within both arenas – feminist studies and disability studies – highlights the ways in which neither field adequately accounts for her. She is instead an ideal model for feminist disability studies, and indeed Frank draws on her relationship with DeVries to interrogate cultural representations of women with disabilities.

Herndon (2002) builds on feminist theory and disability studies to analyze medical and social constructions of fatness as disability. She locates fatness within social, cultural, and political contexts, thereby undermining the notion that "fat" is strictly a biological category. In doing so, she shows that medicalization is not a useful tool for explaining the stigma associated with being fat – a stigma that especially affects women. While framing fatness as a disability in order to showcase the various politics animating it, Herndon also points to intense social resistance to such a construction of fatness. Herndon names this resistance as chronic reluctance to recognize fat as a social, rather than natural, category, reflecting society's aversion to acceding humanity, citizenship, and attendant benefits to fat people. She suggests that feminists express particular ambivalence about fatness, on the one hand wanting to politically resist "corporeal ultimatums" from the larger society and on the other hand, experiencing individual desires for a particular kind of acceptable body. Understood through a feminist disability studies perspective, fatness draws attention both to social fears of the non normative as well as to feminism's inconsistencies, including aversion to certain body types.

Feminist disability studies broadens our understanding of reproductive technologies and politics, as well. Since the nineteenth century platform of "voluntary motherhood" up to present ongoing struggles to preserve *Roe v. Wade*, the ability of women to make choices about their own bodies has been framed as central to the larger goal of securing women's liberation. Indeed, feminism has often defined reproductive choices as a litmus test of women's social and political agency. Questions of reproduction have also dominated disability studies, but disability studies has come to different conclusions. Disability studies situates the "right to choose" and related issues in a social and technological landscape wherein choice may mean deciding to abort a fetus identified as disabled. Disability studies adopts an essentially sociological perspective, asking which fetuses are mostly likely to be aborted? For disability studies, selective abortion regardless of its potential to preserve women's agency fundamentally interferes with the expression of disabled agency and embodiment.

Prenatal diagnosis, specifically, is revealed to be richly complicated when analyzed through a feminist disability studies lens. Medicalized notions of health and normalcy, along with women's fears and desires, have contributed to the ongoing expansion of diagnostic technologies and categories (Rapp 1999). The termination or birth of an affected fetus are polarized choices stemming from interpretation of the results of prenatal diagnosis. The proliferation of fetal treatments (Casper 1998) makes possible an additional, quite limited option: "fixing" an impaired fetus. Feminist disability studies draws our attention to the ways in which prenatal diagnosis is not only about expanding women's choices (a recognized feminist goal). It is also about normalcy, disability, and cultural intolerance of human variation.

Thomson (2002: 14–15) writes: "Preventing illness, suffering, and injury is a humane social objective. Eliminating the range of unacceptable and devalued bodily forms and functions the dominant order calls disability is, on the other hand, a eugenic undertaking." Feminist studies alone, in its attention to women's rights and bodily autonomy, often fails to recognize the implications of prenatal diagnosis with respect to disability and the lived experiences of people with impairments. Disability studies alone, in its attention to the eugenic implications of elimination of impaired bodies, often fails to consider the impact on women's autonomy of limitations on reproductive choice. Feminist disability studies highlights medicine's relentless focus on cure and/or elimination at the expense of collective health and well being and also interrogates biases in feminist and disability scholarship.

As these examples illustrate, for feminist disability studies to be rooted in both feminism and disability studies and yet different from either feminism or disability studies, it must take into account the ways in which disability studies and feminist studies may be in conflict. From the perspective of feminism and disability studies, society disables and genders people in ways that yield consistent and disempowering effects. Yet, as critical intellectual enterprises with activist roots, feminism and disability studies are in tension over what each imagines as the practical implications of its theoretical perspectives. Both feminism and disability studies are interested in

recovering agency lost through the hierarchical machinations of gender and disability. Each emphasizes the need for autonomy and choice for women and disabled people, respectively. A key project of feminist disability studies, then, is continually to work to disentangle conflicts and tensions between feminist agency and disabled agency, using the spaces and gaps between these productively and critically.

Feminist disability studies must also come to terms with its relationship to the academy, specifically to disciplines that may welcome feminist disability studies and simultaneously contribute to the methodological and theoretical underpinnings of the field. Feminist disability studies may find an institutional home and intellectual kinship in sociology, specifically in scholarship on the body and on differences. The project of sociology is denaturalization, in the sense that sociology is fundamentally about questioning the taken for granted. Feminist disability studies begins with the assumption that natural accounts of disability and of gender will always be inadequate for understanding people's experience. Both sociology and feminist disability studies work towards undermining or at least complicating essentialist notions of the body. Some strands of sociology, specifically symbolic interactionism and constructionism, are fundamentally concerned with how meaning is produced through social interaction, offering theoretical and analytic tools for feminist disability studies projects.

Sociology's emphasis on social structure and institutions may also contribute to feminist disability studies. As Thomson (2002) has noted, a core premise of feminist disability studies is that representation structures reality. Sociology has the tools to extend a reverse analysis revealing how social structures organize representations. In other words, a structural analysis illustrates how definitions of normalcy become embedded in social structures and thus reveals how disability is shaped on a macro level. As an activist enterprise, feminist disability studies must develop a multi level analysis in order to address the complex processes through which oppressions emerge. Narratives of the body, bodily experience, and representation are important for developing a gendered understanding of disability, but so too are structural exclusion and institutional norms.

Feminist disability studies has employed "disability" as a catch all to refer to bodies that are culturally identified as sick, impaired, ugly, deformed, or malfunctioning. One of the most valuable contributions of feminist disability studies is its emphasis on the importance of intersectionality. However, one question feminist disability studies must struggle with is the limitations of using "disability" in reference to widely varying bodily experiences. The deployment of disability as a universal category might be politically useful in its ability to unite large groups of people – particularly as biomedical technologies proliferate and challenge what it means to be human – and theoretically useful by highlighting the social processes underlying the identification of a variety of bodies, including those gendered female, as deviant. But there may be consequences of expanding conceptual categories of disability to include *all* non normative bodies, for the details of a particular embodiment or impairment may be central to understanding lived experiences. For studies of difference to be fully engaged and relevant, feminist disability studies must resist generic analyses of intersectionality in favor of contextual analysis focused on specific permutations of embodied, gendered difference.

feminist methodology

Nancy A. Naples

Feminist methodology is the approach to research that has been developed in response to concerns by feminist scholars about the limits of traditional methodology to capture the

experiences of women and others who have been marginalized in academic research. Feminist methodology includes a wide range of methods, approaches, and research strategies. Beginning in the early 1970s, feminist scholars critiqued positivist scientific methods that reduced lived experiences to a series of disconnected variables that did not do justice to the complexities of social life. Feminists were also among the first scholars to highlight the marginalization of women of color in academic research and to offer research strategies that would counter this trend within academia (Baca Zinn 1979; Collins 1990). Feminist scholars also stress the importance of intersectional analysis, an approach that highlights the intersection of race, class, gender, and sexuality in examining women's lives (Crenshaw 1993). Some of the earliest writing on feminist methodology emphasized the connection between "feminist consciousness and feminist research," which is the subtitle of a 1983 edited collection by Stanley and Wise. Over the years, feminist methodology has developed a very broad vision of research practice that can be used to study a wide range of topics, to analyze both men's and women's lives, and to explore both local and transnational or global processes.

Feminist sociologists like Dorothy Smith (1987) pointed out that the taken for granted research practices associated with positivism rendered invisible or domesticated women's work as well as their everyday lives. She argued for a sociology for women that would begin in their everyday lives. Feminist philosopher Sandra Harding (1987, 1998) has also written extensively about the limits of positivism and argues for an approach to knowledge production that incorporates the point of view of feminist and postcolonial theoretical and political concerns. She stresses that traditional approaches to science fail to acknowledge how the social context and perspectives of those who generate the questions, conduct the research, and interpret the findings shape what counts as knowledge and how data is interpreted. Instead, she argues for a holistic approach that includes greater attention to the knowledge production process and to the role of the researcher. Harding and Smith both critique the androcentric nature of academic knowledge production. They argue for the importance of

starting analysis from the lived experiences and activities of women and others who have been left out of the knowledge production process rather than start inquiry with the abstract categories and a priori assumptions of traditional academic disciplines or dominant social institutions.

In 1991, sociologists Mary Margaret Fonow and Judith A. Cook published a collection of essays in a book titled *Beyond Methodology: Feminist Scholarship as Lived Research*. The authors in this collection discussed how different methodological techniques could be used to capture the complexities of gender as it intersects with race, sexuality, and class. The authors also explored the ethical dilemmas faced by feminist researchers, such as: How does a researcher negotiate power imbalance between the researcher and researched? What responsibilities do researchers have to those they study? How does participatory research influence analytic choices during a research study? Feminist scholars have consistently raised such questions, suggesting that if researchers fail to explore how their personal, professional, and structural positions frame social scientific investigations, researchers inevitably reproduce dominant gender, race, and class biases (see Naples 2003).

Fonow and Cook (2005) revisited the themes that were prevalent when they wrote *Beyond Methodology* and highlighted the continuity and differences in the themes that dominate discussions of feminist methodology at the beginning of the twenty first century. They found that the concerns about reflexivity of the researcher, transparency of the research process, and women's empowerment remained central concerns in contemporary feminist methodology. They also point out the continuity in the multiple methods that are utilized by feminist researchers, which include participatory research, ethnography, discourse analysis, comparative case study, cross culture analysis, conversation analysis, oral history, participant observation, and personal narrative. However, they note that contemporary feminist researchers are more likely to use sophisticated quantitative methods than they were in the 1980s and 1990s.

Another important text that provides an overview of feminist methods in the social sciences is that of Reinharz (1992). Following

a comprehensive review of feminist methods with illustrations from diverse feminist studies, Reinharz identifies ten features that appear in efforts by feminist scholars to distinguish how their research methods differ from traditional approaches. These include the following: (1) feminism is a point of view, not a particular method; (2) feminist methodology consists of multiple methods; (3) feminist researchers offer a self reflective understanding of their role in the research; and (4) a central goal of feminist research is to contribute to social changes that would improve women's lives. The themes of reflexivity and research for social change are two of the most important aspects of feminist methodology that distinguishes it from other modes of research.

REFLEXIVITY

Reflective practice and reflexivity include an array of strategies that begin when one first considers conducting a research project. Reflective practices can be employed throughout the research process and implemented on different levels, ranging from remaining sensitive to the perspectives of others and how we interact with them, to a deeper recognition of the power dynamics that infuse ethnographic encounters. By adopting reflective strategies, feminist researchers work to reveal the inequalities and processes of domination that shape the research process. Wolf (1996) emphasizes that power is evident in the research process in three ways: first, the differences in power between the researcher and those she or he researches in terms of race, class, nationality, among other dimensions; second, the power to define the relationship and the potential to exploit those who are the subjects of the research; and third, the power to construct the written account and therefore shape how research subjects are represented in the text. Feminist researchers argue that dynamics of power influence how problems are defined, which knowers are identified and are given credibility, how interactions are interpreted, and how ethnographic narratives are constructed. Feminist researchers stress that if researchers fail to explore how their personal, professional, and structural positions frame social scientific investigations, researchers

inevitably reproduce dominant gender, race, and class biases.

Harding (1987) argues for a self reflexive approach to theorizing in order to foreground how relations of power may be shaping the production of knowledge in different contexts. The point of view of all those involved in the knowledge production process must be acknowledged and taken into account in order to produce what she terms "strong objectivity," an approach to objectivity that contrasts with weaker and unreflective positivist approaches. In this way, knowledge production should involve a collective process, rather than the individualistic, top down, and distanced approach that typifies the traditional scientific method. For Harding, strong objectivity involves analysis of the relationship between both the subject and object of inquiry. This approach contrasts with traditional scientific method that either denies this relationship or seeks to achieve control over it. However, as Harding and other feminist theorists point out, an approach to research that produces a more objective approach acknowledges the partial and situated nature of all knowledge production (see Collins 1990). Although not a complete solution to challenging inequalities in the research process, feminist researchers have used reflective strategies effectively to become aware of, and diminish the ways in which, domination and repression are reproduced in the course of their research and in the products of this work. Furthermore, feminist researchers argue, sustained attention to these dynamics can enrich research accounts as well as improve the practice of social research (Naples 2003).

Feminist ethnography and feminist work with narratives are two of the methods in which feminist researchers have been the most concerned with processes of reflexivity. Examining work that utilizes both of these methods, the range of approaches that count as feminist is especially evident. For example, Chase's (1995) approach to oral narratives includes attention to the way women narrate their stories. Rather than treat the narratives as "evidence" in an unmediated sense of the term, Chase is interested in exploring the relationship between culture, experience, and narrative. Her work on women school superintendents examines how

women use narrative strategies to make sense of their everyday life experiences as shaped by different cultural contexts. In contrast, Bloom (1998) adopts a "progressive regressive method" derived from Sartre's notion of "spirals" in a life to examine how the individual can overcome her or his social and cultural conditioning, "thereby manifesting what he calls 'positive praxis.'" Drawing on Dorothy Smith's institutional ethnographic method, DeVault (1999) utilizes narratives she generates from ethnographic interviews to explore how relations of ruling are woven into women's everyday lives such that they are hidden from the view of those whose lives are organized by these processes of domination. The institutional and political knowledges that DeVault uncovers illustrate the link between institutional ethnography and feminist activism. In the context of activist research, feminist analysts using Smith's approach explore the institutional forms and procedures, informal organizational processes, as well as discursive frames used to construct the goals and targets of the work that the institution performs. This approach ensures that a commitment to the political goals of the women's movement remains central to feminist research by foregrounding how ruling relations work to organize everyday life. With a "thick" understanding of "how things are put together" it becomes possible to identify effective activist interventions.

POSTCOLONIAL AND POSTMODERN CHALLENGES

The call for reflective practice has also been informed by the critiques of third world and postcolonial feminist theorists who argue for self reflexive understanding of the epistemological investments that shape the politics of method (Alexander & Mohanty 1997). Postmodern and postcolonial critiques of the practice of social scientific research raise a number of dilemmas that challenge feminist researchers as they attempt to conduct research that makes self evident the assumptions and politics involved in the process of knowledge production in order to avoid exploitative research

practices. Postmodern feminist scholars emphasize the ways disciplinary discourses shape how researchers see the worlds they investigate. They point out that without recognition of disciplinary metanarratives, research operates to reinsert power relations, rather than challenge them. Many feminist researchers have grappled with the challenges posed by postmodern critics. Wolf (1996) explains that for some feminist scholars postmodern theories provide opportunities for innovation in research practices, particularly in the attention they pay to representation of research participants or research subjects and to the written products that are produced from a research study. However, many other feminist scholars are concerned that too much emphasis on the linguistic and textual constructions decenters those who are the subjects of our research and renders the lives of women or others whom we study irrelevant.

Postmodern analyses of power have destabilized the practice of research, especially research that involves human subjects. If power infects every encounter and if discourse infuses all expressions of personal experience, what can the researcher do to counter such powerful forces? This dilemma is at the heart of a radical postmodern challenge to social scientific practice in general, but has been taken up most seriously in feminist research. Naples (2003) argues that one partial solution to this dilemma is to foreground praxis, namely, to generate a materialist feminist approach informed by postmodern and postcolonial analyses of knowledge, power, and language that speaks to the empirical world in which one's research takes place. For example, in her work, by foregrounding the everyday world of poor women of different racial and ethnic backgrounds in both the rural and urban US and by exploring the governing practices that shape their lives, she has worked to build a class conscious and anti racist methodological approach (see also Alexander & Mohanty 1997).

While postmodern and postcolonial feminist scholars point to the myriad ways relations of domination infuse feminist research, they also offer some guidance for negotiating power inherent in the practice of fieldwork. For example, Mohanty (1991) calls for "focused, local

analyses" to counter the trend in feminist scholarship to distance from or misrepresent third world women's concerns. Alexander and Mohanty (1997) recommend "grounding analyses in particular, local feminist praxis" as well as understanding "the local in relation to larger, cross national processes."

RESEARCH FOR SOCIAL CHANGE

A consistent goal expressed by those who adopt feminist methodology is to create knowledge for social change purposes. The emphasis on social action has influenced the type of methods utilized by feminist researchers as well as the topics chosen for study. For example, feminists have utilized participatory action research to help empower subjects of research as well as to ensure that the research is responsive to the needs of specific communities or to social movements (Reinharz 1992; Naples 2003; Fonow & Cook 2005). This approach to research is also designed to diminish the power differentials between the researcher and those who are the subjects of the research. In an effort to democratize the research process, many activist researchers argue for adopting participatory strategies that involve community residents or other participants in the design, implementation, and analysis of the research. Collaborative writing also broadens the perspectives represented in the final product.

A wide array of research strategies and cultural products can serve this goal. Yet such strategies and cultural products can be of more or less immediate use for specific activist agendas. For example, activist research includes chronicling the history of activists, activist art, diverse community actions, and social movements. Such analyses are often conducted after the completion of a specific struggle or examine a wide range of different campaigns and activist organizations. This form of research on activism is extremely important for feminists working toward a broadened political vision of women's activism and can help generate new strategies for coalition building. However, these studies may not answer specific questions activists have about the value of certain strategies for their particular political struggles. Yet these

broad based feminist historical and sociological analyses do shed new light on processes of politicization, diversity, and continuity in political struggles over time.

On the one hand, many activists could be critical of these apparently more “academic” constructions of activism, especially since the need for specific knowledges to support activist agendas frequently goes unmet. The texts in which such analyses appear are often not widely available and further create a division between feminists located within the academy and community based activists. On the other hand, many activist scholars have developed linkages with activists and policy arenas in such a way as to effectively bridge the so called activist/scholar divide. Ronnie Steinberg brought her sociological research skills to campaigns for comparable worth and pay equity. She reports on the moderate success of the movement for comparable worth and the significance of careful statistical analyses for supporting changes in pay and job classifications. As one highlight, she reports that in 1991 systematic standards for assessing job equity developed with her associate Lois Haignere were translated into guidelines for gender neutral policies incorporated by the Ontario Pay Equity Tribunal. In another example of feminist activist research, Roberta Spalter Roth and Heidi Hartmann testified before Congress and produced policy briefs as well as more detailed academic articles to disseminate their findings about low income women’s economic survival strategies. Measures of a rigid positivism are often used to undermine feminists’ credibility in legal and legislative settings. Even more problematic, research generated for specific activist goals may be misappropriated by those who do not share feminist political perspectives to support anti feminist aims. For example, proponents of “workfare” programs for women on public assistance could also use Spalter Roth and Hartmann’s analysis of welfare recipients’ income packaging strategies to further justify coercive “welfare to work” measures.

Some feminist scholars working directly in local community actions have also brought their academic skills to bear on specific community problems or have trained community members to conduct feminist activist research. Terry

Haywoode (1991) worked as an educator and community organizer alongside women in her Brooklyn community and helped establish the National Congress of Neighborhood Women’s (NCNW) college program, a unique community based program in which local residents can earn a two year Associates degree in neighborhood studies. By promoting women’s educational growth and development within an activist community organization, NCNW’s college program helped enhance working class women’s political efficacy in struggles to improve their neighborhood.

CONCLUSION

Feminist methodology was developed in the context of diverse struggles against hegemonic modes of knowledge production that render women’s lives, and those of other marginal groups, invisible or dispensable. Within the social sciences, feminist researchers have raised questions about the separation of theory and method, the gendered biases inherent in positivism, and the hierarchies that limit who can be considered the most appropriate producers of theoretical knowledge. Feminist reconceptualizations of knowledge production processes have contributed to a shift in research practices in many disciplines, and require more diverse methodological and self reflective skills than traditional methodological approaches. However, some feminist scholars question whether or not it is possible to develop a reflexive practice that can fully attend to all the different manifestations of power (Stacey 1991). However, since feminist methodology is open to critique and responsive to the changing dynamics of power that shape women’s lives and those of others who have been traditionally marginalized within academia, feminist researchers often act as innovators who are quick to develop new research approaches and frameworks.

feminist pedagogy

Vicky M. MacLean

Although many, if not most, academics and others in the public arena today assume the need for a feminist pedagogy aimed at enhancing the educational experience of women and girls globally, this has not always been the case. A growing awareness of the need for feminist pedagogy was created by the pioneering research and pedagogy of committed feminist scholars (Hall & Sandler 1982; Sandler & Hall 1986; Harding 1987, 1992; Weiler 1988; Geismar & Nicoleau 1993; Rosser 1993, 1995; Maher & Tetreault 1994). *Feminist pedagogy* begins with the premise that gender and the social inequality it represents in the wider society are often reproduced in the classroom. Existing curricula and classroom practices contain sexist biases and patriarchal assumptions as reflected in the fact that the contributions of women are often absent from textbooks; girls and women are portrayed in stereotypic ways in much of the literature of all disciplines; girls and women are often directed to certain fields of study and are directed away from others; and teaching practices typically favor the learning styles of boys and men. Teachers informed by principles of feminist pedagogy seek to express feminist values and goals in the classroom and to challenge traditional androcentric knowledge (Geismar & Nicoleau 1993). Those adopting a feminist pedagogy ultimately seek to advance the status and education of women and girls by

providing them with educational experiences that encourage consciousness raising, empowerment, and voice through active and innovative educational strategies (Naples & Bojar 2002). While there is no single definition of feminist pedagogy, basic principles include: (1) the centrality of gender as an analytical tool; (2) multiculturalism and inclusion of all students; (3) collaborative knowledge construction; (4) collaborative teaching; (5) encouraging voice through linking personal experience with learning; and (6) democratization of the teacher's authority and power. *Feminist multicultural pedagogy* is sometimes used to emphasize an awareness of the ways in which differences of race/ethnicity, class, gender, sexual orientation, age, geopolitical location, and religious diversity can potentially translate into oppressive classroom interactions that reproduce dominant hierarchies, or alternatively, can contribute to enriching cultural interactions (Weir 1991; Brady 1993).

There are at least three distinctive variants of feminist pedagogical models: psychological, liberatory, and positional (Tisdell 1995, 1998; Grace & Gouthro 2000). The *psychologically oriented model* emphasizes the importance of relational connectivity in developmental learning and seeks to create a non combative and nurturing interaction dynamic in the classroom and between teacher and student. The psychological model is influenced by theories of women's psychology espoused by Carol Gilligan in her classic book, *In a Different Voice* (1982), and by Belenky, Clinchy, Goldberger, and Tarule's *Women's Ways of Knowing* (1986). These works provide a critique of the male stream moral development theory of Kohlberg, arguing that women's realities are fundamentally shaped by relational contexts of connection and attachment. The feminist psychological approach to teaching is therefore based on a model that seeks to create safe and non intimidating classroom environments for interaction, exchange, and instructor evaluation. In such environments a familial language of caring and responsibility replaces the more sterile technoscientific language of objectivity. Teachers may invest considerable energies in generating positive relationships with and among students early in the curriculum cycle, even sacrificing a measure of course content to positive experiential

exercises that promote social exchange. Using experiential learning strategies, educators anticipate a long term payoff in group dynamics and individual student development. In this context, a teacher's central authority is subtly redefined as facilitation; the teacher becomes a guide from the side as she or he facilitates the creation of a cooperative learning environment that features collaboration, mutual responsibility, and sharing. Knowledge (and sometimes evaluation) is co created through student participation rather than being centrally located in the unilateral authority of the teacher as expert. However, connection is not limited to student-teacher and student-student relationships; it is additionally emphasized in relation to the connection of knowledge to lived experience, and of learning in the classroom to learning outside of the classroom (Baxter Magolda 1992: 223-4; Naples & Bojar 2002). These other types of connectivity can be particularly important in the retention of women students who often fail to see the relevance of their learning to the applications of their everyday lives (Grace & Gouthro 2000). The primary strength of the psychological model lies in the importance placed on interpersonal connectivity in the developmental processes of learning. The underlying assumption of the model is that women will flourish and discover their own voices of authority in learning environments that promote connectivity, validate personal experience, and topically highlight the relevant connections of course information to everyday life outside of the classroom. Its major limitation is its tendency to universalize the generic woman, ignoring positional and subjective differences and structural relationships of power related to race or ethnicity, class, age, affectional orientation, and abilities.

The *liberatory model*, in contrast, focuses on difference in the intersections of relationships of power, not only in terms of social position such as race, ethnicity, class, and gender, but also important intersections in the personal, political, and the pedagogical. The focus is on the emancipation and empowerment of girls and women as a historically oppressed and politically disenfranchised group. Variations on the liberation model include critical approaches that take up issues of democracy, freedom, and social justice; postmodern approaches that address

identity, difference, and voice; poststructural approaches that interrogate language, meaning, and multiple subjectivities; and postcolonial and black insurgent approaches. The latter address revising history and countering tradition, exploring diaspora experience, and exposing privilege, exclusion, and distorted cultural representations of race and power (Grace & Gouthro 2000: 17). Liberatory models typically address the production of knowledge, assuming that knowledge that is valued is associated with valued identities or groups in a culture. Traditional school curricula rely on bases of knowledge that are often biased and/or exclude or marginalize the contributions and experiences of oppressed groups. It is not sufficient to simply "allow" these marginalized groups to participate in discourses on traditional topics; women and other minorities must be included in the design of curricula and instruction (Hughes 1998). Recognition of differences and of exclusions also informs liberatory pedagogical practices that seek to transform social relationships through raising critical consciousness and advocating equitable policies and programs for inclusion. Finally, liberatory models of critical pedagogy also seek to address issues of authority in relationship to voice and coming to voice for women. Coming to voice involves the politics of being heard, and this often means that authority is openly debated. Liberatory models break from psychological models in that they do not work from the premise that a safe environment is a necessary prerequisite for coming to voice. In fact, the classroom environment is a contested terrain where open debate and dealing with difference is often riddled with conflict and emotion. The underlying assumption of liberatory models is that in a transformative environment some danger and risk are necessary. Because education is political, those with a stake in maintaining the status quo will resist change (Grace & Gouthro 2000: 19). Tisdell (1995: 72) notes, for instance, that liberatory pedagogies address similarities and differences among women and that the point is coming to voice in spite of discomfort.

Positional feminist pedagogy has been influenced by poststructural feminism with its emphasis on the intersecting social locations of race/ethnicity, class, and gender. Positional pedagogies seek to construct a multiperspective

discourse of interrogation, disruption, and intervention in order to resist patriarchal control of knowledge, theory, and pedagogy (Luke & Gore 1992). Aware that institutional discourses as well as persons holding positions of authority coordinate knowledge, poststructural feminists value and address the multiplicity of intersections of power. Grace and Gouthro (2000: 20) note that multiple identities, subjectivities, meanings, and differences are explored with the goal of contesting the politics of patriarchal control in educational institutions as sites for the production of knowledge. Explorations of meaning and power are particularly explored from margin to center, that is, from the perspective of marginalized groups such as women and race or ethnic groups to white males as the center of power. The aim according to Luke and Gore (1992) is to develop feminist projects of *standpoint* that locate women in relation to one another and in relation to men. In the classroom this is translated to mean that pedagogical experience and texts are both politically significant and historically contingent. The feminist agenda is to confront masculinist language, theory, and cultural constructions that maintain the status quo; it seeks in the process to shift viewpoints by building a pedagogy of possibility (Ellsworth 1993). Central to this approach is the belief that knowledge is actively constructed in relationships of difference and position (Maher & Tetreault 1994; Maher 1999: 49). Maher (1999: 50) argues that in positional pedagogies, differences of authority and other variables brought to the classroom are not "fixed identities" needing bridging, but rather serve as important markers for shifting power relationships. Rather than seeking to replicate power relationships, the goal is to challenge and to change them.

