When corporations superficially adopt principles of critical pedagogy to sell products, they introduce elements of confusion to those new to the concepts of critical pedagogy. For example, “praxis” became the name of a standardized test used to evaluate teachers in training. A main goal of critical pedagogy challenges people to think and act against forces of commodification and the stratified categories that perpetuate social injustices. Such categories inherently define most, if not all, standardized tests, and place pressure on critical pedagogues to conform instead of transform.

Henry Giroux, another noted critical pedagogue, chose to leave the more culturally credentialled Penn State University, after 10 years, for McMaster University in Canada, because he observed increased alliances among corporate values and interests in the United States’ university system. Giroux’s move exemplifies problems faced by critical pedagogues. On one hand, they draw emotional and material support for their ideas and their communities from people raised according to capitalistic values. On the other hand, the principles they live and learn by inherently reject capitalistic values and ways they find support (such as commodification of educational services and concepts). Concepts drawn from social constructivism address these issues through exploration of how people “socially construct” their society, culture, and realities through enactment of recurring stratified interactions.

critical qualitative research

Gaile S. Cannella

In the first edition of *The Handbook of Qualitative Research* (Denzin & Lincoln 1994), Kincheloe and McLaren (1994) begin by describing research and theory that could be labeled criticalist. Such work assumes socially and historically embedded power relations, “facts” as ideologically inscripted, language as both constructing and limiting consciousness, oppressions as multiple and interconnected, and research as producing and reconstituting (however unintended) systems of power.

Further, criticalist research assumes the need for emancipatory actions that lead to increased social justice and social transformation.

These assumptions would, at first, appear to construct new “critical truths” for a postmodern age, and have done so when dominated by an unrelenting focus on the victimization of those who have been oppressed (whether socioeconomically, sexually, racially, or otherwise). This is certainly a focal point that is warranted within the confines of patriarchy and racist, economic imperialism. However, recognizing that the practice of research has often itself resulted in the production and reproduction of power for researchers, along with an increasing awareness of diverse forms of resistance, critical qualitative researchers attempt to challenge even the construction of critical truths. Therefore, various forms of critical qualitative research are embedded within a self-conscious criticism that requires that the researcher continually challenge her “will to conduct research” as well as the “will to define and impose equity and justice.” The researcher’s ideological and epistemological biases are referenced from the beginning, are politically self-conscious, and are open to revision. This critical self-consciousness even challenges “master narratives” that would “lead to emancipation” while at the same time maintaining as major purposes the elimination of oppression and the construction of an emancipatory social transformation that would be recognized as tentative and shifting.

These criticalist, self-conscious assumptions have led to reconceptualizations of research in ways that affirm diverse knowledges and ideologies. These reconceptualizations challenge truth-oriented belief structures that are not even considered questionable from within forms of science that function as if ahistorical and apolitical. Critical qualitative research even deconstructs and blurs the boundaries of traditional disciplines. The following are examples of critical research questions that can provide the reader with a feel for the range of possibilities for exploration, research, and critique from within and across disciplinary boundaries:

- How did the creation of the “Orient” benefit European cultural strength and identity?

- How have androcentric orientations influenced the selection of problems identified as important for human cultural research?
- Does/how does the culture of caring in secondary schools create privilege for some students and serve as a form of erasure and exclusion for others?
- What are contemporary ways of speaking/acting within academic communities that are used to discredit forms of research that are not positivist and/or experimental in nature?
- How have particular forms of knowledge (and resultant knowledge bases) used in educational practices privileged particular groups of people and disqualified others?

Although the term *critical* most often evokes thoughts of neo Marxist “critical theory,” critical qualitative research is actually a hybrid and emergent form of inquiry. Calls for a critical social science (Popkewitz 1990), a postimperialist science (Lather 1998), and indigenous research agendas (Tuhiwai Smith 2001) are attended to as research is constructed that would uncover the ways that social relations are shaped by ideology and such research explores how these relations can be altered. This type of research is embedded within the history of qualitative research that has resulted in a scholarly environment in which diverse voices and ways of living in the world have been heard and respected. Additionally, critical qualitative research draws from the range of theoretical perspectives that have challenged notions of universalist truth, have acknowledged the political and power orientations of human knowledge(s), and have fostered emergent, activist orientations.

THE LEGACY OF QUALITATIVE RESEARCH

Qualitative research, as conceptualized from within ontological and epistemological perspectives that acknowledge the connections between knower and known (e.g., naturalistic, phenomenological), is foundational to the construction and contemporary acceptance of critical qualitative research. While specific “qualitative” methods may be used by truth oriented

scholars, the field of qualitative research overall has fostered a paradigm dialogue that challenges deterministic notions like generalizability and validity, as well as deconstructed the “will to truth” found in dominant constructions of science. Qualitative research in general has created a scholarly environment in which diverse research questions and methodologies are encouraged and fostered with the recognition that change, emergence, and new constructions (even as related to research questions and data collection methods) are necessary. This intellectual environment is necessary for a critical science that would unveil societal power relations, while at the same time engaging in self conscious examination of assumptions and biases even within the specific research that is being conducted.

Further, the various strengths of qualitative research as the avenue for diverse paradigmatic perspectives is directly related to and applied in critical scholarship. First, objectivist approaches have been discredited as not humanly possible, a position that can result in disciplinary boundary crossing, the acknowledgment of ideological embeddedness, and increased contextual awareness. Second, the acceptance of human subjectivity within qualitative research practices ensures an advanced rigor that attempts to make assumptions and biases clear up front. The various forms of qualitative research have attempted to document “lived experience,” often as played out in the lives of those who have suffered societal injustices and those whose voices have not usually been heard, or even acknowledged. Third, some forms of qualitative research have been implicitly critical in nature as research purposes and collaborations have dealt directly with the imbalance of power in society. Examples include research that addresses women’s/gender issues, ethnic/linguistic minority issues, race, and various practices of marginalization (Lincoln & Cannella 2004).

HYBRID AND DYNAMIC THEORETICAL ORIENTATIONS

A range of theoretical positions has challenged modernist truth orientations while at the same time introducing diverse explanations for the

construction (and imposition) of power within social relations. These various theoretical and even anti theoretical lenses have been/are being combined and reconfigured as needed in the practice of critical qualitative research. Perspectives that are employed include critical theory, poststructuralism, a range of feminist forms of critique that challenge patriarchy and sexism, queer theory, cultural studies, and postcolonial critique. These hybrid combinations result in “unthought of” ways of understanding the world and vantage points from which to examine rhizomes, tentacles, and sites of power and oppression. These previously unthought interpretations and contingencies foster border understandings, unrecognized possibilities, and the celebration of diverse and shifting identities.

When the term *critical* is used regarding scholarship, most scholars immediately think of the work in critical theory conducted at the Frankfurt School in Germany. Certainly, the neo Marxist work of Horkheimer, Adorno, and Marcuse while living in the US generated a site from which power could be explored while at the same time creating avenues for resistance, hope, and democratic possibility. However, a range of scholars who represent various power oriented traditions influence critical qualitative research. Continental theorists like Foucault and Derrida, Latino scholars like Friere and Fals Borda, and feminists like Kristeva and Irigaray would be included. Work in cultural studies and the various forms of tricontinental scholarship most often labeled postcolonial critique also represent perspectives that recognize power while avoiding its construction as a new truth. Perhaps more importantly, no theoretical view is treated as pure; each is increasingly emergent and hybrid. Feminism has reconceptualized cultural studies – poststructuralism and feminism have reconceptualized critical theory – postcolonialism has reconceptualized poststructuralism, and on and on. Critical qualitative research uses these hybrid constructions and even combines and revises them as needed to address particular social questions and problems.

Critical qualitative research methods of data collection and analyses include the range of qualitative techniques such as ethnographic interviews, participant observation, focus group

discussions, and document analyses that can be structured or emergent as needed. However, power oriented theoretical perspectives have made possible an expanded group of methods that include archeology, genealogy, deconstruction, and juxtaposition. As researchers attempt to gather data that would address issues like the construction of dominant discourses/knowledges, regulations/rules regarding who is authorized to speak, and the ways that subjects are constructed and positioned, new methods are often needed, chosen, and even designed. For example, a researcher may find, upon attempting to determine the impact of welfare reform on individuals, that money has been redeployed away from welfare services to programs that attempt to promote heterosexual marriage for the poor; the study, although begun using predominantly ethnographic interviews, may be revised to collect quantitative data as to the location and use of allocated funds in various state government locations. Finally, even though critical qualitative research methods appear to privilege language and various forms of discourse analyses (in a broad sense), the methodologies are not considered bounded by such perspectives and are open to emergent designs and diverse data orientations.

Depending on the actual theory/practice used in the particular research, critical qualitative scholarship has faced a range of criticisms. As examples, work with poststructural leanings tends to appear rationalist and “stereotypically” masculine; scholarship that uses postcolonial critique is judged as reinscribing power within the academic community; as discussed previously, the research faces the same criticisms leveled at qualitative research in general as being without rigor or objectivity. However, if the underlying assumptions of critical qualitative research are consciously placed at the forefront – especially the recognition that research is conceptually a power oriented construct or that theories can be used to reconceptualize each other but do not create new truths – then the criticisms become strengths.

EMERGENT, ACTIVIST ORIENTATIONS

Criticalist research is not simply hybrid and emergent, but, perhaps most importantly,

strives for actions that would increase the possibilities for social justice oriented societal transformation. The research questions that are implied are especially useful contemporarily when qualitative paradigms that challenge dominant truth orientations are coming under fire. Further, the discourse of research is currently being used to reinforce dualistic thinking that legitimates power for some and discredits and labels others as immoral, evil, not patriotic, socialist, or incompetent. Words like *accountability*, *profits*, *experimental or clinical trials*, and *evidenced based* are being used. Critical qualitative research demonstrates that research is never apolitical, is always complex and even ambiguous, requiring a critique of the underlying assumptions. In this contemporary postmodern time, critical qualitative research generates questions such as:

- How are children being “used” to perpetuate specific political agendas? How are they helped and harmed through such discourses?
- What is hidden or ignored related to the implementation of research results (e.g., in the field of education) in the contemporary labeling of decades of scholarship as “poor quality”?

The most activist possibility for critical qualitative research is to contribute to a critical social science that constructs public imaginaries (and continuous discussions) that embrace the complexities and ambiguities of research, yet at the same time recognizes its usefulness. These public discourses would place resistance to research at the center even as research is conducted to address contemporary societal problems; construct research collaborations with the public while at the same time avoiding the denial of difference; explore ways to challenge our positions of privilege (including those of researchers); question “knowing” as the very purpose of research; challenge public discourses that privilege forms of legitimation that reinscribe oppressive power(s); reconceptualize forms of representation that avoid oppressive results and interpretations; construct a critical public research dialogue; and create nonimpositional forms of critical transformative actions.

critical realism

Jamie Morgan

Critical realism in its contemporary usage emerged out of debates in the philosophy of science in the 1970s (e.g., Harré & Madden 1975; Bhaskar 1997). It focused on what could be argued from the relative success of laboratory experiment to create artificial closed systems where causal relationships could be isolated and explored. It was argued that such closed systems of regular causal relations were rare outside the laboratory and that non social reality consisted of complex and stratified structures in open or variable and changing systems. The purpose of natural science method was to explain the powers of these structures as tendencies to act in particular ways. Because, in the ordinary course of things, regular outcomes

were rare outside the laboratory it was then inferred that reality could be analytically distinguished into structures, the outcome of their complex interplay, and human experience, perception, or interpretation of those outcomes. It was then argued that this distinction could make sense of the difference between theory and the rest of reality in quite a different way than the philosophies of idealism or materialist empiricism (Morgan 2006). Idealism argues that reality is mind dependent, while materialist empiricism argues that reality consists of a series of external objects of sense perception that are the basis of causal laws. Critical realism argued that neither actually accounts for natural science method. Idealism could not account for how laboratory experiment, methods, and theories could also fail as well as succeed. Empiricism could not account for why laboratory experiment was necessary at all if reality could be reduced to sense perception of causal regularities. Accordingly, it was argued that reality was mind practice affected in a continuing interplay of theoretical research programs of *depth reality*. This approach, as part of a broader movement termed scientific naturalism, had major implications in the philosophy of science in terms of mediating between the important insights of different responses to the failure of logical empiricism and positivism, particularly by acknowledging Kuhn and Lakatos's focus on the sociological conditions of scientific method and theoretical development (Sayer 1992).

At first sight critical realism does not seem particularly relevant to social science. However, it has been a growing influence within social theory and sociology, especially in the UK and Scandinavia, but also in the US via the *Journal for the Theory of Social Behavior*, initially for two reasons. First, it provides a philosophical argument for why positivism may be inappropriate as an account and method within natural science and, as such, undermines the universal science project that underpins the application of positivism to social science, especially the mathematical aspects of economics and behavioristic sociology which rely heavily on statistical methods, prediction, and closed system modeling. Second, it provides an alternative to forms of strong relativism in some

kinds of constructivism and postmodernist social theory that also reject positivism in social theory. The basis of this alternative was to adapt the natural science depth realist argument to societies. The conceptual problem was that humans, unlike electrons, think. The complexity and variability of society could not therefore be of the same kind as the rest of reality because change clearly has a different significance for a critical language using entity than it does for a weather system. The methodological problem was that there is also no obvious analogue to the laboratory on which to base any argument. The critical realist solution that developed through the early 1980s (Bhaskar 1998) was to revive the agency structure debate. Others, particularly Anthony Giddens, W. G. Runciman, Charles Tilly, and Pierre Bourdieu, were also pursuing this line of inquiry.

Both Giddens and Bhaskar explore and reject theories of methodological individualism and structuralism. Methodological individualism is rejected on the basis that although human action is central to social reality there are problems with reducing that reality solely to the beliefs and actions of the individual because it then becomes impossible to account for where beliefs come from, how actions and their goals are constrained, enabled, and conditioned, how goals sometimes fail, and why there may be unintended consequences (for the actor and for society at large) from the action, or lack thereof. Structuralism is rejected on the basis that although it is plausible to argue that every action must have a condition, it is implausible to translate that condition into a strong sense of conditioning because if structure is deterministic there is no sense that things can be otherwise and the characteristics of a critical language using entity are lost. The solution favored was to argue for a kind of analytical dualism where agency and structure are distinct but mutually dependent. Put another way, structure is the ever present condition and continuous outcome of human activity and, though human activity is conditioned by structures, no individual's activity is simply the interplay of structural forces. Giddens refers to this as structuration and Bhaskar as the transformational model of social activity. For Bhaskar and for critical realists, structures are real, with

real causal powers. However, those powers are practically and conceptually dependent in a different way than is the case for the objects of natural science. Most importantly, they are powers in the sense that they provide a relational authority and rules for particular actions for individuals, which also set in motion consequences and outcomes for those individuals and others. A banking system exists only insofar as there is a concept of banking and a practice of banking within a society. The act of banking reproduces the banking system, the act relies on a relation and its characteristics (one's status as a customer with a given credit rating, etc.) but is personalized by individual goals (applying for a mortgage to buy a particular house), and is also depersonalized in terms of indiscriminate effects for the individual (changes in the recycling of the dollar by China can affect the availability and interest rates for mortgages in the US).

What critical realists generally take from the agency structure problem is that a form of depth realism does apply to society. Society is a relatively enduring set of structures in complex stratified relations that are continually reproduced, inadvertently changed, and sometimes consciously and critically appraised and transformed by the humans whose activity sustains them. The powers and characteristics of structures and agents provide the background to each interaction of agents and structures from which particular events arise that cannot be reduced solely to how the agent perceives or experiences that event or interaction. Methodologically, in the absence of any analogue to the laboratory, social science can investigate the characteristics of structures and the effects on the socialization of agents to explore tendencies in the possibilities of action. As such the sociologist might focus on the interpretations of the individuals and thus seek to understand their motives and goals in a personal way, but can also link this to broader themes of how they fit into tendencies to act and provide explanations of that in terms of relatively enduring structures. Critical realism therefore accepts that the traditional explaining–understanding distinction refers to different methods, but rejects that the former is applicable to nature and the latter to society (Sayer 1992). As such, critical realism is a form of philosophical naturalism.

By the mid 1990s critical realism had become a vibrant multidisciplinary research community in the social sciences. At least three main strands of debate have emerged as significant to sociology and social theory. First, concerning the degree to which sociology does or does not benefit from or even require basic philosophical argument about the metaphysics of social reality and its significance for social science (Callinicos 2004), arguments vary from discussions of the applicability of naturalism to social science to debates concerning the relative merits of different meta theories, such as pragmatism versus realism (Kivinen & Piironen 2004), Marxism and critical realism (Brown et al. 2002), and – particularly in terms of later systematic developments by Bhaskar (1993) – to debates concerning the degree to which one can make substantive philosophical claims about reality and what this means for the appropriate relationship between science and social theory and philosophy (Morgan 2004). Second, there is a broad debate between realists on what kinds of research methods are compatible with social science (Carter & New 2005). Since critical realism rejects theorizations of society that are based on closed system assumptions, it also rejects research approaches that model or seek to do no more than identify particular regular relations between variables as accounts of events (e.g., age and suicide). This raises the issue of what value there might be in particular tools or methods such as analytical statistics. Critical realists tend to be split over this issue (Olsen & Morgan 2005). Third, there is a continuing debate focused on the agency structure problem itself. Margaret Archer has been the prime mover within critical realism in developing a distinctive approach to the agency structure problem. Her particular contribution has been a close critique of Giddens, arguing that his form of dualism collapses agency and structure together and that it is more plausible to separate them out on the temporal basis that structure always precedes an act of agency (Archer 1995). If one does not maintain this distinction it not only becomes impossible to explore the way in which agency uses and elaborates upon structures, but it also becomes impossible to differentiate how the agent is more than simply a product of and reducible to structures (Archer 2000, 2003).

Stones (2005) has replied directly to this critique, defending structuration on the basis that it is compatible with the "objectivity" of structure.

Others have contributed different lines of development and critique of the concept of structure in particular. Porpora (1998) defends an account of structure as systems of human relations among social positions. The philosopher Rom Harré, an early progenitor of what has become critical realism, has developed a critique of causal powers inherent in structures on the basis that only agents have particular powers to act (Valera and Harré 1996). Lewis (2000), following Porpora, has responded by differentiating the concept along Aristotelian lines. Structures may be material causes in the sense that they are the materials from which events are brought about, but are not themselves the means by which, or efficient causes by which, events are brought about. Finally, the social philosopher Ruth Groff (2004) has developed this position in terms of the overall coherence of the metaphysics of critical realist argument. The work of all these academics points to the current diversity of opinion and positions within and regarding critical realism.

critical theory/Frankfurt School

Lauren Langman

Critical theory, the legacy of the Institute for Social Research at the University of Frankfurt, is rooted in the philosophies of Kant and Hegel, and in Marx's critique of capitalism which claimed that it exploited and alienated workers, while its ideologies of reason, freedom, and

democracy disguised its actual operations. "Critical theorists" integrated Weber's notions of rationality and Freud's theories of character and desire into a theory of capitalism and its culture. They looked at sociology, political science, philosophy, art, literature, and cultural studies, including film theory and popular culture, to fashion a multidisciplinary, multidimensional, dialectical social theory largely concerned with the alienation, domination, and commodification and dehumanization in modern societies (Kellner 1989). Critical theory thus embraced the notion of *totality*: society was an outcome of a number of not always harmonious parts and levels; contradictions and tensions are seen as inherent. It is *critical* in the sense of critique as explicating what is not empirically given but apprehended through critical reason. Thus, unlike most social theories, it is very concerned with epistemology. Nor does it attempt "objectivity" because this is assumed both to promote and to hide domination. Rather, as an *emancipatory theory*, it seeks to foster the freedom, equality, and fraternity promised by the Enlightenment thinkers, these qualities being incompatible with late capitalism and hence undercut by technological logic, consumerism, and mass culture. It promotes a society where people may create democratic communities and realize their creative, unique human potentials.

To comprehend the rise of critical theory we need to consider at least two factors: the then state of Marxist theory and the social conditions of Germany following World War I. Marxist theory, as embraced by the Communist International, had become an "official orthodoxy" of economically determined laws of history as the progression of class conflict. But many academics, loyal to Marx's visions, such as Korsch and Lukács, began to reexamine consciousness and ideology after capitalist societies had entered a new phase with major economic, social, and technological changes. Finance had become as important as manufacturing and sales, while the welfare state and Keynesian economics were embraced. Nationalism had become a major social force and consumerism was beginning to grow. New and unprecedented technologies of mass production, rapid transportation, electronic communication, and even

warfare had transformed the early twentieth century. Yet while they focused on culture and ideology, they maintained the Marxian notion of immanent critique of capitalism, its alienation and reification, its mode of producing value through exploitation, and ideologies that disguised its actual operations.

World War I was an industrial war in which modern weapons such as battleships, machine guns, tanks, and even planes led to millions of deaths. Empires had fallen. The progressive Weimar government of post war Germany was relatively weak and little able to both forge a new democratic society and at the same time pay huge reparations imposed by the Versailles Treaty. The mood of the times, its angst and ennui, was captured in the existential philosophy of Heidegger, the novels of Kafka and Mann, the art of Grosz, and the music of Schoenberg. But these same conditions fostered the rise of fascism.

It was in this context that a uniquely talented collection of scholars came together in the mid 1920s to establish the Institute for Social Research, loosely affiliated with the University of Frankfurt. The best known of these men, whose work is influential to this day, were the philosophers Horkheimer, Adorno, and Marcuse, and sociologist turned psychoanalyst Erich Fromm. The goal of the group was to retain Hegel's notion of the movement and promise of reason, to rethink the Marxian critique of capital and the categories of its analyses in view of the social and technological changes of the age, and to develop an interdisciplinary theory that would go beyond the boundaries of economics, philosophy, sociology, and even psychoanalysis.

Their first task was to revive the tradition of Kant's critiques of reason as actively engaging and constructing the world. But with Hegel, they agreed that reason was historically determined, yet that unfolding of history promised human freedom and joyous consciousness. Weber, however, argued that rationality, i.e., *instrumental reason*, led to capitalist prosperity and technologies of domination over nature. Yet that same logic dehumanized people and led to their entrapment into "iron cages."

Inspired by the discovery of Marx's writings on alienation and Lukács's analysis of the reification of consciousness, the critical theorists

looked at the consequences of various epistemologies. More specifically, the logic of the physical sciences, when applied to the human sciences, served the goals of domination by reducing people to objects or reified entities, much as did capitalism. The logic of scientific objectivity and rationality fostered passivity and sustained the domination of capital. When Erich Fromm introduced Freud to the group, depth psychology – specifically, the theory of the superego as internalized authority – became part of a larger critique of domination.

In Germany in the 1920s, given a worldwide depression and growing unemployment, there were frequent conflicts between the left and right, and often bloody fights in the streets. In 1933, aided by the votes of many workers, the Nazi Party gained political power. The world would soon face the most massive war and unprecedented genocide in its history. In this latter context, the Frankfurt School began to investigate how and why such atavistic barbarism could surface in what had been one of the most culturally advanced societies in the world. They soon began a large scale study of the patterns of authority found in the families of modern society. This research revealed how a certain character type – the sadomasochistic authoritarian – when beset by economic hardships and social uncertainty, was disposed to follow a powerful leader who would forge new kinds of communities, promise a restoration of a former greatness that would provide the people with pride and dignity. Meanwhile, there were scapegoats to blame for adversity. The Jews had long served that role. The appeal of fascism and reception to its propaganda depended on (1) the psychological gratifications it gave to the individual; (2) a reactionary ideology that provided meaning in an increasingly heartless world; and (3) rituals and social organizations that offered a sense of community. Moreover, the Nazis brilliantly refined and exploited the new mass media, film and radio, for the purposes of propaganda and mobilizing an entire population, and the ruling classes supported Hitler as the bulwark against Bolshevism.

Fearing Hitler, the Frankfurt scholars moved to France and eventually the United States. After the war, Horkheimer and Adorno returned while Marcuse and Fromm chose to

remain. By then Fromm had both drifted away and faced exclusion. Nevertheless, the basic insights of the earlier period were developed and refined, as in large scale studies of authoritarianism in the US (Adorno et al. 1950). Following the concern with fascist political propaganda, they noted how the “culture industry” – the producers of books, films, music, and television, including advertising the “good life” – served political functions by fostering deception and escapism, paving the way for celebrity politicians like Reagan or Schwarzenegger.

During the 1960s, between a protest movement against the war in Vietnam and a growing counterculture that comprised the vanguard of the sexual revolution, Marcuse became a folk hero to progressive youth involved in what was called the “movement.” Marcuse’s trenchant *One Dimensional Man* (1964) argued that “one dimensional, rational thought” sustained an “administered society” while the mass media inculcated “false needs” that were gratified in consumer behavior that integrated the person into the society, yet coopted his or her agency to erode the possibilities that critical thought and resistance would overcome the status quo. Although capitalism had once required “surplus repression” of desire, with affluence and consumerism, “repressive desublimation” (sexual freedom) made people feel free while being entrapped.

Critical theory diverged from orthodox Marxism by not regarding class conflict as the basis of social change. The working classes, coopted by bourgeois ideologies and enthralled by consumer goods, were no longer seen as the agents of progressive social change. Finally, socialist revolution was not seen as inevitable nor even desirable, given the despotism and gulags of the USSR. Theorists eventually became pessimistic about the possibilities of progressive social transformation. Many ultimately retreated to the high culture of the educated German bourgeoisie where they found freedom in aesthetics as a realm still free of commodification.