Yet another example of positional pedagogy is *engaged pedagogy* promoted by bell hooks in her book *Teaching to Transgress: Education as the Practice of Freedom* (1994). Engaged pedagogy as conceptualized by hooks is not another model per se, but rather is an achievement. It is a pedagogy achieved within the intersecting locations of the personal, historical, and political spheres. It involves issues of naming and representation, agency and struggle, resistance and risk taking. For example, a common teaching practice used by hooks is to interrogate the

meanings and representations behind popular media presentations of gender and race/ethnicity within the context of contemporary "white supremacist capitalist patriarchy." She raises the important question, "whose imagery, fantasy, experience or interest is portrayed?" As critical consumers of popular culture, it is up to the individual and groups with common interests to resist distorted representations of reality. Resistance requires a choice to transform existing social relations, but this is in fact a risky undertaking that may come at considerable costs. Nonetheless, the practice of freedom requires resisting distorted representations of the self and of others. Educators drawing from an engaged pedagogy thus become holistically connected in and to their teaching and refuse to disconnect the personal from the professional. Classrooms often become "untidy spaces" as conflict and difference inform critical thinking (Grace & Gouthro 2000). In connecting private experiences to public happenings, educators and learners build knowledge bases that recognize the complexity of social relationships and the needs of individuals to be understood as whole people. Drawing from Freire's *Pedagogy of the Oppressed* (1970/1993), hooks argues that education can potentially become a practice of freedom when it is understood that knowledge is a field in which both student and teacher must labor. Hence, when the classroom becomes a place for participatory learning, personal experience and formal ideas are joined.

The models of feminist pedagogy described here are ideal constructions with many commonalities that inform teaching. Many teachers blend aspects of each of the three models described with other pedagogies that emphasize the different learning styles of different students. What sets feminist pedagogy apart is the attention given to the communal and supportive nature of learning, the recognition that social inequalities are reproduced in educational institutions, and the desire to improve the experiences and possibilities for women and girls as learners in institutions that often produce "a chilly environment" for education (Hall & Sandler 1982; Sandler & Hall 1986). The three models described are conceptualized from a common need to validate the personal experiences of students, especially women and girls, in a context that raises critical consciousness about

the masculine biases in the curriculum and in the organization of education and other social institutions. Whereas the psychologically oriented model turns on the importance of developing nurturing, non combative developmental relationships with students, liberatory and positional pedagogies recognize that "coming to voice" can be a political and conflicted process. Liberatory and positional pedagogies make overt the relationships of power both within and outside of the classroom. Knowledge is recognized and critiqued for serving dominant group interests. Teachers utilizing such approaches recognize that experimenting with new teaching methods and bringing the experiences of excluded groups from margin to center will disrupt the traditional canon and generate oppositional standpoints. The epistemological stance underlying these two models is that truth is "political, positional and linked to the struggle for social change" (Maher & Tetreault 1994: 47). Hence, there is no safe place. Struggle for knowledge and change in this context is clearly a group undertaking, one which cannot be achieved by individuals working outside of communities of those who share similar struggles. This stance presents a more sociological and collective orientation to learning and to liberatory empowerment.

In reality, translating theories of feminist pedagogy into practice is riddled with contradictions, particularly for women and for people of diverse ethnicity, race, religion, or sexual orientations. The institution of education, with its vested interests and canonical tradition, rarely promotes or supports innovative and critical processes among its teachers. In higher education, departments of Women's and Gender Studies, African and African American Studies, and Centers for Multicultural Studies have become institutional havens for independent and radical thinkers in many respects, but they have also become "colonized" bastions for learning and political struggle. Too often teachers and academic scholars lack the community support of their home disciplines and of administrators when attempting to develop multicultural pedagogies. In higher education, feminist teachers who overvalue and/or overinvest in classroom work often pay a price when it comes to tenure and promotion. Balancing the pressures of teaching, student advising, and

committee work – which too often fall unevenly on women faculty – against research and publication demands is an area of interpersonal and political struggle (Weir 1991). Hard choices are made in prioritizing workload demands. Despite these constraints, however, since the 1970s all levels of education have become infused to some degree with the principles of feminist pedagogy. A growing body of publications in the field of education has come to reflect this social transformation, although it is still a work in progress (Weiler 1988; Maher 1999; Naples & Bojar 2002).

feminist standpoint theory

Nancy A. Naples

Standpoint theory is a broad categorization that includes somewhat diverse theories ranging from Hartsock's (1983) feminist historical

materialist perspective, Haraway's (1988) analysis of situated knowledges, Collins's (1990) black feminist thought, Sandoval's (2000) explication of third world feminists' differential oppositional consciousness, and Smith's (1987, 1990) everyday world sociology for women. Many theorists whose work has been identified with standpoint theory contest this designation; for example, Smith (1992) has been particularly vocal about the limits of this classification. She explains that it was Harding (1986) who first named standpoint theory as a general approach within feminism to refer to the many different theorists who argued for the importance of situating knowledge in women's experiences. Standpoint theorists are found in a wide variety of disciplines and continue to raise important questions about the way power influences knowledge in a variety of fields. Harding (2003) has brought together the most influential essays on feminist standpoint theory to demonstrate the power and utility of standpoint theory for feminist praxis.

Feminist standpoint theory was initially developed in response to debates surrounding Marxist feminism and socialist feminism in the 1970s and early 1980s. In reworking Marx's historical materialism from a feminist perspective, standpoint theorists' stated goal is to explicate how relations of domination are generated in particular ways. Standpoint theory also developed in the context of third world and postcolonial feminist challenges to the so called dual systems of patriarchy and capitalism. The dual systems approach was an attempt to merge feminist analyses of patriarchy and Marxist analyses of class to create a more complex socialist feminist theory of women's oppression. Critics of the dual systems approach pointed out the lack of attention paid by socialist feminist analyses to racism, white supremacy, and colonialism. In contrast, feminist standpoint theory offers an intersectional analysis of gender, race, ethnicity, class, and other social structural aspects of social life without privileging one dimension or adopting an additive formulation (e.g., gender plus race). Standpoint theory retains elements of Marxist historical materialism for its central premise: knowledge develops in a complicated and contradictory way from lived experiences and social historical context.

SIMILARITIES ACROSS DIFFERENT APPROACHES

Despite the diverse perspectives that are identified with standpoint epistemology, all standpoint theorists emphasize the importance of experience for feminist theorizing. In this regard, many point out the significance of standpoint analysis's connection to consciousness raising, the women's movement's knowledge production method. Consciousness raising (CR) was a strategy of knowledge development designed to help support and generate women's political activism. By sharing what appeared as individual level experiences of oppression, women recognized that the problems were shaped by social structural factors. The CR process assumed that problems associated with women's oppression needed political solutions and that women acting collectively are able to identify and analyze these processes. The consciousness raising group process enabled women to share their experiences, identify and analyze the social and political mechanisms by which women are oppressed, and develop strategies for social change.

Standpoint theorists assert a link between the development of standpoint theory and feminist political goals of transformative social, political, and economic change. From the perspective of feminist praxis, standpoint epistemology provides a methodological resource for explicating how relations of domination contour women's everyday lives. With this knowledge, women and others whose lives are shaped by systems of inequality can act to challenge these processes and systems (Weeks 1998: 92). One example of this point is found in Pence's (1996) work to create an assessment of how safe battered women remain after they report abuse to the police. Pence specifically draws on Smith's (1987) approach to shift the standpoint on the process of law enforcement to the women who the law attempts to protect and to those who are charged with protecting them. Pence developed a safety audit to identify ways criminal justice and law enforcement policies and practices can be enhanced to ensure the safety of women and to ensure the accountability of the offender. Pence's safety audit has been used by police departments, criminal justice and probation departments, and family law

clinics in diverse settings across the country. Pence asserts that her approach is not an evaluation of individual workers' performances, but an examination of how the institution or system is set up to manage domestic violence cases.

Standpoint theorists are critical of positivist scientific methods that reduce lived experiences to a series of disconnected variables such as gender, race, or class. For example, Harding has written extensively about the limits of positivism and argues for an approach to knowledge production that incorporates the point of view of feminist and postcolonial theoretical and political concerns. She argues that traditional approaches to science fail to acknowledge how the social context and perspectives of those who generate the questions, conduct the research, and interpret the findings shape what counts as knowledge and how data is interpreted. Instead, she argues for a holistic approach that includes greater attention to the knowledge production process and to the role of the researcher. Harding and Smith both critique the androcentric nature of academic knowledge production. They argue for the importance of starting analysis from the lived experiences and activities of women and others who have been left out of the knowledge production process rather than start inquiry with the abstract categories and a priori assumptions of traditional academic disciplines or dominant social institutions.

STANDPOINT DEFINED AS EMBODIED IN SPECIFIC ACTORS' EXPERIENCES

Despite the shared themes outlined above, the notion of standpoint is conceptualized differently by different standpoint theorists. Naples (2003) has identified three different approaches to the construction of standpoint: as embodied in women's social location and social experience, as constructed in community, and as a site through which to begin inquiry. Many feminist theorists understand standpoint as embodied in specific actors who are located in less privileged positions within the social order and who, because of their social locations, are engaged in activities that differ from others who are not so located. The appeal to women's embodied social experience as a privileged site

of knowledge about power and domination forms one central thread within standpoint epistemologies.

Critics of this approach to standpoint theory point out that the reliance upon a notion of women or any other marginalized group as having an identifiable and consistent standpoint leads to the trap of essentialism. For example, feminist scholars who center on the role of mothering practices in generating different gendered "ways of knowing" (e.g., Belenky et al. 1986), or who argue that there are gendered differences in moral perspective (Gilligan 1982), have been criticized for equating such gendered differences with an essentialized female identity (Spelman 1988). However, many feminist theorists who contribute to the embodied strand of standpoint theorizing argue that due to relations of domination and subordination, women, especially low income women of color or others located in marginalized social positions, develop a perspective on social life in the US that differs markedly from that of men and middle and upper income people (Collins 1990; Sandoval 2000). Black feminist and Chicana standpoint theorists argue that the political consciousness of women of color develops from the material reality of their lives.

However, Collins and Hartsock emphasize that there is a difference between a so called women's standpoint and a feminist standpoint. Jaggar (1989) points out that a women's standpoint is different from women's viewpoint or women's specific experiences. In contrast, they argue, a standpoint is achieved and as a consequence of analysis from a specific social actor, social group, or social location rather than available simply because one happens to be a member of an oppressed group or share a social location (see Weeks 1998). Rather than view standpoints as individual possessions of disconnected actors, most standpoint theorists attempt to locate standpoint in specific community contexts with particular attention to the dynamics of race, class, and gender.

STANDPOINT AS A RELATIONAL ACCOMPLISHMENT

This second strand of feminist standpoint epistemology understands standpoint as relational

accomplishment. Using this approach, the identity of "woman" or class or other embodied identities is viewed as constructed in community and therefore cannot be interpreted outside the shifting community context. Collins (1990) draws on the construction of community as a collective process through which individuals come to represent themselves in relation to others with whom they perceive share similar experiences and viewpoints for her analysis of black feminist thought. Collins argues that a standpoint is constructed through "historically shared, *group* based experiences." Like the embodied approach to standpoint theorizing, group based approaches have also been criticized for unproblematically using women's class and racial identities to define who is or is not part of a particular group. However, those who draw on a relational or community based notion of standpoint emphasize the collective analytic process that must precede the articulation of a standpoint. Both Sandoval (2000) and Collins (1990) utilize this approach to standpoint (although Sandoval does not describe her approach as a "standpoint epistemology," it does share many of the features outlined above). Sandoval's (2000) analysis of oppositional consciousness has much in common with Hartsock and Collins's approach, in that her analysis of oppositional consciousness focuses on the development of third world feminism as a methodology by which oppressed groups can develop strategies for political resistance. Sandoval's model offers a methodological strategy that contests previously taken for granted categorization of women's political practice such as liberal, radical, or socialist. The oppositional methodology she presents draws on multiple political approaches such as equal rights or liberal, revolutionary, and separatist political strategies. Rather than privilege one approach, Sandoval argues that oppressed peoples typically draw on multiple strategies to form an oppositional methodology. Sandoval treats experience as simultaneously embodied and strategically created in community and concludes that this dynamic interaction affects the political practice of third world women. Although Sandoval locates her analysis in a postmodern frame and Hartsock resists such a move, the legacy of historical materialism links their work within a broadly defined feminist

standpoint epistemology. In fact, Hartsock acknowledges the power of Sandoval's analysis for challenging essentialized views of identity and identity politics.

STANDPOINT AS A SITE OF INQUIRY

The third strand of feminist standpoint epistemology provides a framework for capturing the interactive and fluid conceptualization of community and resists attaching standpoint to particular bodies, individual knowers, or specific communities or groups. Standpoint is understood as a site from which to begin a mode of inquiry, as in Smith's everyday world institutional, ethnographic approach to epistemology. Smith (1992) explains that her approach does not privilege a subject of research whose expressions are disconnected from her social location and daily activities. Rather, she starts inquiry with an active knower who is connected with others in particular and identifiable ways. This mode of inquiry calls for explicit attention to the social relations embedded in women's everyday activities. Smith's analysis of standpoint as a mode of inquiry offers a valuable methodological strategy for exploring how power dynamics are organized and experienced in a community context.

POSTMODERN CRITIQUES OF STANDPOINT THEORY

Postmodern theorists are especially critical of standpoint theory (Clough 1994; King 1994). They argue that the notion of standpoint presumes that it is possible to identify and locate what are socially constructed and mobile social positions. While standpoint theorists emphasize that perspectives from the vantage point of the oppressed remain partial and incomplete, a central problematic of feminist standpoint analyses is to determine how partial are particular perspectives (e.g., Haraway 1988). Clough (1994) aims her criticism of Collins's approach right to the heart of standpoint analysis when she emphasizes that privileging experience in any form, even with attention to the partiality of that experience, is a problematic theoretical move.

Few postmodern critics offer alternative research strategies. Those who do offer some

alternative often limit their approaches to textual or discursive modes of analysis. For example, following an assessment of the limits and possibilities of feminist standpoint epistemologies for generating what she calls a "global social analytic," literary analyst Hennessy (1993) posits "critique" as materialist feminist "reading practice" as a way to recognize how consciousness is an ideological production. She argues that, in this way, it is possible to resist effectively the charge of essentialism that has been leveled against standpoint epistemology. In revaluing feminist standpoint theory for her method, she reconceptualizes feminist standpoint as a "critical discursive practice." Hennessy's methodological alternative effectively renders other methodological strategies outside the frame of materialist feminist scholarship. However, even poststructural critics of feminist standpoint epistemology within the social sciences also conclude their analyses with calls for discursive strategies. For example, Clough (1994: 179) calls for shifting the starting point of sociological investigation from experience or social activity to a "social criticism of textuality and discursivity, mass media, communication technologies and science itself." In contrast, standpoint theory, especially Smith's (1990) approach, offers a place to begin inquiry that envisions subjects of investigation who can experience aspects of life outside discourse. Standpoint theorists like Smith tie their understanding of experience to the collective conversations of the women's movement that gave rise to understandings about women's lives which had no prior discursive existence. In this way, despite some important theoretical challenges, standpoint theory continues to offer feminist analysts a theoretical and methodological strategy that links the goals of the women's movement to the knowledge production enterprise.

CONCLUSION

In sum, standpoint theorists typically resist focusing their analyses on individual women removed from their social context. Knowledge generated from embodied standpoints of subordinates is powerful in that it can help transform traditional categories of analyses that originate from dominant groups. However, as

many feminist standpoint theorists argue, it remains only a partial perspective (Haraway 1988). Naples (2003) argues that by placing the analysis within a community context, it is possible to uncover the multiplicity of perspectives along with the dynamic structural dimensions of the social, political, and economic environment that shape the *relations of ruling* in a particular social space. Haraway (1988) explains that situated knowledges are developed collectively rather than by individuals in isolation. Hartsock (1983) and Collins (1990) both emphasize that standpoints are achieved in community, through collective conversations and dialogue among women in marginal social positions. According to Collins, standpoints are achieved by groups that struggle collectively and self reflectively against the *matrix of domination* that circumscribes their lives. Hartsock also emphasizes that a feminist standpoint is achieved through analysis and political struggle. Given standpoint theory's emphasis on a process of dialogue, analysis, and reflexivity, the approach has proven extremely vibrant and open to reassessment and revision. As a consequence, standpoint theory remains an extremely important approach within feminist theory.

feminization of labor migration

Mako Yoshimura

Feminization of migration is characterized by an increase in the number of female migrants since the 1980s and by a concentration on female specific work such as domestic helpers,

nurses, entertainers, and so on in the process of globalization. While the movement of peoples, both internal and international, has been observed historically in various forms, the feminization of migration has been highlighted during the period of rapid economic globalization since the 1980s. Early research on migration noticed the differences between men and women found in immigration statistics, but paid little attention to this aspect of the subject. Gender structure only became part of the discussion after the early 1980s.

In the 1980s, gender based academic work focused on rural–urban female labor migration in the domestic labor market in developing countries in Asia and Latin America. Many case studies focused on young women mobilized as wage labor in factories by multinational corporations in free trade zones and industrial estates. This research was part of a discussion on the issues relating to the new international division of labor (NIDL) and the way global capital was relocating labor intensive production. There was a preference for female labor because women were considered to have “nimble fingers” that fit them for labor intensive processes, and women were therefore exploited as lower paid, unskilled wage labor, as had happened during the early stages of capitalist industrialization in western countries. In the late 1980s, at a second stage of internationalization of labor markets, research highlighted the fact that female migrants often worked in sweatshops and lower skilled and lower paid service jobs in urban areas of industrialized countries.

Research on these topics developed theoretically during the 1990s and various approaches were applied to the study of migration and gender, analyzing the topic by considering elements such as class, stratum, ethnicity, and age, along with nationality. Where traditional research on migration dealt mainly with settlement and assimilation, more recent works focus on temporary “sojourning,” relations with home communities, diaspora as the migrant community, cultural gaps, conflicts, prejudice in host countries, and the like. Transnationalism is also an important subject to be analyzed.

Much of the early work on gender and migration used quantitative methods. For example, one of the earliest collections of articles on gender and migration, a special issue of

International Migration Review published in 1984, had 19 articles, and nearly all were based on quantitative analysis (Willis & Yeoh 2000: xii–xiii). Quantitative methods, such as analyzing census data and mounting large scale questionnaire surveys, have always been popular. Interest in migrants' experiences and questions of identity have highlighted the importance of other methods. Recent trends in migrant research have led to greater use of methods such as interviews, life histories, and participant observation in order to learn about migrants' identities, networks, households, reproduction, carework, social constructions, transnationalism, gender relations, and so on. In dealing with these issues, a qualitative analysis is central to an examination of the complicated dynamics of migration and the changing gender structure at the micro level, and to compensate for the biases and omissions of macro level data analysis.

The International Labor Organization has estimated that there are currently 86 million migrants, half of them women. In traditional discussions, women migrants were assumed to be spouses or family members accompanying male migrants. Also, women immigrants increased as the spouses and family members of immigrants in the 1970s, when the western countries stopped new immigrants after the oil shock. However, recent works indicate that women migrate to seek economic independence and personal freedom or autonomy, as well as support for their own families.

The proportion of female migrants is high in many countries in Asia. For example, the female ratio of the total overseas migrant workers in the Philippines is 72 percent, in Indonesia it is 78 percent, and in Sri Lanka it is 84 percent. Women work primarily as domestic helpers and nurses. The female share in migration increased in the 1980s, when male migration to the Middle East (which had increased dramatically during the oil boom of the 1970s) began to fall off.

Some 7.76 million Philippine nationals work overseas (3.39 million registered, 1.51 million unregistered, and 2.87 million permanent residents) – equivalent to 10 percent of the population or 23 percent of total labor forces. While unemployment in the Philippines is nominally 10.2 percent, the estimated latent

unemployment rate was above 20 percent in 2003. It is not unusual for Filipinos/Filipinas to seek overseas jobs, as Filipinos/Filipinas have worked abroad since the early twentieth century. While the early overseas workers went to plantations in Hawaii and California, the current situation is different. The sexual division of labor is clear: women work overseas as domestic helpers, nurses, entertainers, and so on, while men work overseas as construction workers, engineers, seamen, and so on. Remittances from overseas workers amounted to US \$76.4 million in 2003. The Philippine government encourages overseas work and the Philippine Overseas Employment Agency (POEA), the Department of Labor and Employment (DOLE), and the Philippine Overseas Labor Office (POLO) support overseas workers by checking employers and training workers.

Domestic labor for housekeeping, childcare, or nursing care for elderly people is now engaged as paid work in the market. And it relies on migrant women and ethnic minority women. Not only in advanced industrialized or rich oil producing countries, but also in newly industrializing economies in Asia, migrant domestic helpers are employed because of the shortage of unskilled labor in local labor markets. In developing societies such as Singapore, Taiwan, Hong Kong, and Malaysia it is a kind of status symbol for the new middle class to employ migrant domestic helpers.

In the western world in the late nineteenth century a considerable part of domestic work in middle and upper class households was performed by servants. The nature of domestic work changed with the extension of electricity, gas, and water service and the development of home appliances. At the same time, most children ceased to be involved in economic activity and became school pupils. There was a decrease in the supply of labor from rural areas and the informal sector, along with a change in the nature of domestic work and childcare, as middle class housewives came to bear the domestic work and the childcare.

Married women in advanced industrialized countries increasingly worked as wage labor from the 1970s onwards. The increased burden of wage labor and domestic work borne by women, together with the decline in the birth rate, a growing proportion of elderly people,

labor shortages, and budget cuts for public welfare services, led to the externalization of carework, and migrant workers became an option for this sort of labor.

When women leave home to work overseas, their family members may hire women who are relatives, neighbors, or migrant women from rural areas to take their place as caregivers. A chain of carework is thus formed that transcends borders and the national framework. Hence, a discussion of migration should include transnational motherhood as well as the global chain of care work. Because of the externalization of carework, the reproduction of labor or human beings is often done outside of homes, and there are many countries that depend on migrant workers as lower paid caregivers. The feminization of migration dissolved and transformed the national framework of reproduction, as the globalization of the economy incorporates not only production, but also reproduction.

The rights of migrant women workers are often violated. Employers or agents may keep migrants' passports and travel documents, and many migrant workers are not paid until the end of their contracts. Differences of language, culture, and religion frequently cause miscommunication and misunderstanding and are a basis for discrimination and prejudice against migrant workers. There have been many reported instances of mental and physical abuse (including verbal abuse) against migrant domestic helpers. Some employers do not allow any holidays and restrict meals, telephone calls, and occasions for going out and meeting friends. Even when employers are nice to workers, they may be forced to endure long workdays and may be on call 24 hours a day if employers have babies or small children. Migrant domestic helpers often live in employers' houses and they are not thought of as "proper" workers, since domestic work is not considered as formal work.

Moreover, many women migrants work in the sex industry. In Japan, although entertainer visas are supposed to be for performers with special skills, most female migrant workers who come as entertainers engage in the sex related industry as bar hostesses, strippers, or prostitutes. Around 140,000 Filipino women came to Japan on entertainer visas in 2003. This is big business, partly related to the Japanese mafia and local mafias in Southeast Asia. The

trafficking in persons also involves forced labor and prostitution. Mail order brides or picture brides are sometimes used for unauthorized work or trafficking in persons in illegal sectors, including sex related activities. It is crucial to understand how this phenomenon is a byproduct of the globalization of the economy. Research on the topic must deal not only with migrant women, but also with the host community and economies that link migration and working circumstances.

The general problem is that the protection of human rights and workers' rights is poorly developed in the case of female migrant workers because they face discrimination in the societies where they work, and also because carework is generally identified as housework or shadow work and they are not considered as skilled labor. It is important that human rights are appropriately protected, and a migrant woman should be esteemed as a worker and as a human being, regardless of her legal status.

The feminization of migration displays many aspects of the gendered structure of migration, such as the global chain of carework, gender ideology, and transnationalism. It must be examined in the context of the globalization of the economy that transformed the capitalist mechanism of utilization of female labor, and global capital's reproduction process.

feminization of poverty

Susan W. Hinze and Dawn Aliberti

Diana Pearce (1978) coined the term “feminization of poverty” in the late 1970s to describe the increasing overrepresentation of women and children among the poor in the United States. Since then the gender gap in poverty has increased, although some evidence suggests that improvements in women’s earnings are beginning to close the poverty gap between women and men (McLanahan & Kelly 1999). Currently, of those in poverty, 38 percent are women, 26 percent are men, and 36 percent are children (US Census Bureau, 2004). However, the economic disadvantage of women is not a uniquely American experience, and scholarship in recent years highlights the need for a more global perspective on the feminization of poverty.

GENDER AND POVERTY IN THE UNITED STATES

The poverty line in the US is set by the Social Security Administration and calculated by multiplying the lowest cost for a nutritionally adequate food plan (as determined by the Department of Agriculture) by three. This calculation assumes a family spends one third of its budget on food. Those falling below this set annual income are defined as poor and entitled

to government assistance (for criticisms of the absolute poverty definition, see McLanahan & Kelly 1999). The official poverty rate in 2003 was 12.5 percent, or 35.9 million people, and the official poverty line for a family of four was \$18,810 (US Census Bureau, 2004). The 2004 Annual Demographic Survey (a joint project between the Bureau of Labor Statistics and the Bureau of the Census) estimated that 11.2 percent of males fell below the poverty line, compared to 13.7 percent of females. Another framing is that adult women are 1.5 times more likely to be poor than are men.

McLanahan and Kelly (1999) examine trends in men’s and women’s absolute and relative poverty rates between 1950 and 1996. Using Census Bureau data to calculate sex poverty ratios (see Table 1), they find a dramatic increase in sex poverty ratios between 1950 and 1970. For white middle aged adults, a “defeminization of poverty” occurred in the 1970s and 1980s. However, among the elderly, the feminization of poverty has increased significantly. Overall, poverty rates for elderly women and men have decreased since the 1950s, but men’s rates fell more quickly. Hence, elderly women today are more than twice as likely to be poor as are elderly men. In summary, while women were only slightly more likely than men to be poor in the 1950s, today they are 50 percent more likely than men to be poor (US Census Bureau, 2004).

Family status matters for the feminization of poverty. In 1960, most poor families contained both men and women; by contrast, almost

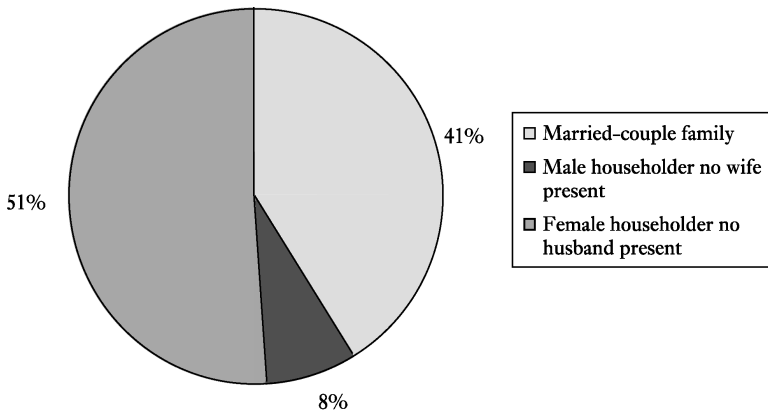

Figure 1 Poverty by household type.

51 percent of poor families today are headed by a woman with no husband present (US Census Bureau, 2004). By comparison, 41 percent of poor families are married couple families, and 8 percent are headed by a man with no wife present. (See Fig. 1.)

A look at gender differences in median family income by household type highlights the role of family status. Median family income for all families in 2003 was \$43,318. Clearly, having two parents in the home decreases the chances of poverty for families. In married couple families, the median income is \$62,405. However, even in married couple families, the poverty rate is 5.4 percent. The median family income for family households headed by women was \$29,307 for 2003 (with no husband present), compared to \$41,959 for households headed by men (with no wife present). Currently, 28 percent of all female headed households live below the official poverty line, compared to 13.5 percent headed by men. This is a significant issue since the percentage of female headed households has grown in the past few decades (up from 10 percent in 1950) and can be accounted for by a number of factors, including high rates of divorce, later ages at first marriage, less likelihood that pregnant teens will marry, and, in some communities, the high rate of incarceration of young men.

Past analyses of poverty by gender have been criticized for overlooking or downplaying racial and ethnic inequalities. The current scholarship recognizes that the feminization of poverty

can only be understood by an examination of how race/ethnicity and age intersect with economic status. Within each racial/ethnic category, women are more likely than men to be poor; however, older women and women of color have always been the most vulnerable. As Figure 2 reveals, 26.5 percent of African American women fall below the poverty line, compared to 11.5 percent of white women and 24 percent of Latino women. In short, an African American woman is almost two and a half times more likely to be poor than is a white woman and a Latino woman is twice as likely as a white woman to be poor (US Census Bureau, 2004).

Statistics also reveal that the face of poverty becomes disproportionately female with age. Figure 3 shows that 7.5 percent of men aged 75 and over are poor compared with 14.3 percent of women (US Census Bureau, 2004, March supplement). Another framing of the same data is that women 75 and over are 1.9 times as likely to be poor as men. Gender disparities are also significant for those in the 18 to 34 year category (coinciding with the childbearing years), with women 1.5 times as likely to be poor as men.

As Pearce (1978) noted in her now classic article, explanations center on work and welfare. Women are underrepresented among the beneficiaries of the more generous, work related social insurance benefits, but overrepresented as recipients of public assistance, a far less generous, means tested program. In short, the

Figure 2 Percent poverty by race and gender.

dualistic structure of the US social welfare system works against women (Fraser 1993). The “masculine” social welfare programs are social insurance schemes (unemployment insurance, Social Security, Medicare, SSSI) primarily benefiting men as rights bearers and rewarding productive labor. The “feminine” social welfare programs (TANF, formerly AFDC, food stamps, Medicaid, public housing assistance) are less generous, have a heavy surveillance component, and devalue reproductive labor.

Following Pearce’s work, McLanahan and Kelly (1999) trace how changes in the family, changes in the economy, and changes in the welfare state have contributed to the feminization of poverty. We examine each in turn, with emphasis on social policies that help or hinder women’s economic progress.

First, several demographic shifts in family structure are important for understanding the feminization of poverty. Later ages at first marriage, combined with increasing divorce rates,

together produce a larger proportion of adult women living independently (McLanahan & Kelly 1999). Since women tend to earn less than men, they are at greater risk for poverty. Some argue that no fault divorce laws have contributed to the poverty of female headed households, by changing economic outcomes for women. Spouses are treated as equals, despite evidence that in financial terms, women are rarely equal. With no fault divorce, alimony awards are less frequent, and women are disproportionately penalized. The decline in income for women post divorce is estimated to be between 30 and 50 percent, in part because women's salaries are lower than men's. Along with the high divorce rates, the twentieth century has witnessed increases in the proportion of children born to unmarried mothers. In 1960, approximately 6 percent of children were born to unmarried mothers, rising to 34 percent of children by 2002 (CDC Division of Vital Statistics, 2002). Birth rates for unmarried women vary widely by race/ethnicity. The proportion of births to unmarried white women is 23 percent, followed by 43.5 percent for Hispanic women and 68 percent for black women. While birth rates have been increasing slightly for unmarried white and Hispanic women, they are decreasing for unmarried black women. Since women earn less than men, and since women are more often in charge of dependants, single mothers remain at risk for poverty. The poverty of female headed households is due, in part, to inadequate child support laws and lack of enforcement. Only about 62 percent of custodial mothers are awarded child support, and the average awards are relatively small (about \$3,800 per year) (US Census Bureau, 1999). Of those who receive awards, approximately 24 percent never receive payment and another 24 percent receive only partial payment (US Census Bureau, 1997). A final demographic shift contributing to the feminization of poverty is the increase in the proportion of elderly living independently. That trend, combined with increased life expectancy, has increased poverty for women relative to men given their longer life expectancies (McLanahan & Kelly 1999).

Second, economic changes in the twentieth century have contributed to the feminization of poverty. Ehrenreich and Piven (1984) trace the feminization of poverty to the "family wage"

system, which granted men wages sufficient to support a wife and children. This achievement, an outcome of late nineteenth and early twentieth century labor struggles, positioned women as secondary workers, reinforced occupational sex segregation, and legitimized systematic wage discrimination against women. The legacy of this system is apparent in the persistent wage gaps between women and men that characterize today's labor market. Figure 4 shows median incomes for women and men, full time workers only, from 1960 to 2000 (US Census Bureau, 2004).

As Table 2 shows, in 1960, women working full time earned 61 percent of male wages. By 2003, women full time workers earned 76.3 percent of male wages. Median earnings for women in 2003 were \$31,653 compared to \$41,503 for men. A robust, interdisciplinary literature exists on reasons for the wage gap; explanations include human capital differences, occupational sex segregation, wage penalties for motherhood, variation in job characteristics (e.g., industry, union membership), and discrimination. However, increases in women's labor force participation and educational levels in the past two decades have resulted in increased wages for women relative to men. Consequently, we find a "defeminization" of poverty or reduced sex poverty ratio, primarily for white, middle aged adults. In addition, men's wages have stagnated since the 1970s, which also contributes to the declining sex gap in poverty.

Jacobs and Gerson (2004) warn that corporations benefit from a bifurcated workforce, with some workers (mostly professionals and the highly educated) working overtime, and other workers, generally those with less education, working part time. Approximately 72 percent of part time workers are women. Since women are disproportionately represented in the "non standard" or contingent workforce as part time, temporary, or home workers, their wages and earning power over the life course suffer (Presser 2003), contributing to the feminization of poverty.

Third, McLanahan and Kelly (1999) present data on the role of social security in reducing poverty among elderly women and men, and the role of welfare in reducing poverty for single mothers. After 1970, government transfers for women of childbearing age began to decline;

about the same time, poverty rates for women of childbearing age stopped declining. The passage of the Personal Responsibility and Work Opportunity Act in 1996 has contributed to decreased welfare caseloads, and increased employment among recipients. However, any increased earnings from work have been offset by the loss in public assistance (Institute for Women's Policy Research, 2002). In sum, welfare reform has not helped "solve" the problem of poverty for women, and some evidence suggests it has created new problems, especially for children. Finally, during the 1950s-1970s, the rise of social security benefits for retired adults contributed to declining poverty rates for the elderly. Despite the declines, the feminization

of poverty among the elderly has persisted into the twenty first century, for two primary reasons: (1) pensions for never married women are lower than pensions for never married men; (2) elderly women are more likely to live alone (given longer life expectancies), and thus more likely to live on one pension rather than two.

GENDER AND POVERTY CROSS NATIONALLY: THE ECONOMIC NORTH

A cross national picture of the feminization of poverty must be segmented into an examination of other Economic North (or industrialized)

countries and countries of the Economic South. Cross national comparisons with other industrialized countries prove particularly illuminating for understanding potential solutions for the US situation. In short, labor market and social welfare policies together can be significant deterrents to the feminization of poverty. As Goldberg and Kremen (1990: 36) note, "Cross national data reinforce the conclusion that one of the world's wealthiest nations is not generous to single mothers and their children."

In their examination of five capitalist and two socialist countries from the Economic North, Goldberg and Kremen (1990) conclude that the feminization of poverty is most pronounced in the United States, where it was first identified, *and* occurs where single motherhood is widespread and where labor market or social welfare policies are insufficient to reduce poverty. In Sweden, for example, single motherhood is as prevalent as it is in the US, but a combination of labor market and social policies has together helped Sweden achieve a relatively low rate of poverty for single parent families. Japan presents a very different case. The wage gap between women and men is much higher in Japan than in the US, and Japan has very minimal social assistance programs. However, what prevents the feminization of poverty in Japan is the low rate of single motherhood. Goldberg and Kremen (1990) argue that the prospects for single motherhood are so bleak that few mothers risk economic independence from men.

Using Luxembourg Income Study data, Christopher et al. (2000) present gender poverty ratios based upon pre transfer, pre tax income, and post transfer, post tax income (see Table 3). From row one, note that the gender poverty ratio (pre transfer, pre tax income) is highest

for the United States (1.42) followed, in descending order, by Australia (1.37), the Netherlands (1.34), the United Kingdom (1.30), Germany (1.19), Canada (1.15), France (1.12), and Sweden (0.92). Row two reveals that the US, Australia, Canada, France, and Germany reduce the ratio of women's to men's poverty rates by 5 percent or less through tax and transfer systems, while the Netherlands and Sweden, with the most generous welfare states, do the most for women relative to men. They conclude that "the welfare states of the five other nations (the US, Australia, Canada, France and Germany) make no more than trivial redistribution that reduces the gender disparity in poverty rates" (p. 213). They also note that if Sweden is "doubly blessed" (a lower proportion of single mothers and a more generous welfare state), the United States is "doubly damned" with "high levels of single motherhood and a welfare state that is relatively stingy and redistributes little, if at all, by gender" (p. 214). Christopher et al. (2001) conclude with a warning that single motherhood is on the rise in most industrial nations, placing more women at risk for poverty in the absence of increased earnings for women or improved state subsidization of the costs of rearing children.

GENDER AND POVERTY CROSS NATIONALLY: THE ECONOMIC SOUTH

What is the global evidence for the feminization of poverty among Economic South nations? Standardized poverty measures are difficult to obtain, but the United Nations reports issued for the Fourth World Conference on Women

Table 3 Ratio of women's to men's poverty rate in eight nations and under simulations

<i>Ratio based on:</i>	<i>US 1994</i>	<i>Australia 1994</i>	<i>Canada 1994</i>	<i>France 1989</i>	<i>Germany 1994</i>	<i>Netherlands 1991</i>	<i>Sweden 1992</i>	<i>UK 1995</i>

(Beijing) in 1995 indicated that of the 1.3 billion people in poverty, 70 percent are women. The Platform for Action adopted at the conference called for the eradication of the persistent and increasing burden of poverty on women. However, according to a 2005 report from the Women's Environment and Development Organization, since Beijing, women's livelihoods have worsened, with increasing insecure employment and reduced access to social protection and public services. In general, women's economic contributions are undervalued (to the tune of \$11 trillion per year in 1995) and women work longer hours than men, yet share less in the economic rewards.

The male/female median earnings ratios are lowest (with women earning as little as 20 percent of men's earnings) in the North African and Middle Eastern countries of Libya, Iraq, Saudi Arabia, Bahrain, United Arab Emirates, Oman, and Qatar (State of the World Atlas, 1999). While some evidence suggests the pay gap is shrinking worldwide (e.g., see UN Development Fund for Women), as in the US, other evidence from the Women's Environment and Development Organization suggests poverty is on the rise for women in Economic South nations.

Understanding women's poverty in Economic South nations requires attention to the social and legal institutions that do not guarantee women equality in basic human and legal rights, including access to and control of land or other resources, in employment and earnings, and social and political participation. In particular, the lack of land rights in Western and Central Africa keeps women in an endless cycle of poverty. According to experts at the UN women's conference sponsored by the International Fund for Agricultural Development (IFAD), rural women own 1 percent of the world's land but head at least 25 percent of all households. Internal conflicts, HIV/AIDS, male migration within and outside the country, natural disasters, and structural adjustment policies all contribute to the poverty of rural women.

What kind of reforms are necessary to reduce female poverty in Economic South nations and meet Millennium Development Goals by 2015? According to experts at the IFAD conference, discriminatory inheritance practices

that disregard female ownership must be ended. Without property, women are denied credit, and without credit, women cannot generate income. Without resources, children are unable to go to school and the cycle of poverty continues. For example, in Malawi and Zambia, custom dictates that the husband's patrilineage, which includes his father, his father's sisters, his brothers, and any male descendants of the patrilineage, collects all property in event of his death. Widows, and they are increasing with the AIDS crisis, and their children are left destitute. Reforms include microfinancing programs, and greater inclusion of women in post conflict governments. While the CEDAW (Convention on the Elimination of All Forms of Discrimination against Women), adopted by the UN General Assembly in 1979, is a powerful tool for combating property discrimination, it is often trumped by traditional chiefs who dictate land ownership laws.

Since the 1970s, feminist scholars have produced an abundant literature on development and gender, highlighting the need for the use of a critical gender lens when developing measures to eradicate poverty. Development programs focused on helping southern countries convert to market economies have been criticized for being gender blind or "gender neutral," which ultimately disadvantages women (Ward 1990; Blumberg et al. 1995). For example, the introduction of high yield rice in Asia displaced wage earning opportunities for women through mechanization. Development projects that help local citizens grow crops for cash, rather than local food production, undercut women by diverting water from home gardens and for domestic use. Structural adjustment programs (SAPs) imposed by the International Monetary Fund resulted in cuts to wages and social services, as well as rises in the cost of basic goods and services. These cuts had a more deleterious effect on women given their greater responsibility for providing food, water, and health care for families (Blumberg et al. 1995). Furthermore, feminist scholars have argued that engendering poverty eradication measures requires close examination of gender relations and unequal distributions of resources and power, starting at the level of the household. Measures that increase women's income are more likely to positively affect family well being

than are measures to increase men's incomes because women tend to use a higher proportion of their earnings on children and household expenses. However, incorporating women into formal labor markets is not always sufficient (an "add women and stir" approach) if women end up in the informal sector of the economy, or on the lowest rungs of the labor hierarchy (Ward 1990; Blumberg et al. 1995).

In short, policies to eradicate poverty must incorporate a gender lens and close examination of the political economy of class, markets, and work processes. Beyond improving conceptual and theoretical approaches to poverty, a gender and development approach also works from the "bottom up" to empower women to transform the structures that contribute to their subordination. As women's activism in the 1980s and 1990s has demonstrated, women's agency is a powerful force for change. Sociological scholarship on the global feminization of poverty recognizes the importance of enhancing women's participation in local, national, and international decision making and policymaking.

fertility: adolescent

Elizabeth Cooksey

Adolescent fertility refers to the childbearing of women who are less than 20 years old. Despite recent declines in adolescent fertility levels throughout the world, over 15 million babies are born to adolescent women each year. Adolescent fertility rates (defined as the annual number of live births to girls aged 15-19 per 1,000 girls aged 15-19) vary considerably by world region. The worldwide average for the period 2000-5 is estimated at approximately 50 per 1,000, but rates in Sub Saharan Africa average 127 per 1,000 where countries such as Liberia, Niger, and Uganda have rates above 200 per 1,000. Adolescent fertility is also relatively high in Latin America and the Caribbean at 71 per 1,000. Together, the industrialized countries have an average rate of 24 per 1,000. As a region, East Asia and the Pacific has the lowest figure of only 18 per 1,000 due to rates of 5 or less in China, Japan, and Korea (UN Population Division 2002).

Regardless of the social setting within which adolescent childbearing takes place, there are potentially serious negative health implications associated with adolescent fertility, although the risks are higher in the developing world. Complications resulting from pregnancy and

childbirth are the leading cause of death for female youth in less developed countries where an estimated 70,000 teenage girls die each year from causes related to pregnancy and child birth. Maternal mortality is defined as the number of maternal deaths per 100,000 live births and is exacerbated by inadequate nutrition prior to and during pregnancy, and inadequate medical care during pregnancy, and especially during labor. Because adolescent girls have not finished growing themselves, especially in terms of their height and pelvic size, they are at greater risk of obstructed labor, which occurs when the infant cannot pass through the birth canal. Reproductive health is therefore especially worrisome when the mother is 17 or younger, as her own body is still developing and obstructed labor can lead to serious injury or death for the mother as well as for her infant. Maternal mortality ratios for girls aged 15–19 years can be more than double those of women who give birth in their twenties and early thirties, and very young mothers who are less than 14 years old when they give birth have maternal mortality rates five times higher than those of women in their early twenties.

Adolescents are also more likely than their older counterparts to suffer pregnancy related complications that can lead to infertility and disability. Obstetric fistula is the most devastating of all pregnancy related disabilities and is usually the result of obstructed labor. If the mother survives, she can sustain such severe tissue damage to her birth canal that she is left incontinent. Nerve damage to her legs can also make it difficult to walk. Affected women are often rejected by their husbands and shunned by their communities. They are also at risk of recurrent urinary tract infections that can eventually lead to renal failure and death.

Pregnancies may also be unwanted: an estimated 5 million girls aged 15–19 currently seek abortions every year rather than carrying their pregnancy to term. Forty percent of these abortions are performed under unsafe conditions, a factor that contributes to high rates of maternal mortality and morbidity. In Sub Saharan Africa, for example, where abortion is either illegal or severely restricted, complications resulting from abortions are a major cause of death among adolescent women.

Infants born to teenagers also run a higher risk of low birth weight, prematurity, birth injuries, stillbirth, and dying during infancy. Low birth weight infants have a far greater risk of experiencing lifelong disabilities such as mental retardation, cerebral palsy, and autism. Worldwide, approximately 1 million children born to teenage mothers die each year. Infant mortality rates for births to teenagers are as much as 80 percent higher than those for 20 to 29 year old women. Some of this age differential may be due to the higher level of first pregnancies among adolescents, as first pregnancies carry a higher risk of complications than do later births. However, even after the first month of life, infants born to adolescent mothers still have poorer survival prospects than those born to mothers in their twenties. Demographic and Health Surveys data from the mid to late 1990s showed that in Sub Saharan African countries such as Mali, Mozambique, and Niger, one of every six children born to teen mothers failed to live to age 1.

Approximately two thirds of the world's adolescents live in Africa, Asia, the Near East, Latin America, and the Caribbean, and 80 percent of adolescent births occur in the developing countries of Asia, Africa, and Latin America where children born to teenagers account for about 13 percent of all births. Due to a legacy of past high fertility, the number of adolescents worldwide is projected to increase, and by the year 2020 about three quarters of the world's adolescent girls will be living in the developing nations. However, this increase in numbers should be more than offset by declines in teenage birth rates as a result of ongoing urbanization, the progress being made by many nations toward providing better educational opportunities for girls, and the concomitant delay in age at first marriage.

In all developing countries, marriage constitutes the predominant context for childbearing. Teenage fertility levels are closely related to age at marriage as countries with large proportions of young women marrying in their teen years are also countries where adolescent fertility is elevated. Although the trend in many developing countries is toward a later age of first marriage, teenage marriages still prevail in many areas of the world. In Sub Saharan Africa, for example,

nearly 60 percent of women were married by age 20 in the late 1980s and early 1990s. By the late 1990s, this figure had dropped, but still about half of women married prior to age 20.

Not only is fertility closely related to the age at which women marry, but additional important related factors are urbanization and the provision of educational opportunities for girls commensurate with those available to boys. In developing countries, fewer urban than rural women begin childbearing in their teen years, in part reflecting later ages at marriage. Limited education is both a cause and effect of adolescent childbearing: girls who become pregnant are often forced to leave school, and women with more education also marry and have children later. Results from survey analyses using data from the 1990s show that, on average, the proportion of young women with primary schooling who begin childbearing as adolescents is approximately two thirds that of women with no schooling, and for young women with secondary or higher education the proportion is less than one third.

Education is also related to maternal and child health outcomes. In developing countries, poorly educated mothers are less likely to receive prenatal care and to be assisted by trained medical personnel at the birth of their children than are their more highly educated peers. Children of mothers with no education are also more than twice as likely to die or to be malnourished than children of mothers with at least a secondary education.

Although the negative health implications of adolescent pregnancy and childbirth exist regardless of societal structure, the extent to which adolescent fertility is viewed as problematic varies by country. In some parts of Asia and Africa where daughters are viewed as an economic liability and have the potential to bring shame on the family if they are not married at a young age, early marriage and childbearing is culturally desirable. Results from Demographic and Health Surveys data collected in the mid to late 1990s in 11 Sub-Saharan African countries show that in nine of these countries, more than one third of young women were married before age 18. Seventy percent of girls in Mali were married prior to age 18. In Côte d'Ivoire, Madagascar, Mali,

Mozambique, and Uganda, more than half of 18 year olds were either already mothers or were pregnant with their first child.

In other, more industrialized areas of the world, such as the United States, adolescent childbearing is viewed with concern by society in general as it is associated with reductions in human capital, decreased labor force options, depressed earnings, and a higher likelihood of long term poverty for both mothers and their children, increased total fertility, and a diminished likelihood of marriage. But although these associations are real enough, the question remains as to whether adolescent childbearing is the *cause* of these adolescent mothers' reduced socioeconomic well being and the concomitant increased societal costs. Alternatively, do these adverse outcomes reflect preexisting differences in the backgrounds of teens who give birth that differentiate them from their counterparts who delay childbearing?

The task of disentangling the effect of adolescent childbearing *per se* from any spurious association due instead to factors that might jointly determine both adolescent fertility and the adverse consequences that occur is a difficult one. However, several studies have taken unique methodological approaches to do so. To control for the selective differences in the background and personal characteristics of teen mothers, Geronimus and Korenman (1992, 1993), for example, compared the life course of pairs of sisters raised in the same family, only one of whom became a teen mother. Hotz et al. (1997) contrasted the later educational achievements, earnings, and receipt of public assistance of teens who miscarried with those of teens who carried their pregnancies to term. Lichter and Graefe (2001) also compared teens who gave birth with those who either miscarried or aborted in order to ascertain if unwed childbearing "caused" delayed or non marriage.

The results from these and other studies suggest that failing to account for selection bias can lead to a considerable overstating of the negative consequences that might accrue from teenage childbearing, at least with respect to achieved education and earnings, and hence to the magnitude of government subsidies expended. While teen childbearing reduces high school graduation rates, teen mothers are more

likely to earn their GEDs by age 30, to work more hours, and to earn more than those who delayed – although they earned less in their teens and early twenties, the situation was reversed in their late twenties and early thirties (Hotz et al. 1997). Sometimes, however, early childbearing does appear to have permanent effects, for example to increase the total number of children born, and, by reducing the likelihood of later marriage for the vast majority of American teens who give birth outside of marriage, to increase the time spent as a single mother (Lichter & Graefe 2001). The jury is still out on how detrimental these effects might be on the children born to young mothers.

In the United States, teenage birth rates have declined more than 20 percent since 1991. While increased abstinence among teens accounts for approximately one quarter of this fertility decline, most of the drop resulted from changes in the contraceptive behaviors of sexually experienced teens who were increasingly likely to use injectable contraceptives which have very low failure rates, and to use contraception at first intercourse, especially condoms. Abortion rates among teens also declined steeply over the same period.

Adolescent fertility rates in the United States today are less than half the level they were at the peak of the baby boom in the late 1950s: in 1957 the adolescent fertility rate was 96.3 per 1,000, whereas the comparable figure in 2001 was only 45.8 per 1,000. However, the vast majority of adolescent births during the baby boom era were to women who were married at the time of birth, and this situation is reversed today. Eighty five percent of adolescent births were within marriage in 1957, whereas only about one fifth of births to American teens currently occur within marriage. Most teens who give birth today continue to reside within their family of origin, and recent research has shown that adolescent childbearing can negatively impact other family members by increasing family financial hardship and stress, and by socializing younger sisters for early parenthood. Because adolescent parents have not acquired the necessary resources to parent, they need assistance from others, which also drains the resources of their extended families.

Despite quite dramatic declines in US adolescent fertility rates, US teens continue to

experience substantially higher birth rates than those of teens in other industrialized countries. Data from 1998 showed that more than one fifth of 20 year old women in the United States had given birth while in their teens. This contrasts with 5 percent or less in Belgium, Denmark, Finland, France, Greece, Italy, Japan, Republic of Korea, Luxembourg, Netherlands, Norway, Spain, Sweden, and Switzerland (UNICEF 2001). Teenagers in the United States are also more likely than their counterparts in other developed nations to have sexual intercourse before age 15, and each year approximately 19,000 girls aged 14 and under become pregnant.

Within the United States there are significant differences in levels of adolescent fertility by various social, cultural, and demographic factors. For example, black, Hispanic, and Native American youth have traditionally had higher rates than white and Asian youth. Since 1990 the largest decline in adolescent birth rates has been among black teens, and Hispanic teens now have the highest teen birth rates among the five racial and ethnic groups. Native American youth currently have rates about one and a half times the white rate. The rate for black youth is approximately 1.7 times the white rate, and the Hispanic rate is more than twice as high. States with large rural populations, above average poverty rates, and below average education levels also have the highest adolescent birth rates. In some of the nation's poorest rural areas, adolescent fertility rates exceed those in many developing countries.

Adolescents are generally viewed as being too young to become parents, especially at younger ages when they may not be biologically, economically, or socially prepared for bearing and rearing children. A girl's body has yet to fully develop, making childbirth dangerous and debilitating. Parenthood can severely curtail future educational plans and it is often those adolescents who are least well prepared to successfully nurture and raise a child who are most likely to become teenage parents. Those who come from economic disadvantage tend to initiate sexual intercourse at younger ages, conceive less effectively, and have more unintended births. The cycle of poverty is a difficult one to break, but education is a key weapon in the fight as it is not only related to delayed marriage and

childbearing, which pushes motherhood into developmentally safer ages, but it also prepares girls to be better mothers and have babies that are more likely to survive and thrive.

fertility: low

S. Philip Morgan

Low fertility implies a “not low” referent; there are two. The first is “high fertility.” High fertility can be defined as some maximal, hypothetical level for a population, i.e., one with early marriage, close birth spacing, and

no attempt to control family size. Fifteen births per woman provides a reasonable estimate of mean maximal fertility. The highest observed levels of fertility are closer to ten births per woman, and even in the absence of substantial contraceptive use and abortion can be one half this level. Regardless, low fertility implies much lower levels – levels approximating two or fewer births per woman. The fertility transition refers to the societal shift from “high” to “low” fertility (and is produced by deliberate attempts to achieve small family sizes).

A second definition, and one emphasized in most contemporary discussions of low fertility, adopts as a referent replacement level fertility. The concept is straightforward: a birth cohort of women replaces itself if the cohort averages one female birth per woman that survives to reproductive age. After adjustment for low levels of mortality and for normal sex ratios at birth (common features of developed countries), replacement fertility is approximately 2.1 births (male and female) per woman. Given this referent, low fertility implies levels well below what is needed for replacement.

A practical weakness of this cohort fertility measure is that it cannot be calculated until the cohort reaches (or nearly reaches) the end of the childbearing years. Thus, the most commonly used measures of fertility are not cumulative measures for birth cohorts, but are measures calculated for calendar years (i.e., period measures). The most commonly used period measure, the total fertility rate (TFR), is calculated from age specific rates for a given year and is thus unaffected by population age composition. It also has an intuitive meaning; i.e., the number of children women would have if they experienced a given year’s age specific rates throughout their childbearing years. As above, assuming low mortality levels and normal sex ratios, replacement level TFR approximates 2.1 births per woman.