By the late 1960s, a new generation of critical theorists had emerged. Jürgen Habermas (1984) often is considered the most important philosopher of the late twentieth century. His critical social theory attempted to incorporate

Weberian rationality, Schutz's concern with life world, Parsons's structural functionalism, and Mead's symbolic interactionism. In his attempt to resurrect the "uncompleted project of modernity," Habermas was concerned with the nature of communication, about which Marx said little. He showed how the rise of print media enabled a bourgeois "public sphere" where people could debate and argue various truth claims to arrive at certain social understandings and eventually overthrow monarchies. But eventually, in view of media commercialization, the critical aspects of media would wane. In his work on epistemology, he clearly differentiated rational/technical interests in *controlling* the world, practical/hermeneutic interests in *understanding* the world and other people, and emancipatory/critical interests in *overcoming domination*. He would later argue that the colonization of the life world – the realm of practical interests taken over by rational technical interests – secured domination through both passivity and marginalizing alternative forms of the social as "unpractical." His work also examined the nature of crises, student protest in the 1960s, and so on. Much like his teachers, there was little interest in the worker, perhaps because workers had become part of the forces conserving and protecting the society.

In his best known and most debated work, Habermas (1984) argued that communication was not well analyzed by Marx. Building upon ordinary language philosophy (Searle, Austin) and the developmental theory of Piaget and Kohlberg, he argues that speech acts have a goal of mutual understanding. But for various reasons, with the evolution of modernity, instrumental rationality has come to dominate all spheres of life, leading to distorted communication. Rejecting the Freudian theories of character, desire, and repression, but following Freud's model of therapeutic interpretation and understanding, he has argued that capitalist markets, the modern state, and bureaucratic organizations embracing instrumental reason and technological thought colonize the life world and attenuate communicative competence. His more recent work has become concerned with questions of justice and constitutionalism.

Today we might note what has been considered a third generation of critical theorists. Scholars such as Douglas Kellner, Andrew

Feenberg, and Timothy Luke have been at the forefront of the critiques of technology as having both liberating and dominating moments. Kellner, attempting to incorporate certain aspects of postmodernism, has written a number of scathing critiques of media and popular culture/current events including the first Gulf War, the O. J. Simpson trial, the theft of the 2000 US presidential election, and the corruption of the Bush dynasty. We might also note the work of Axel Honneth, who has been concerned with the need for recognition often lacking today, and Nancy Fraser's critiques of the meanings of "needs."

Other critical theory scholars worth noting might include Moishe Postone, who has rekindled the concerns with Marx's value theory, Harry Dahms, who has been rethinking alienation and globalization, Robert Antonio, who has been interested in globalization, David Smith, who has noted relations of current authoritarianism and genocide, and Lauren Langman, for whom psychoanalysis still provides trenchant insights into such diverse realms as consumerism, nationalism, Islamic fundamentalism, aspects of popular culture, and the alternative globalization movements. Moreover, there has been a resurgence of interest in some of the other Frankfurt School scholars such as Benjamin and Bloch.

To illustrate the value of critical theory for today, recall the central question of why German workers were attracted to Hitler and fascism, which proved to be contrary not only to their class interests but also to their very lives. Moreover, how could they commit the barbarities of the camps and "willingly" execute Jews? Many contemporary critical theorists can remember when the US was fighting an imperialist war against communism in Vietnam. Incidents such as My Lai or Operation Phoenix sanctioned the torture and deaths of many peasants. The hatred and dehumanization of the Vietnamese enemy "Other," much like the Nazis toward the Jews, could easily sanction torture, rape, and murder on a large scale.

Many blue collar voters supported that war and voted for Nixon, who continued a failed policy. More recently, workers gave G. W. Bush their votes and early support for the premeditated invasion of Iraq. Why do people support the policies of such leaders? Critical

theory suggests at least two reasons. First, the ideologies that shape consciousness emanating from the “culture industry,” from Rambo movies in the 1980s to Fox News of today, much like the propaganda of the Nazis, present damning worldviews, values, and depictions of Others that are not subjected to critical reason and democratic debate. Moreover, the conservative Christian segments of society see geopolitics in terms of a good Us and evil Others. Second, there is a large number of authoritarian personalities with sadomasochistic tendencies who, in face of economic threats, seek a strong, powerful, tough “father figure” who will use violence to protect his frightened followers. Given the anxieties and uncertainties of job security in these days of globalization, automation, and outsourcing, such men, and now even women, support “tough guys” or “strong men.”

Critical theory can be considered a product of capitalist domination that inspires intellectual, social, and political critique. Critical theory, with its multidisciplinary, dialectical analysis and critique of advanced capitalist society, its shallow consumerism and its suppression of human freedom, is not, nor can it really be, one of the dominant schools of social thought. But at the same time, the power of its logic, its capacities to reveal and clarify what might otherwise be obscured, mean that it will remain an enduring part of social theory and retain an influence that extends far and wide, even to those who would question its premises and conclusions. As long as social systems breed alienation, oppression, and domination, critical theory will seek to understand and to alleviate these problems.

cross-sex friendship

Michael Monsour

Friendships between males and females, here after referred to as cross sex friendships, are non romantic (but not necessarily non sexual), voluntary, non familial relationships in which both individuals label their association as a friendship. The distinguishing characteristic of a cross sex friendship is that the friends are of different biological sexes. Similar to other kinds of friendships, such as same sex friendships, interracial friendships, and friendships of sexual minorities, cross sex friendships are characterized by generic benefits in the form of mutual trust, loyalty, fun, enjoyment, and social support which manifests itself as aid, affect, and affirmation. From a symbolic interactionist perspective, however, cross sex friends also offer one another the unique benefit of providing an insider's perspective on how members of the other sex think, feel, and behave. The bestowing of insider perspectives between cross sex friends enables males and females of all ages to take the role of the other sex, thereby increasing their understanding of their friend and the gender their friend represents.

Cross sex friendships have a protean nature, meaning that their form and function change as they appear in different stages of the life cycle. Consequently, a thorough understanding of cross sex friendships requires taking a

life cycle approach to those relationships. A life cycle approach focuses on how cross sex friendship experiences in earlier stages of life influence cross sex friendship experiences in subsequent stages of life. Those experiences encompass everything from the micro level for maturation of cross sex friendship schemas and communicative practices to macro level societal and group norms concerning the appropriateness of such relationships and how they should be initiated and maintained. The transition from one stage of life to another is often marked by dramatic events and processes such as puberty, getting married or staying single, divorce, having children, entering the work place, and retirement. These transitional events and processes have an impact on how cross sex friendships are initiated, maintained, and some times discontinued.

Friendship historians agree that cross sex friendships were exceedingly rare in the United States until the 1970s. Scholarly analysis of the friendships between men and women can be traced back to 1974, with the publication of the landmark article "Cross Sex Friendship" by Booth and Hess in the *Journal of Marriage and the Family*. There has been a steady increase in the number of published investigations of cross sex friendships since 1974, but the numbers pale in comparison to the research conducted on same sex friendships and other sex romantic relationships. Researchers investigating cross sex friendships use a fairly wide range of methodological tools and strategies. The most common of these methods are surveys, observational analysis (most often of children in day care centers, preschool, and elementary school), and qualitative interviewing. With a few exceptions in which investigators observe children over the course of three or four months, there has been very little longitudinal research (but see Griffin & Sparks 1990).

Investigations of cross sex friendships have uncovered important findings when viewed from a life cycle perspective. Two significant life cycle milestones to recognize and study are when individuals have their first opportunity to mingle with members of the other sex (typically a family member), though they do not realize they are doing so, and when they have their first opportunity to interact with members of

the other sex and know that they are doing so. Life cycle experts generally agree that children are able to differentiate between the sexes around the age of 2 or 3 years. At that point, developing gender schemas guide how they think and behave in reference to members of the other sex (Martin 1994). Research has established that some 1 year olds form cross sex friendships (Howes 1996), though a more typical developmental age for those friendships is 3 or 4 years when the word "friend" actually becomes part of their working vocabulary (Bukowski et al. 1996). Cross sex friendships between toddlers and preschoolers are not the same as cross sex friendships in middle school, where participants have entered puberty and are contending with sexual identity issues and societal messages about appropriate gender behavior. Adolescent friendships between heterosexual boys and girls are quite different than the ones formed in earlier life because puberty introduces romantic and sexual tensions. Those friendships are also invariably affected by social network factors such as clique and crowd formations. Friendships in young and middle adulthood are similarly beset by romantic and sexual challenges. If an individual gets married and has children, his or her cross sex friendships change in that married individuals tend to form couple friendships with other married individuals rather than pursuing individual friendships with members of the other sex. Cross sex friendships of older Americans are affected by factors not as salient as they were in earlier stages of the life cycle, e.g., mobility, health issues, and the death of a spouse (Adams & Blieszner 1989). Despite the differences in cross sex friendships in stages of the life cycle, there are also similarities in that in each stage of life, cross sex friends support one another and enjoy each other's company.

From a structural perspective, there are a number of social and structural facilitators and barriers to cross sex friendship. The most obvious structural barriers to cross sex friendships are sex segregation in schools and many work environments, social network structures in elementary and middle school such as crowd and clique affiliations, and mobility issues in old age. There are also, however, structural facilitators of cross sex friendship formation.

Just as the workplace and school settings can inhibit the formation of cross sex friendships, they can also encourage and even require cross sex interaction, which creates the potential for friendships to develop. Structural facilitators and barriers to cross sex friendships are interrelated and must be studied as such. Researchers need to examine as many structural characteristics as methodologically possible if they want to understand the structural inhibitors and accentuators of cross sex friendship.

In every stage of the life cycle, social barriers to the initiation and maintenance of cross sex friendships originate from third parties or the cross sex friends themselves. Most commonly, social barriers are obstacles created by individuals in a person's social network that discourage the formation of friendships between men and women and boys and girls. Parents may discourage their elementary age children from having sleepovers that involve members of the other sex, even at the innocent age of 5 or 6. A man's or woman's jealousy over the cross sex friendship of their spouse or lover jeopardizes many cross sex friendships. The friends themselves may also present social barriers to their friendship, for example if one friend has a hidden agenda and secretly wants the relationship to be romantic in nature. Social barriers to cross sex friendship also reflect normative relational constraints, which are societal norms that place constraints on where, when, and how cross sex friendships may be initiated, developed, and maintained.

The significance of cross sex friendships to society and the individuals who constitute that society is largely unexplored terrain. An essay of this length cannot begin to cover the complexities of friendships between females and males. Indeed, even entire books are woefully inadequate. Unfortunately, cross sex friendships have been marginalized in the sense that relationship scholars pay them relatively little attention, and heterosexual laypersons often believe that the paradigmatic or ideal relationship between a male and a female should be a romantic one. Research has established one thing, however; males and females of all ages can be friends, and the benefits of those friendships are often qualitatively different than the

friendships formed between members of the same sex and even romantic relationships.

crowd behavior

Clark McPhail

Herbert Blumer was the most influential crowd sociologist of the twentieth century. To his credit, he recognized in mid career that "sociologists had done a rather miserable job in studying the crowd systematically because they had done little to assemble empirical accounts" (Blumer 1957). He attributed this to the lack of "a well thought out analytic scheme which would provide fruitful hypotheses and lead to more incisive observations." But systematic study of "the crowd" proves to be impossible precisely because that concept, despite considerable cachet, is not a useful tool for investigating the phenomenon to which it purportedly refers. "The crowd" implies a homogeneity of actors and motives and, consequently, continuous and mutually inclusive action. Scholars who have taken a slightly different tack have produced extensive empirical evidence that refutes both those implications and their consequences.

Over the past two decades sociologists working at different levels of analysis have adopted "the gathering" as a more neutral and useful concept for referring to a temporary collection of at least two persons in a common location in space and time without regard to their actions or motives. All temporary gatherings have a *life course* consisting of three phases. An assembling process forms the gathering by bringing two or more persons together in a common location. A dispersing process terminates the gathering by vacating that location. The gathering is a kaleidoscopic mix of elementary forms of collective action by two or more of its members alternating or concurrent with their various individual actions. These three phases of temporary gatherings are not independent, but do divide a hitherto complex phenomenon into more manageable pieces for research and lend themselves to different and appropriate research methods that have produced the evidence summarized here.

Temporary gatherings of human beings are ubiquitous. Multitudes, crowds, and mobs have preoccupied preachers, politicians, and police for centuries because of their concerns with

persuading, producing, or controlling the behavior of the members of such gatherings. Most scholarly concerns have been with political gatherings that challenge the status quo. Late nineteenth century and early twentieth century scholars were critical of those gatherings and the allegedly disreputable and irrational character of the actors and actions that composed them. Contemporary scholars have been more concerned with describing and explaining than with discrediting political gatherings. Many collective action scholars have systematically coded newspaper archives to create databases with which to plot the rise and fall in the frequency of protest events, campaigns, and waves as measures of the life course of social movements.

Other scholars have been more concerned with describing and explaining the actions that compose the political gatherings of which protest events, campaigns, and waves are composed (Wright 1978; McPhail & Wohlstein 1983). Some have extended those concerns to similarities and differences across prosaic, religious, sport, and political gatherings. While both description and explanation of these units of analysis are equally worthwhile, far more attention has been given to the latter than to the former. Consequently, explanations have often been advanced for phenomena that are rare if not apocryphal. It is useful to provide a broad description of the phenomena to be explained before briefly reviewing the relevance of existing explanations for collective phenomena.

Some temporary gatherings assemble periodically, ranging from national independence days and inaugurations to daily prosaic gatherings on street corners. Ad hoc gatherings are assembled non periodically but are announced and mobilized well in advance (e.g., sport events, political and religious rallies); still others assemble in impromptu fashion (e.g., at the scene of fires or auto accidents, or for upset victory celebrations). Extensive surveys of participants (and sometimes non participants) in political gatherings and riots, in religious rallies, periodic holiday celebrations, and sport victory celebrations establish three noteworthy facts. First, individual attributes and attitudes do not predict who will or will not participate. Second, participation is a function of (1) *solicitations*

from friends, family, or acquaintances with whom the solicited are connected in social networks (Oliver & Marwell 1992) and (2) the *availability* to assemble when and (3) *means of access* to where the gathering in question occurs (McPhail & Miller 1973). Third, most people assemble for most gatherings with one or more friends, family, or acquaintances, remain together, and eventually disperse with those companions. Thus, most gatherings are composed of some singles but predominantly of small groups of companions. Those companions act alone; they interact with one another; and they occasionally act together with other singles and small groups in more inclusive collective actions. This contributes to the dynamic mix of alternating and varied individual and collective actions across the duration of most temporary gatherings.

Efforts to characterize entire gatherings by one or another prevailing attribute (e.g., "active crowd" versus "expressive crowds") have not proved effective because entire gatherings are never exclusively one or the other. The emotional expressions of cheering and applauding in religious, sport, and political gatherings, or the weeping and wailing at religious funeral gatherings, are themselves expressive actions. But it is rare for any collective action (or expression) to include the entire gathering and when that occurs it is of brief duration.

McPhail (1991) defines collective action as any activity that two or more individuals take with or in relation to one another. He inductively generated a taxonomy of elementary forms of collective action from on site observation records of hundreds of prosaic, religious, sport, and political gatherings over a period of three decades. Schweingruber and McPhail (1999) reported that the most characteristic feature in a periodic political gathering was alternation between and variation in the proportion of people engaged in different elementary forms of collective action. McPhail et al. (2006) further documented that feature in a systematic quantitative description of the proportion of people participating in various "directions of facing," "body positions or movements," "types of voicing," and "types of manipulation" in a large religious gathering over the course of a 9 hour period. Their evidence further refuted the classic stereotype of

"the crowd's" continuous and uniform action throughout the rally phase of the gathering and provided new evidence on the distinctive "milling" phase that precedes (and often follows) religious, sport, and political rallies. This study also established several similarities in the elementary forms of collective action in this religious gathering (e.g., cheering and clapping) that have been reported in quantitative studies of sport and political gatherings.

It is not surprising that violence against person or property was not observed in this religious gathering, but it is important to note that violence is the exception rather than the rule in most gatherings. Extensive examination of videotape records of the 1990 Poll Tax Riot in London and the 1992 South Central Los Angeles riot indicates that there were far more onlookers than participants in violence, and the latter participated intermittently rather than continuously. This reflects at the micro level what is now well established in archival studies of thousands of political gatherings in Europe from 1830 to 1930 (Tilly et al. 1975) and in the US during the twentieth century Civil Rights Movement: violence against person or property occurred in less than 10 percent of those political gatherings.

Routine dispersals have rarely been investigated, although there are numerous opportunities to do so. Sport stadiums and arenas containing tens of thousands of spectators routinely empty in 10–15 minutes after the contests' conclusion. University lecture halls filled with hundreds of students are routinely vacated in 5 minutes after the scheduled end of the class period. Movie theaters offer another venue for investigation, as do periodic worship services of all faiths.

Coerced dispersals traditionally involved police or military agents of social control escalating the level of force necessary to compel gathering members to "cease, desist, and disperse." These actions stemmed from the agents' assumptions that "crowd" members were incapable of controlling themselves, derived in large measure from traditional sociological stereotypes of the crowd. More recently in democratic nations in Europe and North America, police agencies that routinely deal with political protest gatherings have gradually moved toward regulating dispersal by

negotiating in advance with protest organizers the time, place, and manner that political gatherings commence, continue, and conclude (Della Porta & Reiter 1998).

Emergency dispersal has been extensively investigated by students of disaster planning and management as well as by fire and safety engineers. The most consistent and important finding for students of temporary gatherings is that incapacitating fear and/or irrational actions (a.k.a. panic) are rare phenomena. Rather than losing control when faced with life threatening problems, most individuals are creative problem solvers. Research consistently establishes that individuals are more likely to act altruistically than egoistically to assess the welfare of their companions and to assist in their safe evacuation (e.g., Johnson et al. 1994).

The preceding describes some of the phenomena to be explained; viz., what people do collectively in the formation, development, and termination of temporary gatherings. Any general theory of collective action should address all three phases; the majority of extant collective action theories fail to do so. Transformation (a.k.a. contagion or deindividuation) theories offer no explanation for the formation of "the crowd." They claim that individuals within "the crowd" lose control of their cognitive processes, mindlessly comply with the suggestions of charismatic leaders, and unwittingly imitate the actions of those around them. One alleged consequence of this "deindividuation" is mutually inclusive collective behavior. The same irrational mindlessness allegedly produces "panic" in emergency dispersals. However, neither on site observation records nor ex post facto interviews of participants provides any support for either of those claims. There is no mutually inclusive behavior; there is no evidence of lost cognitive control. Further, Postmes and Spears's (1998) meta analysis of 60 experimental studies of the deindividuation phenomenon established no support for the claim of impaired cognitive processes. Finally, the absence of individual cognitive control postulated by these theories simply does not fit and cannot explain the dynamic alternation and variation in what individuals do alone and together over the course of most gatherings.

Predisposition (a.k.a. convergence) theories claim that crowds form because two or more

individuals with the same innate or acquired predispositions to behave – attitudes, personality types, and grievances – converge on the same location for the same reasons. The urban riots, civil rights, and anti war demonstrations of the 1960s provided repeated opportunities to empirically examine those claims and yielded virtually no support. The mutually inclusive behavior that should occur within a gathering after similarly predisposed persons have assembled does not occur. Finally, the theories based on similar predispositions cannot account for the alternating and varied individual and collective actions constituting the phenomena to be explained.

Emergent norm theories claim that mutually inclusive behavior is an illusion. Its adherents claim instead that crowds are composed of individuals with diverse predispositions that lead them to participate in different ways; this includes the interaction among individuals attempting to determine what they should do in ambiguous and uncertain situations. That interaction is said to yield an emergent norm that constrains most people to behave collectively consistent with that norm and that restrains others from behaving inconsistently. Some critics charge that emergent norm theories imply compromised or crippled cognitive processes under the conditions of ambiguity and uncertainty. Without question, interaction among companions in the situation is the source of some decisions about what to do with or in relation to one another; however, all collective action in all gatherings does not stem from such interaction. Some derives from repertoires shared by many if not most members of a gathering enabling them to independently generate collective action (e.g., cheering or applause) without consultation with companions or solicitation from a third party; and, other collective action (e.g., civil disobedience) is planned and rehearsed well in advance of the gathering in which it is launched.

Rational choice theories acknowledge diversity in the phenomena to be explained. They recognize the influence of interaction upon individuals while deciding the costs and benefits of alternative courses of collective action. Rational choice theories are a step in the right direction because they place individuals in control of their own behavior. However, they are

flawed in several ways: they do not explain how alternative courses of action are initially formulated; they offer but one criterion – the mini max calculus – in terms of which a course of action is selected; they fail to accommodate errors and unanticipated consequences and the necessary adjustments required in the face of such negative feedback; and, last but not least, they fail to embody the behavioral choice that was rationally made. In short, they do not connect cognition to action.

Complexity and control systems theories begin with the recognition that the phenomena to be explained are variable and dynamic. These theories argue that the varied and dynamic yet coordinated actions to be explained can only be understood by assuming that the individual actors who participate in those actions are autonomous, heuristic, interdependent, and adaptive agents. McPhail et al. (2006) use a negative feedback, control system model of such actors to make sense of the three most common ways in which collective action has been observed to develop in many gatherings. These purposive actors adjust their actions in order to realize their goals or to display their approval (or disapproval) of others or their own words and deeds that realize or are consistent with those goals. Collective action by two or more individuals requires similar goals; these can be established independently, interdependently, or by adopting them from a third party. Thus, some collective actions (e.g., *cheering* and *applause* and the alternation between *sitting* and *standing*) were independently generated by the actors without consulting their companions or third party solicitation. Other collective actions (e.g., *conversing within convergent facing clusters* and *milling pedestrian clusters* in the pre rally and post rally period) were interdependently generated within the small companion groups that assembled, remained, and dispersed together in this as in most temporary gatherings. Still other collective actions (e.g., the distinctive prayer prostrations and huddles during the religious rally) resulted from voluntary compliance with the solicitations of a third party. That compliance was not collectively mindless obedience to the suggestions of charismatic speakers as hypothesized by traditional explanations because the observed proportion complying never approached unanimity.

Thus, complexity explanations recognize that some collective actions result from autonomous, self directing actors who can independently generate and pursue similar goals and independently participate in collective evaluations of the outcomes. Most of these actors are also embedded in small groups of companions who can interdependently generate their own goals, interdependently pursue their own collective actions, and evaluate the outcomes. Intermittently, these same individuals, acting alone or in consultation with their companions, can adopt the goals proposed by third parties, resulting in still other forms of collective actions by larger proportions of the gathering. These three means of generating collective action can occur separately at different times or concurrently in different sections of large gatherings. This may explain why the kaleidoscopic collective actions that occur across the duration of temporary gatherings are purposive but are neither mutually inclusive nor continuous.

cults: social psychological aspects

Gary Shepherd

The term cult has become, since the latter part of the twentieth century, one of the most controversial concepts in the social sciences. The term was originally employed by scholars of religion to signify a system of activities centering on an object of worship, but the concept has been gradually changed by sociologists to identify a particular residual type of religious group that fell outside the boundaries of recognized religious organization. Subsequently, scholarly attempts to redefine or specify the dimensions and implications of cult groups have proliferated, while at the same time the term cult has been appropriated for polemical purposes by opponents of unconventional religious organizations who characterize such organizations under the cult label as dangerous to both individuals and the larger society. The mass media in modern nations have largely adopted and disseminated these morally charged, negative definitions, and thus pejorative notions of the term cult and of the many

groups to which it is uncritically attached have become virtually universal among the general public. Many scholars of contemporary religions, especially sociologists, have now chosen to drop the term cult as a descriptor of a type of religious group, concluding that it is a conceptually polluted concept, and replaced it with a morally neutral term, such as new religious movement or alternative religious group. Others have argued that the term cult has a scientifically useful conceptual function and should be retained even though there is not yet a social science consensus on its essential definitional characteristics.

Both Durkheim, in *The Elementary Forms of Religious Life* (1915), and Weber, in *The Sociology of Religion* (1922), employed a classical conception of cult as designating a ritual system of worship activities. Durkheim focused attention on what he saw as the essential function of cultic activity within a community, namely to periodically renew, through participation in sacred rites, a collective sense of social unity and moral force around a set of shared values that constitute the community itself. Weber emphasized the rationalizing tendencies of cultic organization over time, particularly through the emergence of priestly roles to articulate, elaborate, coordinate, officiate, defend, propagate, and otherwise administer the system of religious practices and doctrines centered on the worship of a god or gods or other supernatural entities.

The rationalizing tendencies of religious organization noted by Weber were further elaborated by Ernst Troeltsch's attempt to specify the characteristics of Weber's two types of religious community organization: the church (a socially inclusive, less restrictive membership group embracing and embraced by the larger society) and the sect (an exclusive, particularistic, and restrictive membership group that by its strict requirements sets itself apart from and at odds with both the parent religious body and the larger society). In *The Social Teachings of the Christian Churches* (1931) Troeltsch placed the categories of Christian sects and churches along a dynamic, cyclical continuum in which sects were seen as typically breaking away from established churches to reclaim a perceived lost purity of belief or practice, only to gradually accommodate worldly pressures in

order to flourish, thereby acquiring church like characteristics that in turn generate a new schismatic cycle. He recognized, however, that even within Christianity not all organized religious expressions fit comfortably within the church-sect continuum, notably religious associations that give priority emphasis to achieving personal, non rational experiences. Troeltsch assigned such expressions to a residual category called mysticism, which was conceptually only vaguely connected to the church-sect continuum.