Note that any fertility level below replacement, if maintained sufficiently long, would bring about dramatic population decline. But current concerns focus on very low fertility or “lowest low” fertility, levels that imply dramatic population decline within several generations. For 2000, Paul Demeny (2003: 2) calculates the population weighted average TFR of Europe as 1.37. Given Europe’s 2000

mortality rates and this fertility level, a population of 1,000 would replace itself with 645 persons and after a century the population size would be 232 persons! Of course, any designation is arbitrary, but the implications of TFRs of 1.8 and 1.3 are dramatically different. Thus, for our discussion here we define a TFR below 2.0 as low fertility and a level of 1.5 or below as very low fertility; but these two benchmarks indicate that low fertility is a matter of degree (more than kind).

THE GLOBAL SPREAD OF LOW FERTILITY AND ITS CONSEQUENCES

Low fertility is rapidly becoming a pervasive, global phenomenon. Using data for 2000, the United Nations lists only 16 (of a total of 187) countries as *not* showing clear evidence of a fertility decline. Lingered high fertility has become geographically isolated and affects fewer of the world's people. Only 3 percent of the global population lives in countries not yet in fertility transition. The UN projects that all of these countries will soon begin a transition toward replacement level fertility. In contrast, 64 countries had replacement level fertility or lower in 2000. Twenty three recently made the transition to low fertility and another set of 41 countries has had several decades of low fertility punctuated by a baby boom and bust. Taking these countries together, 44 percent of the 2000 global population lived in countries with low fertility.

Between these extremes are 105 countries now experiencing fertility declines, 96 percent of which have their most recent estimate as their lowest recorded fertility. Thus, we say they are in transition because empirical evidence shows that, once begun, these declines do not stop until fertility reaches replacement or below. As of 2000, only two countries (Uruguay and Argentina) had halted their transition at a fertility level substantially above replacement levels. Others with currently high TFRs could do so, but evidence clearly suggests that arrested declines will be rare.

Given the population growth concerns of the last half century, this evidence and UN projections of these trends portend a remarkable achievement: the diffusing of the "population

explosion" and the realistic potential for an end to global population growth shortly after mid twenty first century. However, concerns of rapid population growth are being replaced by concerns about very low fertility. At the aggregate level, low fertility implies declines in population size and an aging population. Declines in population size, in turn, mean fewer domestic consumers, producers, and warriors. An aging society implies an increase in the ratio of older, dependent persons to working age persons. These changes in size and composition require societal adjustments. Perhaps most crucial are labor force shortages and the provision of income maintenance and medical care for large elderly populations (compared to the working age population). Immigration provides a partial solution but requires that immigrants are willing to come and that natives are willing to tolerate immigrant flows large enough to offset low fertility. The latter are especially challenging when large flows of immigrants are needed to compensate for very low fertility. Societies could also dramatically transform social support for the elderly. Public support could be based on need and retirement ages could be dramatically increased. The political palpability of such changes is uncertain.

DECOMPOSITION AND PROXIMATE DETERMINANTS APPROACHES TO STUDYING LOW FERTILITY

Fertility research has benefited greatly from decomposition and/or proximate determinants approaches. The former disaggregates fertility into constituent parts to assess which ones are responsible for overall change. The latter links fertility to its most important proximate causes; in turn, these proximate causes become factors to be understood. The rationale for this level of explanation is that it identifies more precisely "what needs to be explained."

Decomposition Approaches

Classic demographic approaches disaggregate fertility along two dimensions: parity (e.g., the number of prior births of the woman) and the mothers' ages at births (or the timing of

fertility). If one examines fertility by parity, then one can see whether current trends are produced by changes in the birth propensity of childless women, those with one child, or those at higher parities. For example, the transition from high to low fertility has resulted from the declining incidence of higher parity births. In contrast, fertility trends in low fertility populations hinge on the behavior of women with no or few births. For instance, Norman Ryder (1980) shows that the fertility behavior of childless women and those with one child accounts for substantial parts of the American baby boom and bust (the 1945–80 period). John Bongaarts and Griffith Feeney's (1998) work illustrates the crucial importance of postponed first births for understanding contemporary cross national fertility trends and differentials.

As the mention of postponed first births indicates, the age of childbearing at each parity is important. As defined above, the TFR has an intuitive meaning; i.e., the number of children women would have if they experienced current age specific rates throughout their childbearing years. The TFR for women childless at the beginning of the year can be interpreted as the proportion that would have at least one child given current rates. This definition makes clear the hypothetical nature of the measure. No birth cohort of women necessarily experiences exactly the rates of a given period. In fact, timing shifts across cohorts are common and can be quite dramatic. For example, let us assume that 80 percent of women will always have at least one child. Now let us allow for a decline in the ages of first birth. As long as this trend toward earlier childbearing continues, the period measure will rise above 0.8. In effect, births that would have occurred in the future under the previous timing regime are being pushed earlier and are inflating the birth rate in the current year. In a parallel fashion, increases in ages at first birth push births into the future, depressing estimates of the first birth period rate in the current period. Bongaarts and Feeney (1998) show that a good estimate of this effect is the change in the mean age at childbearing at that parity. For example, if the mean age of first births increases by 0.15 a year, then the first birth TFR is reduced by a factor of 0.85 ($1.0 - 0.15 = 0.85$). Thus it

follows that given an underlying quantum of fertility (say 0.80 having a first birth), declines in mean age at childbearing increase the TFR, and postponement of fertility depresses TFR relative to underlying quantum.

These associations are important because changes in fertility timing can have prolonged and substantial effects on period rates. Part of the reason for low rates observed during the 1980s and 1990s was a pervasive shift upwards in the ages at childbearing (especially controlling on the woman's parity). Bongaarts and Feeney show that timing shifts can reduce period rates by 10–20 percent for up to two to three decades. Thus a country with a TFR of 1.7 may not have any birth cohort of women that averages fewer than 2.0 births ($2.0/0.85 = 1.7$). So shifts to later childbearing are a significant part of the contemporary story of very low fertility. But the end of postponement would still leave many countries with fertility well below replacement. Low fertility explanations thus must account for both fertility postponements (changes in timing or tempo) and for fewer births per woman (lower quantum). The causal explanation may differ for these two components and decomposition analyses push researchers to understand these twin causes: fertility postponement and fewer births.

Proximate Determinants

In settings where birth control and abortion are available and widely used, decisions to have children play a central role in models of fertility by linking more distal determinants to fertility. This framework does not suggest that intentions always play a dynamic role in contemporary fertility change. In fact, in developed countries fertility intentions have changed little in the past two decades and vary little across developed countries; there exists a remarkably persistent and pervasive desire for two children. Thus, cross country and cross time variation must be explained by timing changes (discussed above) and women's/couples' ability and determination to realize intentions (not changes or difference in intentions).

In this conceptualization, the level of current fertility (the TFR) equals the number of children women intend but increased or decreased

by a set of factors women cannot anticipate and thus have not been incorporated into their reports of childbearing intentions. If all women realized their intended parity (IP), then the $TFR = IP$. Some factors inflate completed parity vis à vis intended fertility, e.g., unwanted fertility, replacement of children that may have died, and additional children needed to satisfy strong gender preferences. Other factors would reduce fertility relative to intentions. These factors include changes in the timing of fertility discussed above, subfecundity and infecundity associated with older ages of childbearing, and competition with other energy and time intensive activities that may lead persons to revise downward their intentions, especially at older ages.

The primary explanation for very low fertility codified in this model is that women (on average) fail to realize their intentions for even small and modest sized families. This insight directs our attention to factors that influence attainment of these goals. The process producing this lower than intended fertility is a life course process of fertility postponement that increases the likelihood that at older ages intentions will be revised downwards or infecundity will come into play.

FUNDAMENTAL CAUSES OF LOW FERTILITY

The weakness of the decomposition and proximate determinants approaches (discussed above) is that they leave the fundamental or exogenous cause unspecified. As a result, these explanations are only partial and beg the question: why is it that childlessness is greater or intentions are more likely to be met in one country compared to another?

Few would dispute that the transition from high to low fertility results from industrialization and post industrialization that increased "costs" (broadly conceived) of bearing and raising children. The timing of these fertility declines vis à vis particular aspects of socioeconomic change (and the resultant changes in child cost) was variable because populations had to recognize and conceptualize changing child costs and rationalize new fertility regulation behaviors. The new fertility regime

was one of small families. No country has become economically developed without experiencing the transition to small families.

But this powerful explanation for the fertility transition is not very useful for explaining variation in low fertility or for predicting its future course. Instead, there are two competing explanations. The first focuses on the cost/difficulty of childbearing and rearing in all contemporary settings. But it views the degree of incompatibility as variable, contingent on a set of society specific factors that decrease/increase incompatibility. For instance, all developed countries have experienced increases in female labor force participation. However, some societies experience increases in women's labor force participation with little change in fertility; for others, similar changes have accompanied sharp fertility declines. To account for these variable responses, one needs to document the institutional factors that make work and family more (or less) compatible for women in some countries than others. The most complete explanations require idiosyncratic explanations. But general patterns can be described. Peter McDonald (2000) argues that societal gender equality reduces work/family incompatibility. Specifically, when women enter the workforce but other institutions (e.g., the family, gender relations) do not make adjustments, it makes the joint roles of mother/worker very difficult. Some employed women resolve this incompatibility by having no or only one child. Greater gender equality (accompanying increases in women's non family work) eases women's work/family burden. Such adjustments facilitate women having the moderate number of children that they intend. The state can also respond with policies that encourage gender equality and that recognize the burden of bearing and caring for children. Public provision of children's health care and day care provide important examples. Finally, the market can respond; examples include widely available flex time for employees and consumer goods and services that substitute for home production.

A second explanation (for variation in low fertility) focuses on a putative irreversible shift toward an ideology that stresses individualism and self actualization. This ideology encourages women/couples to consider whether becoming a parent or having another child would make

them happier or their life more meaningful. Dirk Van de Kaa (2001) and Ron Lesthaeghe and Paul Willems (1999) argue that this spreading ideology has fostered a second demographic transition – later union formation, greater cohabitation, frequent union dissolution, and very low fertility. Given the very high direct and indirect costs of childbearing and rearing and this ideology that makes parenthood one of a range of acceptable lifestyles, these authors are pessimistic about fertility recuperating to approximate replacement levels.

FUTURE RESEARCH AND KEY UNANSWERED QUESTIONS

A key unanswered question is whether countries now undergoing a fertility transition will experience fertility well below replacement levels in the coming decades. Current evidence and theory suggest that settings with great gender inequality may experience the most dramatic fertility declines as women in these societies undertake non familial employment. However, the experience of developed countries may encourage more rapid adoption of strategies to reduce work/family competition for women's time and energies. The widespread adoption of effective policy responses is a second plausible scenario. Thirdly, some societies may be able to maintain fertility at/above replacement levels by embracing fundamentalist ideology or identifying motherhood/parenthood strongly with group identity. Such cultural/ideological responses gird families and women to accept the high costs of parenthood.

But equally important is the course of future fertility in countries that already have low fertility. Fertility postponement explains a significant part of contemporary very low fertility, but when postponement abates (as it eventually must), many countries will still have fertility levels well below replacement levels. One of the key questions for the twenty first century is whether and how effectively societies will respond. Comparative research can contribute by identifying effective responses or "packages" of responses that prove effective. The challenge is fundamental because replacement of the population is required for societal survival and because the costs of childbearing and rearing in

contemporary settings are huge. The changes in institutions and the redirection of resources toward parents and children that will likely be required pose a huge challenge for societies with very low fertility.

fertility: nonmarital

Kelly Musick

Nonmarital fertility – or having a child outside of marriage – has become an increasingly important phenomenon demographically, socially, and politically. Fully one in three US births were to unmarried women in 2000, compared to just 5 percent in 1960. This change has generated a great deal of concern. Many worry because unmarried mothers tend to be younger and less advantaged socially and economically than married mothers, and their children tend not to do as well as those living with two married biological parents. Others worry that the growing number of families formed outside of marriage is weakening the institution of marriage. Policy makers have introduced measures in recent years explicitly designed to reduce the number of births to unmarried women. The 1996 welfare reform legislation, Personal Responsibility and Work Opportunity Reconciliation Act (PRWORA), for example, includes incentives for states to reduce their rates of nonmarital childbearing, and reauthorization legislation includes resources to strengthen and promote marriage through outreach and counseling.

Three indicators are used to measure the extent of nonmarital fertility: the number of births to unmarried women; the nonmarital birth rate, or the proportion of unmarried women who have a birth each year; and the nonmarital birth ratio, or the proportion of all births that occur outside of marriage. In the United States, each of these indicators shows a dramatic increase in nonmarital fertility between 1960 and 1990 and a slowing or stabilization thereafter. These trends reflect changes in marital behavior. Men and women are getting married later, they are more likely to live together before marriage, and their marriages are less likely to last. They are spending an increasing number of years unmarried and sexually active, putting them at greater risk of having a child outside of marriage.

The United States is not unique in experiencing changes in marriage and fertility. Nonmarital fertility, cohabitation, and delayed marriage are common features of family life in many western industrialized countries. The

level of nonmarital childbearing in the US falls about in the middle compared to its European counterparts. Nonmarital fertility rates in the US are comparable to those in the United Kingdom and France; rates are lower than those in the Scandinavian countries and higher than those in Germany, Italy, and Spain.

The underlying causes of nonmarital fertility in the US and elsewhere must be understood in the context of changes in marriage, i.e., changes affecting the desirability, feasibility, or necessity of marriage. Four main ideas have received considerable attention in policy and academic circles. First, Gary Becker and the new home economics posit that women's growing economic independence has eroded the benefits of marriage. According to Becker and others, gains to marriage are derived from a highly specialized division of labor in which women depend on men's earnings in the labor market and men depend on women's caretaking and child rearing at home. As men's and women's roles become more complementary, they become less dependent on marriage. Although the dramatic increase in women's labor force participation in recent decades mirrors the decline in marriage and the increase in nonmarital fertility, the bulk of the evidence does not support the economic independence hypothesis. Women with greater resources, i.e., those with more education and higher earnings potential, are in fact more likely to marry than women with poorer economic prospects.

The second commonly offered explanation for changes in marriage and fertility focuses on men's economic prospects. William Julius Wilson, Valerie Oppenheimer, and others have argued that declines in men's wages have made it more difficult for couples to establish stable family lives. In *The Truly Disadvantaged* (1987), Wilson emphasizes structural changes in the economy over the past 30 years that have drastically reduced the earning power of low skilled men. He argues that declines in labor force participation and wages have created a lack of "marriageable men," particularly among African Americans. Research shows that men's economic prospects are an important predictor of marriage, although they cannot fully explain declines in marriage rates.

Third, welfare has been blamed for declines in marriage and increases in childbearing

outside of marriage. In his 1984 book, *Losing Ground*, Charles Murray uses a fictitious couple to illustrate how the availability of government assistance makes remaining unmarried a rational choice for low income women. He argues that because single women are eligible for more help than married women, couples are better off living together than marrying. Although welfare reform legislation in the mid 1990s attempted to change this, disincentives to marry remain. Moreover, like female employment and earnings, welfare makes women less dependent on men. Although the welfare argument continues to have considerable political currency, trends in benefit levels and family change provide little support: real welfare benefits began to erode in the 1970s and 1980s, as nonmarital childbearing continued to rise. Robert Moffitt has extensively studied the micro level association between welfare and family formation, and concludes that welfare has affected marriage and childbearing over the years, but the magnitude of the effect is small relative to other factors.

Finally, attitudes and values have been discussed as a potentially important factor behind increasing nonmarital fertility. In recent decades, men and women have become more tolerant of nonmarital childbearing and related behaviors, including sex outside of marriage, cohabitation, and single parenthood. Greater acceptance of family life outside of marriage has reduced the social and family pressure to marry, even as young people continue to express the desire to marry. Attitudinal change has gone hand in hand with increases in nonmarital fertility and cohabitation. It is difficult, however, to determine whether changes in attitudes have fueled changes in the family or, rather, whether increasing diversity in family life has led to more tolerance of a range of family behaviors. Some see changing values as an inevitable reaction – with costs as well as benefits – to increasing individualism, secularization, and gender equality (e.g., Bumpass 1990). Others view them more skeptically as indicators of family decline with harmful consequences for children (e.g., Popenoe 1993).

A good theory of nonmarital fertility should explain not just why it has increased, but why it is more common among some groups than others. Patterns of nonmarital fertility vary considerably by socioeconomic status, race, and

age. Nonmarital births tend to occur to women who are relatively disadvantaged socially and economically. In the early 1990s, for example, over half of all births to women with less than a high school degree were to unmarried women, whereas this was the case for just 5 percent of births to women with a college degree. There has been little research on education differences between married and unmarried mothers in European countries with similarly high levels of nonmarital fertility. We do know, however, that unmarried mothers are less likely to be poor in Europe than in the US. This is due in part to Europe's relatively generous public assistance programs; it may also be related to the greater likelihood of unmarried mothers in Europe to be living with their partners when their children are born. In the US, levels of nonmarital childbearing also differ significantly by race, although the gap has been closing. In 2002, 23 percent of births to white women, 44 percent of births to Hispanic women, and 68 percent of births to black women were nonmarital (data from Table 7, *National Vital Statistics Report*, Vol. 52, No. 9).

Unmarried mothers are younger on average than married mothers. Thirty percent of all nonmarital births – and most first nonmarital births – are to women in their teens. Teenage childbearing has been a public issue of great concern since the 1970s. It entered the national agenda not when it was at its peak, but as the proportion of unmarried teenage mothers grew and fewer teenagers opted into marriage following a premarital conception. Rates of teenage childbearing have reached record lows in recent years (the lowest levels since the Centers for Disease Control and Prevention began calculating them in 1976), falling substantially over the course of the 1990s, particularly among blacks. Despite declines, rates of teenage childbearing continue to be much higher (by two to ten times) in the US than in other developed countries. They remain a public issue, moreover, because the vast majority of teenage births are outside of marriage; indeed, given the delay in marriage, a much higher percent are nonmarital today than when teen births were more common.

Although age is an important dimension of nonmarital fertility, nonmarital childbearing is too often viewed as synonymous with teenage

childbearing. Policy and academic discussions have focused on young first time mothers, paying little attention to the 70 percent of nonmarital births to women in their twenties and older, many of whom already have children. Because of the focus on teenage mothers, research and debate have primarily addressed the factors leading to early sex and unintended pregnancy. The processes leading to an unmarried birth are likely very different for older women.

There is little research on the consequences of nonmarital fertility for mothers and children. Two related literatures – on single parent families and teenage childbearing – shed light on the question but do not address it directly. Single parenthood results from nonmarital childbearing and divorce, and many studies do not distinguish between the two. Among those that do, families headed by never married and divorced mothers seem to be related in similar ways to child well being. Children from single parent families tend to fare more poorly than children from biological married parent families in terms of school achievement, occupational attainment, and income. Girls from single parent families are also more likely to become single mothers later in life. Teenage childbearing is associated with a host of negative outcomes for mothers: teenage mothers are less likely to graduate from high school and college and more likely to live in poverty. Young unmarried mothers are less likely to marry than women without children.

While associations between well being, single parenthood, and teen parenthood are well established, the extent to which negative outcomes are a consequence of single parenthood and teen parenthood remains unclear. Women who enter into these statuses are different from those who do not, and it is difficult to distinguish between preexisting differences and causal effects. Teenage mothers, for example, come from relatively disadvantaged families, which places them at greater risk of dropping out of high school and falling into poverty, independent of early childbearing. Analysts have carefully designed studies to minimize the preexisting differences between women who have had a teen birth and those who have not. One approach has been to compare later life outcomes of sisters or cousins – who presumably share many

important family characteristics – with and without a teen birth. Another approach has attempted to use the “random” event of having a miscarriage to compare the outcomes of teen women who did and did not give birth but are otherwise similar. These studies find that preexisting differences account for a sizable share of the association between teenage childbearing and mothers’ outcomes, but probably not all. Similarly, the relationship between single parenthood and child well being is due at least in part to preexisting differences between women who become single mothers and those who do not. For example, children who grow up in highly conflicted two parent families fare about as poorly on many measures as children from single parent families, suggesting that unmeasured differences in the quality of parental relationships may account for differences between children from single parent and two parent families. Family background, education, and income are other dimensions on which women are differentially selected into single parenthood.

In recent years, the focus on early childbearing has given way to a more detailed examination of the romantic relationships and living arrangements of unmarried mothers. This shift has been driven by changes in the characteristics of unmarried mothers, including increases in the average age at birth and, particularly, increases in cohabitation. Since the 1970s, cohabitation outside of marriage has become a common and acceptable behavior: half of all couples now live together before marriage. As of 1995, 40 percent of all nonmarital births were to cohabiting couples, and nearly all of the increase in nonmarital fertility since the late 1980s was due to increases in births to cohabitators. Cohabitation may have very different implications for father involvement, child well being, and welfare dependence than single motherhood. These facts are just beginning to be digested by policymakers and social commentators. Policy attention since 2000 has begun to shift from pregnancy prevention among teen women to marriage promotion among young adults.

Research is starting to address key questions about the relationship context of births to unmarried women, the stability of these relationships, and the level of father involvement

typical of them. Analyses are being extended to couples' decisions to cohabit rather than marry and implications of this choice for children. The Fragile Families Study, a representative sample of nonmarital births in cities of 200,000 and over, is unique in collecting information from both parents, irrespective of their living arrangements. These data have allowed researchers to examine a range of parental relationships into which children are born, including those in which parents are uninvolved romantically, romantic visiting relationships, and cohabiting relationships. These data have shed light on the role of unmarried fathers in the lives of their children and the relationships of unmarried mothers and fathers. Recent research is also moving away from the assumption that most births to unmarried women are unintended. Kathryn Edin and Paula England are analyzing qualitative data designed to distinguish between planning a child outside of marriage, ambivalence, and contraceptive mis use and failure.

Decisions about having children, cohabiting, marrying, and ending a relationship are closely intertwined. Nonmarital fertility is difficult to study because it lies at the intersection of these family processes. In addition to conceptual difficulties, small sample sizes and truncated life histories often limit our ability to empirically examine meaningful differences in the pathways women follow through childbearing, cohabitation, and marriage. The context of nonmarital births is heterogeneous with respect to mother's age, parental relationships, and father involvement, and this heterogeneity is likely important for child outcomes. Understanding differences in the contexts of nonmarital families, while at the same time paying attention to differences in how children experience family transitions according to their sex and developmental stage, is a challenge for future research.

fertility and public policy

John Bongaarts

Fertility levels vary widely among contemporary populations, from a high of 7.9 births per woman in Niger to a low of 0.8 in Macao (United Nations 2005). These levels are largely

the result of decisions made by individual couples who are trying to maximize their families' welfare. In the least developed countries, fertility is high because children are valued for the social and economic benefits they provide to their families and the cost of childbearing and rearing is typically low. In contrast, in the most industrialized countries, couples want and have small families because the value of children is relatively low and their costs are high. The fertility that results from this individual decision making is not necessarily optimal from a societal point of view, thus suggesting a potential role for government intervention.

Many governments regard the fertility level of their countries as unsatisfactory. A world wide survey of population policies undertaken by the United Nations found that the proportion of countries that are not satisfied with their level of fertility has increased from 47 percent in 1976 to 63 percent in 2003 (United Nations 2004). In the developed world (Europe, North America, Japan, Australia, and New Zealand) 58 percent of countries consider fertility too low and none considers it too high. In the developing world (Africa, most of Asia and Latin America) 58 percent of countries consider fertility too high and 8 percent too low. A range of public policies have been developed in response to these concerns.

POLICY RESPONSES TO HIGH FERTILITY IN THE DEVELOPING WORLD

In the 1950s and 1960s declines in mortality caused a sharp acceleration of population growth throughout the developing world. This growth led to widespread concern about its potential adverse consequences for human welfare and the environment, particularly in the poor countries of Asia, Latin America, and Africa where growth was expected to be most rapid. As a result, in the 1960s and 1970s funding and technical assistance expanded enormously for developing country governments that were willing to take action. Efforts by these governments to curb rapid population growth focused on reducing high birth rates because other demographic changes (raising the death rate or massive emigration) were obviously not

desirable. The large majority of governments attempted to reduce high birth rates through the implementation of voluntary family planning programs. The aim of these programs was to provide information about and access to contraception to permit women and men to take control of their reproductive lives and avoid unwanted childbearing. Only in rare cases, most notably in China, has coercion been used. Newly available contraceptive methods such as the pill and IUD greatly facilitated the delivery of family planning services. Successful implementation of such programs in a few countries in the 1960s (e.g., Taiwan and Korea) encouraged other governments to follow this programmatic approach.

The choice of voluntary family planning programs as the principal policy instrument to reduce fertility is based largely on the documentation of a substantial level of unwanted childbearing and unsatisfied demand for contraception. When questioned in surveys, large proportions of married women in the developing world report that they do not want a pregnancy soon. Some of these women want no more children because they have already achieved their desired family size, while others want to wait before having the next wanted pregnancy. A substantial proportion of these women are not protected from the risk of pregnancy by practicing effective contraception (including sterilization) and, as a result, unintended pregnancies are common. In the mid 1990s, 36 percent of all pregnancies in the developing world were unplanned and 20 percent of all pregnancies ended in abortion (Alan Guttmacher Institute 1999). The existence of an unmet need for contraception, first documented in the 1960s, convinced policy makers that family planning programs were needed and would be acceptable and effective.

The effectiveness of this approach was supported by experiments such as the one conducted in the Matlab district of rural Bangladesh (Cleland et al. 1994). When this experiment began in the 1970s, Bangladesh was one of the poorest and least developed countries, and there was considerable skepticism that reproductive behavior could be changed in such a setting. Comprehensive family planning and reproductive health services were provided in the treatment area of the experiment. A wide

choice of methods was offered, the quality of referral and follow up was improved, and a new cadre of well trained women replaced traditional birth attendants as service providers. The results of these improvements were immediate and pronounced, with contraceptive use rising sharply. No such change was observed in the comparison area. The differences between these two areas in contraceptive use and fertility have been maintained over time. The success of the Matlab experiment demonstrated that appropriately designed services can reduce unmet need for contraception even in traditional settings.

The expansion of international and national investments in family planning programs in the 1970s and 1980s coincided with a massive decline in fertility in much of the developing world. Fertility had been high and stable at about 6 births per woman until the late 1960s, when a sharp decline began. By 2000 fertility had dropped by half to about 3 births per woman on average. The largest declines occurred in Asia and Latin America, but declines are now also underway in many parts of Africa. There is little doubt that family planning programs made a substantial contribution to this decline by reducing unwanted pregnancies (Bongaarts 1997). However, it is also true that much of the decline would have happened anyway because of the rapid social and economic changes that occurred in much of the developing world in recent decades. The resulting modernization of societies has reduced desired family size which, when implemented through the rising use of birth control, has brought about lower fertility.

Family planning programs are limited in their ability to lower fertility because they aim to reduce unwanted fertility and their effect on desired family size is apparently weak or non-existent (Freedman 1997). The implication of this finding is that countries in which wanted fertility is high will need declines in preferences to complete their fertility transition. Such declines are usually achieved by improvements in socioeconomic conditions. It is widely believed that desired fertility is most responsive to improvements in human development, in particular in female education and child survival (Caldwell 1980; Sen 1999). This conclusion is strongly supported by the fact

that low fertility has been achieved in some very poor societies such as Sri Lanka and the state of Kerala in India. Although poor, these populations have high levels of literacy and female empowerment and low infant and child mortality. The most effective public policies to reduce high fertility therefore pursue two general options: strengthen the family planning program and encourage human development. The former is aimed primarily at reducing unplanned pregnancy and the latter at reducing the demand for children.