Howard Becker, in *Systematic Sociology* (1932), exchanged the term cult for mysticism, resulting in an influential shift in the sociological designation of cult as a particular type of religious group rather than referring only to the structuring of worship activities within all religions. Becker's definition of a cult included the characteristics of loosely structured, non demanding, non exclusive, and transient associations between individuals in urban settings who share interest in a limited set of esoteric spiritual beliefs typically propounded by a charismatic but not necessarily authoritarian teacher leader. Variations on the defining characteristics of cults as a type of religious group have subsequently proliferated. The greatest stimulus to reconceptualization and study of groups identified as cults occurred in the mid 1960s through mid 1970s as a consequence of certain elements within the hippie oriented youth counterculture (e.g., the Jesus Movement, the New Age Movement, the Communitarian Movement, etc.) and especially the increasing visibility and proselytizing activities of foreign and non Christian religious groups within western nations generally and the US in particular (e.g., the Unification Church, or "Moonies," the Divine Light Mission, the International Society for Krishna Consciousness, or "Hare Krishnas," etc.).

Although some sociologists argued that these contemporary, radically different groups were best seen as extreme variations of religious sects, most concluded that it was useful to expand the cult concept in a way that would account for more dynamic, structured, innovative, and purposive new religious movements that seemed to be more than just dissenting splinter groups from an already established religious tradition. Both Geoffrey Nelson's

Sociological Review article on "The Concept of Cult" (1968) and Milton Yinger's *The Scientific Study of Religion* (1970) emphasized the radical break from established religious worldviews characteristic of cults and the potential for cult groups to grow, increase their organizational complexity, and elaborate their own coherent, innovative worldview. From such developments over time, new religious traditions are formed that may, depending on a complex of social and historical conditions (and parallel to the institutional path of some sects), even ascend to the status of institutionalized "church" in the Weberian sense.

This line of thinking on cults was most clearly extended and articulated by Rodney Stark and William Bainbridge in their article "Of Churches, Sects, and Cults: Preliminary Concepts for a Theory of Religious Movements" (1979) and in their more comprehensive book, *The Future of Religion: Secularization, Renewal, and Cult Formation* (1985). Stark and Bainbridge distinguish cults as religious novelties that are not the product of schism from the established religions within a particular host society. Cults may originate in one of two ways: either from borrowing or "importing" their essential elements from an alien cultural tradition (i.e., from outside of the host society), or through the religious innovations of charismatic leaders who assert a new order of belief and practice that is substantially independent of established religious traditions. An example of the former would be the International Society of Krishna Consciousness (the "Hare Krishnas") in America (but not in India, where ISKON would be a sect of Hinduism); an example of the latter would be primitive Christianity in ancient Judea and adjacent areas of the Roman Empire. A contemporary cult may be present itself as the kind of amorphous, esoteric, and low commitment social enterprise identified by Becker in either of the two forms. The first form, according to Stark and Bainbridge, is the audience cult – a mystical or spiritually centered set of topics and ideas that are promoted through various media means. Adherents or advocates of these ideas are fundamentally consumers of the occult rather than members of a concrete religious organization. The second form is the client cult, which revolves around a kind of patient-therapist relationship in which

adherents seek personal assistance, guidance, or reassurance (psychological, physical, or spiritual) directly from agents who claim access to various supernatural powers. Neither of these forms creates a strong social identity for participants, and both are seen as focused on magical manipulations of non empirical forces to achieve desired empirical ends. However, cults may also coalesce into much more distinct membership groups with strict requirements, organizational hierarchies, broadly conceived ideologies, and long term aspirations for growth and influence. Stark and Bainbridge refer to this development as a cult movement and see such movements, in rare cases, as having the potential eventually to become transformed into new religious traditions. Even though the vast majority of cult movements do not succeed in achieving this outcome, cult movements are still seen as significant religious responses within secularized segments of modern society in which the appeal of established faiths has considerably weakened.

Sociological understanding of cults, however, has had little impact on public perceptions. From the 1960s onwards, the apparent proliferation of non conventional or alien religious groups in western societies, which were primarily successful in recruiting young people coming from conventional backgrounds, was deeply disturbing to many parents, mainstream Christian clergy, and various secular groups. From this public consternation emerged new, pejorative, polemical, and non scholarly definitions of cults. For many in the Christian clergy, a cult essentially came to be understood as any religious group that deviates from what are defined as orthodox Christian beliefs and practices – a “fake” religion that tempts people away from “true” religion. Such faith based, ethnocentric definitions considerably widen the category of groups labeled as cults, prominently including such well known American born religious organizations as the Church of Jesus Christ of Latter Day Saints (the “Mormons”), the Church of Christ, Scientist (Christian Science), and the Jehovah’s Witnesses.

Secular opponents of various unconventional religious groups (including some academic sociologists but mostly clinical psychologists, a variety of different types of therapists,

entrepreneurial and self styled “cult experts,” and several different anti cult organizations), beginning in the early 1970s, emphasized the dangers that cult groups were presumed to pose for both individuals who were snared by them and to the larger society that harbored them. Lists of identifying cult characteristics included (and currently still do) notions of “brain washing” or mind control tactics employed as recruitment and retention devices; fraudulent motives and totalitarian methods of charismatic leaders; exploitation or abuse of duped or cowed members for the benefit of leaders; secrecy and isolation from the outside world; a potential if not an actual tendency toward the use of violence; and so on.

This understanding of cults as dangerous or destructive groups engaging in fraudulent or even illegal activities was (and remains) largely adopted and disseminated by the mass media. Several spectacular and tragic episodes involving unconventional religious groups since the late 1970s have garnered massive media attention (e.g., the People’s Temple slayings and mass suicide in Jonestown, Guyana; the Rajneeshpuram takeover of a small Oregon community; the prolonged siege and fiery deaths of the Branch Davidians in Waco, Texas; the subway poison gas attacks by Aum Shinrikyo in Japan; and the mass suicides among followers of the Solar Temple in Switzerland and Heaven’s Gate in California). Other highly publicized, controversial groups whose reported activities continue to reinforce the widespread perception of cults as dangerous threats that need to be exposed and suppressed include the Church of Scientology (throughout Europe particularly) and the Falun Gong/Dafa movement (in mainland China).

Anti cult organizations such as the Cult Awareness Network (now defunct) and the American Family Federation have long advanced the claim that cults “brainwash” their members to such an extent that individuals within the group are significantly impeded in exercising full free agency and are thus largely helpless to avoid the abuse to which they are presumably subjected. This claim was bolstered from non random interview samples of ex group members and became the basis for involuntary removal of members from groups labeled as destructive cults by hired “deprogrammers”

until the American Psychological Association officially declared "brainwashing" to be an unscientific concept in the late 1980s, and American courts began convicting deprogrammers on charges related to kidnapping.

In contrast, most sociologists of religion continue to advocate a more detached, objective, and analytical understanding of cults and their relationships to conditions in both mainstream religions and society generally. Of the hundreds of groups that can reliably be identified as cult movements, only a very small fraction have or are likely to have violent confrontations with outsiders. Sociologists who specialize in the study of cult movements through field research or direct observations typically find that most groups they investigate, while espousing beliefs or practices that may seem outlandish, restrictive, or otherwise unappealing to outsiders, generally develop a core of sincere and committed followers whose right of religious choice ought not be trammled by indiscriminate negative labeling. The term new religious movement (NRM) has been widely adopted as a substitute for cult by many sociologists in order to neutralize the negative connotations that have accumulated around the term cult and to emphasize the need to examine every group on its own observable merits rather than simply stigmatizing unconventional religious organizations on the basis of a pejorative stereotype. Nevertheless, controversy over the nature of cults, how cults ought to be studied, whether the term itself ought to be discarded, and what kinds of policies, if any, ought to be adopted toward religiously deviant groups by secular authorities, continues.

cultural capital

Elliot B. Weininger and Annette Lareau

The French sociologist Pierre Bourdieu, working with various colleagues, developed the concept of cultural capital in the early 1960s in order to help address a particular empirical problem – namely, the fact that "economic obstacles are not sufficient to explain" disparities in the educational attainment of children from different social classes (Bourdieu & Passeron 1979 [1964]: 8). Bourdieu argued that, above and beyond economic factors, "cultural habits and . . . dispositions inherited from" the family are fundamentally important to school success (Bourdieu & Passeron 1979 [1964]: 14). In doing so, he broke sharply with traditional sociological conceptions of culture, which tended to view it primarily as a source of shared norms and values, or as a vehicle of collective expression. Instead, Bourdieu maintained that culture shares many of the properties that are characteristic of economic capital. In particular, he asserted that cultural "habits and dispositions" comprise a *resource* capable of generating "profits" that are potentially subject to *monopolization* by individuals and groups; and, under appropriate conditions, that can be *transmitted* from one generation to the next (Lareau & Weininger 2003).

As the originator of the concept of cultural capital, Bourdieu was notoriously disinclined to

elaborate the meaning and significance of concepts outside of the concrete context offered by empirical research. At the most general level, however, he emphasized that any “competence” becomes a capital insofar as it facilitates appropriation of a society’s “cultural heritage” but is unequally distributed, thereby creating opportunities for “exclusive advantages.” In societies characterized by a highly differentiated social structure and a system of formal education, Bourdieu further asserted, these “advantages” largely stem from the institutionalization of “criteria of evaluation” in schools – that is, standards of assessment – which are favorable to children from a particular class or classes (Bourdieu 1977).

Bourdieu (1986) further argued that cultural capital exists in three distinct forms. In its “embodied” form, cultural capital is a “competence” or skill that cannot be separated from its “bearer” (i.e., the person who “holds” it). As such, the acquisition of cultural capital necessarily presupposes the investment of time devoted to learning and/or training. For example, a college student who studies art history has gained a competence which, because it is highly valued in some institutional settings, becomes an embodied form of cultural capital. Additionally, Bourdieu suggests that the objects themselves may function as a form of cultural capital, insofar as their use or consumption presupposes a certain amount of embodied cultural capital. For example, a philosophy text is an “objectified” form of cultural capital since it requires prior training in philosophy to understand. Finally, in societies with a system of formal education, cultural capital exists in an “institutionalized” form. This is to say that when the school certifies individuals’ competencies and skills by issuing credentials, their embodied cultural capital takes on an objective value. Thus, for example, since persons with the same credentials have a roughly equivalent worth on the labor market, educational degrees can be seen to be a distinct form of cultural capital. Because they render individuals interchangeable in this fashion, Bourdieu suggests that institutionalization performs a function for cultural capital analogous to that performed by money in the case of economic capital.

Nevertheless, despite the similarities between cultural and economic capital, Bourdieu also

recognized that they differ from one another in important respects. In particular, he noted that the legitimization of inequality in cultural capital occurs in a manner that is highly distinct from the legitimization of economic inequality. Despite the fact that cultural capital is acquired in the home and the school via exposure to a given set of cultural practices – and therefore has a social origin – it is liable to be perceived as inborn “talent,” and its holder “gifted,” as a result of the fact that it is embodied in particular individuals. Moreover, because the school system transforms “inherited” cultural capital into “scholastic” cultural capital, the latter is predisposed to appear as an individual “achievement.” For example, scholars have demonstrated that middle class parents typically talk more to infants and young children than do working class or poor parents. As a result, middle class children often have larger vocabularies when they enter school, and subsequently score more highly on standardized tests measuring verbal skills (Lareau 2003). Nevertheless, teachers, parents, and students themselves are likely to interpret the differences in test scores as a matter of natural talent or individual effort.

Bourdieu’s arguments concerning cultural capital were notable because they vociferously challenged the widespread view of modern schooling as a mobility engine that promotes or demotes people through the class structure simply on the basis of their talents and efforts. Indeed, from Bourdieu’s highly critical vantage point, modern systems of schooling are far more adept at validating and augmenting cultural capital inherited from the family than they are at instilling it in children who enter the institution with few or none of the requisite dispositions and skills. Consequently, he maintained, the educational systems of modern societies tend to channel individuals toward class destinations that largely (but not wholly) mirror their class origins. Moreover, they tend to elicit acceptance of this outcome (i.e., legitimation), both from those who are most privileged by it and from those who are disfavored by it (Bourdieu & Passeron 1977 [1970]).

The concept of cultural capital also had tremendous impact in sociology because it placed culture at the core of stratification research. Bourdieu’s subsequent work used the notion

of cultural capital to further reinforce the premise that culture is directly implicated in social inequality. This is especially apparent in the thoroughgoing reconceptualization of social class that he presented in *Distinction* (1984 [1979]; Weininger 2005). For Bourdieu, classes are differentiated from one another in terms of the overall *volume of capital* (economic plus cultural) controlled by individuals or families. Within classes, “class fractions” are differentiated from one another by the *composition* of the capital controlled – or in other words, by the ratio of economic capital to cultural capital. Using this reconceptualization, *Distinction* analyzed the aesthetic practices and preferences of classes and class fractions located across the French social structure, focusing, in particular, on the taste or distaste for “highbrow” art forms (painting, music, literature, drama, etc.). Bourdieu’s data indicated that each class (and class fraction) exhibited a relatively unique pattern of tastes, one consistent with its particular mix of cultural and economic capital. Thus, for example, professors and artistic producers – one fraction of the dominant class – utilized their superior endowment of cultural capital to appreciate the most avant garde forms of art. By contrast, employers, the fraction of the dominant class richest in economic capital, tended to prefer less intellectually demanding forms of art, and especially those which conformed to traditional conceptions of beauty, and which connoted a sense of luxury. These differences of taste, Bourdieu argued, should be viewed as claims for the prestige constitutive of status, in Weber’s sense of “social honor,” which Bourdieu termed “symbolic capital.” As such, these differences were said to play an integral role in the legitimation of class stratification.

Within English language sociology, the concept of cultural capital began to make its way into the literature starting in the late 1970s with the translation of *Reproduction* (Bourdieu & Passeron 1977 [1970]). Given its genesis in Bourdieu’s study of the French educational system, it has unsurprisingly been in the field of educational research that the notion of cultural capital has triggered the greatest amount of empirical research and theoretical reflection, and the greatest contention. However, the concept has proven fruitful in a number of other

research areas. For example, proceeding from Bourdieu’s interest in the way that different forms of capital are implicated in complex patterns of stratification, Eyal et al.’s (1998) examination of the class structure of post communist societies in Central Europe focuses on cultural capital. Contrary to many predictions, they argue, members of the bureaucratic *nomenklatura* did not successfully exploit their authority under communism to appropriate large amounts of state property during the privatization process that marked the transition to capitalism. Nor have the small scale entrepreneurs who were tolerated in the final decades of state socialism managed to leverage their “head start” and become a full blown capitalist class in the post 1989 period. Rather, in countries such as the Czech Republic, Hungary, and Poland, a stratification system has emerged which can be characterized as a type of “capitalism without capitalists.” In this system, cultural capital stands as the most important basis of power and privilege. Thus, the dominant class in these societies can be described as a “cultural bourgeoisie” rather than an economic bourgeoisie. This cultural bourgeoisie, which is a diverse group that includes former technocrats and dissident intellectuals, has largely monopolized the skills, know how, and credentials (i.e., cultural capital) that have become critical to occupational success. The authors demonstrate that possession of cultural capital makes possible access to leading positions in the economy and the state and, conversely, that lack of cultural capital is a substantial barrier.

The concept of cultural capital has also proven highly productive in the study of aesthetic tastes and preferences. In this context, sociologists have evaluated the association between social position and taste, concentrating on the upper class predilection for exclusively “highbrow” aesthetic forms at the heart of *Distinction*. The evidence for this proposition strongly indicates that in the contemporary United States, for example, the relation is different from that charted by Bourdieu. Thus, Peterson and colleagues (Peterson & Kern 1996; Peterson & Simkus 1992) report that in matters of cultural taste, “elites” in the US are more accurately characterized as “omnivores” than “snobs”: status claims now tend to hinge on familiarity with a wide variety of genres

within each cultural form (music, literature, film, etc.) – genres that range from the high brow (e.g., classical music and opera) to the middlebrow (e.g., Broadway show tunes) and the lowbrow (e.g., country music and rock). Those claiming status are expected to be able to distinguish laudable examples of each genre according to standards of judgment that are unique to it. Despite the fact that it differs substantially from the form of aesthetic competence delineated in Bourdieu's account of French lifestyles, this "cosmopolitan" orientation is clearly conditional upon indicators of social class such as education, and therefore prone to function as a form of cultural capital. Indeed, Bryson (1996) goes so far as to dub it "multi cultural capital."

At the same time that it has been incorporated into various areas of English language sociology, the concept of cultural capital has also been the object of considerable criticism. Giroux (1983) has argued, for example, that when culture is viewed primarily as a form of capital, it becomes impossible to acknowledge the role it plays in enabling those in subordinate positions to resist domination. Similarly, Lamont (1992) asserts that conceptualizing culture in this manner prevents sociologists from recognizing that it contains repertoires which actors use to evaluate the moral quality of their own experiences and those of others – repertoires that do not necessarily have the character of a resource implicated in stratification processes. These debates are sure to intensify as scholars continue to interrogate the relation between culture and inequality. Regardless of the shape that they take, Bourdieu's concept of cultural capital, with its distinctive focus on the social value of cultural habits, dispositions, and skills, is likely to be an important part of the discussions in theories of inequality, the sociology of culture, and the sociology of education in the future.

cultural capital in schools

Elliot B. Weininger and Annette Lareau

One of the central goals of sociological studies of education has been to understand the role of schools in society. Do schools promote equal opportunity? Do schools help to recreate social stratification? In American society, where the ideology of meritocracy has taken root, American social science researchers have been preoccupied with issues of mobility and status attainment. The concept of cultural capital offers an alternative to the classic view of schools as the "great equalizer" which assesses students based on their raw talent or merit. Instead, the concept of cultural capital suggests that students' performance in schools draws on students' cultural resources where the habits, dispositions, and skills that children learn in the home are unequally valued by educators. For example, in this perspective children who learn classical music or other highly valued cultural practices at home may have an advantage in the educational setting compared to children who learn hip hop music or other cultural practices that are accorded lower social value. The profit yielded by cultural capital is linked to the value accorded to particular skills, dispositions, and habits by educators and other people in positions of power in dominant institutions. The concept of cultural capital plays a large role in arguments concerning social reproduction, in which schools are posited to play a key role in channeling individuals toward class destinations that reflect their class origins, and in legitimating inequality.

The concept of cultural capital grew out of the work of the French social thinker Pierre Bourdieu and his broader theory of social life. As Lamont and Lareau (1988) note, Bourdieu offers differing definitions at various points in his numerous writings. Bourdieu's most influential discussions of cultural capital in

education can be found in an early co authored work (Bourdieu & Passeron 1977) and in an article (Bourdieu 1977). Bourdieu's (1986) article offers the most direct discussion of the topic.

As with many core sociological concepts, the notion of cultural capital has been subject to a profusion of definitions in the literature. There has also been a profusion of indicators used to measure it. DiMaggio (1982), in a highly influential article, focused on students' attitudes, activities, and information regarding art, music, and literature. The assumption made by DiMaggio (and those who have followed him) is that proficiency with highbrow aesthetic culture of this sort enables students to carry out "status displays" which teachers, in turn, are inclined to reward. Lamont and Lareau (1988) defined cultural capital as "institutionalized, i.e. widely shared, high status cultural signals (attitudes, preferences, formal knowledge, behaviors, goods, and credentials) used for social and cultural exclusion." In doing so, however, they argued that in order for a given set of attitudes or preferences to be declared "cultural capital," this institutionalization must first be empirically documented. This argument was widely ignored. Instead, in part as a result of the constraints of representative survey data, empirical research has largely followed the work of DiMaggio and settled for indicators of cultural capital that hinge on knowledge of or facility with "highbrow" aesthetics (e.g., attendance at art museums, theater, or plays). While some studies have established a relationship between this type of "high status cultural consumption" and educational experiences, others (De Graaf et al. 2000) have found that parents' language use in the home, particularly in the form of reading, is more influential.

Some scholars, such as Kingston (2001), have declared the concept and the literature it has spawned to be of little or no value. Lareau and Weininger (2003), in a comprehensive review, criticize the English language literature for unnecessarily narrowing the concept by focusing on "highbrow" aesthetic culture. They also object to the partitioning of effects attributable to cultural capital from those attributable to "human capital" or "technical ability." They call for a broader conception of cultural capital which stresses the micro interactional strategies

through which children and their parents gain advantages in schools. For educational research, they stress the value of Bourdieu's definition of cultural capital as "the educational norms of those social classes capable of imposing the . . . criteria of evaluation which are the most favorable to their children." Although abstract, this definition implies the need to look critically at the standards which determine success in school and at the strategies that families pursue in relation to these standards. For example, child rearing practices that emphasize language development or parent involvement in schooling offer cultural capital to family members (Lareau 2000).

In sum, while pursuing different empirical approaches, researchers using the concept of cultural capital generally challenge the view of schools as adhering to objective and socially neutral standards of success. Instead, the concept of cultural capital stresses the ways in which the standards for success are drenched in family cultural practices. Advantaged families transmit an advantage to their children because educators proclaim the cultural practices in these families to be more valuable. From this vantage point, the role of schools in society – despite the well intentioned beliefs of educators – too often offers an advantage to children from the dominant class as they approach school with a set of powerful, albeit largely invisible, cultural advantages which they draw on to comply with standards for school success.

cultural criminology

Jeff Ferrell

Cultural criminology explores the many ways in which cultural dynamics intertwine with the practices of crime and crime control in contemporary society; put differently, cultural criminology emphasizes the centrality of meaning and representation in the construction of crime as momentary event, subcultural endeavor, and social issue. From this view, the appropriate subject matter of criminology transcends traditional notions of crime and crime causation to include images of illicit behavior and symbolic displays of law enforcement; popular culture constructions of crime and criminal action; and the shared emotions that animate criminal events, perceptions of criminal threat, and public efforts at crime control. This wider cultural focus, cultural criminologists argue, allows scholars and the public alike to better

understand crime as meaningful human activity, and to penetrate more deeply the contested politics of crime control.

At a fundamental level cultural criminology in this way integrates the insights of sociological criminology with the orientations toward image and style offered by the field of cultural studies. Within this broad confluence of the criminological and the cultural, though, cultural criminology has emerged from a rather more complex co evolution of sociology, criminology, and cultural analysis. A fundamental starting point in this emergence is the work of scholars associated with the Birmingham School of Cultural Studies, the National Deviancy Conference, and the “new criminology” in Great Britain during the 1970s. Reconceptualizing the nature of contemporary power, these scholars explored the cultural and ideological dimensions of social class, examined leisure worlds and illicit subcultures as sites of stylized resistance and alternative meaning, and investigated the mediated ideologies driving social and legal control. Around this same time, American sociology provided a second starting point for what was to become cultural criminology: the symbolic interactionist approach to crime and deviance. As conceptualized in labeling theory and embodied in the naturalistic case study, this interactionist model likewise highlighted the contested construction of meaning around issues of crime and deviance, and in this sense explored the situated politics of even the most common of crimes.

As these two orientations co evolved – with American interactionists and ethnographers providing phenomenological inspiration for British scholars, and British cultural theorists and “new criminologists” offering American scholars sophisticated critiques of legal and ideological control – the transatlantic foundations for today’s cultural criminology were laid. With the rapid growth of punitive criminal justice systems in the US and Great Britain during subsequent decades, and the concomitant ascendance of an administrative “criminal justice” in place of a critical sociological criminology, however, little was immediately built from these foundations. It was not until the mid 1990s that a distinct cultural criminology began to emerge (e.g., Ferrell and Sander’s *Cultural Criminology*). While drawing on earlier

British and American conceptualizations, cultural criminologists now began to integrate into their work the sensibilities of postmodernism and deconstruction as well; elaborating on the “symbolic” in symbolic interaction, they began to explore the looping circulation of images, the representational hall of mirrors, that increasingly define the reality of crime and justice. In an echo of earlier transatlantic conversations, contemporary cultural criminology by intention also emerged as an integration of scholarly work from Great Britain, the US, and beyond.

Cultural criminologists’ transatlantic analysis of contemporary urban graffiti exemplifies the depth and complexity of this approach. Hip hop graffiti, the most pervasive form of contemporary urban graffiti, emerged out of the US hip hop movement of the 1970s as a stylized medium for displaying artistic ability and negotiating subcultural status. The practice of this illegal street graffiti also embodied what its practitioners called the “adrenaline rush”: the vivid, intoxicating experience of executing alternative artistry in situations of extreme physical and legal risk. As an increasingly prominent form of illicit public display, hip hop graffiti quickly attracted the attention of legal authorities who saw it as violating their own aesthetics of legal control. In response, authorities launched high profile media campaigns designed to define such graffiti exclusively as vandalism and threat, and aggressively enforced new anti graffiti ordinances, all of which accelerated graffiti’s experiential adrenaline rush, pushed the graffiti underground from subculture to counterculture, and helped construct hip hop graffiti over the next two decades as a global phenomenon. As hip hop graffiti has continued to develop in the new millennium, cultural criminologists note, so has this ironic spiral of culture and crime. Hip hop graffiti artists now maintain their own websites, art galleries, and magazines, and surreptitiously hang their paintings in the Louvre, the Museum of Modern Art, and the Tate Museum. Legal and political authorities counter by continuing to orchestrate media campaigns meant, above all, to poison the public perception of urban graffiti. US shoe companies in turn sell “SuperStar Graffiti” sneakers, US fashion designers stage graffiti demonstrations and promote hip hop graffiti video games, British advertisers employ

graffiti artists to paint corporate logos in city streets and appropriate existing hip hop graffiti for CD covers and ad campaigns – and graffiti practitioners continue to be arrested and incarcerated on charges of graffiti vandalism and destruction of private property (Ferrell 1996; Alvelos 2004).

In the same way that cultural criminology's analytic approach to contemporary crime issues embodies these sorts of interlocking cultural, critical, and interactionist frames, its methods emerge from its roots in naturalistic case study. While cultural criminology incorporates a variety of methods – among them textual, semiotic, and visual analysis – some of the more prominent work in cultural criminology has been characterized by forms of extreme ethnography. Immersing themselves in illicit subcultures, attempting at times to “become the subject matter,” constructing at other times auto ethnographies of their own lives, cultural criminologists have embraced ethnographic method as an avenue into the situated meaning and subtle symbolism constructed within criminal subcultures and events. In part this approach has been underpinned by cultural criminology's conceptualization of illicit subcultures like that of hip hop graffiti as collectivities of shared meaning and perception, linked by elaborate symbolic codes as much as by calculated criminal endeavor. Yet it has also been founded in a particular etiology of crime that points, at least in part, to crime's origins inside the immediacy of the criminal event, and to the shared experiences and emotions that develop within moments of criminality and crime control (Katz 1988; Lyng 1990). For cultural criminologists, the primacy of criminal subcultures, criminal events, and the meanings and emotions they spawn confirms the importance of methods that can move criminologists inside them; in the same way this focus reconfirms the value of a Weberian, *verstehen* oriented criminology and sociology.

Such experiences and emotions have also come into focus as part of cultural criminology's emphasis on everyday existence as an essential arena of criminality and control. Cultural criminology highlights the currents of carnivalesque excitement, pleasure, and risk taking that animate everyday life, but equally so the many capillaries of daily control designed

to contain and commodify these experiential currents (Presdee 2000). In fact, cultural criminologists argue, it is this very tension that accounts for various contemporary confluences of crime and culture: the aggressive policing of alternative subcultures and their styles; the mediated consumption of crime as commodified titillation and entertainment; and the shifting and always contested boundaries between art and pornography, music and political provocation, entertainment and aggression, crime and resistance. In all of these cases, cultural criminologists attempt to account for the political economy of crime by locating it inside the dynamics of the everyday, amid the ambiguities of day to day transgression and control.

While exploring the everyday meanings of crime and control, cultural criminologists have in this way also endeavored to fix these situated meanings within larger historical patterns. In a contemporary world shaped by the endless circulation of images and symbols, for example, conventional dualities of the “real” and the “representational” seem to make less and less sense – and so cultural criminology emphasizes the permeability of images as they flow between the mass media, criminal subcultures, and crime control agencies, and likewise the essential role of image and ideology in constructing crime control policies and practices. Following this line of analysis, cultural criminology suggests that everyday criminal justice has now become in many ways a matter of orchestrated public display, and an ongoing policing of public perceptions regarding issues of crime and threat. Shifts such as this are in turn seen to reflect still other dimensions of contemporary life, among them the emergence of a globalized economy of image and consumption, the tension between late modern patterns of social inclusion and exclusion, and the uncertain dynamics of personal and cultural identity within these arrangements (Young 2003). In this context cultural criminologists highlight especially the importance of the global city to the understanding of crime and crime control. With its contested cultural spaces of consumption and display, its amalgam of illicit subcultural dynamics, and its spatial and symbolic practices of everyday policing, the city seems an essential embodiment of contemporary social and cultural trends.

Throughout this range of substantive and theoretical work, cultural criminologists have quite explicitly challenged the conventional practices of criminology and criminal justice on two fronts. A first challenge has been issued in the area of style. Turning their cultural critique to the practice of contemporary criminology and criminal justice, cultural criminologists have noted there a style of writing wanting in elegance and engagement, and a social science culture of detached obfuscation operating so as to maintain a facade of objective neutrality. In response, cultural criminologists have noted the slippery politics of such representational codes – codes that have functioned, in both the historical emergence of criminology and the contemporary ascendancy of criminal justice, as cultural displays masking intellectual alliances with political and economic power. Relatedly, cultural criminologists have noted the role of this arid criminological culture in sanitizing what would otherwise seem among the most engaging of subject matters: crime, violence, guilt, and transgression. In this context, cultural criminologists have sought to revitalize the enterprise of criminology, and to restore something of its humanistic orientation, through styles of research and presentation designed for engagement and effect. Along with the texture and nuance offered by ethnographic research, these have included the development of biographical and autobiographical writing styles, the incorporation of evocative vignettes drawn from popular culture, and the inclusion of visual materials and visual analysis. While better communicating the everyday importance of crime and crime control, cultural criminologists argue, such styles also offer a more honest accounting of criminologists' involvement with the politics of crime and crime control.

Cultural criminology's second challenge has occurred in the realms of theory and method. Cultural criminologists argue that survey research methods and quantitative data analysis – dominant modes of research within the objectivist culture of criminology and criminal justice – remain dominant not because of their innate scholarly merit, but due in large part to their utility in generating the sort of distilled data necessary for the administration of the criminal justice system. In fact, cultural criminologists contend, such modes of research

remain useful in this context precisely because they are meaningless: that is, because they drain from crime its situated meaning and seductive symbolism, leaving behind only the residues of statistical analysis. Likewise, rational choice theory and similar criminological theories founded on assumptions of instrumental rationality miss, from the view of cultural criminology, the very essence of much everyday criminality: pleasure, excitement, anger, and risk. As with other reductionist approaches, such theories may buttress calls for individual responsibility and punitive justice, and in this sense may find a home within the current practice of criminal justice, but they can hardly account for the inherent sensuality, ambiguity, and irrationality of crime itself.

Emerging from the alternative and critical criminologies of the 1970s, cultural criminology in these ways provides, by practice and intention, a contemporary alternative criminology, and a cultural critique of contemporary crime control arrangements. With its interdisciplinary foundations and emphasis on meaning, mediated representation, and style, it may also hold out the possibility of significantly expanding the analytic range and substantive scope of future criminological scholarship.

cultural critique

Douglas Kellner and Tyson E. Lewis

Cultural critique is a broad field of study that employs many different theoretical traditions to analyze and critique cultural formations. Because culture is always historically and contextually determined, each era has had to develop its own methods of cultural analysis in order to respond to new technological innovations, new modes of social organization, new economic formations, and novel forms of oppression, exploitation, and subjugation.

The modern European tradition of cultural critique can be traced back to Immanuel Kant's (1724–1804) seminal essay entitled "What is Enlightenment?" Here, Kant opposed theocratic and authoritarian forms of culture with a liberal, progressive, and humanist culture of science, reason, and critique. By organizing society under the guiding principles of critical reason, Kant believed that pre-Enlightenment superstition and ignorance would be replaced by both individual liberty and universal peace.

Friedrich Nietzsche (1844–1900) historicized Kant's version of critique through a technique called genealogy. Nietzsche argued that Kant's necessary universals are born from his torial struggles between competing interests.

Compared to Greek culture, Nietzsche saw contemporary Germany as degenerate. Prominent figures such as David Strauss and Friedrich Schiller represented "cultural philistines" who promoted cultural conformity to a massified, standardized, and superficial culture. Thus contemporary culture blocked the revitalization of a strong, creative, and vital society of healthy geniuses. Here Nietzsche rested his faith not in universal categories of reason but rather in the aristocratic will to power to combat the "herd mentality" of German mass culture.

Like Nietzsche, Karl Marx (1818–83) also rejected universal and necessary truths outside of history. Using historical materialism as his major critical tool, Marx argued that the dominant culture legitimated current exploitative economic relations. In short, the class that controls the economic base also controls the production of cultural and political ideas. Whereas Nietzsche traced central forms of mass culture back to the hidden source of power animating them, Marx traced cultural manifestations back to their economic determinates. Here culture is derived from antagonistic social relations conditioned by capitalism, which distorts both the content and the form of ideas. Thus for Marx, cultural critique is essentially ideological critique exposing the interests of the ruling class within its seemingly natural and universal norms.

Whereas Kant defined the proper uses of reason for the creation of a rational social order, Sigmund Freud (1856–1939) argued that the liberal humanist tradition failed to actualize its ideal because it did not take into account the eternal and unavoidable conflict between culture and the psychological unconscious. Freud argued that the complexity of current society has both positive and negative psychological implications. On the one hand, individuals have a certain degree of security and stability afforded to them by society. Yet at the same time, this society demands repression of aggressive instincts, which turn inward and direct themselves toward the ego. This internalization of aggression results in an overpowering super-ego and attending neurotic symptoms and pathologies. For Freud, such a conflict is not the result of economic determination (as we saw with Marx), but rather is a struggle

fundamental to the social contract and is increasingly exacerbated by the social demand for conformity, utility, and productivity.

With the Frankfurt School of social theory, cultural critique attempted to synthesize the most politically progressive and theoretically innovative strands of the former cultural theories. Max Horkheimer (1895–1971), Theodor Adorno (1903–69), and Herbert Marcuse (1898–1979) are three of the central members of the Frankfurt School who utilized a transdisciplinary method that incorporated elements of critical reason, genealogy, historical materialism, sociology, and psychoanalysis to analyze culture. While heavily rooted in Marxism, the members of the Frankfurt School increasingly distanced themselves from Marx's conception of the centrality of economic relations, focusing instead on cultural and political methods of social control produced through new media technologies and a burgeoning culture industry. In the classic text *Dialectic of Enlightenment* (1948), Horkheimer and Adorno demonstrate that Kant's reliance on reason has not resulted in universal peace but rather increasing oppression, culminating in fascism. Here reason becomes a new form of dogmatism, its own mythology predicated on both external domination of nature and internal domination of psychological drives. This dialectic of Enlightenment reason reveals itself in the rise of the American culture industry whose sole purpose is to produce docile, passive, and submissive workers. Marcuse argued along similar lines, proposing that the American "one dimensional" culture has effectively destroyed the capacity for critical and oppositional thinking. Thus many members of the Frankfurt School (Adorno in particular) adopted a highly pessimistic attitude toward "mass culture," and, like Nietzsche, took refuge in "high" culture.

While the Frankfurt School articulated cultural conditions in a stage of monopoly capitalism and fascist tendencies, British cultural studies emerged in the 1960s when, first, there was widespread global resistance to consumer capitalism and an upsurge of revolutionary movements. British cultural studies originally was developed by Richard Hoggart, Raymond Williams, and E. P. Thompson to preserve working class culture against colonization by the culture industry. Thus both British cultural

studies and the Frankfurt School recognized the central role of new consumer and media culture in the erosion of working class resistance to capitalist hegemony. Yet there are distinct differences between British cultural studies and proponents of Frankfurt School critical theory. Whereas the Frankfurt School turned toward the modernist avant garde as a form of resistance to instrumental reason and capitalist culture, British cultural studies turned toward the oppositional potentials within youth subcultures. As such, British cultural studies was able to recognize the ambiguity of media culture as a contested terrain rather than a monolithic and one dimensional product of the capitalist social relations of production.

Currently, cultural critique is attempting to respond to a new era of global capitalism, hybridized cultural forms, and increasing control of information by a handful of media conglomerates. As a response to these economic, social, and political trends, cultural critique has expanded its theoretical repertoire to include multicultural, postcolonial, and feminist critiques of culture. African American feminist theorist bell hooks is an exemplary representative of new cultural studies who analyzes the interconnected nature of gender, race, and class oppressions operating in imperialist, white supremacist, capitalist patriarchy. Scholars of color such as hooks and Cornell West critique not only ongoing forms of exclusion, marginalization, and fetishization of the "other" within media culture, but also the classical tools of cultural criticism. Through insights generated by these scholars, cultural criticism is reevaluating its own internal complicity with racism, sexism, colonialism, and homophobia and in the process gaining a new level of self reflexivity that enables it to become an increasingly powerful tool for social emancipation.

cultural diversity and aging: ethnicity, minorities, and subcultures

Peggye Dilworth Anderson and Gracie Boswell

Current US Census population projections (2004) clearly show a growing number of diverse racial, ethnic, and cultural groups in American society. Parallel to this increase in diversity, the number of older adults in America is increasing. Older adult members of society are increasing at a faster rate than any other subgroup in America, and among this aging population, the percentage of the population who are members of minority groups will grow, between 2000 and 2050, at an even faster rate than the white majority. In 2002 (US Census 2002), the older population numbered 35.6 million; this was an increase of 3.3 million or 10.2 percent since 1992. Minority populations are projected to represent 26.4 percent of the elderly population in 2030, up from 17.2 percent in 2002. Between 2000 and 2030, the white population 65 and older is projected to increase by 77 percent compared with 223 percent for older minorities, including Hispanics (342 percent), African Americans (164 percent), American Indians, Eskimos, and Aleuts (207 percent), and Asians and Pacific Islanders (302 percent). Accompanying this tremendous boom in population growth and ethnic makeup will be economic problems as well as promises of

diversity. These economic problems and promises will be directly associated with living arrangements and health care needs of increasingly frail members of the population as well as the satisfaction of the supply and demand requirements for diversified goods and services of a vibrantly aging population (Angel & Hogan 2004).

In light of the demographic changes noted above, the need to understand diversity beyond racial categories and changes in the numbers of group members is a major challenge for researchers and other scholars of the twenty first century. Of great importance is to understand the range of factors that represent cultural diversity in a society. Central to this understanding is how best to define cultural diversity to reflect the changing and emerging identities of diverse groups. The biggest challenge in this definition is rooted in the term culture. Half a century ago, one study identified 150 definitions of culture (Kroeber & Kluckhohn 1952). Goodenough's (1999) definition of culture is a set of shared symbols, beliefs, and customs that shape individual and group behavior. He also suggested that culture provides guidelines for speaking, doing, interpreting, and evaluating one's actions and reactions in life. Goodenough's (1981) concept of cultural frame provides further insight into how individual characteristics and experiences, such as gender and age, can influence cultural beliefs and values. He suggested that cultural frame allows us to understand how an individual's culture is developed through the incorporation of the totality of one's experiences, interactions, and thoughts with the norms and expectations one perceives as being held by other group members. Therefore, due to differences in individual cultural frames, people can simultaneously be cultural group members and hold cultural beliefs that are not shared by some members of the group (Goodenough 1981).

At the expense of compounding the complexity inherent in the term culture, an understanding of what diversity means in the twenty first century is also important. Today the term diversity represents a more inclusive concept than in the past. It is used to model current dialogue and ideologies about inequality and social structures that are used to help resolve problems of social and professional interactions

in a pluralistic society. Although it is under the rubric of multiculturalism that culture, ethnicity, and race have been the usual variables of research interest, diversity is a multilevel and multidimensional concept that addresses more than culture, ethnicity, and race.

Representing the concerns of many interest groups, many variables may be used to bracket a linkage with diversity. Here, age is pulled into the diversity equation along with culture, ethnicity, and race. The inclusion of age is of paramount importance in social, economic, and legal institutions. In order to better appreciate the *raison d'être* for including age as a factor in the dialogue on diversity, we must move beyond mere awareness of negative attitudes toward the elderly to the cold hard facts supported by the social demographics of aging.

The discourse on cultural diversity and aging in social science research speaks to examining the theoretical and conceptual frameworks and perspectives that allow for capturing the cultural-historical background (values, beliefs, identities, and meanings assigned to experiences) and sociopolitical conditions (economic status and access to goods and services) of diverse groups. When culturally relevant, these frameworks and perspectives should also allow for defining and giving meaning to certain concepts from a cultural frame of reference. However, since theories of aging evolved out of a traditional Eurocentric social and cultural milieu, they have not proven effective in explaining aging in a culturally diverse context. In *Multiculturalism and Intergroup Relations* (1989), Ujimoto posited that traditional theories of aging (i.e., disengagement and activity) were not adequate to theorize about the Japanese ethnic population in Canada, because of the history of discriminatory practices endured by this group in relation to the majority Caucasian population. Similarly, this assertion is supported for some racial or ethnic minority groups in America, who were once thought to merge into a "melting pot" with Americanism as the central identifying group characteristic. Contemporary perspectives on diversity are centered on multiculturalism and cultural competence that take into account larger societal values and beliefs, and diverse cultural beliefs as well.

Multiculturalism became the buzzword of the 1990s in order to address the cultural

pluralism caused by the interrelationships between many racial and ethnic groups in America. Acknowledging individual differences, multiculturalism seemed to imply a commitment to a greater good for the whole society. However, in order to make this claim, some thing must be at stake for the various racial or ethnic groups that make up the society. Therefore, the central premise underlying multiculturalism was to recognize and respect the cultural heritages of various minority groups, while not creating alienation of one from the other. Otherwise, the result would be nothing more than the old pre Brown "separate but equal" ideology which was a dismal failure for already marginal members of society. By moving beyond the "melting pot" perspective, multiculturalism was a concept that embodied tolerance and less ethnocentrism. However, cultural bias was already pervasive due to cultural pluralism.

In order to assure that the various institutions in society were equitable for all members of the various groups, a system had to be in place that encouraged and facilitated culturally sensitive interactions between various interest groups. This recognition, along with the reality of widespread inequities, has moved contemporary discourse forward to what is referred to as a need for more "cultural competence." At any rate, cultural competence is not believed to be a state of being; instead, it is thought to be "a process of becoming over time," as suggested by Campinha Bacote in *The Process of Cultural Competence in the Delivery of Health care Services* (2003). This has been especially true with regards to interactions between aging individuals in the health care setting. In the context of the health care setting, cultural competence was described in the Commonwealth Fund field report (Betancourt et al. 2002) as being able to provide care to patients with diverse values, beliefs, and behaviors. This includes tailoring delivery to meet patients' social, cultural, and linguistic needs. Cultural competence was also described as both a vehicle to increase access to quality care for all patient populations and a business strategy to attract new patients and market share.

Betancourt et al.'s definition of cultural competence is steeped in humanistic terminology as well as a political economy perspective,

whereby the idea of a moral economy is invoked by acknowledging that cultural factors impact social institutions and change along with political and economic processes. Building upon the concept of multiculturalism and moving toward the dynamism represented by cultural competence, there are orientations which members of various interest groups and races or ethnicities might adopt or at least come to terms with. The three orientations are what Martin (1997) describes as diversity orientations, based on the interactions of different cultures, ethnicities, and races. The cultural orientation assumes that individuals abandon their ethnocentrism and learn rules guiding the behaviors of people from other cultures. The ethnic orientation assumes that individuals of different ethnic identities deserve equal respect. The oppression orientation, with regards to race, assumes dignity and power are restored to the oppressed minority. With this power, healing should take place in the psychological, economic, and political domains regarding interrelationships of the members of society. There is no clear evidence in American society that shows that these assumptions of diversity orientations have been realized. For this reason, diversity is the unfinished business of the twenty first century for social scientists to ponder.

As we move forward to address issues surrounding culture, ethnicity, or race, other social constructs will be called into question in the search for greater tolerance for individual differences and the need to dispel social inequalities. Research questions with other social constructs (i.e., age, gender, sexual orientation, disability, social class, language barriers, and religious and spiritual orientations) require examining the multiple concerns of multiple interest groups. This level of investigation beyond culture, race, and ethnicity embodies the new discourse on diversity that specifically includes age.

Although growing old has been thought to have marginalizing influences, many other factors weigh in to create an even more complex set of circumstances and individual differences that are demanding attention. Overshadowing the new demands on social structures will be the various factions representing racial subgroups and interest groups, not only stratified by age and race or ethnicity, but also impacted by gender, sexual orientation, religious or

spiritual tradition as well as other unnamed constructs. These competing interests of subgroups, stratified by various constructs of interest, signify the non monolithic nature of diversifying variables (i.e., age and gender) and recapitulate the notion that diversity is a multilevel and multidimensional concept that addresses more than culture, ethnicity, and race. However, of the three constructs, cultural diversity in the context of an aging society is of more paramount concern. Mindful of a rapidly aging society, social interactions need to place high priority on social changes in a variety of institutions, including the workplace, the health care arena, faith based organizations, communication networks, educational as well as leisure pursuits, and many other unlisted institutions.

Although the research terminology is new, cultural diversity is an outgrowth of the racial inequality debates of the past 50 years. Due to these past unresolved issues and changes in demography, current research on aging is challenged by many new methodological concerns. Consequently, aging is just one of the many social structures that is so dynamic that it begs to be addressed in the context of cultural diversity. The differences between the health outcomes of elderly whites and blacks have been well documented over the past 30 odd years. In some cases this research has informed the need for new policies, but in other cases it has simply raised more questions about the role of structure and agency and debates about social causation or social selection in studies of life stress. Furthermore, Williams (2004) has pointed out that inherent in the use of race to study health differences between groups of individuals is a tendency to mask problems associated with racism. By merely controlling for race of individuals or even stratifying by age, the richness of social and cultural contexts may be lost (Dilworth Anderson et al. 2002). While research that merely emphasized racial differences in outcomes might have been the necessary foundation for current theorizing, it did not go far enough.

Taking the context of cultural diversity into consideration, many contemporary methodological challenges are disclosed in the social science of aging. One of the main areas of investigation for diversity research is "inclusion." The science of inclusion goes

beyond racial and ethnic differences to address gender and poverty as well as language barriers that impact health differentials. These may be just a few of the factors forming the building blocks of diversity, which have been dictated by policy and that now affect what Curry and Jackson (2003) refer to as a science of inclusion. Among the main challenges embedded in this science of inclusion are the means of recruiting and retaining individuals from diverse backgrounds in health research. The idea of cultural competency becomes an important consideration in these recruitment and retention efforts, as the need to establish credibility becomes so essential in minority communities (Curry & Jackson 2003; Levkoff & Sanchez 2003). Additionally, training of investigators for diverse groups and research topics must become a priority as the scientific community grapples with issues of aging and associated disabilities.

Other methodological concerns include addressing the appropriateness of measures (i.e., are CES D scales useful for blacks?). Cross disciplinary methods (i.e., combining sociology and medical anthropology) as well as mixed methodologies (i.e., using qualitative to inform quantitative) are also important tools to use in investigating older adults and understanding the cultural contexts where they are found. Simultaneously, there is a need to display the qualities necessary for recruitment and retention of participants among diverse older adult populations (Yeo 2003).

As we look toward the future of research on aging and cultural diversity, theories and methods that are appropriate for inclusive scientific research should be a priority. Those theories and methods must be appropriate for research questions that address cultural complexity (i.e., aging of the gay and lesbian community, cultural heterogeneity of Latino and Asian Americans, spirituality and religiosity in health care). In other words, racial and ethnic groups should not be investigated as if they were monolithic entities. They each have their complex sets of problems and circumstances that need to be recognized as unique. For example, there are no typical persons of color (i.e., all persons with Afrocentric genetics in America are not African Americans), Asian, or Latino etc.

It is also important to not study aging in a vacuum. Older adults have a history. This

history encourages the use of the life course perspective as a useful methodological tool in the future. However, there must be ways to safeguard individuals with specific genetic predispositions from culturally biased or ethnically insensitive research that drives health policy.

New approaches to studying death and dying need to be addressed for an aging and culturally complex society. In order to prepare for this, more effort needs to be made in order to understand the health beliefs and attitudes as well as spiritual and religious beliefs and orientations of diverse cultural groups of older adults.

Finally, research in our pluralistic society is appropriate for cross national investigation. Jackson (2002) posits that the cultural complexity of the United States provides excellent models for research on aging that advances the field beyond investigating separate national and cultural perspectives. This would further advance understanding aging and cultural diversity in a global societal context.

cultural feminism

Kristina Wolff

Cultural feminism seeks to understand women's social locations in society by concentrating on gender differences between women and men. This type of feminism focuses on the

liberation of women through individual change, the recognition and creation of "women centered" culture, and the redefinition of femininity and masculinity. Cultural feminism utilizes essentialist understandings of male and female differences as the foundation of women's subordination in society.

Early cultural feminists sought to reclaim and redefine definitions of femininity and masculinity through recognizing and celebrating women's unique characteristics. Cultural feminists believe that women are inherently nurturing, kind, gentle, egalitarian, and non-violent. These tenets can be traced back to the *first wave* of feminism. During this time, scholars such as Jane Addams and Charlotte Perkins Gilman stressed the superiority of women's values, particularly compassion and pacifism, believing that these would conquer masculine qualities of selfishness, violence, and lack of self control in relation to sexual behavior. This was also a means to challenge the dominant cultural discourse that women were inferior and subservient to men. Efforts at fighting women's subordination included working for women's suffrage, women's right to free expression, and women's culture as well as outreach to poor and working class women. The decline of this early stage of cultural feminism has been attributed to World War I and societal reaction to these early feminists' opposition to the war.