POLICY RESPONSES TO LOW FERTILITY IN THE DEVELOPED WORLD

In the 1990s fertility transitions in most developing countries were well underway or even nearing completion and, as a result, these issues became less urgent. Attention of the scientific and policy communities then increasingly turned to a relatively new and unexpected development, namely the very low fertility observed in most developed societies. Until the 1990s demographers widely expected fertility to level off at or near the replacement level of about 2.1 births per woman at the end of the transition, and population projections made by international agencies such as the UN often incorporated this assumption. This view is now seen as ill founded because fertility in virtually all modern societies has dropped below the replacement level. The average fertility of the developed world in 2000–2005 is estimated at 1.6 births per woman and in several countries fertility is less than 1.3 (United Nations 2005).

Low fertility has become of concern because further declines or even a continuation of current levels will lead to rapid population aging and to a decline in population size. These demographic developments in turn will have substantial social and economic consequences. In particular, rapid population aging threatens the sustainability of public pension and health care systems (OECD 1998; World Bank 1994). These popular programs have been successful in improving the health and welfare of the elderly. However, expenditures by widely implemented pay as you go programs, which rely on transfers from younger to older generations,

are becoming increasingly burdensome on the contributors and are eventually unsustainable as old age "dependency rates" rise to high levels.

Identifying and implementing reforms of public pension and health care systems under these changing demographic conditions represent an urgent new challenge for public policy. Avoiding action is no longer a feasible option because an unprecedented and harmful accumulation of debt would then result. In the past, the rising cost of public support for the elderly has often been covered by raising taxes, but these have reached such high levels that expenditure-reducing approaches are now given highest priority. Reforms now focus on achieving reductions in future benefits even though this option is difficult politically because large proportions of pensioners receive public benefits. In addition, efforts are being considered to encourage later age at retirement by removing incentives to early retirement. Reforms adopted in recent years are generally phased in slowly, thus leaving current pensioners largely unaffected; their impact will therefore be felt mainly by future retirees.

Demographic options are generally ignored in the ongoing debate about reform. Many governments are reluctant to support pronatalist measures because of a disinclination to interfere with personal decision making regarding family size, or because of the apparent inconsistency of advocating pronatalism at home while supporting efforts to reduce fertility in poor developing countries; in addition, they may hope that fertility will soon increase again without intervention (Caldwell et al. 2002; Demeny 2003; Gauthier 1996). Furthermore, low levels of recent fertility have not yet led to declines in population size in most developed countries, because the effects of below replacement fertility have been offset temporarily by modest levels of immigration and population momentum. It seems likely, however, that growing concerns about the implications of population aging will stimulate more interest in efforts to encourage higher fertility directly or indirectly. For example, family support measures such as subsidized childcare, reduced taxes for families with children, and paid parental leaves are widely acceptable and could be expanded. A recent review of the impact of such measures by Caldwell et al. (2002) concludes that they do

raise fertility modestly provided the subsidies are sufficiently large. The fact that desired family size in most developed countries is still around 2 indicates that actual fertility is lower than desired and strongly suggests that birth rates can be raised by policies that reduce the cost of childbearing and help women to combine a career with childbearing.

Most governments of OECD countries are now well aware of the challenges posed by population aging caused primarily by low fertility. The modest ongoing reforms of pension and health care systems are a step in the right direction, but they are far from adequate. It is likely that further reform will include direct and indirect measures to support families to achieve their desired fertility.

fertility: transitions and measures

Sharon Kirmeyer

Childbearing, or the fertility of human populations, has changed profoundly in the last several centuries. Four aspects are basic for measuring and studying human fertility: *age*, *parity* (number of children ever born), length of *birth interval*, and *population reproductivity*. Additionally, there are cross cutting issues of time perspective and of fertility dimensions. The variety of fertility measures at a given time is both a result of the data available and a precondition to expansions in data collection efforts.

COHORT VERSUS PERIOD ANALYSIS

Fertility measures are expressed to reflect childbearing either in the time period in which they occur, or at the end of the (reproductive) life time of a cohort.

Period fertility rates and analyses are cross sectional and give a "snapshot" of a population for a short period of time. A major advantage of period rates is that they are immediately calculable. A second is that they provide the annual contribution to population growth through fertility.

Cohort fertility rates and analyses concern a group of persons with a common temporal experience, such as a birth or marriage date. They take into account the events occurring to women (or men) until the end of their reproductive years. More stable than period rates, they provide the means to evaluate long term population evolution. The main disadvantage in calculating cohort measures is that they require, at minimum, 30 years of data.

The basic tool to translate period to cohort measures is through the Lexis diagram. The time of the event is on the horizontal axis, the time lapse on the vertical. A period rate employs events at given ages (or durations) for time on the horizontal axis. A cohort measure uses a diagonal span to calculate the rate for individuals entering the cohort at the stated points. More complex tools have been recently developed for period-cohort translation.

QUANTUM, TEMPO, AND DISPERSION

Fertility measures reflect three comprehensive dimensions of natality. Demographic *quantum* is the number of lifetime events per person. In fertility per se, it is the number of children ever born to a woman. Fertility *tempo* refers to the timing of births. This is most commonly expressed as the mean age of childbearing, and secondarily, the duration of intervals between births. A third dimension is that of *dispersion*. Dispersion measures variation, not central tendency, and can be based on age, parity, or birth interval.

Currently, the quantum and tempo aspects of fertility are drawing scrutiny as 20 European countries have period total fertility rates of 1.4 or below. A simple approach by Bongaarts and Feeney to remove major effects of tempo serves to approximate the fertility quantum by adjusting for changes in mean age of childbearing.

DIRECT (AGE BASED) MEASURES OF FERTILITY

Direct measures of fertility are classically obtained from vital registration records, which provide the numerators (births), and from censuses, projections, or continuous registration

systems, which provide the population denominators. Large population surveys can provide sufficient "person years" for stable estimates of direct measures.

The *crude birth rate* (CBR) provides the number of live births per 1,000 population in a given time period. The CBR is a measure of a population's overall growth, but it can mask – or exaggerate – fertility differences between two populations which have very different age structures.

The *general fertility rate* (GFR) is the number of live births in a time period to women of reproductive age, usually expressed per 1,000 women aged 15 to 44 or 15 to 49. This measure is generally available from vital registration. It removes from the denominator most of the population not directly exposed to childbearing, and as such removes most of the age compositional differences between populations. However, it does not control for age variation within the reproductive years.

The *age specific fertility rate* (ASFR) is the number of births to women of a certain age divided by the number of women in that age group (e.g., women aged 25 to 29). The distribution of ASFRs resembles an inverted U, conventionally starting at age 15 and ending at age 50. Birth rates are low in the teen years, rising in the twenties, and tapering off in the late thirties and forties. Many consider studying fertility changes in terms of age specific rates the most fruitful for social and demographic comparison.

The *total fertility rate* (TFR) represents the average number of children ever born to a woman if she were to move through her reproductive years maintaining ASFRs of the current time period. Using period rates, it is a synthetic figure. As both a summary indicator and a standardized rate, the TFR is employed in health, economic, historical, and other analyses. The TFR plus coexisting mortality levels establish the "replacement level fertility" for a population.

When women begin having children at older ages, the *mean age of childbearing* advances and the period total fertility rate falls. If childbearing moves to younger ages, the period TFR increases, at least temporarily. In recent years, the mean age of childbearing has shifted substantially to later ages in all regions but Eastern

Europe. With this change in birth timing, the tempo effect depresses the TFR.

INDIRECT (AGE BASED) METHODS AND MODELS

From the 1960s through the 1980s, a plethora of *indirect measures* was generated which estimated primarily TFRs and secondarily ASFRs in developing countries. This was due to the dual conditions of data deficiency – censuses being then the primary data source – and the national and internationally funded family planning and development programs which needed fertility measures to track outcomes. Surveys like those produced by the World Fertility Survey program were not large enough to produce reliable direct estimates. While many national surveys have become larger, indirect estimation continues to be used due to the limitations in data supply and quality.

Indirect measures of fertility are used under a variety of conditions. Indirect measures are necessary when vital statistics and large surveys are not available for calculating ASFRs and TFRs – the case when only census data are available. Also, other data are often incomplete, of dubious quality (especially in reference to age), or are based on small sample size; hence indirect measures may provide better estimates than would direct measures. Similarly, indirect measures can aid in data quality evaluation. Also, estimates are based on five year age and time intervals; interpolation techniques provide useful single year rates. Meaningful short and medium range projections of fertility are well grounded in fertility models, especially those containing alternate scenarios.

Indirect methods (i.e., indirect measures which incorporate other demographic estimates) may be classified into four groups: methods based on average number of children ever born per woman of specified ages – and often information about births in the past year; methods based on census age–sex distributions and life table functions – which reverse survive enumerated populations; regression based methods yielding fertility measures from demographic variables or permitting translation among fertility measures; and methods which partially use models – the strongest employing mothers'

own children data classified by mothers' and children's ages. As surveys have increased in size, permitting statistically reliable direct estimation of age based period measures, these indirect methods retain utility in interpreting historical data, or producing small area (or sub population) estimates.

Many indirect measures are *biodemographical models*, that is, they are based on reproductive processes. Three are mentioned here, distinguished for their simplicity of expression and their ability to explain change in fertility levels and composition.

In the 1970s, the Princeton University based European Fertility Project was established to characterize the decline of fertility that took place in Europe during the nineteenth and early twentieth centuries. A set of *indices* referring to total fertility (I_f), marital fertility, marriage, and illegitimate fertility formalized the theoretical fertility transition (Coale & Watkins 1986). Saridon provided the means to convert the I_f into the more easily interpretable TFR.

Coale and Trussell elaborated a general model consisting of marital states and fertility pertaining to those states which would closely describe age based fertility. Their three parameter model contains elements of natural fertility, deliberate control of childbearing (contraception and abortion), and cohabitation.

The *intermediate fertility variables* follow from the early framework of Davis and Blake and the subsequent work of many researchers who quantified elements of the reproductive process. Of the 11 variables named by Davis and Blake, Bongaarts identified four which explain the most variation between countries and are the most sensitive to change (marriage, contraception, induced abortion, and infecundability). These are often referred to as the *proximate determinants of fertility*.

Non biodemographical models are of a statistical or mathematical nature. Through smoothing, interpolation, and projection, they generate natural ASFR curves. They have been classified as being curves expressed by parametric mathematical formulae; models based on the relational approach; non parametric statistical models, such as those based on the principal component method; and non parametric curves – such as the various splines and higher degree polynomials.

PARITY BASED MEASURES

The study of *distributions by completed parity* of either actual or synthetic (period) cohorts with emphasis on parity progression ratios represents an evolution in perspective. As such, modern fertility is not a series of spontaneous events subject to biological factors, such as age and exposure. Rather, it is a behavioral process controlled by individual decision making regarding whether or not to bear a subsequent child.

A *parity progression table* parallels a conventional life table, substituting r , the number of children ever born, for the time parameter of decrement, x . The cohort is initiated with all women having yet to bear any children. The principal *parity progression functions* and their life table counterparts are:

$\lambda_r [\sim I_x]$, the parity attainment proportion;

$\delta_r [\sim d_x]$, the proportion at parity r at completed fertility;

$\rho_r [\sim p_x]$, the parity progression ratio; and

$\eta_r [\sim e_x]$, the expected number of children after r ;

Additional key measures derived from the basic parity progression table include: the *maternal TFR*, which follows the observation that countries' total fertility rates vary substantially due to the proportion childless in a cohort. This rate is the mean number of children ever born to women who become mothers.

Samuel Preston transformed mothers' cohorts by parity to the number of children born to their mothers. This switches the perspective to the children's, making it possible to estimate *mean number of siblings*. Mean number of siblings is higher than a mother's average fertility rate due to overrepresentation from large families.

The *Gini mean difference*, derived directly from parity progression functions, measures heterogeneity (or concentration) of the parity distribution. This provides a simple indicator to evaluate populations in terms of their parity dispersions.

Finally, to evaluate the impact of changing parity progression ratios on a new (overall)

fertility level, Barkalov adapted Pollard's *decomposition* technique. Applying decomposition, the percent of change in TFR may be attributed to each parity progression ratio.

BIRTH INTERVAL BASED MEASURES

Birth interval analysis has not been given as much attention as age based analysis. But with the growth of large surveys containing many covariates, the study of birth intervals provides information on the dynamics of family growth, control of reproduction, health consequences for mothers and infants, as well as tempo measures for formal demographic analysis.

The extent and frequency of gathering data on birth intervals has expanded. Traditionally, limited data have come from censuses and vital registrations (primarily: last birth date). Longitudinal surveys are the most appropriate for accuracy, but are difficult to implement. An abundance of data have come from retrospective birth histories. The World Fertility Surveys of the 1970s included 60 surveys from developed and developing countries. The largest retrospective enterprise includes the multiple rounds of Demographic and Health Surveys (at least 170 surveys) and the similar Reproductive Health Surveys, both supported by the US Agency for International Development. Recently, another round of 20 surveys took place in more developed countries (Family and Fertility Surveys), including the ongoing US National Survey of Family Growth. The World Fertility Surveys spurred the development of methods to analyze birth intervals. They are based primarily on events as numerators and person years of exposure in the denominator.

Birth intervals are ultimately bounded by age of menarche and menopause. They are classified as *first* (from time of first exposure to pregnancy) *interval*, *closed intervals* (between births), and the *open interval* (between the last birth and time of survey or presumed menopause). Birth interval analysis encounters several problems. Birth interval analysis is subject to expected data deficiencies: misreporting of event dates and age of mother, and underreporting of events. The first birth interval is problematic, as the date of first exposure to

pregnancy is difficult to determine in almost any population. Censoring occurs when a birth interval is not complete; it biases estimates by eliminating the longer intervals characteristic of subsets of the population. Survival analysis, borrowed from mortality analysis, addresses many issues encountered in working with birth intervals.

REPRODUCTIVITY

Particular attention to measures of population replacement, or *reproductivity*, came into play during the fertility nadirs experienced by Europe and North America between the world wars and in the last decade of the twentieth century. Also, the sustained high fertility rates of many parts of the "third world" – particularly in the 1970s and 1980s – generated concern about long run population growth. A set of measures made it possible to map where a country was in terms of replacing itself, and what that portended in the long run.

The *gross reproduction rate* (GRR) is a simple means to show, on average, the number of girls born to a woman. It is closely approximated by multiplying the total fertility rate by the current proportion of babies who are female. This simple method provides a sense of the ratio of daughters who will replace their mothers. But it does not take into account the possible mortality of women prior to reaching specific childbearing ages. As such, it may greatly overstate the number of daughters replacing their mothers.

The *net reproduction rate* (NRR) is the summary measure which best represents the ratio of female births in two generations. It is calculated using life table functions. The NRR is the average number of daughters which would be born to a woman if she passed through her lifetime conforming to the age specific fertility and mortality rates of a given year. A net reproduction rate of unity signifies that a population is exactly replacing itself. Above 1, the population is more than replacing itself; conversely, an NRR of less than 1 signifies a population which is declining in size. As the NRR takes mortality into account, a rule of thumb often uses a total fertility rate between 2.1 and 2.3 as being that which equates a *replacement level of fertility*.

For many years, the *intrinsic rate of growth*, or growth rate of a closed population with constant fertility and mortality, was of heuristic interest. Dublin and Lotka's (1925) formulation was incorporated into many formal analyses and long term projections, but had little immediate relevance. With the recent sustained low fertility and mortality of Europe, discussions concerning future national age structures and dependency ratios (vis à vis social security needs) are sparked by the longer generation lengths coupled with negative intrinsic rates of growth.

fetishism

Gert Hekma

A fetish is a more or less concrete object of sexual desire. It can be a part of the body, an object, a situation, or some abstraction. Breasts, buttocks, feet, hair, and genitals belong to the parts of the body; clothing, shoes, whips, dildos, uniforms, cars, or specific materials such as leather, silk, satin, velvet, and rubber are possible objects; situations can be cinemas, saunas, dark rooms, dinner tables, beaches, or prison cells; and more abstract examples of fetishism include youth, beauty, hospitality, power, submission, and humiliation. Ultimately, any part of the body, object, situation, or abstraction can become a fetish and, on the other hand, all sexual pleasure depends on fetishes. Naming or reading the word can be as exciting as the object to which it refers.

The term fetish comes from religion studies. The Portuguese named an object of African religious veneration a *feticão*, an object bestowed with surplus value (McClintock 1993; Nye 1993; Pettinger 1993). Karl Marx used the term in this sense for his economic theory, and in 1888 the French scholar Alfred Binet used it for the sexual theory he expounded in "Le Fétichisme dans l'amour." In the 1880s, which saw the beginnings of sexology, Binet asked why people had obsessive desires for nightcaps or women's ponytails. According to him, the coincidental association of sexual excitement and remarking a certain object produced the concrete, contingent, and individual form of a fetish. He differentiated between small and large fetishes, the first being additional and the second being essential to sexual pleasure. Many people like large breasts, but some can only

become excited when they have them in their hands or minds. Although Binet designed his view as a general theory of sexual perversion, his predominantly social theory was obscured by biological theories then current in psychiatry. The trend at that time was to explain perversion by way of physiology, not society. Several doctors wrote books in which they described concrete cases of fetishism. Only the Freudians adapted Binet's term and view for psychoanalysis, but it did not become one of their core concepts.

Since the recent postmodern turn, the erotic version of the term fetishism has been revived mostly in the humanities. It is an interesting term for the social sciences because it connects sexual pleasure to the social world where the fetish is picked up, and breaks down the dichotomy of homo and heterosexual and of subject and object. McCallum (1999: 154) suggests that the fetish challenges "the domination of the subject over the object" and eliminates the need for other subjects. The fetish is not abstract but instrumental and stimulates agency and passion. It is beyond the genders of sexual object choice. Different from love, sexual pleasures most often have a concrete and contingent aim and the concept of fetish captures this neatly. Apter and Pietz (1993: 4) can thus assert that "feminist essentialism is resisted through fetishism's implicit challenge to a stable phallic referent." In fetishism, the sexual aim is not a gendered object but something more specific, going beyond homo, hetero, or bisexual choices. These characteristics make the fetish an ideal concept for post feminist and queer theory where it has been applied profusely in the humanities (Apter & Pietz 1993), specifically in fashion studies (Steele 1996). In sociology, the concept is rarely used in its sexual meanings. It is remarkable that the grand masters of sociology, who lived in close proximity to the urban environments where sexologists and sexual subcultures are to be found, rarely paid any attention to sexual variation, and never to fetishism.

Although all people have fetishes, the term is mainly used in circles of sexual specialization such as subcultures, pornography, and Internet chat rooms and websites. The most common although still rare objects of sociological research have been leather or S/M commu-

nities. The main focus of research has been the origin of specific sexual choices or the organization of subcultures, but not specifically on fetishism. In surveys the topic of sexual choice goes rarely beyond homosexual and heterosexual, although in some cases unusual or deviant variations have been included, being an erotic interest of about 10 percent of the population. Fetishist preferences must be far more general. Most of those who are curious probably do not venture into the existing subcultures but instead play out their desires with their partner or in fantasy. The authors of the largest sex survey in the United States indicated that in most monogamous couples, sexual desires will differ. This means that the chances are minimal that partners will erotically satisfy each other's special wishes (Laumann et al. 1994). The absence of concrete physical places for the various fetishes, even in the largest cities, makes the desire highly abstract, as in most postmodern theorizing. It might be that the proliferation of web sites devoted to sexual variations will favor the emergence of relevant places and organizations, as occurred in the gay world with rubber, skin heads, sports clothing, and sneakers. The variety begs the question of how to find partners. Curiosity for each other's fetishes could bridge the gap between different desires.

Given the poor state of knowledge on fetishism, the most important first step in sociological research will be qualitative research to delineate themes and contexts, for example by interviewing people about their fetishes and putting down their sexual scripts. As no studies are available, the future direction will be to demarcate the contents and contexts of fetishist interests, their organization, and their place in sexual relations. The concept has a highly the-oretic quality, as it breaks down various dichotomies of gay and straight, object and subject, social and individual. It could be a central concept for a postmodern sociology of sexuality, while it reflects at the same time the realities of erotic pleasures.

Feuerbach, Ludwig (1804–72)

Clifford L. Staples

Ludwig Feuerbach was born into a large, prominent, academic family in Landshut, Bavaria. His father was a distinguished professor of jurisprudence, and three of Ludwig's four brothers went on to noteworthy careers in mathematics, law, and archeology. But unwilling to heed his father's advice to steer clear of radical ideas, and unable to negotiate the repressive atmosphere of academic and political life in mid nineteenth century Germany, Feuerbach became an important academic failure. Some social theorists and sociologists are familiar with Feuerbach's writings on religion, but most sociologists know Feuerbach primarily because of his influence on the young Karl

Marx – a central figure within the sociological tradition. Feuerbach's critique of Hegel provided Marx with the occasion to, in turn, critique Feuerbach, and in the process Marx worked his way toward a thoroughly sociological approach to such core topics as history, ideology, and social evolution – topics approached before Marx usually as theological or philosophical problems. For his time and place, Feuerbach was a radical, though not quite radical enough for Marx.

Feuerbach's life took a familiar modern trajectory from youthful religiosity toward naturalism and eventually to a materialist humanism typical, if not universal, among contemporary sociologists. Having a highly learned and opinionated father, however, made it difficult for Feuerbach to develop an independent intellectual life. As a young man he was interested in studying theology, but soon (along with many of his contemporaries) was swept up in the excitement about Hegel. Unfortunately, Feuerbach's father despised Hegel, and young Feuerbach was forced to fib his way to Berlin to hear the master by telling his father he was going off to study with the respected theologian Friedrich Schleiermacher. Eventually, and against his father's wishes, Feuerbach moved into philosophy and in 1828 successfully defended a dissertation on Hegel. But even in this early work it was already clear that he would not remain a strict Hegelian. Famously, he sent Hegel a copy of his thesis along with a suggestion that Hegel's work was not as Hegelian as it ought to be. He also pointed out that Christianity was not – as Hegel had argued – the ultimate religion. Details aside, it is Feuerbach's approach to religion, and by extension all forms of ideology, that would prove so useful to Marx and others inclined to challenge religious and political orthodoxies.

Between 1828 and 1837 Feuerbach, as a professor at the university in Erlangen, published several well received books and articles and was on his way to a successful career as an academic. However, and once again against his father's advice, Feuerbach also published anonymously, in 1830, *Thoughts on Death and Immortality*. In this book he extended and developed his critique of Christian dogma. Specifically, he challenged accepted Christian views on the survival of the soul after death – a risky move in a

near theocracy – but, for good measure, he also poked fun at popular Christian religious beliefs. The authorities banned the book and when Feuerbach, widely suspected of being its author, refused to deny it, he found himself dismissed from his position. Thus, even before Feuerbach had written much of interest to Marx or to sociology, he had already managed to get himself fired from the only academic position he would ever hold. We might have heard nothing more from Feuerbach had he not married into a moderately wealthy family in 1837, allowing him to continue with his intellectual work without having to earn a living from it.

Up through his brief career as an academic, Feuerbach wrote in a very abstract and speculative style of metaphysics of little interest to modern sociologists. But with the publication in 1841 of *The Essence of Christianity* Feuerbach pointed the way toward a secular, materialist humanism that most sociologists, not only Marxists, now take for granted.

The Essence of Christianity made Feuerbach famous in Germany and established him as a leader, along with Bruno Bauer and eventually Karl Marx, of the “Young Hegelians” – students of Hegel who sought to realize the master’s idealism by grounding it in social and political realities. What Feuerbach had to say about Christianity is less important, for the sociologist, than the paradigm shift he initiated with respect to how we might think about and understand religion and, more generally, ideology. A theologian studies religion for what it promises to tell us about God, or the nature of our relationship to God. The humanist, however – and this would include all secular sociologists from the ardent positivist to the committed interpretivist – assumes that the study of religion tells us not about God, but about human beings. Indeed, the skilled sociologist of religion is, at least heuristically, an agnostic, suspending judgment about the reality of the supernatural in order to focus on religion as a human social practice. Feuerbach, in particular, viewed religion as a projection of human needs and desires. Feuerbach, like Marx after him, wants us to see that religious striving represents an alienation of man from himself, and it is only through the proper understanding of man’s relationship to himself that he will find the liberation he is seeking in God. It is

this turning away from the supernatural to the natural, material, and the human that marks Feuerbach’s contribution to social thought and social analysis.

In his Paris writings of 1844 Marx laid the philosophical foundation for all his later work. Marx constructed this foundation by combining Hegel’s idealism with Feuerbach’s materialism. The concepts of *species being* and alienation, as well as the anthropological and materialist approach to nature, human labor, and social existence, all owe a great deal to Feuerbach.

As important as Feuerbach was to Marx’s early thinking, Marx himself thought that Feuerbach’s signal contribution to philosophy was his “transformative method,” which Feuerbach had applied so tellingly to Hegel. Indeed, Marx himself was to use this same method to address another problem some years later. What Feuerbach found so troubling in Hegel was the master’s willingness to generate abstractions (like “spirit” or “thought”) which he then endowed with power and agency. Feuerbach’s “method” was to reverse the equation, showing the abstractions to be the consequence or result of human thought or action. So, studying religion tells us more about people than it does about God because people created God, God did not create people.

Feuerbach’s “transformative method” is nothing less than a guide to how a critical sociologist should confront the problem of reification. Reification occurs when people “forget” that ideas and institutions are created by human beings, and as a result they endow them with power and agency. This happens, for example, with the word “society,” as when someone says “society turns people into consumers.” At one level this is just a shorthand way of pointing to a problem that needs further analysis. However, too often, such statements are offered as an explanation or answer, and when used in this way they stunt critical sociological thinking because they treat an abstraction created by human beings, “society,” as an agent.

Marx, of course, put Feuerbach’s method to work on the key concepts of classical political economy, such as the commodity. *Capital* is subtitled “a critique of political economy” and by this Marx signaled that he intended to transform bourgeois abstractions into the capitalist class relations which produced them. In doing

so he was doing to capitalist ideology what Feuerbach had done to Hegelian ideology.

But, of course, Marx was not entirely happy with Feuerbach. However important it was to think oneself out of the dead ends of philosophical abstraction or the obfuscations of bourgeois economics, for Marx, philosophy was always undertaken for the purpose of social transformation or revolution. It is for this reason that his final word on Feuerbach was: "The philosophers have only interpreted the world, in various ways; the point is to change it." Content with his own interpretations, Feuerbach spent his latter years reworking his earlier work and dabbling in geology. He died in 1872 at the age of 68.

figurational sociology and the sociology of sport

Eric Dunning

The figurational tradition of sociological research and theory was pioneered by Norbert Elias (1897–1990), a German of Jewish descent who became a naturalized Englishman in 1952. His work is best seen as an attempt to synthesize the central ideas of Auguste Comte, Karl

Marx, Max Weber, and Sigmund Freud. Other influences were: Georg Simmel, Kurt Lewin, Wolfgang Kohler, J. B. Watson, and W. B. Cannon. Elias studied philosophy and medicine to doctoral level in Breslau before switching to sociology in Heidelberg in 1925. There, he came under the influence of Karl Mannheim, a founder of the sociology of knowledge, and Alfred Weber, brother of the more famous Max and a leading cultural sociologist.

Three aspects of Elias's life help to explain characteristic features of his sociology. First, his experience of World War I, in which he served in the Kaiser's army on the eastern and western fronts, and the rise of the Nazis sensitized Elias to the part played by violence and war in human life. Such experiences also intensified his awareness of "decivilizing" as well as "civilizing" processes – he described the rise of the Nazis as a "breakdown of civilization" – and reinforced his view that "civilizing controls" rarely, if ever, amount to more than a relatively thin veneer. Second, the repeated interruption of his career by wider events – World War I, the German hyperinflation of 1923, the Nazi takeover ten years later, exile to France and then to Britain, internment as an "enemy alien" – helped to sensitize Elias to the interdependence and interplay of "the individual" and "the social," "the private" and "the public," "the micro" and "the macro." And third, Elias's study of medicine and philosophy helped to problematize for him aspects of philosophy, contributing to his move to sociology and his original work in what are now known as the "sociology of the body" and the "sociology of emotions." That Elias was a pioneer of the sociology of sport is perhaps best understood in that context. He opposed the "mind–body" dichotomy and did not share the common prejudice that sport is a "physical" phenomenon of lower value than phenomena connected with the realm of "mind." The theory of "civilizing processes" is generally regarded as having been Elias's major sociological contribution.

THE THEORY OF CIVILIZING PROCESSES

Contrary to a widespread misconception, Elias did not use the concept of a "civilizing process"

in a morally evaluative way. He also frequently enclosed words such as “civilization,” “civilized,” and “civilizing” in inverted commas in order to signal this. “Civilizing process” was, for him, a technical term and he did not imply by it that people who can be shown to stand at a more advanced level than others, for example ourselves relative to people of the feudal era, are in any sense “morally superior” or “better.” That, of course, is almost invariably how the people who call themselves “civilized” view themselves. But how, Elias used to ask, can people congratulate themselves when they are the chance beneficiaries of a blind process to the course of which they have personally contributed little, if anything at all? To say this, of course, is not to deny that there are victims as well as beneficiaries of “civilizing” processes.

The theory of civilizing processes is based on a substantial body of data, principally on the changing manners of the secular upper classes – knights, kings, queens, court aristocrats, politicians, and business leaders, but not, for the most part, the higher clergy – between the Middle Ages and modern times. These data indicate that, in the major countries of Western Europe, a long term unplanned process took place involving four principal components: the elaboration and refinement of social standards; an increase in the social pressure on people to exercise stricter, more continuous, and more even self control over their feelings and behavior; a shift in the balance between external constraints and self constraints in favor of self constraints; and an increase at the levels of personality and habitus in the importance of “conscience” or “superego” as a regulator of behavior. That is, social standards came to be internalized more deeply and to operate not simply consciously and with an element of choice, but also beneath the levels of rationality and conscious control.

At the risk of oversimplification, one could summarize Elias’s theory by saying that he attributed these European “civilizing processes” to five interlocking part processes, which he also studied in considerable empirical detail. They included: the formation of state monopolies on violence and taxation; internal pacification under state control; growing social differentiation and the lengthening of interdependency chains; growing equality of power chances between social classes, men and women,

and the older and younger generations; and growing wealth.

Elias showed how, in the course of a civilizing process, overtly violent struggles tend to be transformed into more peaceful struggles for status, wealth, and power in which, in the most frequent course of events, destructive urges come to be kept for the most part beneath the threshold of consciousness and not translated into overt action. Status struggles of this kind appear to have played a part in the split between the “soccer” and the “rugby” forms of football (Dunning & Sheard 2005 [1979]).

THE “CIVILIZING” OF MODERN SPORTS

An aspect of these overall European “civilizing processes” that is crucial for understanding the development of modern sports has been the increasing control of violence and aggression within societies, though not to anything like the same extent in the relations between them. According to Elias, in “modern” societies in which the dominant groups consider themselves to be “civilized,” belligerence and aggression are socially tolerated in sporting contests, including in “spectating,” that is, in people’s imaginary identification with the direct combatants to whom moderate and precisely regulated scope is granted for the release of such affects. In Elias’s words, “this transformation of what manifested itself originally as an active, often aggressive expression of pleasure into the passive, more ordered pleasure of spectating (i.e. the mere pleasure of the eye) is already initiated in education, in the conditioning precepts for young people . . . It is highly characteristic of civilized people that they are denied by socially instilled self controls from spontaneously touching what they desire, love or hate” (Elias 2000 [1939]: 170).

A taboo on touching for all players except the goalkeeper has, of course, become the major distinguishing characteristic of the “soccer” or “Association” form of football. Data also suggest that sports themselves underwent “civilizing processes” in conjunction with these wider “civilizing” developments. That this is the case is shown by studies of: the antecedents of modern sports in the ancient and medieval

European worlds (Elias in Elias & Dunning 1986; Dunning 1999); the initial development of modern sports in eighteenth and nineteenth century England (Elias in Elias & Dunning 1986; Dunning 1999); the long term development of soccer and rugby (Dunning & Sheard 2005 [1979]); and football hooliganism as an English and world phenomenon (Dunning et al. 1988; Dunning 1999; Dunning et al. 2002).

THE FIGURATIONAL/ELIASIAN SOCIOLOGY OF SPORT AND ITS CRITICS

There have so far been six generations of figural sociologists of sport in the United Kingdom: (1) Norbert Elias; (2) Eric Dunning; (3) Patrick Murphy, Kenneth Sheard (2004), and Ivan Waddington; (4) Grant Jarvie and Joseph Maguire (Jarvie & Maguire 1994); (5) Sharon Colwell (2004), Graham Curry (2001), Dominic Malcolm (2004), Louise Mansfield, and Stuart Smith (2004); and (6) Ken Green (2004), Daniel Bloyce, Katie Liston, and Andrew Smith. To this list must be added the names of Ruud Stokvis and Martin van Bottenberg (2001) in the Netherlands and Michael Krueger (1997) and Bero Rigauer (2000) in Germany. Interestingly, Rigauer has attempted to wed a figural perspective with a Marxist one.

Criticizing and Testing Elias

Elias insisted on the testability of his concepts and theories and called for what he described as a "constant two way traffic" between research and theory. One consequence of this is that his concepts and theories are, like those in the natural sciences, permeated to a greater extent by factual observation, and hence are less abstract than has often been the case in sociology.

Elias's insistence on the testability of his concepts and theories is contradicted by a frequently touted judgment to the contrary. For example, Dennis Smith (1984) argued that the theory of "civilizing processes" is "irrefutable." Such an argument was echoed two years later by the anthropologist Edmund Leach when he suggested in a review of Elias and Dunning's *Quest for Excitement* (1986) that the

"theory is impervious to testing." An example from the sociology of sport is Gary Armstrong, who wrote that Elias's theory "is a fusion of untestable and descriptive generalizations" (1998: 317). Richard Giulianotti went so far as to claim that Elias introduced the concept of "decivilizing spurts" in order "to rebut ... counter evidence" (1999: 45).

These kinds of argument are wrong because they involve the false projection into Elias's work of evaluative notions such as "progress." Elias's work was about "decivilizing" as well as "civilizing processes" from the beginning. One of many examples is furnished by his discussion of feudalization (Elias 2000 [1939]: 195–236). Another is provided when he writes of "the whole many layered fabric of historical development" as infinitely complex," and that "in each phase there are numerous fluctuations, frequent advances or recessions of the internal and external restraints" (p. 157).

Aspects of the theory have also been tested by scholars other than Elias and Dunning (see articles in Dunning et al. 2004). The sports on which these tests were carried out were: baseball, boxing, cricket, gymnastics, motor racing, rugby, and shooting. Figural studies by Maguire and Waddington deal with sport in general, in Maguire's case with sport and "globalization" and in Waddington's with sport, health, and drugs.

film

Douglas Kellner

Film emerged as one of the first mass produced cultural forms of the twentieth century and cinema became one of its distinctive and highly influential industries. Based on new technologies of mechanical reproduction that made possible simulations of the real and the production of fantasy worlds, cinema provided a novel mode of culture that changed patterns of leisure activity and played an important role in social life. Early films were the inventions of technicians and entrepreneurs like the Lumière brothers and Méliès in France and the Edison Corporation in the US.

The first silent films ranged from the documentaries and quasi documentary realist fictions produced by the Lumières and Edison to the fantasy fictions of Méliès. The genres that would characterize Hollywood film began to appear during the first decades of the century with Westerns like *The Great Train Robbery* (1903), the melodramatic social dramas of D. W. Griffith, costume and historical dramas like *Ben Hur* (the first of several versions appeared in 1899), horror films, and comedies by Mack Sennett, Charlie Chaplin, Buster Keaton, and others.

From the beginning, cinema was bound up with the vicissitudes of modernity. Film was a modern, technologically mediated art form, and it captured the novelties of modern life. Cinema's motion pictures depicted the faster pace of

contemporary life, showing railroads and trains, cars and buses, and airplanes changing individuals' experience of space and time in a faster, more dynamic world. Films depicted the vicissitudes of urban modernity with its styles and fashions, its class divisions, crowded streets, and surges of immigrants. Films accustomed audiences to the rhythms and forms of modernity and were, with broadcasting and other forms of media culture, an important force in integrating individuals into increasingly changing and conflicted modern societies. Early films were produced largely for working class, immigrant, and urban audiences, and some critics of the movies thought that they had negative or subversive effects (Jowett 1976). For example, the comedies of Charlie Chaplin made fun of authority figures and romantic dramas were attacked by the Legion of Decency for promoting promiscuity. And crime dramas were frequently attacked for fostering juvenile delinquency and crime. On the other hand, films were believed to help "Americanize" immigrants, to teach their audiences how to be good Americans, and to provide escape from the cares of everyday life (Ewen & Ewen 1982).

In capitalist countries, going to the movies was an important leisure activity that helped initiate audiences into the consumer society where entertainment was paid for and commodified and the commodity of films sold the styles, goods, services, values, and spectacle of the consumer society itself. In the Soviet Union, Lenin reportedly proclaimed after the revolution of 1917 that "of all the arts, film is the most important to us" (cited in Mailer 1967). The Bolsheviks supported a highly productive film industry that in the newsreels of Dziga Vertov documented the early years of the revolution and in the films of Eisenstein, Pudovkin, Dovzhenko, and others provided powerful expressions of Bolshevik ideology and values.

Cinema was part of modern industry, organized first in the US and eventually throughout the world on the assembly line model of production, with studios featuring houses of writers, set designers and buildings, costume and make up crews, the sets where scenes were filmed, and the buildings where films were edited and then marketed. Films in the US and elsewhere became integrated industries

combining production, distribution, and exhibition in one corporation. Its publicity apparatus helped establish the importance of advertising agencies and its star system helped to produce a new type of mass mediated celebrity culture. Film helped to generate new public spaces where individuals congregated to consume culture, and the great movie palaces of the early era of cinema created the impression that culture was becoming increasingly democratized and accessible to the masses.

Eventually, its increasingly massified and standardized products, especially in the Hollywood studio system, but also in national cinemas elsewhere such as Mexico, Brazil, India, China, and Taiwan, helped to contribute to the rise of what sociologists saw as a mass society emerging after World War II through its standardized products and what was assumed to be a homogeneous audience watching the same mass produced artifacts. In Europe, by contrast, the art film tradition that emerged in German Expressionism, a French poetic cinema, and individual works of auteurs like Carl Dreyer, Abel Gance, or Jean Renoir were often supported by the national state, as was the propagandistic cinema of Nazi Germany, the Soviet Union, and Italian Fascism.

Further, after World War II, many national cinema styles emerged as a reaction against Hollywood cinema, including Italian neorealism, French New Wave, Brazilian Cinema Novo, Latin American "Third Cinema," the New German Cinema, the New Taiwanese Cinema, and many other movements throughout the world that wanted to create distinctive styles and types of cinema relevant to local cultures, problems, and audiences.

Debates about relations between film and society and the social effects of film began during the silent era and the medium had both defenders and critics among major intellectuals of the era. Walter Benjamin claimed that the "mechanical reproduction" grounded in film technology and other reproducible forms of culture robbed high art of its "aura," of the aesthetic power of the work of art related to its earlier functions in magic, religious cults, and as a spiritual object in the religions of art celebrated in movements like romanticism or "art for art's sake." In these cases, the "aura" of the work derived from its supposed authenticity, its

uniqueness and individuality. In an era of mechanical reproduction, however, art appeared as commodities like other mass produced items, and lost its special power as a transcendent object – especially in mass produced objects like photography and film, with their photo negatives and techniques of mass reproduction.

While members of the Frankfurt School like T. W. Adorno and Max Horkheimer tended to criticize precisely the most mechanically mediated works of mass culture for their standardization and loss of aesthetic quality (while celebrating those works that most steadfastly resisted commodification and mechanical reproduction), Benjamin saw progressive features in high art's loss of its auratic quality and its becoming more politicized. Such art, he claimed, assumed more of an "exhibition value" than a cultic or religious value, and thus demystified its reception. Furthermore, he believed that proliferation of mass art – especially through film – would bring images of the contemporary world to the masses and would help raise political consciousness by encouraging scrutiny of the world, as well as by bringing socially critical images to millions of spectators:

By close-ups of the things around us, by focusing on hidden details of familiar objects, and by exploring commonplace milieus under the ingenious guidance of the camera, the film, on the one hand, extends our comprehension of the necessities which rule our lives; on the other hand, it manages to assure us of an immense and unexpected field of action. Our taverns and our metropolitan streets, our offices and furnished rooms, our railroad stations and our factories appeared to have us locked up hopelessly. Then came the film and burst this prison-world asunder by the dynamite of the tenth of a second, so that now, in the midst of its far-flung ruins and debris, we calmly and adventurously go traveling. (Benjamin 1972: 236)

Benjamin claimed that the mode of viewing film broke with the reverential mode of aesthetic perception and awe encouraged by the bourgeois cultural elite who promoted the religion of art. Montage in film, its "shock effects," the conditions of mass spectatorship, the discussion of issues which film viewing encouraged, and other features of the cinematic experience produced, in his view, a new type of social and political experience of art which

eroded the private, solitary, and contemplative aesthetic experience encouraged by high culture and its priests. Against the contemplation of high art, the shock effects of film produce a mode of "distraction" which Benjamin believed makes possible a "heightened presence of mind" and cultivation of "expert" audiences able to examine and criticize film and society.

A German exile, Siegfried Kracauer, once close to Benjamin and Adorno, provided one of the first systematic studies of how films articulate social content. His book *From Caligari to Hitler* (1947) argues that German inter war films reveal a highly authoritarian disposition to submit to social authority and a fear of emerging chaos. For Kracauer, German films reflect and foster anti democratic and passive attitudes of the sort that paved the way for Nazism. While his assumption that "inner" psychological tendencies and conflicts are projected onto the screen opened up a fruitful area of sociocultural analysis, he frequently ignored the role of mechanisms of representation such as displacement, inversion, and condensation in the construction of cinematic images and narratives. He posits film-society analogies ("Their silent resignation foreshadows the passivity of many people under totalitarian rule," p. 218) that deny the autonomous and contradictory character and effects of film discourse and the multiple ways that audiences process cinematic material.

Sociological and psychological studies of Hollywood film proliferated in the US in the post World War II era and developed a wide range of critiques of myth, ideology, and meaning in the American cinema. Parker Tyler's studies of *The Hollywood Hallucination* (1944) and *Myth and Magic of the Movies* (1947) applied Freudian and myth symbol criticism to show how Walt Disney cartoons, romantic melodramas, and other popular films provided insights into social psychology and context, while providing myths suitable for contemporary audiences. In *Movies: A Psychological Study* (1950), Martha Wolfenstein and Nathan Leites applied psychoanalytical methods to film, decoding fears, dreams, and aspirations beneath the surface of 1940s Hollywood movies, arguing: "The common day dreams of a culture are in part the sources, in part the products of its popular myths, stories, plays and films" (p. 13). In her sociological study of

Hollywood: The Dream Factory (1950), Horstense Powdermaker studied an industry that manufactured dreams and fantasies, while Robert Warshow in *The Immediate Experience* (1970) related classical Hollywood genres like the Western and the gangster film to the social history and ideological problematics of US society.

Building on these traditions, Barbara Deming demonstrated in *Running Away From Myself* (1969) how 1940s Hollywood films provided insights into the social psychology and reality of the period. She argued: "It is not as mirrors reflect us but, rather, as our dreams do that movies most truly reveal the times" (p. 1). She claimed that 1940s Hollywood films provided a collective dream portrait of the era and proposed deciphering "the dream that all of us have been buying at the box office, to cut through to the real nature of the identification we have experienced there" (pp. 5–6). Her work anticipates later, more sophisticated and university based film criticism of the post 1960s era by showing how films both reproduce dominant ideologies and also contain proto deconstructive elements that cut across the grain of the ideology that the films promote. She also undertook a gender reading of Hollywood film that would eventually become a key part of film criticism.

Another tradition of film scholarship and criticism attempted to situate films historically and to describe the interactions between film and society in more overtly sociological and political terms. This tradition includes Lewis Jacob's (1939) pioneering history of Hollywood film, John Howard Lawson's theoretical and critical works, Ian Jarvie's (1970, 1978) sociological inquiries on the relation between film and society, D. M. White and Richard Averson's (1972) studies of the relation between film, history, and social comment in film, and the social histories written by Robert Sklar (1975), Garth Jowett (1976), and Thomas Schatz (1988). While this tradition produced useful insights into the relationships between film and society in specific historical eras, it tended to neglect the construction of film form and the ways that specific films or genres work to construct meaning and the ways that audiences themselves interact with film.

More theoretical approaches to film began emerging in the 1960s, including the ideological

analyses of the work associated with the film makers and critics in France who published in *Cahiers du cinema*. The *Cahiers* critics called attention to the creative achievements of certain Hollywood directors and in general extolled the work of the cinematic creative artist or *auteur*. Their interest in Western and gangster films helped to generate genre theory as well.

Building on this work, in the 1970s, the extremely influential British film journal *Screen* *Cahiers* texts and other works of French film theory, including Roland Barthes, Christian Metz, and various poststructuralist critics who produced more sophisticated formal approaches to film (see Metz 1974; Heath 1981). The *Cahiers* group in turn moved from seeing film as the product of creative *auteurs* or authors (their *politique du auteurs* of the 1950s, taken up by Sarris (1968) and others), to focus on the ideological, political, and sociological content of film and how it transcoded dominant ideologies and had certain political and social effects. At the same time, French film theory and *Screen* focused on the specific cinematic mechanisms that helped to produce meaning.

During the same period of intense ferment in the field of film studies during the 1960s and 1970s, the Birmingham Centre for Contemporary Cultural Studies was discovering that gender, race, and subculture were also important elements of analyzing the relationships between culture, ideology, and society. Pushed by feminism to recognize the centrality of gender, it was argued that the construction of dominant ideologies of masculinity and femininity was a central aspect of film (Kuhn 1982; Kaplan 1983). Studies of the ways that films constructed race, ethnicity, and sexuality also became a key aspect of films studies, and various poststructuralist influenced theories studied the role of film and media culture in the social construction of ideologies and identities (Kellner & Ryan 1988).

There are now a multiplicity of approaches competing to theorize the relations between film and society and to read and interpret film. The theory wars of the past decades have proliferated a tremendous amount of new theories that have been in turn applied to film. Consequently, structuralism and poststructuralism, psychoanalysis, deconstruction, feminism, post modernism, and a wealth of other theoretical

approaches have generated an often bewildering diversity of approaches to theorizing film which join and complexify previous film theory approaches such as the genre theory, auteur theory, and historical sociological approaches. Within the cacophony of contemporary approaches to film, it is not a question of either/or which forces the theorist to adopt one approach, but rather a variety of approaches can be deployed to engage the relations of film to society (for elaboration of a multiperspectival model, see Kellner 1995).

In retrospect, all one-sided approaches to theorizing the relation between film and society are problematical. Although some "authors" had created distinctive and impressive bodies of work, they were often created within the constraints of a specific genre and studio system; thus to fully understand Hollywood film, for example, one needs insight into the production system, its codes and formulas, and the complex interaction of film and society, with film articulating social discourses, embedded in social struggles, and saturated with social meanings. Thus, analyzing the connection between film and society requires a multidimensional film criticism that situates its object within the context of the social milieu within which it is produced and received.

Finally, one of the most dramatic technological revolutions of all time is now unfolding with new entertainment and information technologies emerging, accompanied by unprecedented mergers of the entertainment and information industries and the transmission of increasingly globalized culture (Branston 2000). These new syntheses are producing novel forms of visual and multimedia culture in which it is anticipated that film will appear in seductive new virtual and interactive forms, accessible through computer, satellite, and new mechanisms of transmission like video recorders, DVDs, iPods, and other devices. There is feverish speculation that the Internet and its assorted technologies will create a new entertainment and information environment and currently the major corporations and players are envisaging what sort of product and delivery system will be most viable and profitable for films and other entertainment of the future. Thus, one imagines that the relationships between film and society will continue to be highly significant as we enter a new

century and perhaps new cinematic era that will create novel forms of film and new perspectives on the film culture of the past.

finalization in science

Wolfgang Krohn

Finalization in science is a theory concerning the relationship between science and society from a historical and political perspective. It was developed in the 1970s by Gernot Böhme, Wolfgang van den Daele, and Wolfgang Krohn (Böhme et al. 1972, 1973, 1976, 1978). Its main thesis is that modern science has internal dynamics that allow it to absorb external goals of research on an increasing scale. The expression "finalization" is meant to denote this tendency (Latin *finis*; purpose, goal). This theoretical model is continuous with the paradigmatic view of Thomas Kuhn and with Imre Lakatos's methodology of scientific research programs, but adds additional features concerning the social contexts of science.

With respect to many fundamental disciplines of modern science the model assumes a typical three phase development. The first, or explorative, phase embraces the period prior to the emergence of theories which serve to organize the field. At this point a research program

internally determining the relevance and succession of problems is absent. Rather, all kinds of challenging problems can be experimentally analyzed and classified, and serve to induce competing theories. Examples can be found in mechanics previous to Newton; chemistry before the work of Lavoisier, Proust, and Dalton; electrodynamics before Maxwell; evolutionary biology before Darwin; and genetics before the double helix model. Contemporary examples are neurobiology, research on chronic diseases, and cancer research. The explorative phase allows for multiple, if contingent, couplings of external problems with scientific interests. These couplings are important because they carry the institutional and monetary support of the research fields.

The second or paradigmatic phase is determined by the emergence of an internal research program directed toward the elaboration of a fundamental and unifying theory replacing provisional middle range theories. At this point science policy can only promote, not direct, such research, though prospects of technological returns in a more or less distant future legitimate investment of tax money.

While the formulation of these two phases roughly corresponds to other models, especially those of Kuhn and Lakatos, the original contribution of the finalization model comes from adding a third phase of theory development. Whereas Kuhnian paradigms grant researchers the unedifying business of solving puzzles and the Lakatos research program loses its capacity of progressive problemshift, the finalization model proposes a phase of finalized, or goal oriented, theory development. Central to the argument is the fact that fundamental theories usually cannot be applied to complex empirical systems for which they are valid. Fluid mechanics is a good example of this. On the one hand, it is based on a set of equations – classical hydrodynamics – which basically cover the behavior of all fluids. On the other hand, it turned out not to be applicable to certain viscosity problems posed by aircraft technology. The development of a special "boundary layer" theory was needed – and achieved in the early twentieth century – in order to develop a theoretical model for the construction of aerofoils. These kinds of intermediary theories are called finalized theories, and make up the most

important share of contemporary science. Based on a set of fundamental paradigmatic theories and conditioned by technological, ecological, and social expectations, finalized theories continuously and indefinitely fill up the stock of scientific knowledge. As compared to disciplines in phase two, paradigm formation is no longer the driving force, but rather it is the societal orientation of science that is the force. This shift from internal to external problem generation calls into question received concepts of an autonomous science or of science as an independent social system. However, the emphasis on theory development of sciences in their third phase distances the finalization model from concepts of control and steering.

The three phase model can be taken as an ideal format of a discipline's life cycle. Additionally, finalization theory takes seriously the fact that – independent of Kuhnian revolutions – many paradigms that evolved in the disciplines' second phases remain in a stable state, which Heisenberg called "closed" theories. Classical mechanics, hydrodynamics, relativity theory, and quantum mechanics are cases in point. They serve as reliable knowledge bases for finalized research on externally induced problems. Case studies exemplify the relationships between closed and finalized theories. Contemporary science is predicted to turn to the development of finalized theories on an increasing scale. Epistemologically, such theories search for concepts that allow for the application of foundational theories to complex problems. Socially, they are guided by priorities set by institutions entitled to do so. The finalization model also accounts for normative implications. If societal issues become the guidelines of theory development, the question of interests becomes critical. Who is entitled to have a voice in setting research agendas, defining criteria of relevance, and negotiating the transformation of norms and values in theoretical knowledge? Modern ecology in its tension between including or excluding human goals from nature served as a prototype for pondering these questions.

Shortly after its first publication finalization theory caused a fierce debate among German philosophers of science that soon spilled over into the media. Their predominant point of attack in this early version of "science wars"

was the allegation that, under the cover of a new social epistemology of science, Marxian ideas of socialist planning and control were being advanced. The media resonance included accusations of seeking a "final solution" for science, of threatening science with a "1984 situation," of legitimizing "Lysenkoism." An important factor in this turmoil was the institutional setting. Finalization theory was developed in a newly founded research institute of the Max Planck Society, with its established worldwide reputation. The institute was directed by the physicist philosopher Carl Friedrich von Weizsäcker and the sociologist Jürgen Habermas. Von Weizsäcker's public commitment for social responsibility of scientists and Habermas's writings on "knowledge and human interests" were the hidden targets of the critics. Even if they bore no responsibility for the finalization model, they were implicated to the extent to which their ideas could be traced in its content. (The controversy is documented in Böhme et al. 1983: 275–306.)

More serious criticism was raised by researchers from the emerging field of the social studies of science. For these researchers, the use of the internal–external terminology was unwarranted, the concept of "closed theories" appeared to be too rigid, the adherence to epistemic norms in theory formation was not in line with the programs of relativism, and the focus on the development of research fields was not easily compatible with the rise of laboratory studies. A new interest in finalization theory has emerged in the context of the concept of "knowledge society" and especially in the controversial discussion of the Mode II model advanced by Gibbons et al. (1994). The Mode II model claims a complete shift of the role and function of science as its context of application prevails over its basic research (Mode I). A few reservations notwithstanding, finalization can now be seen as an early attempt at understanding the new order and policy of science that seems to emerge in the contemporary development of knowledge society (Weingart 1997).

financial sociology

Lois A. Vitt

Financial sociology is the study of the relationship between finance, defined as the science of money management, and human society. In addition to money management, finance includes the management of money surrogates, capital instruments and markets, organizations and institutions, households, and governments. Finance is defined, structured, and regulated within a system of national and international laws that reflect power relations within political economies and across state and global markets. In practice, finance is art (e.g., negotiation) and science (e.g., measurement). Financial

measurement of the firm and of investments constitutes the major emphasis within the field of economics as a subdiscipline of finance economics. The entire field of finance may be subsumed within the larger field of economics. Likewise, topics within financial sociology can be found in publications, or taught in courses, on economic sociology.

Relevant financial laws, structures, and policies govern the circulation of money within and among nations and cover various types of money surrogates as well: (1) checks, drafts, debit cards and other plastic cards that store value, or permit deferred payment such as charge cards and credit cards; (2) marketable and unmarketable securities such as notes, stocks, bonds, and shares of other pooled interests; (3) property and the resources that derive from property such as rents, commodities, debt and equity instruments and securities; and (4) business and the resources that derive from business enterprises including skills, labor, products, and services.