Cultural feminism returned during the *second wave* of feminism in the early 1970s, when it reemerged out of the radical feminist movement. *Radical feminism* directly challenges biological definitions of male and female while actively working toward eliminating women's oppression. One aspect of this type of feminism was the minimization of gender differences and advocacy of androgyny. Within the movement, lesbians seeking to achieve recognition for their efforts, as well as visibility, created another body of feminism, *lesbian feminism*. Lesbian feminism focuses on unique issues that homosexual women face within feminism and throughout society, as well as examining the ways in which sexuality is socially constructed. Included in both lesbian and cultural feminism is the practice of separatism, the creation of spaces, groups, and communities that are separate from men. Cultural feminists employed some of the practices of both radical and lesbian

feminism but diverged from them due to its central focus. Cultural feminism emphasizes a need to highlight women's uniqueness and feminine qualities as positive attributes rather than erasing the differences between men and women, as stressed in radical feminism. It also modified lesbian feminism to create a feminism that appealed to a wider audience, while retaining a women centered focus. Cultural feminism is bounded by the practice of concentrating on the differences between genders as its foundation, while placing "woman" at the center. While there is great variety within this body of feminism, the main areas of scholarship focus on individual change, the development of women's culture, the redefinition of femininity and masculinity, and examinations of sexuality.

Foundationally, cultural feminism is the reclaiming and redefinition of female identity. Women's liberation occurs through the rejection of society's conception of "woman" since this is based on a male model of understanding. During a time period when some other branches of feminism were rejecting traditional values of womanhood, challenging and/or erasing what was understood as inherently female, cultural feminists sought to revalidate the essence of what it means to be "female" by embracing and reappropriating female attributes. This practice focuses on honoring one's femaleness through challenging traditional definitions of "woman" as well as the expected gender roles as defined by men. At the same time, traits that are attributed to women, such as the natural ability to nurture, are viewed as positive attributes that should be honored.

The early process of redefining and reclaiming femaleness took shape in a variety of forms and largely concentrated on changing personal behavior and attitudes and on creating a cultural transformation. This included the recognition and development of women's culture to counter women's invisibility, subordination, and often isolation from one another. Women's experience is the foundation of a "sisterhood," based on the belief that all women share a commonality due to gender. Women sought to establish "safe" places, free from male dominance, where they could build community. Often these events or spaces did not allow men to participate, thus giving women freedom

from men and men's subordination. Some defined this process of creating strong relationships and women centered spaces as "female bonding." This label sought to capture the inherent essence in women, one that naturally ties them together. Its purpose is to demonstrate the importance of placing "woman" at the center of their lives. The term also clashes with lesbians, as cultural feminists primarily defined "female bonding" as a non sexual, emotional connection. The result was that lesbianism quickly became subsumed under the label and, once again, left on the margins. Culturally, there was a surge in women's scholarship, art, and literature which focused on issues specifically related to and about women. Throughout the United States, women centered events and spaces were established. This included, but was not limited to, music festivals, businesses and organizations, women's centers, domestic violence shelters and rape crisis centers, and numerous community groups. Additionally, Take Back the Night marches were established to draw attention to rape, domestic violence, and abuse of women.

Central to this cultural shift is the development of an alternative consciousness, one that rejects what is "male" and how society is defined through a male lens. Cultural feminists view essentialist definitions of female and the qualities attached to understandings of femininity as powerful assets for women. Socially conditioned aspects of femininity, which include characteristics such as passivity and submissiveness, are redefined and revalidated as exemplifying women's innate ability to be nurturing, loving, non violent, cooperative, and egalitarian in nature. Men and masculinity are viewed as inherently violent, aggressive, and competitive. Men are seen as the "enemy" by virtue of their biological maleness. Women are subordinated due to men's nature. Women are also secondary because contemporary western society and western thought do not value women's virtues. Instead, male thought and ideas of hierarchy, domination, and independence are held in the highest esteem. Cultural feminism challenges these male values, seeking to change society and methods of governing through emphasizing women's natural ability to solve conflict through cooperation, pacifism, and non violence.

These changes in viewpoint, in placing women at the center, created a shift and dramatic growth in feminist scholarship. Cultural institutions that were often viewed as secondary in importance in society, such as women's roles, primary modes of employment, and motherhood, were now examined through a female lens. For example, Adrienne Rich and Nancy Chodorow examined the richness of women's experiences and roles as mothers, and Carol Gilligan joined Chodorow in utilizing psychological theories to further understand gender differences, thus helping to establish *psychoanalytic feminism*. Deborah Tannen's scholarship explores gender differences in the way men and women communicate with one another. Mary Daly, who also is influential in radical feminism, critiques and creates new languages as well as a feminist theology, both of which place women as central to her development of these new meanings. Ingrained in all of these "new" forms of scholarship is the inherent belief that women have certain innate qualities that should finally be recognized and honored by society, rather than remaining invisible or denigrated.

Included in these critiques and new scholarship was the development of standpoint theory and feminist epistemology. Both recognize that women have a unique perspective based on their experiences as women and that this should be valued, explored, and learned from. Both directly challenge traditional approaches to knowledge and understanding, recognizing these as grounded in and stemming from elite males in society. *Standpoint theory* posits that women's understanding of the world is different from men's, even if it is shaped by men's definitions. This difference is based on women's experiences and knowledge, both formal and informal. Women's perspectives vary in ways that are visible and invisible and affect the ways in which people understand and also approach the social world. Sandra Harding's development of a *feminist epistemology* centers on critiquing society's understanding and creation of knowledge, thus shaping the ways in which science and the quest for knowledge occur. Harding analyzes traditional approaches to expanding knowledge in society from a woman's standpoint to illustrate how women's "ways of knowing" differ from men's. This

ever expanding scholarship assisted in providing a foundation for the establishment of women's studies as a discipline, as well as in the development of many other concentrations and changes in focus of numerous disciplines. In sociology, for example, it provides a foundation for the sociology of sex and gender, feminist sociology, and feminist methods within sociology.

Inherent in the focus on differences between genders is the issue of sexuality and sexual practices. Approaches to sexuality vary. Some cultural feminists embrace women's ability to reproduce and promote it as "the" source of female power. They believe that men are afraid and/or jealous of women and their ability to reproduce and thus they try to control reproduction through a variety of means, including policy and technology. One direct result of this belief was the development of women's resources for health care and reproduction, including the publication in 1970 of *Our Bodies, Ourselves* by the Boston Women's Health Book Collective, which was the first publication dedicated to women's health written by and for women. Other cultural feminists seek to reclaim the power of positive sexual practices and desires through exploring women's fantasies, desires around intimacy, and ability to be open to and want emotional experiences. Addressing the focus of sexual behavior on the pleasures of women links directly back into radical feminism, which sought to highlight the importance of women enjoying sex. This included a reformulation of heterosexual practices that sought to concentrate on women's satisfaction instead of men's.

Some also focus on men's sexual behavior as a specific practice of male domination over women. Female sexuality is believed to naturally concentrate on relationships and intimacy. The focus is on reciprocity and caring rather than solely engaged on physical ecstasy. Sexuality for men is believed to primarily be focused on the merger of power and orgasm. Men naturally concentrate on their own physical desire, seeking to maintain power over women. Men want to be intimate with women in order to satisfy their own needs. In this respect, men and women are viewed as complete opposites.

Some cultural feminists advocate that women embrace their femininity as well as their

sexuality by rejecting sexual activity with men, viewing male penetration as domination. Many of these early feminists were also part of the radical feminism movement. Some of these women also apply the term "female bonding" here to illustrate the conscious focus on surrounding oneself with other women and having them fulfill every need, including as sexual partners. This approach to sexuality led to the creation of the anti pornography movement and also created a split among cultural feminists, particularly those who do not view sexual behavior as a source of men's domination.

One of the accomplishments of cultural feminism was the emergence of the anti pornography movement. This movement materialized out of the establishment of women's groups and organizations, particularly those that focused on issues of domestic violence, abuse, and rape. One of the beliefs of the movement is that men are unable to control themselves, that their desire to dominate women is due to their biological makeup. Women are then responsible for curtailing and controlling their behavior. This approach is very similar to the first wave of feminism, including those women involved in the temperance movement. Pornography is believed to perpetuate our culture's misogyny and also causes violence against women, often because it depicts women being subjected to acts of violence. Some claimed that rape was simply due to men's male essence, and others proclaimed that "porn is the theory, rape is the practice" (see, e.g., Brownmiller 1975; Dworkin 1979). It is believed that pornography also affects women negatively, compelling them to accept the negative images of women. The movement has had a varied history of success, resulting in the creation of anti pornography legislation and increased regulation, particularly around issues of age of participants and the elimination of highly violent images. It also continues to critique the role of pornography in society and has developed another area of feminist scholarship surrounding law, media, and sexuality studies. While many communities adopted strict anti pornography laws, many of these have been overturned on constitutional grounds.

Cultural feminism continues to influence current feminisms as well as other disciplines, including sociology, in particular concerning

issues of women and work, mothering, sexuality, and women's role as "caretaker." Cultural feminism is one of the most successful and influential types of feminism. However, it is not without critics. One of the most common critiques concerns its reliance on applying biological definitions of "woman." The use of essentialist conceptions of "woman" reifies the societal beliefs it seeks to redefine. This key premise tends to invoke a universal conception of what "woman" is, failing to offer a response to traditional patriarchal beliefs of women and men. By embracing socially constructed ideas of femininity and masculinity, there is an implication that women cannot escape their destinies as females. Also embedded within these biological assumptions is the premise that women's duty is to control men because they cannot control themselves due to their inherent essence. By relying on women to change their behaviors and seek to control men, cultural feminism leaves unchallenged the overarching system of patriarchy, which shapes societal understandings and practices of gender. Some early cultural feminists such as Adrienne Rich, Andrea Dworkin, and Susan Brownmiller have also offered critiques, but these are largely based on the application of essentialist definitions of "woman" rather than the belief itself. For some, the application is not complete without female scientists researching women's natural traits from their own perspective, thus countering male biases.

By seeking to unite all women under a banner of a "global sisterhood," many argue that differences based on race, class, nation, status, age, and other complexities in women's lives are erased. In many ways, cultural feminists have broadened their focus and depth of analysis to include other elements of culture. This includes the unique history and practices of women of color in the United States as well as women's experiences in other nations. However, the criticism remains that through maintaining a singular focus on "woman," even with this expansion, these other factors remain in a secondary position. Additionally, many of the feminists who do utilize a wider definition of cultural feminism, one that includes race, class, age, and so on, resist using an essentialist foundation of gender and instead focus on the complexities of all of these differences.

Another strong critique of cultural feminism is that it resulted in establishing "rules" as to "who" could be a feminist. Women were expected to embrace the concept of being "woman centered" or "woman identified." This often resulted in an expectation that women would decrease their involvement with and reliance on men. This practice did not last long, nor was it widely embraced by all cultural feminists. Additionally, men were discouraged from being part of this type of feminism no matter how "liberated" they might have been. Women were expected to change their ideas and behaviors in order to liberate themselves, yet many women felt judged as not being "feminist enough" or "women centered enough," and that only true feminists were in a position to determine who or what "woman" meant. This created and encouraged an elitist attitude within cultural feminism. Additionally, by not challenging patriarchal systems that create and perpetuate the ideology that women are inferior to men, this type of feminism fails to address larger systemic issues and relies on meeting needs within the status quo rather than critiquing the status quo.

cultural imperialism

Kristina Wolff

Cultural imperialism is the process and practice of promoting one culture over another. Often this occurs during colonization, where one nation overpowers another country, typically one that is economically disadvantaged and/or militarily weaker. The dominant country then forces its cultural beliefs and practices onto the conquered nation. This has happened since nations have been warring, beginning with the Greek and Roman empires to the French and British empires, the American Revolution and the rise of communist governments in China and the Soviet Union to present day changes in governments around the world.

Culture can be imposed in a variety of ways, such as through creating new laws and policies concerning what specific types of education, religion, art, and language are to be used. For example, when Native North American tribes were forced onto reservations, the United States government dictated that children attend

Christian based boarding schools, they were taught to read and write English, and the use of their native language was discouraged and/or forbidden.

As a result of this, people find alternative ways of maintaining their culture; sometimes groups are forced into exile and their cultural practices are outlawed. Language or music is adapted as a means to continue the culture. For example, stories can be hidden within song lyrics and rhythms from their traditional music are merged with the new dominant forms as a means of maintaining parts of their culture. As with the Native North Americans, other populations have also been forced to change their style of dress, religion, language, and customs. This is common through the suppression of religion and has happened in various countries including China, Cuba, Germany, the Soviet Union, and Afghanistan.

Cultural imperialism differs from cultural diffusion primarily due to the mechanisms used to change culture and the roles that power plays in the process. Cultural diffusion occurs "naturally" when people and groups from other cultures interact with each other. It does not result in the purposeful reduction or elimination of various cultural aspects.

Cultural imperialism also occurs through programs designed to assist other nations, particularly developing nations. This can range from the ways in which small groups from western nations help out communities and villages to the impact of large international organizations' efforts at creating positive change. It is not uncommon for organizations such as the United Nations or World Bank to place conditions on loans or grants they provide to nations. Often monies are designated for specific projects such as building roads where these groups believe it is most beneficial for the nation, as well as constructing schools or health clinics. Complications arise through this process, such as when curricula are being developed for the schools. By teaching students English, in the belief they are being better prepared for opportunities outside of their native country, this practice, along with the ways in which students are being instructed, reinforces western ideals and behaviors, often to the detriment of their existing culture.

Globalization has created a new vehicle by which cultural imperialism can occur, often

with minimal resistance or acknowledgment that it is happening. Supporters of the expansion of "free markets" argue that cultures are fluid and therefore cultural imperialism is a "natural" part of the growth of trade. If western practices and ideas are the most successful, then it is believed that cultural practices associated with them are better than other cultures. Some of the main challenges to this thinking include investigating what exactly is being transferred or imposed onto other nations, what group benefits from the cultural shifts, and what cultural aspects become lost. Research focuses on examining changes in images and content of art, music, fashion and clothing, sports and recreational activities as well as changes in consumerism, due to the influences of globalization.

Critiques of the effects of globalization often concentrate on "what" is being imposed on other nations. For example, many argue the spread of McDonald's, Kentucky Fried Chicken, and Wal Mart represents positive change as they bring jobs and relatively inexpensive goods to other nations. However, the rapid expansion of these types of restaurants or stores also reflects a specific kind of American culture that is shaped and dictated by corporations. Many ask whether these kinds of businesses reflect US culture or whether they are simply an expansion of US capitalism.

Those who are actively challenging and resisting the spread of western practices and the effects of globalization often reside in places where they are experiencing this "new" wave of cultural imperialism. Scholars are examining the impact of cultural imperialism and larger issues connected to colonialism as a means to retain culture that is in danger of disappearing as well as to develop deeper understandings of the impact of outside forces on their nation and to expose the effects of these practices. Many citizens are openly challenging the oppressive nature of western expansion, creating coalitions and organizations aimed at maintaining cultural traditions and practices. Some nations have created protectionist policies in an effort to slow down the pace of western nations purchasing their land and other natural resources.

cultural relativism

Bernd Weiler

Cultural relativism, a highly complex doctrine surrounded by various epistemological, political, and ethical controversies, can be broadly defined as the view that culture is the key

variable to explain human diversity and that an individual's behavior, thought, emotion, perception, and sensation are relative to and bound by the culture of the group he or she belongs to. Within this frame of thought, culture is usually conceptualized as a holistic, historically grown entity with distinctive features and clear cut boundaries. The period of enculturation during early childhood is regarded as crucial. The autonomy of the individual is seen as more or less negligible, intragroup differences are usually minimized, and intergroup differences maximized. In the history of ideas, the emphasis on the cultural diversity, the cultural relativity, and boundedness of human experience has often been linked to and, at times, conflated with normative relativism, holding that all cultures are of the same "worth" and that an individual's ethical behavior ought to be judged in terms of the values of his or her culture (cf. Spiro 1986). Cultural relativist arguments have also often been employed to support moral skepticism and to criticize the values of one's own culture. Michel de Montaigne's (1533–92) famous essay "Of Cannibals" might serve as a famous example of the argumentative intertwining of the descriptive and the moral aspect of cultural relativism.

The cultural relativist stance is opposed to the universalist position according to which the cultural context is irrelevant to the concepts of truth, beauty, goodness, justice, and so on. It is also opposed to other forms of relativism, such as biological or racial relativism, which holds that differences between groups are due to differences in innate endowments. Analytically, the various forms of cultural relativist arguments can be distinguished along the two dimensions of extent and intensity. In its broadest form, cultural relativism extends to all manifestations of human existence. In this context even truth is regarded as a local and culture bound phenomenon, a position known as epistemological or cognitive relativism. In its narrow form, cultural relativists argue that culture is relevant only to certain aspects of human life (e.g., aesthetics and ethics) and irrelevant to others (e.g., knowledge). With regard to the dimension of intensity, one can distinguish between those cultural relativists who argue that culture is the sole *explanans* versus those who hold that culture is a significant *explanans*

of human thought, emotion, volition, and so on. In its broadest and most intense version, radical cultural relativism, a position favored today by some postmodernist thinkers, can be seen as a form of group solipsism beset with the various methodological difficulties and inconsistencies associated by R. K. Merton with the doctrine of insiderism (cf. Merton 1972).

Cultural relativist patterns of argumentation have been a constant feature of social analysis and criticism in the intellectual history of the West since the days of the "founding fathers" of ethnography, Hecataeus of Miletus and Herodotus of Halicarnassus. Modern day cultural relativism, an intellectual twin of historicism, can be traced back to the eighteenth century critical appraisal and partial rejection of the Enlightenment's over rationalistic and atomistic picture of the human being and its progressivist conception of history. Opposing the stage theories of civilizational development, the thinkers of the so called Counter Enlightenment, most notably Vico, Möser, and Herder, argued that every historical period and every culture has to be understood as an end in itself and as intrinsically valuable. The German American cultural anthropologist Franz Boas and his students (e.g., A. L. Kroeber, R. H. Lowie, E. Sapir, R. Benedict, M. Herskovits, and M. Mead), the scholars most often associated with the doctrine of cultural relativism in the twentieth century, can be seen as the heirs to this Counter Enlightenment's emphasis on the uniqueness of each culture. By criticizing simultaneously unilineal theories of social evolutionism, racial relativist explanations of cultural differences, and the axiological relativism à la Lévy Bruhl's prelogical mentality, Boas and his school contributed decisively to the contemporary relativistic and pluralistic concept of culture (cf. Stocking 1982 [1968]). The epistemological and moral issues associated with cultural relativism have been hotly debated within and without anthropology throughout the twentieth century. Identifying a number of human universals, critics argued that there existed a "common denominator of cultures" and that the diversity of cultural forms was limited by the psychophysical constitution of humans (e.g., B. Malinowski), the external environmental constraints (e.g., M. Harris), and/or the possible number of

functional relations and logical combinations of society's subsystems (e.g., G. P. Murdock). With regard to the moral questions, it was above all the human rights movement, arising in the aftermath of World War II, that severely challenged and undermined cultural relativist thinking. If one contextualizes the cultural relativism of the early twentieth century, however, it is important to note that to the first generation of professional anthropologists cultural relativism was not so much a codified doctrine and an epistemological position as part of the attitudinal tool kit when working in the field. As such, it amounted to a liberal minded plea for tolerance, implying the postulate to rid oneself of one's own cultural prejudices, to suspend moral judgments, and to approach "strange" cultural values as "objectively" as possible. This legacy still deserves attention as even today a certain dose of cultural relativism might be a good, if not the best, medicine against the universal disease of ethnocentrism.

cultural reproduction

Adrian Franklin

Cultural reproduction is frequently considered to describe how cultural forms (e.g., social inequality, privilege, elite status, ethnicity) and cultures themselves are transmitted intact, from one generation to another. This idea emanates strongly from original work by Pierre Bourdieu in the 1970s on the role of the education process in reproducing class inequality and from such ethnographic classics as Paul Willis's *Learning to Labour* (1977) that showed how inequality could be reproduced culturally despite the best efforts of a benevolent education system. However, subsequent work on the concept of culture suggests that a concentration on class reproduction implies a very restricted sense of the term "reproduction," and that more significant dimensions of reproduction inhere in the idea of culture itself (Jenks 1993). Indeed, Jenks shows how cultural reproduction lies at the heart of more traditions of sociology than Marxism and neo Marxism.

The word culture derives from the notion of growth and development and does not imply stasis or repetition. Williams (1981) shows how

by the eighteenth and nineteenth centuries the word had itself grown to mean not only husbandry but also human development, specifically the cultivation of aptitude and understanding or, in other words, cultural capital or *change*. Critically, it remained only a *verb* until the nineteenth century. Another way of looking at this is suggested by Jenks, who argues that the idea of culture emerged from the noun *process*, in the sense of nurture, growth, and bringing into being – in fact to cultivate in an agricultural or horticultural sense. "Culture as process is emergent, it is forthcoming, it is continuous in the way of reproducing and as in all social processes it provides the grounds and parallel context of social action itself" (Jenks 1993: 1).

Drawing on definitions of culture from anthropologists, Jenks suggests that culture embodies the idea of accumulated resources (material and immaterial) that a community might employ, *change*, and pass on. Essentially it is the socially learned behavior and the shared symbolism of a community: it reveals and structures, empowers and constrains. The problem with cultural reproduction as Jenks sees it also concerns a restricted sense of the term reproduction. The tendency within Marxist traditions of sociology has been to see reproduction phenotypically. In this, reproduction is restricted negatively to repetition, to the copy or, in a weaker sense, to "imitation" or "likeness." As replication it implies a metaphor of restraint or the restriction on choice, and here of course is where ideology, state apparatuses, and symbolic violence are deployed in Marxian terms.

However, reproduction also has the *genotypic* sense of excitement, positivity, and vibrancy – as is implied in the newness of sexual and biological reproduction. Here the image changes to one of generation rather than repetition, of change and new combinations, innovation and creativity.

Jenks argues that in several traditions of sociology there is an implicit sense of a more positive form of cultural reproduction. In Durkheim's work the challenge of cultural reproduction was "to search for the appropriate collective credo that will ensure the reproduction of solidarity in the face of change" (Jenks 1993: 8). In other words, for Durkheim, it is a

defining feature of cultures that forms of solidarity will be produced in changed circumstances. The churning nature of modernization undermined mechanical forms of solidarity based on traditional societies, but new organic forms appeared among the newly individualized cultures of the city. As Jenks argues, "the Durkheimian tradition views reproduction with an optimism, indeed a positivism; its metaphors are consensual rather than divisive and its motivation is integrative" (1993: 8).

Equally, for ethnomethodologists there is a strong sense of creative cultural reproduction emanating from ordinary conversation and interaction. According to this view an inarticulate consensus must exist between competent social actors in order for interaction to work at all. And it is within the contexts of conversations and interactions that the business of cultural reproduction, whether of restraint and replication or innovation, is carried out/negotiated.

Cultural reproduction as a process must therefore be tracked and watched over time in methodological terms, and Willis's ethnographic work on the working class "lads" in a Midlands school remains the archetype. In this study it was shown that the lads were not failed by an educational system geared solely to reproduce the privilege of the elite but by their own culture whose appeal proved stronger than the alien culture of education based social mobility. Willis shows how the cultural richness of working class culture competed with that offered by the school and how the lads embodied this culture and used it against the school and its teachers. However, this study took place in the context of a vibrant and secure labor market for blue collar workers. A later (1990s) study was completed when that labor market had all but evaporated (Mac an Ghaill 1994) and this showed how new circumstances engendered new forms of cultural response. Mac an Ghaill did find a group corresponding to the lads, but unlike the superconfident 1970s group, they were undergoing a crisis of masculinity as the economic base of their culture had disappeared. Meanwhile, the new circumstances had produced a more fragmented masculine culture at the school with far more reaching out for the cultural capital that the school could offer.

Blasko's work in Hungary also found that schools offering cultural capital had been used effectively by working class parents and children to achieve social mobility and by the upper classes to maintain their existing positions (Blasko 2003: 5).

cultural resistance

Stephen Duncombe

Cultural resistance is the practice of using meanings and symbols, that is, culture, to contest and combat a dominant power, often constructing a different vision of the world in the process. The practice is as old as history. The Hebrew Scriptures, for example, were a cultural means with which to create Jewish identity and then hold on to that identity in the face of Roman oppression. The stories of Jesus and Mohammed served similar functions. The modern theory of cultural resistance, however,

was first articulated in the mid nineteenth century by Matthew Arnold.

Arnold wrote his famous essay *Culture and Anarchy* at a time when his England was under going massive change: industrialization, urbanization, and an extension of the franchise to the working classes. Whereas some considered this progress, Arnold saw only chaos. But culture, as “the best which has been thought and said” (1990 [1869]: 4), offered a solution. It was a way to resist and rise above the politics and commerce and machinery of the day, providing a universal standard upon which to base “a principle of authority, to counteract the tendency to anarchy which seems to be threatening us” (p. 82). Culture was a Platonic platform where “total perfection” could be cultivated, eventually returning to the messy material world – if at all – in the form of an ideal state to guide society.