Three overarching levels of analysis include *personal finance*, the financial management of individual and household income, saving, and consumption; *corporate finance*, the financial management of organizations and business; and *public finance*, the financial management of government. Areas of prospective study within (and interactions among) these three levels touch all dimensions of social life: politics, taxes, art, religion, business, housing, health care, poverty and wealth, consumption, sports, transportation, labor force participation, and education. While each has a vast accumulated sociological literature of its own, the *financing* associated with these domains of modern social life has in the past usually been subsumed under “social policy.”

Yet the financial policies, institutions, structures, and practices within any given society impact well being for every individual and social group within a society, and increasingly, global well being. George Ritzer (1995) clearly points this out in his analysis of credit cards and society: “Money and the credit card are so centrally important in modern consumer society that they take us very quickly to the core of that world.”

The idea for a “sociology of finance” was probably introduced by Randall Collins who,

when reviewing Mayer's *The Bankers* (1979), wondered why sociologists were not rushing to study financial organizations. Although sociological analysis of life insurance companies and markets emerged about the same time, relatively few studies appeared until the 1990s. To date, sociological analysis that is intentionally trained upon the financial laws, policies, markets, networks, firms, transactions, costs, customs, and human interactions is still in its infancy but holds enormous promise.

Paul Hirsch, at the 1993 Annual Meetings of the American Sociological Association, suggested that sociology was still "asleep at the wheel" in tracking how the discipline examines social change and the institutions of banking and finance. At the same session, a typology of financial sociology was presented which demonstrated that relevant areas for sociological study, in fact, are so numerous that it is nearly impossible to find social reality not connected in some direct way to money and finance. Does the young but growing field of economic sociology take up the slack?

THE INTERSECTION OF ECONOMIC SOCIOLOGY AND FINANCIAL SOCIOLOGY

Auguste Comte coined the term "sociology" in 1838 and paved the way for other social thinkers to develop theories of society. As sociology became its own discipline, social problems increasingly were analyzed as if they had no economic dimension and economic problems as if they had no social dimension. Economists and sociologists seldom looked back until Richard Swedberg fostered a dialogue between the two fields. Swedberg's thought provoking interviews in 1990 with well known economists Gary Becker, Amartya Sen, Kenneth Arrow, and Albert O. Hirschman, and sociologists Daniel Bell, Harrison White, James Coleman, and Mark Granovetter, helped to bridge the boundary between economics and sociology.

There is a growing dialogue between these fields, as economists take on many more social topics and sociologists become interested in rational choice and other economic theories. While economic sociology begins to flourish, however, financial sociology is emerging as a

subfield that would have been impossible to conceptualize during the last half of the nineteenth and much of the twentieth centuries. Although closely related, the disciplines of economics and finance are distinctive. Whereas economics makes a number of abstract assumptions for purposes of analysis, finance is a socially constructed (and manipulated) set of principles that intentionally facilitate and manage transactions between and among governments, organizations, groups, and households. Financial sociology incorporates, by definition, the painstakingly constructed theories of sociology to analyze its impact on individuals, families, and societies, and there are important purposes for such specific sociological analysis.

Human societies have taken many forms throughout history, and remarkable diversity is still evident today in the world. So are the great differences among societies that flourish and those that still struggle. These differences have been attributed to what Lenski and colleagues termed *sociocultural evolution*, the changes that occur as a society gains new technology. The more technological information a society has, the faster it evolves. However, technology alone is not all that is needed for social and economic development. New technology must be *financed*.

Hernando de Soto's (2000) analysis of capital offers sociology some insights that further explain the great differences among societies. Why, he asks, have the efforts of third world and former communist nations to organize a modern capitalist economy not been met with more success? "From Russia to Venezuela, the past half decade has been a time of economic suffering, tumbling incomes, anxiety, and resentment." Although many of these nations have balanced budgets, cut subsidies, welcomed foreign investment, and dropped tariff barriers, according to de Soto, their efforts have been repaid with bitter disappointment. Yet the cities of the third world and the former communist countries teem with entrepreneurs who are talented, enthusiastic, and have an astonishing ability to grasp and use modern technology. In fact, the unauthorized use of communications, weapons, and consumer technology increasingly presents western nations with serious problems of patent violations and product control.

Even in the poorest countries, the poor save, according to de Soto and his team of researchers

who gathered data block by block, and farm by farm, in Asia, Africa, the Middle East, and Latin America. The aggregate savings, commercial and residential buildings, businesses, and other assets of these countries are often held, however, in defective forms. There are few modern laws, working infrastructures, institutions, and markets to turn these assets into capital for investment and growth. In short, there has been little or no ability to create the financing – for individuals, businesses, or governments – that exists and is generally taken for granted in the West.

Two modern movements, however, may be transforming societies worldwide: the industrialization of developing countries through globalization and the transition of advanced societies from industrial based into service economies. In his 1991 book *Money and the Meaning of Life*, Jacob Needleman observed: “money is the main, moving force of human life at the present stage of civilization. Our relationship to nature, to health and illness, to education, to art, to social justice, is all increasingly permeated by the money factor.” More recently, Peter Marber (2003) chronicled the sociofinancial changes already in process that are impacting life expectancy, literacy, education, consumption, and growing prosperity in developing societies as a result of globalization. While industrialization in the third world has its social costs and its detractors, according to Marber, “more people in more places have access not only to goods, but also to art, ideas, and innovation,” as a direct result of globalization. Radical changes are occurring globally that affect not only what people value and want, but also governance, the environment, the roles of women and families, religion, and religious conflict.

FINANCIAL SOCIOLOGY TODAY

Groundbreaking sociological research entered the literature on financial sociology during the past decade and a half. Studies of human emotions and behaviors in the context of money and finance have appeared (e.g., Millman 1991), as well as work on banking and credit at both the macro and micro levels. In *Expressing America*, George Ritzer (1995) focuses Georg Simmel’s “relationist” theories (as well as the theories of

Mills, Marx, and Weber) on money and credit cards to gain insight into fundamental characteristics of the social world. Ritzer finds evidence of rampant consumerism, debt, fraud and crime, and invasions of privacy, among other social problems, that go far beyond credit cards themselves. These problems are not new to sociologists, but approaching them via a financial route permits a different awareness of their causes and consequences. According to Ritzer (1995), “the credit card, as well as the industry that stands behind it and aggressively pushes its growth and expansion, is not only important in itself, but also as a window on modern society.”

Robert Manning’s *Credit Card Nation* (2000) chronicles the history of debt and credit since the deregulation of financial services in the US in 1980. Manning reveals the costs in human terms of Americans’ growing dependence on credit cards and predicts that tomorrow’s senior citizens are at risk for increasingly aging into debt. His work includes a chapter devoted to the social consequences of credit card debt on college students based on in depth interviews and 1999 cross sectional survey data of college students. The study, introduced by the Consumer Federation of America, was a national revelation that young lives were being ruined by credit card debt. Manning’s analysis of the consequences of student debt has been noted by credit card companies as well as universities and other organizations that sponsor so called “affinity cards” and profit by doing so.

The interactions between individuals and families and public-private interests that both enable and support the growth of financial innovations are not unique to credit cards. Such micro-macro interactions are present in many, if not all, consumer financial innovations. They positively or negatively impact the housing, health care, pension, insurance, education, retirement, and brokerage activities of modern society, depending upon the degree of oversight that exists to curb excesses. They positively or negatively affect individuals, families, and communities, and when large numbers of people are affected, they can become public issues (Ritzer 2001). For older adults, college students, low income individuals and families, and other affected segments of society, credit card excesses and punitive practices are fast becoming public issues.

flânerie

Heidi L. Reible

Flânerie, in a narrow sense, refers to the act of idle strolling in nineteenth century Paris, while visually collecting social artifacts of metropolitan life – the human sights and material culture

of the urban crowd. In a wider sense, it is immersion in an anonymous, spectatorial gaze that gives license to wandering and observing. *Flânerie* engenders reflexivity as both an action and a process of observation that perceptively elucidates social phenomena. Text and sketches of the passing moment serve as witnesses to these random readings of the crowd. *Flânerie* embodies pleasure in the form of mobile observation. It is an aesthetic action, art form, and social phenomenon that resonate in masculine public space.

The *flâneur* is a figure of modernity, a solitary man of leisure with no destination. He passionately performs the act of idle walking while furtively consuming spatial and temporal impressions. Sociologically, he stands in a contested space, as an intellectual in mass culture, as a “natural” in an artificial environment. The *flâneur* has been described as a bum, idler, artist, observer, gastronome, social commentator, literary figure, scavenger, intellectual, and poet. At the core, he possesses a way of seeing the world and being in the world that intrinsically reveals meaningful, social commentary.

Charles Baudelaire, a mid 1800s poet, and Walter Benjamin, literary critic in the early 1900s, were instrumental in creating the poetic enigma and physical entity that became the literary figure of the *flâneur*. Both described him as a man who was simultaneously a part of the crowd and yet alone on the streets of the urban landscape. They conceptualized the social type of the *flâneur* as individualized, itinerant, and dissociated from discursive group or community contact. He was a collector, an accidental detective, and a rag picker, who possessed acuity in deriving social relevance from the fragments of everyday experience. They situated the concepts of *flâneur* and *flânerie* within visual sight of commodities and in spaces of leisure. Urban spectacle inspired Baudelaire's poetic ruminations on the subject. It was the City of Lights that became the original city of *flânerie*.

Industrialization in Paris and a subsequent increase in production of saleable commodities were instrumental events that gave rise to visually spectacular places of consumption through which the *flâneur* strolled in the early

1800s. Architectural innovations in iron working techniques and glass manufacturing, as well as the proliferation of visual media, played an important role in developing the city. Large plate glass windows allowed strollers to view available goods. These places of consumption became spaces of leisure that privileged "visual" participation within mass culture. Buying, as well as window shopping, became a new pastime. Advertising, architecture, technology, and the emerging presence of women shoppers drew the gaze of the *flâneur*. Mid century, Baron Georges Eugène Haussmann developed reconstruction plans that would accommodate the economic and demographic growth that had changed the capital into a burgeoning city. More than 100,000 buildings were razed to replace old streets and disorganized districts. Several of the arcades of Paris, areas of elegant shops filled with displays of commodities, were built during implementation of the Haussmann project, and incorporated such structural innovations.

Flânerie was irrefutably a masculine pursuit. The female *flâneuse* was absent in the city, as reflected in the writings of Baudelaire and Benjamin. Gendered restrictions of movement reflecting customary societal limitations of the time excluded women from public spaces. The private space of home was a woman's approved sphere of influence. Those who chose a public presence were often looked upon as prostitutes, a corporeal commodity. Though the arcades initiated a shift in access to gendered, public sites of leisure consumption, the masculine maintained a position of privilege. Even as these newly bounded public places became acceptable spaces of leisure for respectable women, *flânerie* remained culturally intolerable. "Looking" was problematized as a gendered act of consumption; woman was object to the *flâneur's* gaze.

This history usefully informs a culture of consumption that continues privileging the "visual." *Flânerie* maintains relevance as it raises the potential for understanding social phenomena collected as visual fragments embedded in performance of daily public life. Thorstein Veblen (1967 [1899]), in *The Theory of the Leisure Class*, was one of the first to critique leisure practices as conspicuous consumption,

and to emphasize leisure's significance to society. Television, the Internet, newspapers and magazines, billboards, movies, as well as interiors and exteriors of mass transit buses are examples of a visual culture that continues to generate opportunities for new ways of "seeing" ordinary life as it interfaces with leisure.

Recent literary discourse brings emergent interpretations of *flânerie* and its social relevancy to the present. It has been suggested that *flânerie* is allied with browsing in shopping malls, with traveling to novel places, with aural grazing of radio waves, with channel surfing television, with cooking and eating food, with wandering in Disneyland, as well as with lurking in cyberspace in chat rooms on the Internet. Future directions in research may include the use of *flânerie* as a method in the study of everyday leisure, or induce efforts to locate and observe *flânerie* as it takes place in twenty first century life. In addition, it is germane to continue debates that legitimate evidence to support the physical presence and perspicacity of the *flâneuse* in the urban environment, past and present. Whether these ideas are consistent with the poetic thoughts of Baudelaire, or the writings of Benjamin in the context of modernity, requires further exploration and discussion.

folk Hinduism

Vineeta Sinha

Accounts of Hinduism have predominantly been approached via literary and textual avenues, through which its ancient, philosophical, abstract, and transcendent features are high lighted. Even ethnographic accounts of Hinduism have been dominated by attention to the Sanskritic and Brahmanic elements derived from such a scriptural, elitist grounding. Such foci are limited because of the neglect of oral traditions and attention to Hindu practices, particularly at the local, regional levels and the role of specific household and cult deities, rituals, and festivals in sustaining a religious worldview. Writing in 1976, the late Indian social anthropologist M. N. Srinivas noted the “downgrading of folk religion” (1976: 288–90) and the scholarly neglect of the “folk” elements in Hinduism both by western and Indian social scientists, arguing that this is a viable, independent, and legitimate realm for social science theorizing.

By a “folk” variety of Hinduism is meant these specific features: the privileging of mediums and trance sessions; the intimate, familiar, unmediated approach to the deity (given the absence of a religious intermediary); the ability to sense, feel close to, and talk to deities; the importance of devotion, intuition, emotion, and religious experience; the offerings of non vegetarian items, alcohol, and cigars to the deity; the absence of text based, ritual procedures (*arccanai*, *abishegam*, and the chanting of *mantras*, *slokas*) for approaching the deity; a pragmatic, day to day orientation, valuing rituals of self mortification and equality of all before god. The eventual turn to “folk” dimension and “little community” (Redfield 1956) has been consequential for the simple reason that it rightly draws attention to an erstwhile neglected empirical domain of study. Much is now known about the ritual universe of folk Hinduism, the mythology of specific village deities, the logic of ritual performances, the significance of festivals and other ritual events to manage the uncertainties of daily living. This description of “folk Hinduism” does not exist in isolation. This is only one half of a dichotomy that has

identified, named, and ranked two types of religious styles – captured in the more universal metaphor of the “Great” and “Little” traditions (Singer 1972). In the Hindu context, the “Sanskritic”–“non Sanskritic” divide approximates this classification.

Despite the pervasive use of such descriptions as “folk religion” and “folk Hinduism,” the category “folk” has not been sufficiently problematized (Chatterji 2001). An etymology of the English word “folk” leads to such connotations as “ordinary,” “common people,” and “masses.” The association of “folk” with peasants and rural populations – who are further typified as being illiterate, unsophisticated, and simple minded in contrast to the more urbane, cultured, and educated city dweller – has meant that the term is by no means neutral. Extending such logic, the folk dimension already being ranked lower, members who participate in “folk” practices are assigned specific sociological identities, and are further presumed to be carriers of specific values and mores. This awareness prompts us to ask: What is meant by “folk” varieties of religion and Hinduism? So far, there has been little debate in the literature about what these descriptions signify and the value, if any, of continuing to use them as frames of analysis. Yet, they continue to be used in a taken for granted manner without being adequately conceptualized. Given the history of “folk Hinduism” and the awareness that it does have a built in comparative dimension vis à vis “elite” notions of Hinduism, its unreflective use is highly problematic.

Although some aspects of the folk/little/popular/non Sanskritic Hindu (descriptions which have been used interchangeably) practice have been marginalized over time, this domain reveals a persistence (and in some places shows signs of being revived) within India, and especially amongst overseas Hindu communities in Fiji, Mauritius, South Africa, Singapore, and Malaysia. The overwhelming evidence for the preferred attachment to village based religious practices amongst fourth and fifth Singapore and Malaysia born Hindus is sociologically fascinating. Despite specific substantive shifts in the constitution of Hinduism in this region over time, the ritual complex surrounding the veneration of local, household, and village deities – a strong feature of folk Hinduism – is

one stable element that continues. This is to be expected given the specific profile of Indian and Hindu presence in British Malaya since the nineteenth century. Large numbers of Indians were brought in from Tamilnadu to undertake infrastructure work in British Malaya. Much of this labor was drawn from the lowest rungs of the Indian class and caste hierarchy, that is, from the non Brahmin and Adi Dravida communities. The veneration of village deities and rituals associated with them were continued by these sectors of the migrant community in their new homes. The village deities – *gramadevata* – from Tamilnadu thereby came to Malaya and were firmly placed in the religious landscape of the Malayan Peninsula. Today, the observance of festivals such as *timiti* (fire walking) and *tai pucam*, the large numbers of temples dedicated to village deities, and the attraction to village rituals tell the story of Hindu migration to Malaya.

The Hindu communities in Malaysia and Singapore have been in the region for close to two centuries. From the outset, they have existed in a societal context that is not structured according to principles of caste and embedded in a largely non Hindu, multiracial, multireligious environment, where Hinduism is a minority religion. The Hindu community is clearly not homogeneous in this diasporic location: caste may not be an issue as before, but new class barriers have been erected, and are felt to be in force. Agamic temples (i.e., temples adhering to the Agamas, a set of texts that outline rules and procedures for temple worship) are associated with the “well off” crowd Hindu elites, temple administrators, Hindu authorities, and the government, but not the Brahmin priests, who are not seen as having any real power or autonomy. This is the domain of “Official Hinduism,” framed by Agamic, Saiva Siddhanta (literally, “the doctrine of Siva” and the name by which the body of literature of the Saivas – followers of Siva – is known) precepts. A preference for a different religious style sees the persistence of the “old” ways, encapsulated as the realm of “Popular Hinduism” (Vertovec 1994). Often the two Hindu spheres, which are quite different, are brought into uncomfortable proximity.

In Singapore and Malaysia, the field of “folk Hinduism” is defined by diversity. The need

for protection from, and control over, unforeseen forces in the management of concrete, day to day problems is cited for the continued reliance on *kaaval devam* (guardian deities), demonstrating the prevalence of a pragmatic orientation – recognized as a typical feature of folk Hinduism. For the middle class and upper middle class Hindus the realm of trances, spirit mediums, and the phenomenon of animal sacrifices are intriguing, unfamiliar, and exotic, and often deemed a superficial form of religiosity. The recognition and labeling of these as the “old” ways reveals a desire to connect with the “past.” In an adherence to the ways of the ancestors, connections with “tradition” are maintained and this is seen as continuity, ideas which are collectively carried in the notion of “persistence.” Yet it is precisely also in the name of tradition that new ground is being broken and boundaries transgressed. This certainly challenges the simplistic equation of modernity with change, and tradition with conservatism and backwardness. Strikingly, there is no accompanying effort to standardize the multiplicity and variation that reign here. One encounters instead a “live and let live” attitude with a desire to remain outside the purview of institutionalized religious boundaries, to practice a style of religiosity that does not need to rely on scarce and guarded resources – such as ritual procedures as dictated by religious texts, the framework of Agamic temples, Brahmin priests, and other ritual specialists and ritual paraphernalia. But their religious universe is sustained through creating and legitimating an alternative set of norms and procedures as guiding principles, but with no accompanying desire for uniformity, or the presence of a central agency trying to regulate the ritual domain. It is not without significance that these very practices which are embraced positively by proponents of the “old ways” are devalued by critics (who are supporters of “Official Hinduism”) as “extreme rituals” and “superstition,” and therefore rejected as “primitive and embarrassing” – in fact deemed to be “un Hindu.”

Substantively, the domain of activities and thinking defined by the phrase the “old ways” is a complex mixture of elements, drawn from diverse religious traditions. Its empirical boundaries could by no means be seen to be replicating fully the ritual style in Tamilnadu

villages. In the Malaysian and Singaporean context, the world of “folk Hinduism” is defined first and foremost by a strong sense of religious syncretism. This entails a free and liberal use of deities, symbols, and ritual practices associated with “other” religious traditions, foremost amongst which is a variety of religious/folk Taoism. Almost without exception, religious structures in this domain reveal the strong presence of deities and other religious paraphernalia from the latter, together with such Taoist deities as Tua Peh Kong, Kuan Yin, and Tai Sing. Physical constructions of religious altars that would be typically recognized as part of a “Chinese temple,” ritual objects such as tall joss sticks, large and small Chinese style urns, floating oil candles, oranges, wooden pieces for seeking permission for 4 digits (a lottery popular in Singapore and Malaysia with a combination of 4 numbers), and so on, together with deities from the vast Hindu pantheon, are also present. Thus one witnesses what the purists would consider “indiscriminate borrowing” from all strands of Hinduism, without concern for recognizing boundaries, almost to the point of being irreverent. The truly syncretic nature of “Hinduism” is evident in the co presence under one roof of deities of the Vaisnavite, Saivite, and Sakti tradition (in the coexistence of Hanuman, Ram, Mariamman, Periyachee, Bhagvati, and Kali), the Brahmanic and non Brahmanic styles of worship (in the veneration of village deities such as Muneeswaran, Sangali Karuppan, Madurai Veeran with Saivite deities like Murukan, Siva, and Ganesh) and in conducting “vegetarian” and “non vegetarian” prayers for respective deities on the same grounds, but with appropriate procedures and deference. For instance, if meat is offered to Muneeswaran, the shrine of Murukan or Ganesh is encased with a curtain or the door closed. Often the presence of a *keramat* (Malay, “grave of a Muslim saint”) and “Datuk God” (literally, “Grandfather God,” the name of a localized deity popularly invoked in religious Taoism, as practiced in Malaysia and Singapore) completes the mixed up but coherent and legitimate religious scene. The prominent presence of ethnic Chinese in these spaces, as devotees, is conspicuous, and these numbers seem to be on the rise in Singapore, Penang, Ipoh, and Kuala Lumpur.

In the Indian context, the different levels of Hinduism carry a strong connotation of caste identity. The categories of “Sanskritic” and “folk” Hinduism explicitly associated the “Great Tradition” with rituals and ideas of the higher castes (if not the Brahmins), and the various instances of “Little Tradition” emanated from the ritual practices of the lower caste groupings, if not those of the outcastes (the Harijans, untouchables). While the category “folk” carries some conceptual utility, its implicit judgmental tone and the assumed low ranking assigned to “folk” practices must be questioned. The sociopolitical, cultural, intellectual, and ideological conditions that led to the emergence of these analytical categories for making sense of Hinduism in India clearly do not exist in the vastly different spaces where migrant Hindu communities are now located. Research from the latter speaks rather of a fusion, synthesis, and reconfiguration of elements drawn from different strands of Hinduism and outside, producing a hybrid, syncretic, and innovative style of religiosity even as tradition is invoked. The continued persistence of a style of Hindu religiosity (including features that would be drawn from “folk Hinduism” but also from other sources) amongst overseas Hindu communities, such as in Singapore and Malaysia, illustrates this point well.

football hooliganism

Gary Armstrong

Combine masculinity, physicality, fantasy, and local pride, mix in sporting excitement and collective grievances, and the possible outcome, dating back to the formation of Association Football in the mid nineteenth century, has been disorder. Since the mid 1960s, incidents in Britain involving football spectator disorder and violence have been labeled "hooliganism." Lacking a precise definition or a legal status, "football hooliganism" has for some 40 years served as a receptacle for a spectrum of prejudices and attributes. Without a precise meaning, hooliganism can have no precise causes. The research process thus needs to examine both the *concept* (and its manifestation) and the *interaction* between definer and defined (Pearson 1983). Negotiations around the criminal justice system are crucial because definitions of deviance can depend on the demands of bureaucracies and the moral entrepreneurship of police, media, and the football authorities. The resulting boundary maintenance mechanisms result in stigmatizations and degradation ceremonies offered by courtrooms and media "name and shame" projects. The establishment of police databases, increasingly via the eye of a lens, provides the ever expanding roll call of "categorical suspicion" crucial to the construction and maintenance of a "social problem" (Armstrong & Giulianotti 1998).

Termed since the 1970s the "English disease," it is unsurprising that academics in the UK are pioneers of the hooliganism debate. Sociologists and psychologists have contributed to related social control policies, often on the

basis of preconceived and, at times, bewildering arguments based on little or no empirical evidence. Early sociological explanations portrayed hooligans as a growing subculture resisting the commercial imperative pursued by many soccer clubs (Taylor 1971). In the early 1980s the hooligan problem was framed within a political crisis that threatened capitalist hegemony, and analyzed within the different conceptions of class relations in Britain (Taylor 1982). However, some scholars became disillusioned in the late 1980s as they saw their ideas enveloped in a belief that all troublemaking fans, believed to be drawn from the aspiring and residual strata of the proletariat, were morally and culturally shallow. This in turn made young working class men fodder for racist movements and a collectivity unworthy of left liberal sympathy (Taylor 1987, 1991).

Crowds and disorder have attracted psychologists and theories since Le Bon (1952). However, research on hooliganism has often been informed by an academic obsession with predictive profiling and "models" of disorder. Typically, avoiding contact with hooligan participants has not prevented the production of elaborate texts that bewilder the sociological imagination. Those that attempted ethnography could only retreat to the classroom and dismiss hooligan disorder as "issue less." The fundamental problem with such an approach is this: when collective behavior occurs, which circumstance is an issue and which one is it? At the same time that politicians first debated the issue in the British Parliament, Marsh (1978; Marsh et al. 1978) attempted to produce an "ethnogenic" social psychological analysis that used observation and interviews to claim that hooliganism was ritualized conflict, common to all civilizations, and played out in particular confines by a career structure of recognizable participant "types." The work of Marsh and his colleagues provided the first attempt at qualitative understanding, but it ignored the complex sociohistorical context of rivalries.

More sophisticated applications of sociological theory appeared in the 1980s when figurationalist metatheory, organized around the idea of network interdependency as advanced by Norbert Elias, was combined with Suttles's (1968) concept of "ordered segmentation" derived in his studies of ethnicity and gang

membership in Chicago. The result was a trilogy of texts from the Leicester School (at the University of Leicester) explaining that hooligans were a product of lower working class exclusion that produced an aggressive masculinity, uncontrolled by civilizing processes, and expressed in disruptive actions, some of which would occur at football matches (Williams et al. 1984; Dunning et al. 1988; Murphy et al. 1990). This theory has been challenged on its historical validity, questioned for its application to football hooliganism, and critically scrutinized on methodological and interpretive grounds by those who conducted qualitative research with hooligan groups. Aside from these criticisms, arguments around civilizing and decivilizing processes are impossible to test and, during a century filled with wars, seemingly inappropriate to use as explanations for fights associated with football matches. Furthermore, the transmission of social values and ideas of emulation or avoidance is complex when examining the reality of the lived experience and the fluidity of social class.

Since the early 1990s, academic research in the UK has addressed ideas about hooliganism as publicized by the police and media and favored by law and order politicians campaigning for support. The police and politicians, themselves coming from notoriously hierarchical occupational cultures, explained that hooligan gatherings could exist only if they had quasi military structures. Therefore, the past 20 years have seen an obsessive search in Britain for the conspiracies of the hooligan "generals" who have a wider political and criminal agenda and whose capture and incarceration are necessary if hooliganism is to be eliminated. Subsequent high profile arrests of suspects identified in these terms produced court cases that could not be prosecuted due to falsified evidence presented by the police. Research since the mid 1990s moved beyond Britain to study actions associated with international soccer matches. Studies by anthropologists and sociologists are generally enlightening because they present data on local sociopolitical contexts. Since the late 1990s, research on global football culture shows that disorder is endemic to the game. Whether observers label such disorder as "hooliganism" will depend on their perceptions of causes.

Research has shown that football hooliganism consists of emerging public enactments of ritualized procedures by constantly changing collections of people. It exists via inter and intragroup negotiations which are never fully agreed upon but which give rise to future discord. Confrontations occur within normative or pragmatic confines. They involve semi choreographed situational scenarios acted out as authorities, playing umpire, persistently try to narrow the boundaries of disorder (Giulianotti & Armstrong 2002). The young people resemble Maffesoli's (1996) "neotribes": open ended, mainly urban groups seeking a cause to be pursued through risky actions occurring in spaces that supply them a multiplicity of meanings. Notions of "performance" and "conduct" are integral to such processes, embedded in notions of social class and habitus (Bourdieu 1984).