Arnold may have been the first modern voice to articulate a strategy of cultural resistance, but it is an intellectual and activist on the opposite side of the political spectrum, the Italian communist Antonio Gramsci, who framed its contemporary use. Gramsci, writing from prison in the late 1920s and 1930s, reflected on why the revolutions he fought for in the West had so far failed. Part of the reason, he concluded, was a serious underestimation of culture and civil society. Power resides not only in institutions, but also in the ways people make sense of their world; hegemony is a political *and* cultural process. Armed with culture instead of guns, one fights a different type of battle. Whereas traditional battles were “wars of maneuver,” frontal assaults which seized the state, cultural battles were “wars of position,” flanking maneuvers, commando raids and infiltrations, staking out positions from which to attack and then reassemble civil society (1971: 229–39). Thus, part of the revolutionary project was to create counterhegemonic culture behind enemy lines. But if this culture was to have real power, and communist integrity, it could not, as Arnold believed, be imposed from above; it must come out of the experiences and consciousness of people. Thus, the revolutionary must discover the progressive potentialities that reside within popular consciousness and from this fashion a culture of resistance. Gramsci’s theories of cultural resistance can be glimpsed in the practice

of Mahatma Gandhi’s invocation of *satyagraha* and Indian tradition to resist British colonialism, and, more recently, in the culture heavy tactics of the rebel Zapatista army in Mexico and the magical realist communiqués of their Subcommandante Marcos.

In the academy, Gramsci’s ideas shaped the mission of the Center for Contemporary Cultural Studies (CCCS) at the University of Birmingham in the 1970s. The CCCS is best known for its subcultural studies, and it was within these mainly working class subcultures that researchers found an inchoate politics of resistance. Dick Hebdige, for example, writes about how punk rockers performed the decline of post war Britain with ripped up clothes, songs mocking the queen, and lyrics that warned: “We’re your future, no future.” Through culture young people contested and rearranged the ideological constructions – the systems of meaning – handed down to them by the powers that be. Cultural resistance, however, was recognized as a double edged sword by CCCS director Stuart Hall and his colleagues. Subcultures opened up spaces where dominant ideology was challenged and counter hegemonic culture created, but these contestations and symbolic victories often remained imprisoned in culture, never stepping outside to confront material power. These were “magical resolutions,” as Stanley Cohen explains, to real world problems.

Cultural studies continues to be concerned with cultural resistance. Readers “re read” romance novels against the grain, and music fans claim ownership of the bands they love through zine writing. Even shopping is championed by John Fiske as an act of resistance: “a sense of freedom, however irrational, from the work involved in working and loving under patriarchy” (1989: 42). But Gramsci’s question of how this cultural resistance translates into a revolutionary strategy, or even the less ambitious question of how these cultural practices translate into material changes, is less often posed. Given the left of center politics of many in the cultural studies camp, it is ironic that culture is often celebrated as an escape – cultural resistance as the conservative Matthew Arnold understood and appreciated it.

Critics have also questioned the efficacy of cultural resistance within a consumer capitalist

economy that needs constant innovation to survive. Within this context, the drive to create an oppositional culture merely serves to create a new market for new products. As Frankfurt School critic Theodor Adorno snidely remarked about the jazz music fan as far back as 1938: "He pictures himself as the individualist who whistles at the world. But what he whistles is its melody" (2002 [1938]: 298). (Adorno did, however, maintain that the patently unpopular atonal music of Schoenberg held out resistant possibilities.)

Today, there is a renewed understanding – by activists, if not yet all academics – that cultural resistance is a necessary, but not sufficient, means of resistance. Using culture as a political tool is absolutely critical in a media saturated society linked by a global communications network. But in a world where the image of Che Guevara sells Swatch watches, cultural resistance, by itself, is not enough.

cultural studies

Elizabeth Long

Cultural studies is an interdisciplinary field that explores the linkages between society, politics, identity (or the person), and the full range of what is called "culture," from high culture and the popular arts or mass entertainment, to beliefs, discourses, and communicative practices. Cultural studies has drawn on different national traditions of inquiry into these connections – from the Frankfurt School's studies of the mass culture industry, and of the psychological processes that undercut democracy in liberal and affluent societies, to French structuralist and poststructuralist critiques of ideology, constraining categorical frames, and a monadic and unified concept of the self. The branch of cultural studies that early drew the most attention from sociologists was that articulated by the Birmingham Centre for Contemporary Cultural Studies, perhaps in part because Birmingham scholars were inspired by some aspects of American sociology, especially the Chicago School tradition, which gave their work a recognizably social dimension.

Taking Birmingham as an example is instructive in pointing out some characteristics of cultural studies as a field. Conventionalized intellectual genealogies often begin with the work of Raymond Williams (1958, 1961), Richard Hoggart (1957), and E. P. Thompson (1963). All three challenged dominant traditions in the humanities in post war England. Hoggart and Williams argued first that literary or "high" culture is just one expression of culture, in the more anthropological sense – the broad range of meanings and interactions that make up social life. Second, they argued that cultural expressions could only be understood in a broader social context of "institutions, power relations, and history" (Seidman 1997). This led Williams (1961) to analyze, for example, the rise of the novel in modern England as part of the gradual evolution of a broad based reading culture, and to discuss the shifting meanings and (sometimes ideological) images that clustered around "city" and "country" as agriculture, industry, and urbanization changed the landscape of England

(Williams 1973). In *The Uses of Literacy*, Hoggart examined the changing culture of the working class through analysis of neighborhoods, pubs, and family interaction as well as popular music and literature in a book that combined personal reflection with historical sociology (Hoggart 1957). E. P. Thompson's *The Making of the English Working Class*, addressing similar problems of historical change in the early nineteenth century, showed that both Marxist conceptions of class and the discipline of history could be fruitfully broadened if culture – whether Methodism or the literary minded corresponding societies developed by skilled craftsmen – were taken into account in analyzing working class English politics (Thompson 1963).

This first generation of British cultural studies scholars were all “men of the left,” confronting the failures of communism, the idiosyncrasies of English working class politics, and the peculiarities of democratization under the sign of commercial culture. All were, in other words, *critical* analysts of what they liked to call “lived experience,” that very term indicating how thoroughly this version of cultural studies integrated cultural expressions with social life. They also were all seriously involved with alternative sites of mainly working class education, whether Workers' Education Association classes or University Extension courses (Goodwin & Wolff 1997), a commitment that led to the rather unusual institutionalization of cultural studies at Birmingham. And for all three, the scholarly moves they made were from the humanities and its traditional categories of analysis and evaluation into a more fully articulated sense of cultural and social reality.

When cultural studies became institutionalized under Hoggart as one subgroup of literary studies at the University of Birmingham in 1964 as the Centre for Contemporary Cultural Studies (CCCS), it retained some distinctive features from its prehistory. For example, staff and student groups cooperated in administering the center, and a Centre General Meeting of administrative and intellectual groups formulated policy. Most innovative, perhaps, were the self governing “subgroups” of researchers (often students) and teachers. Richard Johnson (1997) mentions that in 1974, for example,

there were groups on Art and Politics, Cultural History, Media, Subcultures, Women's Studies, Cultures of Work, and two Marxist Reading Groups. These groups produced most CCCS books and journals, and the “collective book” remained typical of Birmingham scholarship into the 1990s. So, too, did a relatively interdisciplinary and activist approach to scholarly careers, which may have contributed to the precarious institutionalization of cultural studies in Britain and its common location in academic sites that were themselves interdisciplinary.

As a younger generation of scholars moved to the fore in British cultural studies, they brought with them concerns from the student movement (Johnson 1997), and also training in sociology. Seidman, for example, mentions Stuart Hall, David Morley, Dorothy Hobson, Paul Willis, Phil Cohen, Dick Hebdige, Ian Chambers, and Angela McRobbie in this regard (Seidman 1997; Hall 1980b). They turned from the earlier thinkers' humanism to take up insights from sociological studies of deviance, subcultures, and popular culture, and at the same time turned towards strands of European Marxism – notably Althusser and Gramsci – as a corrective to what they characterized as the earlier generation's a theoretical “Englishness.”

Concerned about the new ways social domination operated in a post war world that was, at least for many in Europe, both relatively affluent and at peace, these scholars investigated the culture/society connection as a promising location for understanding this process. Post war shifts in the social organization of cultural and communications media also gave popular forms of culture immense social power. This was particularly true of cultural forms and technologies developing in and exported from the US, which was becoming a global force because of television, Coca Cola, and rock and roll – and later, MTV, the shopping mall, music videos, and theme parks – as well as more traditional forms of economic and military power. This shift also required new ways of thinking that linked culture, as it was linked in people's lives, more closely to society and politics, especially in relation to critical questions about democracy and equality.

Birmingham scholars often used a processual view of Gramsci's ideas about hegemony and

resistance in their analyses of popular cultural forms and usages. Subcultures became a particularly interesting object of study because members of subcultures formed collective and often countercultural identities around styles they fashioned from cultural commodities (Willis 1977; McRobbie, 1984). Birmingham appropriations of both Gramsci and Althusser also emphasized the contingent nature of ideological formations and their relative autonomy – from class determinism, in particular. This foregrounded history and human activity, which Birmingham scholars often discussed as “practice,” as well as opening up consideration of other forms and sites of domination, such as gender, race, or region (Bennett et al. 1986; Hall 1980a, 1991).

The problematic that informed scholars at Birmingham also influenced research arising from different national traditions. So in France, for example, structuralist semioticians like Roland Barthes (1972) drew on a long French preoccupation with language and linguistic culture to investigate how language like cultural forms encoded social domination in popular cultural “mythologies.” Somewhat later, post structuralist thinkers like Michel Foucault (1977, 1978, 1980) moved beyond purely linguistic discourses to understand how power and knowledge shape subjectivity, and Pierre Bourdieu (1977, 1984, 1991), drawing on both anthropology and sociology, considered the way culture, and legitimate culture in particular, influenced both social stratification and personal “dispositions.”

At roughly the same time in Germany, Jürgen Habermas drew on the Frankfurt tradition of critical social thought to examine the failure of formal politics to address new configurations of social domination. His influential response turned toward an analysis of the public sphere – conceived as a “realm” outside of the marketplace and the state, yet not reducible to private life. His formulation was itself profoundly cultural, first, because of its insistence that communication was an aspect of social reality irreducible to economic interests. Second, he discussed the evolution of the public sphere in Europe historically, locating different sites (e.g., the coffee house) and media (the newspaper) of communication that enabled conversation based on reasoned arguments about

fundamental social and political assumptions to take place. In his view, this was a necessary precondition for democracy. Although his conviction that both state and market were eroding the public sphere made Habermas pessimistic about the prospects for genuine democracy in the present, he argued nonetheless for a basic human capacity to engage in the rational discussion it would require (Habermas 1971, 1979, 1984–7, 1989).

Habermas’s work remains at a high level of abstraction, and has filtered into American scholarship mainly as the point of departure for more concrete – and often historical – examinations of “the public sphere” and for critical appraisals of the concept itself (Fraser 1989; Calhoun 1992a, 1992b; Schudson 1998). This kind of interdisciplinary, international borrowing is quite typical of cultural studies, and may partially explain why cultural studies scholarship has been more easily integrated into multidisciplinary fields, subfields, or programs than into more rigidly bounded disciplines. Similarly, the fact that several strands of cultural studies work (as was the case in Birmingham) originated as critical reformulations of the humanities, and have maintained a close connection to interpretive methodologies and to culture itself (however broadly defined), may explain why US cultural studies has been largely institutionalized in humanities rather than in the social sciences, with the exception of anthropology, some culturally inflected areas of sociology, and some aspects of political theory.

Nonetheless, broad questions about how contemporary culture relates to an emerging geopolitical order featuring new constellations of technology and capital and new configurations of collective organization – from regional religious fundamentalisms to transnational corporations and political unions – have continued to bring many scholars into the interdisciplinary arena of cultural studies. Since the academy is itself experiencing the same kind of dislocations, dispersals, and reconcentrations of power that scholars are attempting to understand in the environing social world, the enterprise of cultural studies has generated a broad array of such theoretical and empirical lines of inquiry. For example, urbanists have noted (like Hoggart in the 1950s) that the communities that provided

roots for ethnic or class solidarity have been dispersed by urban renewal, deindustrialization, and other developments effacing an older sense of place in contemporary cities. But more recently, gentrification, global hip hop culture, planned communities, and theme parks have begun to provide other material for thinking through the connections between "community" and identity. So critical geographers have turned to work by Jameson (1991), Lyotard (1984), and other postmodernists to understand how these new urban forms might structure people's experiences and possibilities for collective action (Harvey 1989; Zukin 1991, 1992; Gregory 1994). At the same time, changes in the social organization of sexuality and medical science have led other scholars to take up thinking by Foucault (1978) that examines how discursive formations linking textual knowledge, technical capabilities, and institutional developments have worked to structure contemporary sexual subjectivities and their emergence as socially recognized "identities" (see Butler 1993; Weston 1998; Sedgwick 2003; Seidman 2003; Eribon 2004).

Some of this reinvention involves the disappearance of traditional grounds for disciplinary activity. For example, high cultural texts no longer have the privileged place they enjoyed in early twentieth century public education. This has led critical literary scholars to become self conscious about the historical roots of national literary studies and the sociopolitical dimension of canonization. In turn, this has engendered an examination of the institutions (literary criticism, the discipline of English, the Book of the Month Club) that work to define what we call literature and to assign criteria of literary value (Radway 1997), as well as a broad ranging analysis of popular cultural "texts" and their uses in the social world. Similarly, small scale low technology societies are either vanishing or negotiating their induction into global networks of technology, labor, and consumption. These geopolitical developments have led anthropologists to rethink the relationship between ethnographer and subject, to search at home as well as among traditional Others for ethnographic opportunities, and to recognize affinities between their signature methodology and that of tourists, state department officials, and world music entrepreneurs (Marcus 1999).

Yet, similar opportunities for cultural studies scholarship appear as new disciplinary formations emerge in response to social change. Social studies of science, for instance, have grown up in tandem with the enormous growth of "big science" in the recent past, and their critical take on science comes as much from public questions about an endeavor that has brought us nuclear weapons and environmental devastation along side space flight and the Salk vaccine, as from purely academic developments. Other new areas of investigation that are attracting cultural studies scholars include visual studies, cybercultures and communities (this has also spawned Internet based research methodologies), new technologies of embodiment and possibilities for identity construction, and globalization, which has affected the whole range of what are sometimes called the human sciences.

While this scholarship has spurred some significant departmental or program level institutionalization in American universities, it is most obviously present as a major paradigm in existing interdisciplinary programs, such as American studies, ethnic and women's studies, urban studies, and science and technology studies, and is an important intellectual force in publishers' offerings and conferences both in the Anglophone world and beyond. It is also what one scholar calls an "accent" in more entrenched academic fields, perhaps more welcome in traditionally interpretive disciplines or traditions of inquiry than in those underwritten by positivist epistemology. For this reason, much of sociology has seen cultural studies as a threat rather than an opportunity, yet one can clearly see openings toward cultural studies in cultural sociology, sociology of religion, gender/sexuality, and race/ethnicity, urban sociology, qualitative sociology, and some branches of social theory.

cultural studies, British

John Storey

British cultural studies works with an inclusive definition of culture. That is, it is a “democratic” project in the sense that rather than study only what Matthew Arnold called “the best which has been thought and said” (*Culture and Anarchy*, 1867), British cultural studies is committed to examining *all* that has been thought and said. To put it simply, culture is how we live nature (including our own biology); it is the shared meanings we make and encounter in our everyday lives. Culture is not something essential, embodied in particular “texts” (that is, any commodity, object, or event that can be made to signify); it is the practices and processes of making meanings with and from the texts we encounter in our everyday lives. In this way, then, cultures are made from the production, circulation, and consumption of meanings.

Cultures, therefore, do not so much consist of, say, books, but are the shifting networks of signification in which, say, books are *made* to exist as meaningful objects. For example, if I pass a business card to someone in China, the polite way to do it is with two hands. If I pass it with one hand I may cause offense. This is clearly a matter of culture. However, the “culture” is not so much in the gesture, it is in the “meaning” of the gesture. In other words, there is nothing essentially polite about using two hands; using two hands has been made to signify politeness. Nevertheless, signification has become embodied in a material practice, which can, in turn, produce material.

This is not to reduce everything “upwards” to culture as a signifying system, but it is to insist that culture defined in this way should be

understood “as essentially involved in *all* forms of social activity” (Williams 1981: 13). While there is more to life than signifying systems, it is nevertheless the case that “it would ... be wrong to suppose that we can ever usefully discuss a social system without including, as a central part of its practice, its signifying systems, on which, as a system, it fundamentally depends” (p. 207).

According to British cultural studies, then, to share a culture is to interpret the world – make it meaningful and experience it – in recognizably similar ways. So called “culture shock” happens when we encounter a radically different network of meanings; when our “natural” or “common sense” is confronted by someone else’s “natural” or “common sense.” However, cultures are never simply shifting networks of shared meanings. On the contrary, cultures are always both shared and contested networks of meanings. That is, culture is where we share and contest meanings of ourselves, of each other, and of the social worlds in which we live.

British cultural studies draws two conclusions from this way of thinking about culture. First, although the world exists in all its enabling and constraining materiality outside culture, it is only in culture that the world can be *made to mean*. In other words, culture constructs the realities it appears only to describe. Second, because different meanings can be ascribed to the same “text” (anything that can be made to signify), meaning making (i.e., the making of culture) is always a potential site of struggle and negotiation. The making of meaning is always entangled in what Volosinov (1973) would call the politics of “multi accentuality.” Rather than being inscribed with a single meaning, a “text” can be articulated with different “accents.” That is, it can be *made to mean* different things; in different contexts, with different effects of power. A text is not the issuing source of meaning, but a site where the articulation of meaning – variable meaning(s) – can be produced in specific contexts. We implicitly recognize this when ever we refer to, for example, a feminist reading, a Marxist reading, a queer reading, a postcolonial reading. In each instance, the intertextuality of the text is confronted by the intertextuality of the reader. In this way, then, the symbolic work of “production in use” is never a simple

repetition of the semiotic certainties of the lecture theater or the seminar room. For example, masculinity has real material conditions of existence, but there are different ways of representing masculinity in culture and different ways of being “masculine.” Therefore, although masculinity seems to be fixed by its biological conditions of existence, what it *means*, and the struggle over what it means, always takes place *in* culture. This is not simply an issue of semantic difference, a simple question of interpreting the world differently; it is about relations of culture and power; about who can claim the power and authority to define social reality; to *make the world (and the things in it) mean* in particular ways.

Meanings (i.e., cultures) have a “material” existence in that they help organize practice; they help establish norms of behavior. My examples of different masculinities and the passing of business cards in China are both instances of where signification organizes practice. Those with power often seek to regulate the impact of meanings on practice. In other words, dominant ways of making the world meaningful, produced by those with the power to make their meanings circulate in the world, can generate “hegemonic truths,” which may come to assume an authority over the ways in which we see, think, communicate, and act in the world: that is, become the “common sense” which organizes our actions (Gramsci 1971). Culture and power, therefore, are the primary object of study in British cultural studies.

cultural tourism

Melanie Smith

“Cultural tourism” could be defined as tourism that focuses on cultural attractions and activities as a primary motivating factor for travel. Notwithstanding the broad definitions of culture that abound within postmodern and populist writings, parameters need to be drawn around what is defined as “culture” in this context. It is therefore useful to break the concept of cultural tourism down into a number of subsets. As argued by Smith (2003: 29), “cultural tourism can no longer be considered as a special interest or niche sector, but instead as an umbrella term for a range of tourism typologies and diverse activities which have a cultural focus.”

Richards (2001: 7) suggests that cultural tourism covers the consumption not just of “the cultural products of the past,” but also of contemporary culture or the “way of life” of a people or region. Hughes (1996, 2000) differentiates between “universal,” “wide,” “narrow,” and “sectorized” cultural tourism. These definitions correspond broadly to perceiving culture as a whole way of life; to engaging with specific ethnic or indigenous groups; to experiencing the “artistic and intellectual” activities of a society; to visiting specific heritage attractions or arts venues. Cultural tourism encompasses heritage (both tangible and intangible), the arts (including festivals and events), and contemporary culture insofar as it relates to the lifestyles and traditions of a people or place. Cultural tourism is not simply about the passive consumption of heritage attractions or attendance of festivals, it can also involve a high degree of interaction with local people, as well as the pursuit of creative activities

(e.g., painting, photography, dance). Indeed, Richards and Raymond (2000) suggest that creative tourism is becoming a growth sector within cultural tourism.

As the demand for tourism increases, so apparently does the demand for cultural tourism, which appears to have grown exponentially in recent years. For example, McKercher and Cros (2002) estimate that as many as 240 million international journeys annually involve some element of cultural tourism. This may have something to do with broadening definitions of culture, as well as the apparent diversification of tourist interests (Sigala & Leslie 2005). The cultural tourist could be described as a tourist who is better educated than average (Richards 1996), and generally concerned with knowledge seeking and self improvement, thus the inner journey is likely to be as important as the outer journey. Cultural tourists actively seek difference and authentic and spontaneous (rather than “staged” or contrived) interaction with local people and places (Smith 2003). Tourism may often be described as “travel” whereby the cultural tourist elevates him/herself to the level of an adventurer or explorer. This is particularly the case in the context of indigenous and ethnic tourism. For this reason, cultural tourism has become increasingly politicized, and has sometimes been accused of being imperialistic, Eurocentric, or voyeuristic (Smith & Robinson 2006). However, cultural tourists are by no means homogeneous, neither in terms of motivations nor profiles. For example, McKercher and Cros (2002) differentiate between tourists for whom culture is a primary motivating factor (“purposeful”) and those who are “serendipitous” or “incidental.”

Cultural tourism can be subdivided into a number of typologies for the sake of greater definitional clarity, the facilitation of research, and product development.

HERITAGE TOURISM

Heritage tourism focuses on tangible artifacts from the past, including historical monuments, archaeological sites, religious sites, and museums. This includes World Heritage Sites,

of which there are now over 750 (including the Taj Mahal in India and the Pyramids in Egypt). Intangible heritage is also an important resource (e.g., the traditions, lifestyles, arts and crafts of local people). The interpretation and representation of heritage can be complex and contentious (e.g., concentration camps such as Auschwitz in Poland; Robben Island in post apartheid South Africa). Many heritage sites suffer from over visitation (e.g., Stonehenge in the UK; Ephesus in Turkey), therefore conservation and visitor management issues are of primary concern for this form of cultural tourism.

ARTS TOURISM

Arts tourism focuses on the visual arts (e.g., galleries) as well as performance (e.g., theaters, concerts) and other experiential forms of activity (e.g., festivals and events). There are some concerns that tourism can dilute or “trivialize” the arts. Many ethnic and indigenous art forms (e.g., Caribbean carnivals, Asian Mela festivals, Aboriginal arts and crafts, Andalusian flamenco dancing) are becoming more popular on a global scale, so care needs to be taken to ensure that they are not overcommodified.

CREATIVE TOURISM

Creative tourism involves tourists undertaking creative activities such as painting, pottery making, glass blowing, weaving, photography, and wood carving, either under the guidance of or independently of local people (e.g., with a tour operator). In many cases, creative tourism may be a subsidiary activity rather than a primary motivating factor, although growing numbers of tour operators are now offering special interest tours focused on creative activities (e.g., salsa holidays in Cuba, watercolor painting in Provence, cookery in Tuscany).

URBAN CULTURAL TOURISM

Urban cultural tourism focuses on city activities, which may include certain forms of heritage or arts tourism. Historic cities (e.g.,

Venice, Prague, Oxford) attract large numbers of international tourists. However, increasingly, cultural tourists are being drawn to deindustrialized cities that are being regenerated (e.g., Glasgow, Bilbao, Rotterdam). They may experience cultural mega events (e.g., expos) or visit “flagship” museums (e.g., the Guggenheim in Bilbao) or whole new cultural quarters or waterfronts (e.g., Barcelona, Cardiff).

RURAL CULTURAL TOURISM

Rural cultural tourism may incorporate aspects of indigenous or ethnic tourism, or creative activities. In some cases attractions have been purpose built to help develop tourism (e.g., ecomuseums in France and Scandinavia; historic centers in Ireland, Greece, and Spain). In others, former industrial sites such as coal mines have been regenerated and turned into attractions. For example, Blaenavon in Wales, Ironbridge in the English Midlands, and the Wieliczka salt mines in Poland have all been designated World Heritage Sites. Spinoffs from agro or farm tourism include gastronomic tourism, arts and crafts tourism, not to mention wine tourism (e.g., in the Douro Valley in Portugal; Stellenbosch in South Africa).

INDIGENOUS CULTURAL TOURISM

In this type of tourism, tourists visit indigenous peoples in their own habitat, although in many cases land has been taken from such peoples and they are forced to live in reservations (e.g., North American Indians) or to integrate into mainstream society (e.g., Australian Aborigines, Canadian Inuits). Tourists are generally interested in the lifestyles and traditions of indigenous groups, and may stay with families in their village (e.g., in Indonesian jungles or the Tunisian desert). Trekking and staying with tribal groups is popular in countries like Thailand or the countries of Central and South America. The environmental and sociocultural impacts can be significant, although cultural tourism can also help to raise the profile of indigenous groups and contribute to the renewal of traditions and cultural pride.

POPULAR CULTURAL TOURISM

This form of tourism focuses on some of the more “populist” forms of culture, such as attending sporting events or pop concerts, and visiting shopping malls and theme parks. It may also include visits to film or television locations or studios. In many regenerated former industrial cities, such attractions are proliferating and are often combined with more traditional forms of cultural tourism (e.g., art galleries, architectural features, museums).

The boundaries of cultural tourism are clearly being pushed further and further toward more global and contemporary forms of culture. Although a recognition of definitional and conceptual boundaries is important, the postmodern dedifferentiation of tourism, culture, leisure, and lifestyles can render this a somewhat elusive task.

culture

Lyn Spillman

Although the idea of culture seems common place and indispensable for thinking about human groups and human action, the term has resonated for more than a century with a variety of sometimes dissonant connotations (Kroeber & Kluckhohn 1963; Williams 1976; Smelser 1992). In vernacular usage, it may refer either to all the symbols, meanings, and values shared by members of a group, by contrast to other groups; or else to a specialized realm of expressive activities and artifacts contrasted with other institutional realms, like politics or the economy. Cultural sociologists now encompass both commonsense meanings of the term by treating as "culture" all socially located forms and processes of human *meaning making*, in specialized institutions, and whether or not they are confined to one clearly bounded group.

Cultural sociology is an area of social inquiry into meaning making, defined by its analytic perspective, rather than a particular empirical topic or institutional domain. Cultural sociologists investigate how meaning making happens, why meanings vary, how meanings influence human action, and the ways meaning making is important in generating solidarity and conflict. This analytic perspective applies to a wide range of substantive topics and social domains, contributing to the understanding of key sociological topics such as stratification, political institutions, social movements, and economic action, as well as to specialized domains of cultural production such as the arts, media, science, and religion. As a perspective, cultural sociology contrasts with sociological perspectives which focus on analyzing social structures regardless of the meanings attached to them, and with investigations which, although they might include information about norms, attitudes, and values, do not examine the contingent processes of their formation and change.

Sociological research on culture demonstrated significant intellectual and institutional growth as a well recognized area of inquiry only in the last decades of the twentieth century. As a result, cultural sociologists work with and weave together theoretical perspectives,

concepts, and methodologies drawn not only from classical sociology and its subsequent twentieth century developments, but also from a wide range of other disciplinary sources in anthropology and the humanities. Many significant contributions to the field, as well as its productive issues and tensions, derive their importance and their productivity from new syntheses of a variety of scholarly approaches (Friedland & Mohr 2004; Jacobs & Hanrahan 2005).

The sense in which "culture" refers to a clearly bounded group, by contrast to other groups, emerged in comparative reflection about differences among human populations which was prompted by European exploration and conquest across the globe (Stocking 1968). In this view, the entire way of life of a bounded group is thought to be embedded in, and expressed by, its "culture," and evident in any thing from weapons to religious myths. This idea of culture was central to the formation of cultural anthropology as a discipline (Kuper 1999). In the nineteenth century different cultures were often understood as hierarchically arranged according to western ideas of progress, but these evaluative connotations were pluralized and relativized in the course of the twentieth century, from the work of Boas through to the influence of postmodern and postcolonial theorists more recently. By the mid twentieth century, anthropological approaches had influenced common beliefs about culture, especially (1) that human societies cannot be explained simply by natural environment or human biology; (2) that cultural possibilities are innumerable; (3) that cultures are diverse; (4) that different elements within a culture are patterned and interconnected; and (5) that elements of culture must be understood by placing them in their context, rather than by treating them in isolation. It is indicative of the central importance of anthropology in the development of the idea of culture that sociological dictionaries, textbooks, and encyclopedias referred mostly to anthropology for their explanations of the term until the 1980s. Since then, sociological and anthropological approaches to culture have diverged, with anthropological research influenced more by postmodernism and postcolonial theory than research on culture in sociology. Anthropologists

who were particularly influential in the formation of cultural sociology are Clifford Geertz, especially for the strong rationale he provided for interpretive methods, and Mary Douglas and Victor Turner, for their Durkheimian analyses of cultural categories and of ritual, respectively. Questions canvassed in debates about culture in anthropology in the first half of the twentieth century – such as whether culture should be treated as patterned and emergent or as a collection of discrete traits, how to specify the relation between social structure and culture, how to understand persistence and change in cultural patterns, and how much analytic emphasis to place on “carriers” of culture, such as networks or cultural producers – have reappeared in contemporary sociological work on the topic (Singer 1968).

The sense in which “culture” refers to a specialized realm of expressive activities and artifacts also emerged in the nineteenth century, but it marked an increasingly strong contrast *within* western societies between expressive activities and other realms of social life (Williams 1976; Eagleton 2000). In the social differentiation and conflict of the transition to capitalism, industrialization, urbanization, revolution, and democracy, art and morality were thought to express higher human capacities and ideals than could be seen in economic and political life – though, for the same reasons, they could also be dismissed as unimportant for understanding the core dynamics of modern societies. The classification and evaluation of particular ideas and activities as “cultural” made the realm of culture a basis for critical judgment, as, for instance, for the Romantic writers of the nineteenth century or for critics of mass media in the mid twentieth century. This sense of “culture” became the core of scholarship in the humanities, as in the study of literature or art. It is in this sense that scholars have contrasted “high,” “popular,” “mass,” and “folk” culture, echoing in different ways the implication that culture should be a purer realm of human activity than the mundane realms of economic and political action, though the specific moral valuation attached to each term has often been the focus of extended scholarly debate. Within sociology the study of the arts

and mass culture developed a long tradition, but until recently was mostly considered peripheral to the discipline’s concern with the core dynamics of modern societies. More recently, theoretical approaches and methodologies drawn from the humanities, such as semiotics and narrative theory, have been important in the development of cultural sociology, enabling sociologists to conceptualize and analyze culture as an independent object of inquiry in new ways.

Influential classical social theorists – especially Marx, Durkheim, Weber, Simmel, and Mead – were writing at a time when the multiple senses in which culture might be understood were in flux. Against the background of issues generated by changes in European societies, culture did not become a central concept in sociological theory in the way it did in anthropology (Kroeber & Parsons 1958). Nevertheless, important ideas of each classical theorist seeded the study of culture in subsequent sociological investigation, and continue to do so (Alexander 1990). Marx’s linking of culture and power in the theory of ideology, and his critique of idealist theories, were refined and developed in the work of important twentieth century theorists such as Gramsci, Adorno, and Williams and the related work of the Frankfurt School and the Birmingham School. Weber’s historicist and hermeneutic emphases on understanding the implications of particular sets of ideas – such as those of the Protestant Reformation – as well as his theorization of cultural stratification by status, and of rationalization in modernity, added, for sociologists, an important theory of the historical significance of meaning making processes which remained in productive dialogue with Marx’s theory of ideology. Durkheim’s work on collective conscience, collective representations, cognitive categories, and ritual theorizes cultural processes as essential and constitutive social forces, though this work only had strong impact in sociology towards the end of the twentieth century. Like the other classical theorists, Simmel analyzed in depth the cultural impact of increasing complexity in modern societies, with special attention to issues of the changing nature of individuality and to increasing dominance of “objective” cultural products over autonomously generated “subjective”

culture. In contrast to these European theorists, the work of Mead, and more generally the American pragmatist tradition, influenced later work on culture by providing a basis for examining meaning making processes at the micro sociological level, in interaction and in subcultures (Long 1997).

Nevertheless, "culture" remained a residual category in sociology, and cultural sociologists now find precedents for their studies of collective meaning making under many different labels – for instance, in mid twentieth studies of the arts and of mass culture, in ethnographic studies of mostly deviant or powerless subcultures, in constructivist studies of social problems, and in the sociology of knowledge. Important studies of meaning making were also generated in the mid twentieth century by two major but opposing theoretical approaches: critical theories of ideology and structural functionalist theories of attitudes, values, and norms. However, the productivity of these theories for studies of culture ultimately ran aground on a theoretical impasse (Spillman 1995). Both generated important insights, but they took contradictory positions on the relative significance of domination and solidarity, or conflict and consensus. Both also tended to over generalize about culture, seeing it as a "reflection" of society, oversimplifying internal complexity, active cultural production, and the independent effects of meaning making processes themselves. These issues became the central focus for later sociological research on culture, which drew new theoretical energy from the work of theorists such as Foucault and Bourdieu on cultural power.

From the 1970s there were increasingly frequent calls for new sociological approaches to culture which avoided over generalized assumptions about consensus or ideology, which avoided both idealism and reductionism, and which did not confine themselves either to the study of subcultures or to the study of expressive artifacts like art. Cultural theorists working from a variety of different starting points (Geertz 1973; Bourdieu 1977; Hall 1978; Peterson 1979; Archer 1985; Swidler 1986; Wuthnow & Witten 1988; Alexander 1990) all rejected the contrasting alternatives which had previously shaped sociological approaches to culture, and introduced a variety

of conceptual innovations which generated more particular accounts of meaning making processes. These developments loosened old assumptions and shifted old debates, encouraging an unprecedented growth in sociological analyses of meaning making processes and the institutionalization of cultural sociology (Crane 1994; Smith 1998; Spillman 2002).

Three mid range reconceptualizations of "culture" then emerged in cultural sociology, although different approaches were often productively combined. First, drawing on the sociology of organizations, and on the sociology of knowledge, some scholars argued for a focus on specific contexts of cultural production, an examination of the ways particular meanings, values, and artifacts are generated in particular organizations, institutions, and networks, and how those social contexts influence emergent meanings (Peterson 1976; Crane 1992; Peterson & Anand 2004). This approach challenged over generalizations about cultural "reflection" of societies as wholes, drawing on theoretical resources from the sociology of knowledge and the sociology of organizations. Although many "production of culture" studies focused on specialized realms of mass media, the arts, and sciences, attention to particular institutional circumstances and constraints affecting meaning making processes is also crucial for the study of more diffuse cultural phenomena such as national identity, social movements, collective memory, or religion.

Another mid range approach to culture, influenced sometimes by pragmatism and sometimes by practice theory, focused attention on how interactions and social practices are themselves meaning making processes, and on the context dependent ways in which individuals and groups endow actions with meanings (Certeau 1984; Becker & McCall 1990; Fine & Sandstrom 1993; Swidler 2001; Eliasoph & Lichterman 2003). Like production of culture approaches, this focus on meaning making in action and interaction challenged overly general reflection models of the relation between culture and society; it also relaxed the assumption that meanings and values are entirely shared, coherent, or consistent for a given group or even an individual, providing a better understanding of diverse interpretations of common norms, values, and cognitive frames

and analyzing how individuals and groups draw fluidly on different elements in symbolic repertoires (“toolkits”) according to context. Culture, here, is a contingent and variable element of the ways action is framed. Applicable to understanding any sites of action and interaction, this approach has been applied to such diverse topics as corporate culture, the formation of racial and class identities, audience interpretations of mass media and artistic forms, and everyday engagement with politics.

Third, other sociologists, building on Durkheimian insights, have emphasized the importance of the deep formal structure of discourses for meaning making. Analyses of culture structures have built on two distinct traditions. First, discourse analysts have drawn on theories and concepts of textual structure derived from work in the humanities to analyze meaning making (Alexander 1989; Wuthnow 1992; Mohr 1994; Jacobs & Smith 1997; Franzosi 1998; Alexander 2004). They investigate the deep internal structure of discourses in terms of their categories, codes, genre, and narrative, showing how signifiers derive meaning from their relations in systems of signs. Such analyses of culture as structured discourse introduce to sociology a previously neglected set of influences in processes of meaning making, which provide a basis for constituting culture as a distinct object of inquiry that is analytically independent of, and sometimes causally efficacious for, both institutional and interactional dimensions of meaning making. Second, other cultural sociologists explore links between meaning making and social psychological processes of cognition, especially categorization (Schwartz 1981; DiMaggio 1997; Zerubavel 1997; Cerulo 2002). Analysts of cultural structures in sociology have investigated such topics as political discourse, media texts, and gender, but this approach may be adopted whenever the *underlying* cultural forms which are contingently mobilized in organized cultural production and informal interaction are of interest.

Understanding institutionalized cultural production, practices, and interaction, and “culture structures” as analytically distinct dimensions of meaning making, each worthy of investigation in its own right, has helped cultural sociology specify earlier vague and

overarching assumptions about culture, and the ways it might “reflect” social structures and generate social action. These specifications have also meant that culture is no longer considered to be the “whole way of life” of a clearly bounded group, nor confined to a domain of expressive artifacts and activities distinct from politics or economics. Thus, cultural sociologists investigate specific dimensions of meaning making, but in a wide range of empirical sites. Of course, while many investigations focus primarily on one dimension of meaning making – cultural production, culture in interaction, or culture as text – a full understanding of any particular topic involves all three levels, and many studies touch on all three with different degrees of emphasis. So, for instance, a study of the codes and categories structuring a political ideology may also extend to related processes of institutional production, and a study of variant audience interpretations of television will also include analysis of important features of the textual structure of programming.

At the same time, fundamental disagreements and debates have also emerged between cultural sociologists prioritizing one approach to culture over others. Those who emphasize institutionalized cultural production would view an overemphasis on textual structure as idealist, detached from the political and organizational dynamics of the social contexts in which texts are embedded. Production of culture perspectives also suggest that analyzing meaning in practices and interaction misses the central significance of organized institutional processes for the possibilities available for meaning making in complex societies. Against this, those committed to the “thick description” of meaning making in practice argue that the production of culture perspective elides meaning in favor of organizational dynamics. Practice theorists of various types also suggest that focusing on “culture structures” or cognitive categories underestimates the importance of the many, varied ways in which people interpret cultural codes in different contexts. In the third camp, analysts of “culture structures” argue, like practice theorists, that the production of culture perspective elides the more hermeneutic analysis of meaning making. Against practice theorists, though, they suggest that

focusing on variant contextual uses of meanings, values, and symbols in particular practices inevitably misses the larger cultural framework which constrains and enables particular instances of meaning making.

Such disagreements about emphasizing institutions, emphasizing practices, or emphasizing textual or cognitive structure are fundamental faultlines in cultural sociology, and constitute points of view for mutual critique of particular studies of culture. Tensions between "culture structure" theories (whether textual or cognitive) and "practice" theories are particularly evident in contemporary cultural sociology, but other lines of tension outlined above also continue to regenerate debate. However, such disagreements also generate productive research programs, and some of the richest contributions to contemporary understandings of culture carefully combine analysis of production, interaction, and formal structure while preserving the analytical distinctions between the different cultural dynamics.

Distinctions between the different cultural dynamics have also created new approaches to long lasting tensions in sociology – tensions between interpretation and explanation, between microsocial and macrosocial analysis, between structure and agency, and between an emphasis on consensus and solidarity, on the one hand, and on conflict, domination, and resistance, on the other. Cultural sociology has made significant recent contributions to understanding these issues and bridging these divides. Analyzing meaning making processes along the three dimensions outlined above has encouraged sociologists writing on a wide range of topics to combine interpretive and explanatory strategies; to link micro settings with macro processes in their research designs; to show how the limits and possibilities of meaning making mediate the obduracy of social structures with their intermittent possibilities of agentic change; and to open to investigation the ways solidarity and conflict are empirically mixed.

Important topics which have engaged the sustained attention of cultural sociologists include the construction and reconstruction of class, gender, race, national, ethnic, sexual, and other axes of social identity, distinction, and dispute; the role of meaning making

processes in generating and sustaining political engagement in social movements and in civil society; the discourses and issues generated in political, legal, religious, scientific, and professional institutions; collective memory and historical amnesia; mass media production, texts, and audiences; and artistic products, practices, and institutions (Spillman 2002; Friedland & Mohr 2004; Jacobs & Hanrahan 2005; Jacobs & Spillman 2005).

Important sets of empirical questions receiving increasing attention concern meaning making processes which operate at transnational or global levels (e.g., among immigrants or social movements); meaning making in economic action and industries; how newer communications technologies influence social identities and interactions; and the relation between embodiment, materiality, and the discourses which constitute the significance of that materiality.

Some emerging theoretical and methodological issues in the sociological analysis of culture may change the terms in which the relations between cultural production, practices, and structures are understood. One question receiving renewed attention is the historical impact of specialized arenas of cultural production – such as art, literature, and science – on broader political and economic change. Another issue is the relation between generic psychological and biological capacities for cognition and emotion, and their particular expressions in socially situated meaning making process. Third, theories of meaning making as performance are offering new ways of analyzing links between production, text, and action at both macro historical and micro situational levels. Fourth, there is renewed attention to the ways in which meanings and values have specific causal consequences for social action and for institutional change.

Pressing questions contemporary cultural sociologists are raising or revisiting thus include: What is the best way of combining analyses of culture structures and of practices? When do specialized cultural products and meaning making processes influence broader social change? How should the relation between generic cognitive and emotional processes and meaning making be understood? How does culture link structure and action in moments of

performative contingency? How can the causal impact of meaning making processes be specified while preserving the central importance of interpretation?

The idea of culture has long been both capacious and ambiguous, due to its complex historical origins and intellectual development, and cultural analysis was not generally considered central to sociological inquiry for much of the twentieth century. However, sociologists now think of culture as human processes of meaning making generating artifacts, categories, norms, values, practices, rituals, symbols, worldviews, ideas, ideologies, and discourses. They currently identify and analyze three different types of influence on meaning making: institutional production, interactional process, and textual structure, emphasizing each dimension to different degrees according to empirical topic and theoretical perspective, and often debating their relative importance. These analytic tools have helped avoid over generalization about cultural processes – for instance, about consensus or conflict, about idealism or materialism, about macro or micro levels of analysis, or about structure and agency. In turn, this has encouraged an efflorescence of sociological studies of culture on such topics as identity and difference, group boundaries, political institutions and practices, and the mass media and arts and their audiences. Cultural perspectives are also frequently integrated into research on such standard sociological issues as stratification, religion, immigration, and social movements. Since new empirical topics and theoretical issues in the sociological study of meaning making continue to emerge rapidly, the likelihood is that culture will become much more central to sociological analysis.

culture: conceptual clarifications

Chris Jenks

Raymond Williams (1976) informs us that “culture is one of the two or three most complicated words in the English language,” which is a good place to begin. Despite the contemporary upsurge of interest in the idea – what Chaney (1994) refers to as the “cultural turn” in the humanities and social sciences – culture is a concept with a history. One compelling account is that the idea of culture emerged in the late eighteenth century and on into the nineteenth century as part of (and largely as a reaction to) the massive changes that were occurring in the structure and quality of social life – what we might also refer to as the advance of modernity. These changes at the social, political, and personal levels were both confusing and disorienting, and at least controversial. Such changes, through industrialization and technology, were unprecedented in human experience: they were wildly expansionist, and horizons were simply consumed; they were grossly productive, for good and ill; and they were both understood and legitimated through an ideology of progress. The social structure was politically volatile, being increasingly and visibly divisive. This was a situation brought about through the new forms of social ranking and hierarchy that accompanied the proliferating division of labor, being combined with the density and proximity of populations, through urbanization, and the improved system of communications. In one sense the overall aesthetic quality of life, compared with the previously

supposed rural idyll, was threatened by the machine like excesses of industrial society. There was an increasing gap between the creative and the productive, formulated for materialism by Marx as "alienation," and for the Romantic idealist tradition by Carlyle as a loss of the folk purity of a past era. The machine was viewed as consuming the natural character of humankind, a call to be later echoed in the work of the Frankfurt School, Benjamin's "Age of Mechanical Reproduction," even Marcuse's sense of one dimensionality, and finally the *cri de coeur* of Baudrillard's evocation of postmodernism with its horror of simulacra. Whereas we began with "culture" mediating between humankind and Nature, it can now be seen to mediate between humankind and Machine. This provides us with several available "meanings" of culture.

Another account looks back to classical society. *Civilization*, deriving from the Latin *civis*, is a term descriptive of a state of belonging to a collectivity that embodied certain qualities, albeit self appointed, which distinguished it from the "mass" or more lowly state of being typified as that of the "barbarian." Such was the ancient Greek and Roman sense of identification with nation and state.

In this context the idea of culture is not so much descriptive as metaphoric, and derives philologically from the agricultural or horticultural processes of cultivating the soil and bringing fauna and flora into being through growth. Whereas the former concept, "civilization," is descriptive of a kind of stasis, a membership, a belonging, indeed a status once achieved not to be relinquished, the latter, "culture," is resonant with other ideas of emergence and change, perhaps even transformation. Thus we move to ideas of socialization as "cultivating" the person, education as "cultivating" the mind, and colonialization as "cultivating" the natives. All of these uses of culture, as process, imply not just a transition but also a goal in the form of "culture" itself; it is here that hierarchical notions begin to emerge, such as the "cultured person" or "cultivated groups or individuals" and even the idea of a "high culture," all of which reduce the metaphoricity of process and begin to coalesce with the original notion of a descriptive state of being not essentially unlike the formative idea of civilization itself.

Just as in many forms of discourse *culture* and *civilization* are used interchangeably, so in others *culture*, *society*, and *social structure* are conflated, though not necessarily confused. The idea of culture as a theory of social structure has given rise to the major division between "social" and "cultural" anthropologies, the former stressing universality and constraint and the latter emphasizing relativism and difference between societies. In contemporary cultural studies some would argue that the concept of social structure has been abandoned altogether and that culture has become the sole source of causal explanation.

Social theories that are based on a materialist interpretation of reality, such as the variety of Marxisms, see culture as essentially an ideological set of understandings that arise from the sometimes calculated but more often simply distorted representations of the basic set of power and economic relationships at the heart of the society. Here we would include such thinkers as Marx himself, but also Gramsci, Althusser, Lukács, Goldmann, Benjamin, Adorno, Horkheimer, and Williams. Of course, this group remains varied and subtle in their range of explanations, but all argue essentially for the primacy of the material world and thus produce culture as an epiphenomenon. Contrasting with this body of thought are the interpretive social theorists whose ideas derive more from the philosophies of Kant and Hegel. Within such an idealist tradition culture is realized far more as an autonomous and self sustaining realm of social experience: a repertoire and a fund of symbolic forms that although related to their time are nevertheless both generative and self reproducing in a way that escapes the constraints of materiality. Here culture is liberating rather than constraining; here creativity exceeds replication as a causal force. In the context of interpretive theory we would be addressing the sociologies of Weber, Simmel, Schütz, Geertz, and even Parsons.

Sociologists and anthropologists have come to account for the concept of culture in a variety of ways. In its most general and pervasive sense it directs us to a consideration of all that which is symbolic: the learned, ideational aspects of human society. In an early sense culture was precisely the collective noun used to define that realm of human being which

marked off its ontology from the sphere of the merely natural. To speak of the cultural was to reaffirm a philosophical commitment to the difference, particularity, and supposed plasticity that is "humankind." Human beings inevitably transform their world into, and by way of, a series of symbolic representations. The symbolic then satisfies and absorbs the projections of human beings into objects and states of affairs that are different, and it also acts as a mediator between these two provinces. We no longer confront the natural as if we were continuous with it. We now meet with the natural and, indeed, experience it as preformed, through our vocabulary of symbols which are primarily linguistic but increasingly elaborate out into other forms like custom, convention, habit, and even artifact. The symbolic representations that constitute human knowing are, in their various groupings, classifications, and manifestations, the *cultural*. The very idea of culture therefore generates a concept which, at one level, provides a principle of unification for the peoples of the world, including those who once have and also those who continue to populate the world through time and across space. We can see here the origins of structuralism espoused primarily by Lévi Strauss, but then by Piaget, Chomsky, and others with great impact across a range of social and human sciences.

Culture, for early anthropology, was the common domain of the human; it distinguished our behavior from that of other creatures and it provided a conceptual break with the dominant explanatory resource of biological and, latterly, genetic determinism. From this happy state of egalitarian oneness through the aegis of culture – the very inspiration for cultural anthropology – the story takes a different turn and we move into accounts of diffusion, stratification, hierarchy, and relativism, still clinging to the unrevised central concept of culture. The dominant European linguistic convention equates "culture" largely with the idea of "civilization": they are regarded as synonymous. Both ideas may be used interchangeably with integrity in opposition to notions of that which is vulgar, backward, ignorant, or retrogressive. Within the German intellectual tradition, a different and particular sense of culture emerged that was to assume a dominant place in our

everyday understandings. This was the romantic, elitist view, that culture specified the pinnacle of human achievement. Culture, in this sense, came to specify that which is remarkable in human creative achievement. Rather than encapsulating all human symbolic representation, German *Kultur* pointed us exclusively to levels of excellence in fine art, literature, music, and individual personal perfection. The main body, or in this formulation the residue of what we have previously meant as culture, was to be understood in terms of the concept of *Zivilisation*. This distinction, by no means fine, in many ways reflected the dichotomy provided by Kantian philosophy between the realms of "value" and "fact," and was generative of two different ways of understanding and relating to the world. This divide also informs the distinction between philosophical idealism and materialism and informs discussions over cultural stratification. We might here note that such distinctions also gave rise to the belief that the human spirit (perhaps the *Geist* itself) came under successive threat with the advent and advance of modernity and the inexorable process of material development which, it was supposed, gave rise to an increasingly anonymous and amorphous urban mass society. The impersonal, yet negative, forces of standardization, industrialization, and technologies of mass production became the analytic target for the romantic neo Marxist criticism of the Frankfurt School within their theories of aesthetics, mass communication, and mass society, and also in the early sociology of culture propounded by Norbert Elias with his ideas of the "civilizing process."