Unfortunately, issues of selfhood, agency, and structure have been ignored, often because research on hooliganism has been fueled by narcissistic contemplations combined with crude voyeurism. At the same time, former participants have produced popular autobiographies that often ridicule sociologists. The phenomena and epiphenomena that hooliganism generates are useful sites for exploring social performance, idealized masculinity, media imperatives, applications of commerce to public order policing, identity in urban milieus, and the construction of the status of "expert" social commentators.

Fordism/post-Fordism

Harland Prechel

Taylorism and other forms of scientific management were implemented in many industries in the late nineteenth and early twentieth centuries. However, the formalization of control over the labor process was accelerated when Henry Ford and his engineers systematically applied the principles of scientific management to the entire labor process. *Fordism* represents two critical changes in the historical process of

fragmenting tasks and increasing the division of labor. First, whereas Taylorism developed work rules to standardize the production of parts, Fordism brought these standardized parts to the worker and further separated conception from execution by specifying how the assembly of parts was to be done. Second, using the assembly line to bring work to the worker made it possible to limit interruptions in the labor process and increase control over the pace of work.

By creating more precise control over the labor process and setting the pace of work, Ford discovered that he could pay high wages while maintaining high profits. His capacity to pay higher wages than other capitalists permitted Ford to be more selective when hiring workers and to impose stricter standards on those workers. The incentive of higher wages was particularly important because it allowed Ford to overcome some of the central impediments to capital accumulation during this historical period: absenteeism and labor turnover. Ford's selection of workers was done by his "sociological department," which scrutinized workers' behavior and implemented hiring practices based on his conception of a moral worker. Fordism also entailed internal labor markets by creating job classifications and hierarchies that allowed workers to be upwardly mobile within the company. These internal labor markets created competition among workers, which divided workers against one another and reduced worker solidarity. In addition to transforming the labor process, Fordism is associated with other social changes. Most notable, the mass production of inexpensive commodities contributed to a culture of mass consumption. Fordism also entails a mode of state regulation that attempted to institutionalize economic growth and stability by limiting workers' rights, creating a welfare state, and implementing Keynesian economic policies.

The limitations of Fordism became apparent in the mid 1970s when the 1973 oil crisis and the economic downturn in 1974 resulted in an abrupt halt to economic growth and stability. This capital accumulation crisis represents the transition to *post Fordism*, which represents a new phase of capitalist development. These new institutional arrangements include an acceleration of globalization, the increased role

of the state in balancing production with consumption, restructuring the production process, and the emergence of giant global corporations and financial institutions that exercise control over trade, domestic companies, and many nation states. Despite agreement that a transition occurred, there is considerable debate among social scientists over how to characterize this form of social organization. In contrast to those who characterize post Fordism as global corporate dominance, other scholars view this transition as creating a more flexible form of economic organization and increasing individualism and pluralistic lifestyles. There is also considerable debate over whether post Fordism represents a historical transition or modifies previous trends. Still other scholars challenge the broad generalizations in post Fordist theory for denying the complex and heterogeneous causal processes that operate in different places in the global economy (for more detail, see Amin 1994; Hall et al. 1995).

One dimension of this debate that has been the subject of considerable empirical research is the use of information to control the manufacturing processes. Post Fordism maintains that access to information creates the organizational capability for instant data analysis that is essential to decisions concerning flexible manufacturing, the manufacture of specialized products, and the coordination of diverse corporate interests (Harvey 1991). Whereas some arguments suggest that information fosters decentralization and autonomy at lower levels of the organizational hierarchy (Piore & Sabel 1984), others suggest that access to information contributes to centralization (Dohse et al. 1985). These perspectives have been criticized because they represent a binary logic, conceptualize information in highly abstract terms, and fail to give explicit attention to the kind of information used, the location of information in the organizational hierarchy, who has access to it, and how it is used in the decision making process. To determine whether decision making is tightly controlled or subject to wide discretion, researchers have analyzed the design of information systems, and the organizational distance between the conception and execution of decisions. *Neo Fordism* formulations suggest that contemporary forms of control have continuity with the past and share important

characteristics with Taylorism and Fordism. This line of theorizing maintains that centralization and decentralization must be treated as theoretical constructs that illuminate empirical processes rather than as empirical absolutes, and that decision making and authority must be treated as separate variables so that the spatial location of authority apart from decision making can be considered (Prechel 1994). This research shows that to increase product quality, corporations standardized the decision making process by introducing more formally rational controls (Weber 1978: 224). Advanced accounting techniques and information processing systems were established to further standardize decision making criteria and create a unified system of control over the managerial process. These controls created the organizational flexibility to centralize authority while decentralizing the responsibility to execute production activities conceptualized by engineers and other experts in a centralized plant planning office. These formal controls made it possible to establish control over the managerial process by defining the premise of decision making and distributing information to operating managers on a "need to know basis," which subjects these social actors to a higher level of discipline.

Despite agreement in some areas, there are many unsettled debates in the post Fordist literature. Resolution of these debates will require more precise theorizing about the contingencies (e.g., geographic, historical) within which economic activity is embedded at both the societal (e.g., political legal) and corporate levels.

Foucauldian archeological analyses

James Joseph Scheurich and Kathryn Bell McKenzie

To begin to understand Foucault's archeology, it is first crucial to know that Foucault was *not* referring to archeology as an academic discipline or to any popular picture of an archeologist. Indeed, thinking of Foucault's archeology as having anything to do with digging in the earth for ancient artifacts is not useful at all. As Foucault (1972) says, *The Archaeology of Knowledge* "does not relate to geological excavation." For the most part, these allusions will only get in the way of building an understanding of his archeological method.

The archeologies are his most difficult methodologies to understand and, as a separate, second issue, his most difficult to apply. For example, Scheurich supposedly developed a "policy archeology" as a method for addressing public policy issues, but it fails as a Foucauldian archeology. The reason for this is it uses some archeological concepts, but Foucault's archeology is a complex, tightly interwoven methodology that directly depends on such concepts as *savoir*, *connaissance*, positivity, enunciations, statements, archive, discursive formation, enunciative regularities, correlative spaces, enveloping theory, level, limit, periodization, division, event, discontinuity, discursive practices, and so on. In other words, the nature of this method is

that these constructs cannot be pulled out and deployed separately without fundamentally violating the method itself. To deploy Foucault's archeology with integrity or rigor, then, requires *both* a comprehension of the meaning of each of his numerous constructs (and their relationships and connections) *and* a use of the set of constructs as an interrelated or interwoven whole.

Foucault's best synopsis or summary of his archeological methodology is available in the "introduction" to *The Archaeology of Knowledge*, which was written after he had done three book length archeologies. He says in this introduction that this retrospective revision of his methodology is not exactly the same as he applied it in the three prior archeologies because of the problems he discovered in his three applications. Accordingly, the best suggestion for learning how to do Foucault's archeology is to read carefully and thoroughly, more than once, the three archeologies – *Madness and Civilization* (1988), *Birth of the Clinic* (1994), and *The Order of Things* (1973) – and then read in the same way his reflections on archeology as a method in *The Archaeology of Knowledge*. We suggest this course of study is suggested because virtually all social science texts, even fairly complex theoretical ones, are relatively easy to read and understand compared to reading and understanding Foucault, especially the archeologies.

Some of the difficulty with reading Foucault is typically blamed on his writing style, though this explanation is over blown. For example, the main problem with his writing style is that he uses long sentences, and as the sentences proceed, the referents to key concepts are difficult to follow. However, once a reader has picked up the habit of carefully following the referents, Foucault's sentences are not that difficult to understand. Instead, the main problem in reading Foucault is a lack of knowledge of the French philosophical context within which he wrote and a lack of familiarity with his epistemological approach, which is poststructuralist in its assumptions and which is critical of dominant assumptions and discourses, including those of critical theory, broadly defined. Indeed, part of the difficulty in reading Foucault is that while he is inarguably "critical," his critique significantly diverges from and is critical of

what we typically know as critical theory in the social sciences. Nonetheless, despite the difficulties, it is worth the effort to do the work necessary to develop an understanding of his archeologies and his archeological method. And, in doing so, a “strong” understanding of Foucault’s archeological method does require the development of a solid understanding of his complex, interrelated set of concepts.

Two of the more important of these concepts illustrate the fundamental points that Foucault is making with his archeologies. These are *savoir* and *connaissance*. In a particularly useful interview, which appeared in French in 1966 and then in English in 1994 and which was done after *Madness and Civilization*, *Birth of the Clinic*, and *The Order of Things* but before *The Archaeology of Knowledge*, Foucault defined how he saw archeology at this point:

By “archaeology” I would like to designate not exactly a discipline but a domain of research, which would be the following: in a society, different bodies of learning, philosophical ideas, everyday opinions, but also institutions, commercial practices and police activities, mores – all refer to a certain implicit knowledge [*savoir*] special to this society. This knowledge is profoundly different from the [formal] bodies of learning [*des connaissances*] that one can find in scientific books, philosophical theories, and religious justifications, but it [*savoir*] is what *makes possible* at a given moment the appearance of a theory, an opinion, a practice.

Thus, he is differentiating or contrasting these two concepts, *savoir* and *connaissance*, both of which are critical to understanding his archeological approach.

Connaissance is “formal” knowledge or bodies of knowledge that exist in “scientific books, philosophical theories, and religious justifications.” That is, *connaissance* in the social sciences is the production of social scientists as part of their work; it is what academicians would know as scholarly publications or presentations in articles, books, proceedings, reports, and conferences. In sharp contrast, *savoir* includes “everyday opinions, but also institutions, commercial practices and police activities, mores,” but (and this is critically important) it is *savoir* that “*makes possible* at a given moment the appearance of a theory, an opinion, a practice.” Gutting (1989: 251) makes

this same contrast when he argues: “By *connaissance* [Foucault] means . . . any particular body of knowledge such as nuclear physics, evolutionary biology or Freudian psychoanalysis.” In contrast, *savoir*, Gutting continues, “refers to the [broad] discursive conditions that are necessary for the development of *connaissance*.”

A specific example of the application of these two key archeological concepts can be drawn from *The Archaeology of Knowledge* (1972: 179):

The lynch-pin of *Madness and Civilization* was the appearance at the beginning of the nineteenth century of a psychiatric discipline. This discipline had neither the same content, nor the same internal organization, nor the same place in medicine, nor the same practical function, nor the same methods as the traditional chapter on “diseases of the head” or “nervous diseases” to be found in eighteenth-century medical treatises.

Here, Foucault is showing that the “psychiatric discipline” that appears at the first half of the nineteenth century is qualitatively or substantively different than the “diseases of the head” and “nervous diseases” of the eighteenth century. But on examining this new discipline, we discover two things:

what made it [i.e., the emerging discipline of psychiatry] possible at the time it appeared, what brought about this great change [i.e., changes from eighteenth-century diseases of the head to nineteenth-century psychiatry] in the economy of concepts, analyses, and demonstrations was a whole set of relations between hospitalization, internment, the conditions and procedures of social exclusion, the rules of jurisprudence, the norms of industrial labor and bourgeois morality, in short a whole group of relations that characterized for this discursive practice [i.e., psychiatry] the formation of its statements.

Thus, what created the conditions for the psychiatric discipline to appear as a formal discipline – a *connaissance* – were changes in the broader *savoir* (i.e., changes in practices, procedures, institutions, norms, etc.). For example, “this [discursive] practice is not only manifested in a discipline [i.e., psychiatry] possessing a scientific status and scientific pretensions [*connaissance* or psychiatry as a formal discipline]; it is also found in the operation in legal

texts, in literature, in philosophy, in political decisions, and in the statements made and the opinions expressed in daily life [i.e., *savoir*].”

As a result, Foucault is arguing that to understand the emergence of psychiatry as a formal discipline, it is necessary to understand not only some evolution of formal knowledge (*connaissance*), but also the much less formal “hospitalization, internment, the conditions and procedures of social exclusion, the rules of jurisprudence, the norms of industrial labor and bourgeois morality” and medical texts, popular literature, political agendas, and many other, seemingly mundane, aspects of everyday life; that is, *savoir*.

It is *savoir* that is the focus of study for Foucault’s archeology. He is showing that psychiatry or other formal social science disciplines do *not* simply evolve out of any prior formal disciplines. Instead, he is contending that understanding the emergence of a discipline like psychiatry requires a focus on *savoir*. Foucault’s larger point, though, is that formal disciplines do *not* have a rational historical trajectory since, in fact, these disciplines emerge from the much less rational or even irrational array of practices, procedures, institutions, politics, everyday life discourses, and the like, which, as a result, undermines the rational modernist story of formal disciplines.

Thus, the larger purpose of Foucault’s archeologies is to interrogate various examples – *Madness and Civilization*, *Birth of the Clinic*, and *The Order of Things* (the human sciences) – of the work of reason. And these generate one of Foucault’s most important archeological contentions: the history of reason is “in *Madness and Civilization*, not wholly and entirely that of its progressive refinement, its continuously increasing rationality” (Foucault 1972: 4). In other words, when specific cases of the work of reason are examined, Foucault finds that the historical trajectory of reason is not “progressive refinement” or “continuously increasing rationality.” Instead, there typically is a “discontinuity (threshold, rupture, break, mutation, transformation)” in a particular trajectory – similar, for example, to the one he found between “diseases of the head” and “nervous diseases” of the eighteenth century and a psychiatric discipline in the nineteenth century. Consequently, instead of merely critiquing the

master narrative of reason, Foucault is providing research that demonstrates that the typical characterization of this narrative of reason is not accurate, at least in his three archeological studies.

A second critical contention that emerges out of the archeologies is that disciplines or formal knowledges (*connaissance*) cannot be adequately studied in terms of only the historical trajectories of the formal knowledges themselves (*connaissance*). In contrast, Foucault argues that *connaissance* emerges out of *savoir*, which does include formal knowledge, such as academic books, but also encompasses institutions, legal decisions, mores, corporate practices, norms, and everyday discourse. Thus, in his archeologies, he shows how institutional practices, morality, and the like create the conditions or the possibility for a formal knowledge to emerge. Again, though, this contention undermines the modernist metanarrative of reason. It is no longer so pure or exalted; that is, reason is being problematized.

Problematizing reason, however, is not Foucault’s last larger purpose in the archeologies. For Foucault, the other side of the coin of reason is the human subject: “Making historical analysis the discourse of the continuous [e.g., portraying formal knowledge, *connaissance*, as emerging through a rational, logical, continuous trajectory] and making human consciousness [i.e., the human subject or subjectivity] the original subject of *all* historical development and *all* action are the two sides of the same system of thought [i.e., modernity]” (p. 12; emphasis added). What Foucault contends here is that “man” or the human subject, especially “man” as the creator of history and reason, is an ideological assertion or assumption of modernity. However, social scientists then take this assumption as a given as they construct their theories and research. Moreover, Foucault argues that this ideologically constructed central agent – “man,” the privileged subject of history and life – is simultaneously positioned as both the researcher or theorist and the object of the research or theory. However, for Foucault, this modernist ideology of humanism can be interrogated through his anti humanist archeological methodology, especially in terms of showing that the conditions of emergence of *connaissance* occur through or

within *savoir*. In other words, archeology decenters the modernist subject as the heart of history and reason. As Foucault says in the *Archaeology of Knowledge*, the purpose of his final archeological work before he turned to genealogy as a new method was “to define a method of historical analysis freed from the anthropological [the human subject as the center] theme” and “a method purged of all anthropologism” (p. 16; emphasis added). Unfortunately, Foucault’s problematization of reason and the agentic subject as “two sides of the same system of thought” (Foucault 1972: 12) has largely been ignored by many of those who have appropriated his work. These theorists have used his problematization of reason, while ignoring his problematization of the subject. However, appropriating “one side” of Foucault’s archeology without the other side represents a deep violation of archeology.

For those interested in Foucault and especially for those interested in his archeologies, single archeological concepts cannot just be cherry picked and used by themselves. Foucault intended his array of archeological constructs to be deployed as an integrated set. To learn to do a Foucauldian archeology requires several readings of the three archeologies and the same for his retrospective revision of his archeological methodology in *The Archaeology of Knowledge*. In addition, there are a few books (e.g., Gutting 1989) that are useful, but there is no substantive application of Foucault’s archeology available for study except his own.

Foucault, Michel (1926–84)

Margaret E. Farrar

Michel Foucault was a French philosopher whose work has greatly influenced sociologists and many others, particularly in the areas of crime and deviance, gender and sexuality, health and illness, and social welfare.

Foucault was born into an upper middle class family in Poitiers, France, where his father was a prominent surgeon. Beginning in 1946, he attended the École Normale Supérieure, where he studied with such intellectual luminaries as Maurice Merleau Ponty and Louis Althusser. At ENS he received his licence in philosophy in 1948, in psychology in 1949, and his *agrégation* in psychopathology in 1952. He published *Maladie mentale et personnalité* (Mental Illness and Personality) in 1954, a book that he later disavowed. After a series of jobs in Uppsala, Hamburg, and Warsaw, he returned to France in 1960 to chair the philosophy department and teach at the University of Clermont Ferrand. He received his *Doctorat ès lettres* in 1960 for *Folie et déraison: Histoire de la folie à l’âge classique*, a history of mental illness that focused on the relationship between madness and reason (this would be abridged and published in English as *Madness and Civilization* in 1961). In 1963 Foucault published *Naissance de la clinique* (The Birth of the Clinic). Foucault’s next book, *Le Mots et les choses* (published in English as *The Order of Things*), was a sweeping study of the preconditions for knowledge in the disciplines of biology, philology, and economics. It became a

surprise bestseller in France when it was published in 1966, launching Foucault to international prominence.

May 1968 inaugurated what some have called Foucault's "political turn," when confrontations between students at the Sorbonne and the police ignited a general insurrection across France. Initially, groups of workers spontaneously sided with the students in the conflict; the series of strikes that ensued, however, was discouraged both by union leaders and by the French Communist Party. The rebellion was finally suppressed by the de Gaulle administration. During this time, Foucault was teaching in Tunisia, but he was profoundly affected by the events nonetheless; they confirmed Foucault's deep suspicions regarding universalist and humanist appeals to truth and history, and sparked his interest in studying the many different places that power is exercised in people's daily lives: schools, factories, hospitals, and prisons. When he returned to France, Foucault (and others of his generation, including Jacques Derrida and Gilles Deleuze) renounced the intellectual and political tradition exemplified by Jean Paul Sartre. Speaking out against Sartre and the Marxist tradition he represented, Foucault quickly became a galvanizing figure in intellectual public life. He subsequently helped to found the *Groupe d'Information des Prisons* (the Prison Information Group, or GIP), an organization dedicated to providing a forum for addressing prisoners' concerns and needs.

In 1969 Foucault was elected to the Collège de France, the country's most prestigious institution of research and learning, where he became Professor and Chair of the History of Systems of Thought. Foucault published perhaps his most influential and overtly political book, *Surveiller et punir: Naissance de la prison*, in 1975 (translated into English as *Discipline and Punish* in 1977) from research that originated from his work with GIP. Soon after, he began his multi volume history of sexuality. The first volume, *The Will to Knowledge* (previously known as *The History of Sexuality: An Introduction* in English; *Histoire de la sexualité, 1: la volonté de savoir*) was published in France in 1976. The second and third volumes (*The Use of Pleasure* and *The Care of the Self*) were translated into English shortly before Foucault's death in 1984.

THEMES IN FOUCAULT'S WORK

In an essay written near the end of his life, Foucault explained that the goal of his work over the previous two decades was not, as many thought, to elucidate the phenomenon of power. Rather, he wrote, "my objective ... has been to create a history of the different modes by which, in our culture, human beings are made subjects" (Foucault 1983: 208). According to Foucault, the human sciences (as he called them) are disciplines in both senses of that word: they are fields of expertise (i.e., in the sociological sense, they are "professions"), but they also are implicated in a particularly insidious form of power, whereby man becomes "the enslaved sovereign, the observed spectator" in the production of knowledge (see also Goldstein 1984). Heavily influenced by and indebted to Nietzsche, Foucault's work critiques the "will to knowledge" inherent in the human endeavor to understand ourselves. For Foucault, this will to knowledge operates at the intersection of knowledge and power. Foucault's studies of illness, criminality, and sexuality challenged linear narratives of progress that regard advances in knowledge as part of a clear path to emancipation (Thiele 1990; Owen 1996). For Foucault, the interplay between knowledge and freedom is never that straightforward; in fact, he argued, the modern proclivity to identify and divide the normal from the abnormal can and often does serve as a means of social control. Such categorizations always entail a normative divide between one half of the binary (healthy, sane, law abiding, heterosexual) and the other (sick, insane, criminal, and homosexual). In his earlier work (through *The Order of Things*) Foucault called this juncture of knowledge and power an episteme, a system of thought that defines the field of possibility for the production of knowledge. With the publication of *L'Archeologie du savoir* (*The Archeology of Knowledge*) in 1969, Foucault began to write about "discursive formations" rather than epistemes, perhaps to put some distance between himself and the methods and concepts employed by theorists of structuralism (Foss et al. 1985: 194). Foucault's main concern was the way that certain kinds of language – language enmeshed in professional standards, methodological requirements, and a

community of experts – are endowed with greater claims to truth than others (Dreyfus & Rabinow 1983: 48). Foucault regarded discursive formations as having a constitutive function: discursive practices make subjects by delimiting the boundaries of what it is possible to think. For Foucault, then, knowledge and power are always, and necessarily, intertwined, so that “we are subjected to the production of truth through power and we cannot exercise power except through the production of truth” (Foucault 1980: 93). For example, in *Discipline and Punish* Foucault begins with a startling juxtaposition between the gruesome public execution of Damiens the Regicide in 1757 and a blandly regimental prison timetable from 1837. How, Foucault asks, have we made the enormous transition from one form of punishment to the other in less than 80 years? Foucault’s provocative answer is that it is not that we have become increasingly humane or civilized in our treatment of prisoners; rather, he contends, we have developed more efficient forms of punishment, more sophisticated technologies of power. Through observation, classification, examination, and internment, we have rationalized crime and punishment in both language and practice. The point of shifting from public executions to prisons, Foucault claims, is “not to punish less, but to punish better” (Foucault 1977: 82), and marks a sea change in how we think about crime, criminality, and society. Foucault describes this as the shift from sovereign or juridical power to disciplinary or bio power.

In *Discipline and Punish* Foucault also describes his best known metaphor for this new form of power: the Panopticon, Jeremy Bentham’s unrealized and yet enormously influential design for prisons. The Panopticon consists of a central tower with windows on all sides that look out over a ring of cells that face the tower. Space is organized around vision, so that a maximum number of people can be observed at a minimum cost. In its ideal, most effective form, this disciplinary machine does not even need the guard in the tower in order to operate; all the prisoners require is the possibility of being watched in order to monitor their own behavior. One way glass, for example, can take the place of an actual guard and produce the same results. As an institution that allows for

those in authority to see without being seen, the Panopticon fashions subjects that internalize the force of this authoritative gaze.

Moreover, Panopticism is not limited to prisons and prisoners. According to Foucault, the kind of power exemplified in the Panopticon has been replicated across the modern world in all kinds of institutions. “Is it surprising,” he asks, “that prisons resemble factories, schools, barracks, hospitals, which all resemble prisons?” (Foucault 1977: 228). Through panopticism specifically and bio power more generally, Foucault contends, “visibility becomes a trap.” These observations lead Foucault (1977) to describe the expansion of what he calls a “carceral society” or a “society of normalization” (Foucault 1980).

In his later work, Foucault turned his attention to the production of human sexuality. In “The Will to Knowledge (An Introduction),” Foucault criticizes what he calls the “repressive hypothesis,” the belief that since the nineteenth century we have “repressed” our sexuality under the influence of the Victorian bourgeoisie. Instead of repression, Foucault argues, western society “speaks verbosely of its own silence, [and] takes great pains to relate in detail the things it does not say” (Foucault 1990: 8). Foucault contends that the human sciences make sex an object of study, and serve to “discipline” and normalize various forms of sexual behavior. For Foucault, this discipline is particularly insidious because it shapes individuals’ understanding of themselves. The second two volumes in the series, *The Use of Pleasure (Histoire de la sexualité, II: l’usage des plaisirs)* and *The Care of the Self (Histoire de la sexualité, III: le souci de soi)*, deal with the construction of human sexuality in Greek and Roman antiquity.

It is important to note that the various trans formations that Foucault documents – whether in the realm of crime and punishment, mental illness, or human sexuality – were not the result of one point of origin or a single systemic cause (Foucault 1977: 81); bio power is not initiated by a piece of legislation, a particular group of thinkers, or even a specific economic system. Rather, it is “a multiplicity of often minor processes, of different origin and scattered location” (p. 138). What is more, Foucault contends, this form of power is never reducible to the state or to the prohibitive function of law.

Instead of focusing intellectual energy looking for the centers of power, Foucault famously claims, we need to “cut off the king’s head” and examine the ways that power “induces pleasure, forms knowledge, produces discourse” (Foucault 1984: 63, 61).

INFLUENCE AND CRITIQUE

Foucault’s work has had a tremendous impact in many different disciplines across the humanities and social sciences. Scholars of history, geography, religion, political theory, communications, education, and literature have had to grapple with the implications of his claims, and respond to his challenges. His *History of Sexuality* volumes are considered founding texts in queer theory, and have helped to inaugurate the field of gender studies.

Foucault’s impact on sociology, then, simply cannot be overstated. Some see Foucault’s work as very much an extension of, and complement to, Weber’s analyses of social rationalization (O’Neill 1986; see also Owen 1996). Students of social control and deviance, particularly those influenced by labeling theory, cite *Discipline and Punish* as a revolution in the study of crime and criminality. Foucault’s institutional studies also have had implications for research on organizations (Cooper & Burrell 1988).

Foucault’s work has also been the subject of much debate across the social sciences. Some of the most energetic critiques have been directed at Foucault’s conceptions of power and agency. Foucault rejects what he calls an “economic” model of power, whereby power is something that some “have” and others do not. Instead, Foucault sees power as “something which circulates . . . never localized here or there, never in anybody’s hands, never appraised as a commodity or piece of wealth” (Foucault 1980: 98). For Foucault, power is a field in which we are all implicated. Sangren (1995) argues this conception of power reduces people and institutions to mere objects (rather than subjects) in Foucault’s analyses; power thus assumes the status of an explanatory telos (see also Habermas 1987: 274–5). For this reason, Foucault and theorists influenced by Foucault (such as Judith Butler) have been taken to task for either being too deterministic (and thus incapable of providing

an account of resistance to power) or not deterministic enough (e.g., Fox 1998).

A related critique also stems from Foucault’s account of power as something that is diffuse and dispersed, everywhere and nowhere at the same time. As a result, critics charge, Foucault does not adequately provide a way to differentiate between power and domination. Moreover, Foucault does not articulate a clear set of ethical standards by which to evaluate the morality of different arrangements of power. Indeed, Jürgen Habermas, one of Foucault’s most persistent critics, referred to this as Foucault’s cryptonormativity: his unwillingness to definitively make judgments about the justice or injustice of particular power relations. Foucault responds to this critique by rejecting what he referred to as “the blackmail of the Enlightenment,” the simplistic choice of “for or against” freedom, progress, and reason put to him by his detractors (Foucault 1984: 43).