Within the confines of British and American social theory the concept of culture has been understood in a far more pluralist sense and applied, until relatively recently, on a far more sparing basis. Although culture is a familiar term within our tradition and can be employed to summon up holistic appraisals of the ways of life of a people and their beliefs, rituals, and customs, it is not most common. We social scientists are rather more accustomed to mobilizing such batteries of understanding into "action sets." That is, we tend to use more specific concepts like, for example, "value systems" (even "central value systems"), "patterns of belief," "value orientations," or more

critical notions like “ideologies.” Culture to British and American social theorists tends to have been most usefully applied as a concept of differentiation within a collectivity rather than a way of gathering. That is to say that the concept has become artfully employed in, for example, the sociology of knowledge that Karl Mannheim recommended, and also in the spectrum of perspectives on the sociology of deviance – ranging from Parsonian theory through to symbolic interactionism – in the manner of “subculture.” A subculture is the way of defining and honoring the particular specification and demarcation of special or different interests of a group of people within a larger collectivity. So just as classical sociology in the form of Tönnies or Durkheim, or indeed Comte, had recognized that the composition of the overall collective life emerged through the advance of the division of labor – by dint of the fragile integration through interdependence of a whole series of smaller, internally cohesive, social units – so also does modern social theory by articulating the specific mores of these minor groups, albeit often as “non normative” or even “deviant.” This dispersion of subcultures is at the base of what we might mean by a “pluralist” view of culture; it is modern and democratic and shies away from all of the excesses of a grand systems theory with all of its incumbent conservative tendencies and its implicit “oversocialized conception of man” (Wrong 1961). Such thinking succumbs, however, to the problem of order. Without a coherent, overall theory of culture (which still, in many senses, eludes us) it is hard to conceive of how consensus is maintained within a modern society. In response to precisely this problem, contemporary Marxism has generated the “dominant ideology thesis” which supposes that varieties of hegemonic strategies of mass media and political propaganda create a distorted illusion of shared concerns in the face of the real and contentious divisions that exist between classes, genders, ethnic groups, geographical regions, and age groups. Such a thesis is by no means universally accepted within the social sciences and in many ways the more recent explosion of interest in and dedication to the schizophrenic prognosis of postmodernisms (and even complexity theory) positively accelerates the centrifugal tendencies of the cultural particles.

We can summarize some of the above accounts of the genesis of our concept “culture” through a four fold typology. First, culture is a cerebral, or certainly a cognitive, category. Culture becomes intelligible as a general state of mind. It carries with it the idea of perfection, a goal or an aspiration of individual human achievement or emancipation. At one level this might be a reflection of a highly individualist philosophy and at another level an instance of a philosophical commitment to the particularity and difference, even the “chosenness” or superiority, of humankind. This links into themes of redemption in later writings, from Marx’s false consciousness to the melancholy science of the Frankfurt School. In origin we will see it mostly in the work of the Romantic literary and cultural criticism of William Coleridge and Thomas Carlyle and latterly Matthew Arnold.

Second, culture is a more embodied and collective category. Culture invokes a state of intellectual and/or moral development in society. This is a position linking culture with the idea of civilization and one that is informed by the evolutionary theories of Darwin and informative of that group of social theorists now known as the early evolutionists who pioneered anthropology, with their competitive views on “degeneration” and “progress,” and linking the endeavor with nineteenth century imperialism. This notion nevertheless takes the idea of culture into the province of the collective life, rather than the individual consciousness.

Third, culture is a descriptive and concrete category: culture viewed as the collective body of arts and intellectual work within any one society. This is very much an everyday language usage of the term culture and carries along with it senses of particularity, exclusivity, elitism, specialist knowledge, and training or socialization. It includes a firmly established notion of culture as the realm of the produced and sedimented symbolic, albeit the esoteric symbolism of a society.

Fourth, culture is a social category: culture regarded as the whole way of life of a people. This is the pluralist and potentially democratic sense of the concept that has come to be the zone of concern within sociology and anthropology and latterly, within a more localized sense, cultural studies.

culture, economy and

Marion Fourcade Gourinchas

In traditional academic discourse, culture and economy have long been regarded as separate

analytical spheres: on the one hand, the realm of shared cognitions, norms, and symbols, studied by anthropologists; on the other hand, the realm of self interest, where economists reign supreme. Though the two disciplines overlap occasionally (in economic anthropology mainly), radical differences in the conceptual and methodological routes each field followed during the twentieth century have prevented any sort of meaningful exchange.

By contrast, the interaction between culture and the economy has always been a central component of sociological analysis. All the founding fathers of sociology were, one way or another, interested in the relationship between people's economic conditions and their moral universe. In his famous presentation in the *Preface to a Critique of Political Economy*, for instance, Marx described "forms of social consciousness" essentially as an epiphenomenon of material relations. Later interpretations, however, have suggested that even for Marx and Engels the relationships between "material base" and "superstructure" were far from deterministic. The "western" Marxist traditions that developed in Europe after World War I proposed a somewhat more sophisticated analysis that emphasized the integration of culture into the apparatus of domination – either because the hegemony exerted by bourgeois culture induces the masses into implicitly consenting to their own economic oppression (Gramsci 1971), or because the incorporation of culture into the commercial nexus of capitalism leads to uniformity of spirit and behavior and the absence of critical thinking (Adorno & Horkheimer 2002). Still, in these formulations culture remains wedded to its material origins in capitalist relations of production.

Partly reacting against what they perceived to be a one sided understanding of the relationships between base and superstructure in Marxist writings, Weber and Durkheim both sought to demonstrate the greater autonomy of the cultural realm, albeit in quite different ways. Both insisted that people's behavior is always infused with a meaning that is not reducible to their material positions. Weber (2002), more than anyone else, demonstrated the influence of preexisting ideas and, in particular, religious worldviews on the economic conduct of individuals. For instance, even though their

actions may look rational from the outside, the behavior of early Protestant capitalists was quite illogical from the inside: anxiety about salvation, rather than self interest, motivated them to accumulate. In other words, their search for profit was not based on instrumental rationality, but it made psychological sense given the religious (cultural) universe in which they lived. In fact, Weber considered that all religions condition individual attitudes toward the world and therefore influence involvement in practical affairs – but, of course, they all do it differently, so that the “economic ethics” of individuals varies substantially across social contexts.

It is Durkheim, however, who best articulated the *collective* basis of our meaning making orientation: groups of individuals share certain understandings that they come to take for granted in their routine dealings with each other. Hence how people behave, including in economic settings, is not a priori reducible to a set of predetermined individual preferences and the interests they support. Rather, most of people’s actions are motivated by habit and routine; and preferences, as well as the institutions they support, are informed by cultural norms (Meyer & Rowan 1977). In each society, then, culture and institutions act in tandem to shape individual consciousness and thereby representations of what is understood to be “rational.” This is what DiMaggio (1994) calls the “constitutive effect” of culture. Because these mental maps are widely shared, they have much greater efficacy than others that would be out of place, or misunderstood, in the same context.

CULTURAL SHAPING OF ECONOMIC INSTITUTIONS

As a system of representations that exists separately and independently of individuals, culture may shape economic behavior in many different ways. It may be more or less institutionalized. Corporate cultures, for instance, are often highly formalized, even bureaucratized, but the rules that underlie bazaar interactions, though obviously codified, remain very informal (Geertz 2001). Second, the effect of culture may be more or less profound. Meyer and

Rowan (1977), for instance, have famously suggested that many organizational rules are adopted in a purely ceremonial way, but have little impact on actual practice – a claim that has been notably supported by research on educational institutions and hospitals. On the other hand, substantial evidence has come out of cross national studies of a deep pattern in not only of economic values and norms (Hofstede 1980), but also of economic institutions and organizations (Dore 1973; Hamilton & Woolsey Biggart 1989). The critical question, then, is whether the two are related, and how.

One possible answer has been provided by Dobbin’s (1994) suggestion of the existence of an elective affinity between economic and political culture (see also Beckert 2004). In his comparative analysis of the development of the railway sector in the nineteenth century, Dobbin shows that public officials in three countries sought to achieve economic growth in very different ways, and were influenced in doing so by their cultural perceptions about the nature and sources of the political order in their own nation. In the US, they strove primarily to protect community self determination; in France they oriented themselves towards centralized planning by the state in an effort to avoid logistical chaos; and in the UK they were mainly concerned with protecting the individual sovereignty of firms. Ultimately, then, the economy of each country ended up “reflecting” the polity it originated from.

Some sociologists, however, would argue that there is no such inherent consistency to national cultures. Biernacki (1995), for instance, finds that the process of their formation is eminently fragile, almost serendipitous. In his comparative study of textile mills at the onset of the industrialization process, he finds that the concept of labor had a substantially different meaning in Britain and Germany, but that these differences originated in on the ground practices by workers and employers rather than in some preexisting mental categories. These practical conceptions, derived from the material context of industrialization in each country, tended then to crystallize into full fledged meaning making systems, which became eventually codified in writing by political economists and other intellectuals. Through this process

they acquired a great cultural depth, and ended up shaping a whole set of outcomes in the development pathways of the two countries, such as the wage calculation system, disciplinary techniques within factories, forms of workers' collective action, and even industrial architecture. Yet, even then, the systems remained vulnerable to a change in practices (which eventually took place in the early twentieth century).

EMERGENCE OF CULTURE WITHIN THE ECONOMY

Biernacki's study illustrates particularly well the fact that we should think about the role of culture primarily through its inscription in *practices*. Economic settings, therefore, do not simply display, or reflect, preexisting cultural understandings, but should be regarded as places where distinctive local cultures are formed and carried out. There are two main ways in which this point has been articulated in the sociological literature. The first emphasizes the social meanings people produce (whether voluntarily or involuntarily) through their use of economic settings and economic objects, and is best illustrated by consumption studies. The second suggests that some form of social order (i.e., regulating norms and practices) emerges out of the interpersonal interactions that take place within economic settings, particularly formal organizations and markets.

The first set of questions goes back to Veblen's (1994) and Simmel's analyses of consumption, and was most noticeably extended by Bourdieu (1984). The fundamental idea here is that consumption is not about individual parameters (preferences, income), but is profoundly *relational*. Consumption practices are the site of a competitive struggle whereby individuals seek to position themselves vis à vis other individuals in the social space. For Veblen (1994), it is essentially about vertical hierarchy – leisurely elites seek to demarcate themselves from those below them by wasting money and time on perfectly useless purchases and activities. For Bourdieu, the structure of the social "space" is more complex: education and socialization into high culture (or not) play as much a part as money in determining taste, and beyond,

consumption practices. What structures consumption practices (as all forms of action), then, is what Bourdieu calls *habitus* – a system of dispositions that is formed through the individual's trajectory in the social space (understood, again, in a relational manner vis à vis other individuals).

The study of consumption practices thus provides an extraordinarily rich terrain for analyzing how people relate to one another, both structurally and cognitively. In a creative variation on this theme, Zelizer (1985, 1994) has shown that these relational meanings are not only expressed through *what* people purchase, but often in *how* they pay for it – cash, gift certificates, checks, food stamps. People, in fact, constantly personalize, differentiate, and earmark money in ways that can be understood as metaphors about social relations and identity. (Whether the *how*, like the *what*, is also subject to the logic of habitus, remains to be studied systematically.)

The second question – the cultural universe produced within and by economic institutions – has also given rise to a diverse and extremely rich literature. We may illustrate this point with three examples: anti-trust law, financial markets, and the McDonald's corporation. Fligstein (1992), most prominently, has studied the way in which the legal environment shapes the formation of distinctive economic cultures. Corporate managers, he argues, act on the basis of "conceptions of control" – shared understandings about how a particular market works. These conceptions evolve in close connection with changes in the legal regulation of corporate competition, which tip the balance of power toward management groups with certain organizational cultures at the expense of others. In the course of the twentieth century, for instance, the American corporation was a contested and historically evolving cultural terrain, where conceptions of control shifted from production to sales and marketing, and finally finance and shareholder value. In this case, organizational culture fundamentally emerges out of a combination of institutional forces and power struggles.

Of course, such tacit understandings and patterned practices may emerge in a more decentralized way, out of interpersonal interactions in corporations, factories, workshops, and

markets, including the most “rational” ones. Sociologists, for instance, have revealed the existence of all kinds of rituals, beliefs, customs, and informal control structures that regulate social life in the financial markets – the very heart, supposedly, of instrumental action. In fact, the economic potential of culture has not been lost on corporations, many of which try actively to “engineer” predictable behaviors and commitments on the part of their employees through the use of quasi religious rituals and the enforcement of strict codes regulating social interactions.

The organizational innovations introduced by the McDonald’s corporation are probably among the most potent examples of the cultural effects of corporate logics. As Ritzer (2004) has shown, they had a dramatic effect on human experience and social organization well beyond the boundaries of the firm of origin, helping spread the values and practices of efficiency, calculability, predictability, and control to various organizations and social institutions (education, medicine, and the criminal justice system), both in the US and abroad. The sheer success of this model is thus a precious reminder that instrumental rationality – as Weber worried – is also a very powerful “culture” in and of itself.

THE ECONOMY AS THE CULTURE OF MODERNITY?

The example of McDonald’s suggests a broader point, then: the constitution of economic categories themselves is through and through a social process. Consequently, what gets incorporated (or not) into the sphere of the marketplace reveals much about how we understand ourselves, about our “culture.” As Polanyi (2001) argued long ago, the hallmark of post eighteenth century modernity was the emergence of a distinctive social order dominated by market relations. Following nineteenth century critics (among them Marx, Weber, and Simmel), Polanyi articulated the dehumanizing effect of modern capitalism and calculative rationality on personality and human relations, whereby individuals come to be seen as commodities and means to an end rather than as ends in themselves.

Empirically, however, there is quite a bit of debate about whether such effects really exist: recent economic experiments in small scale societies, for instance, have suggested that market integration is *positively* correlated with human cooperation (Henrich et al. 2004), thereby vindicating earlier commentaries about the civilizing (Hirschman 1977) and socially integrating effects of commerce. It is also unclear whether the penetration of markets has been as universal and far reaching as some skeptics believe. Modernity certainly does not mean that everything has been engulfed into the sphere of the marketplace; for instance, the study of the conditions under which boundary “objects” such as children, death, organs, or art are subject to economic exchange has revealed a quite varied landscape. Hence, as sources of economic benefit, children were *removed* from labor markets around the turn of the twentieth century in the US (and countries that continue to authorize such practices today face grave political and economic pressures). On the other hand, as sources of emotional and social benefit, they were *commodified* in ways that were not foreseen in the nineteenth century, mainly through the adoption, insurance, and consumption markets (Zelizer 1985).

The intellectual challenge, then, is twofold: to specify the distinctive nature of the moral order capitalism relies upon, and to understand how it is produced. Perhaps this challenge is nowhere as obvious as in the current emergence of a new vocabulary that seeks to overcome the conceptual divide between culture and economy, and focuses instead on the always inextricably moral dimensions of economic discourses and practices (Amin & Thrift 2004). Particularly noticeable is the work on logics of moral justification, which identifies the recent appearance of the discursive figure of “connectivity” as a new regime of justification conceived in and for the post industrial capitalist economy (Boltanski & Chiapello 2005). Dezalay and Garth (2002) explore another exciting avenue in their analysis of the mutually reinforcing, profoundly entangled discourses of economic and political individualism (e.g., human rights and the market) and their worldwide diffusion under US hegemony. Finally, Callon (1998) and others have investigated

the *performative* nature of the knowledge forms that sustain the development of capitalism, mainly economics and accounting. They have shown that through their language, techniques, and representations, these disciplines produce a world of “calculative agencies” and create a host of new institutions in which these agencies may exercise their calculative power – thereby formatting, little by little, our cultural selves onto the model fiction of *homo economicus*. This outburst of work seems to signal that sociology is finally ready for a new form of engagement with economics that will demystify it as a cultural form, as the discursive rationalization and active formatting, by capitalism, of itself and for itself – not merely the science of how the economy “works.”

culture, gender and

Andrea Press

The reproduction of our society's sex gender system has been a continuing puzzle for sociologists of gender. The history of western writings on gender has long included ruminations

on the role of culture in constituting gender difference and privilege (Wollstonecraft 1978; Mill 2003; and especially de Beauvoir 1993). Yet during the last 40 years of the sociology of gender, material characteristics – in particular, women's position as paid and unpaid laborers – have received more attention than cultural factors (Hartmann 1980; Blum 1991). These findings have revealed large differences in the paid and unpaid work lives of men and women in our society, and they have led to a number of political reform movements and initiatives – Title IX, the comparable worth movement, lawsuits demanding equal pay for equal work – that have resulted in somewhat more equality in the workplace.

There seem to be limits to these efforts toward workplace equality between the genders, both at the highest levels, where the prototypical “glass ceiling” seems to prevent women from achieving the same levels of leadership afforded to men, and at the lower levels, where women continually seem to function as a “reserve” labor force, dropping in and out of full time paid labor according to the demands of their families (Callaghan & Hartmann 1991). Even a cursory examination of the beliefs and plans of current American college student women indicates that they expect to spend varying degrees of time out of the paid labor force caring for their children (Douglas 2004), a plan which demonstrably contributes to their continuing inequality in the workplace. Hays (1996) documents that a large portion of so called “stay at home moms” actually plan to head back into the labor force as soon as they are able.

These limits have led to a cultural turn of sorts in the field of the sociology of gender. Second wave feminism, influenced by Marxist materialist theory, has challenged the necessity and desirability of gendered social arrangements in both family and workplace. Despite the social movements the second wave has inspired, which have challenged these arrangements, and despite the fact that there is some evidence that they may be slowly changing, their overall persistence is indisputable and is one of the paradoxes of modern social science. In fact, some argue that there is a backlash against feminism which is stronger and more persistent than was second wave feminism

itself. Sociologists of gender, long rooted in a materialist tradition that privileged phenomena related to occupational statuses and earning levels, have turned to culture to explain the persistence of gendered social arrangements in family and workplace.

This turn to culture is partly a result of the influence of new intellectual currents more generally in the social sciences. Poststructuralism, identified with the works of Derrida, Foucault, Lacan, and others, led many in the social sciences and humanities to reflect deeply on the impact of discourse and categories of thought on our analyses of social life. Feminism has been integrally engaged with poststructuralism at a theoretical level. As Barrett describes it:

Feminist theory has been able to take up a number of issues outside the classically “materialist” perspective . . . Poststructuralist theories, notably Derridian deconstructive readings, Lacanian psychoanalysis, and Foucault's emphasis on the material body and the discourses of power have proved very important in this. Feminists have appropriated these theories rather than others for good reasons: these theories address the issues of sexuality, subjectivity and textuality that feminists have put at the top of the agenda. (Cited in Brooks 1997: 6)

Postmodernism has extended the critiques of poststructuralism to challenge some of our most fundamental notions, such as the individual self, linear time, and the concept of space. Feminism's engagement with postmodernism has also been fundamental and complex. As Brooks notes, “the relationship between feminism, poststructuralism, and postmodernism has been both dynamic and productive for feminism and social theory more generally” (p. 6). Some note the conceptual equivalence between postmodern feminism and postfeminism (McLennan, cited in Brooks 1997: 6). While sociologists have often been slowest among social scientists in acknowledging the importance and influence of both the poststructuralist and postmodernist intellectual movements, it is often through the impact of feminist and cultural sociology, both of which are fundamentally interdisciplinary, that these traditions have entered the field and been accorded full consideration.

In light of these observations, what can the variable of culture offer to the study of gender

in sociology? First, like the term gender, the term culture carries with it a long, interdisciplinary, multi perspectival heritage that transcends the limits of the field of sociology. In the discipline of anthropology the concept of culture has long been an organizing term that structures discussion of the object, as well as more recently the “medium,” of analysis for the field (Ortner 1999). In this sense, culture is very broadly conceived in Tylor’s famous definition as a “way of life” (Williams 1981) to be looked at through a series of academic practices that themselves constitute another way of life (Geertz 1973; Clifford 1986). Analysis in the field of anthropology has become extremely self reflexive, while retaining its core interest in the analysis of culture generally as an object of study.

SOCIOLOGY OF GENDER AND THE CULTURAL TURN

Where the sociology of culture has been important in gender studies has been in its attempt to define the use of the concept of culture in sociology. Various and competing definitions have been proffered. Some of these display an affinity with anthropological definitions of culture, descending from Tylor (1958), wherein culture is defined as a set of practices and beliefs that characterize particular societies, subgroups, and groups of societies. Other definitions focus more on the analysis of cultural products, their production, meanings, and uses. Sociologists tend to move back and forth quite easily between these different senses of the term culture and so there is no easy way to characterize the sociological consensus on its use, even as the subfield of the sociology of culture has continued to develop and grow.

Sociology as a discipline began in the US by employing a culturalist definition of culture, adapted from the Tylorian definition of culture as a “complex whole” produced by people’s historical experience, including knowledge, belief, art, morals, law, and custom. This concept was challenged by Radcliffe Brown (1958) and his followers, who proposed in contrast a “structuralist” theory asserting the primary importance of social structure in determining the important facets of social life. After an

initial series of debates, American anthropology became primarily a culturalist discipline in which the Tylorian definition of culture has been prominent. Nevertheless in American sociology the notion that structural issues are of primary importance has of course been prominent. However, of late we have witnessed a cultural turn throughout the social sciences which has affected many of the primary subfields of sociology, including the sociology of gender. This has meant that the importance of culture has been widely recognized throughout the discipline.

Nowhere has this been more primary than with the rise of the sociology of culture, which has now risen to be one of the most popular affiliations elected by members of the ASA. In this group the definition of culture includes both those who use the term in its more amorphous, Tylorian sense to mean patterns of life and ways of living, and those who define the study of culture as focused on the artifacts of recorded culture such as books, media, music, museums, photographs, etc. At the same time, the concept of culture has gained relevance in many other areas of the discipline, including the sociology of gender. This can be seen in recent works by Adams et al. (2005), in addition to areas outside the field of sociology altogether, like the rapidly expanding interdisciplinary field of cultural studies (Grossberg et al. 1992).

When cultural categories are applied to thoughts about gender the concept of culture offers a way to conceptualize those dimensions of our gendered beliefs and practices that can not be reduced to social structural or biological features alone. With regard to the paradox of gender difference, culture has proved to be an important variable. Sociologists have turned to culture to explain a variety of findings about gender that persist even as consciousness about structural discrimination and inequality has been raised and discussed. Indeed, there appears to be a core aspect of gender which is culturally, rather than biologically or structurally, determined.

The issue of mothering serves as a key example of this explanatory dynamic wherein the concepts of gender and culture intertwine. While biological explanations account for the fact that women give birth, sociologists of

gender realized early on in the discipline that recourse to the mothering “instinct” was inadequate as an explanation of why women performed so much more of the labor involved in mothering than did fathers or male caretakers (Hartmann 1980; Rich 1986). Yet an initial turn by gender sociologists to labor market explanations left gaps as well: gender sociologists became adept at explaining what labors women performed in the paid labor force, ways they were inadequately compensated for this work, and how women performed the vast majority of unpaid labor in the home – mothering included. But such discussions fell far short of offering adequate explanations for how this state of affairs came about. That women perform unpaid labor does not explain how this situation came about, nor why it persists. It is to this explanatory level that cultural explanations of mothering are directed. They fall into different categories, depending on the approach to culture which is used.

“Women mother” begins one paradigmatic feminist work on mothering (Chodorow 1978). This book posed the question of why it is that women do the work of mothering virtually universally across cultures and throughout history. This question has been answered in many different ways by those who analyze the intersection of gender and culture in the institution of motherhood. Psychoanalysis has long provided a key set of terms used in cultural analysis, although of course psychoanalytic theory employs only one particular set of cultural tools. These focus on the penetration of culture into the reproduction of our personality processes. Chodorow draws on psychoanalytic categories as they are structured by our cultural arrangements. She argues that a nuclear family, in which it is almost exclusively women who do the work of mothering, reproduces the capacity to mother in daughters, but not in sons, who are treated more distantly because of their anatomical difference from the mother. The psychoanalytic theory Chodorow uses is itself dependent on a series of cultural arrangements and conditions for the truth of its insights. While her basic insights revolve around the psychoanalytic preoccupation with the reproduction of psychological relationships between people in the family, these relationships themselves are embedded in a series of culturally

determined patterns which structure the family and its interpersonal matrix.

Other gender sociologists have drawn from psychoanalysis as well to explain phenomena as disparate as gender identity in the military (Williams 1989), women’s relationships to their bodies (Martin 1987), and our culture’s patriarchal thrust more generally (Dinnerstein 1976). Newer works by Chodorow (1999) summarize the importance of psychoanalytic theory for gender and other areas of sociology.

While Chodorow and others turn to psychoanalytic categories, other sociologists turn to more explicitly historical and ideological – but equally cultural – reasons why women perform the role of mothering. Those examining American society often cite the role of American cultural traditions (Hays 1996) or American mass media culture (Douglas 2004) in maintaining and reproducing the “custom” of female labor in the family and home. These cultural explanations have been important because they fill in where other types of explanations fall short of explaining the persistence and ubiquity of gender inequality.

Cultural explanations account for not only why women consent to perform unpaid labor in the family, but also explain why women resist other types of explanations, and criticisms of their actions – such as those offered by the women’s movement or feminist academics, which label this extra labor as oppressive or exploitative. Women’s own explanations for their lives often reject such accounts, substituting instead the idea that they perform family labors out of love and devotion. Larger cultural factors like their belief in religious ideas about women’s familial role, or their adherence to certain secular notions about the importance of traditional family values, can be invoked to help make sense of why women consent to a gendered division of labor that analysts find oppressive.

Hays (1996) and Douglas (2004) interrogate the history and development of current cultural ideas and policies about motherhood in our society, each in turn exposing the different ways these ideas and policies disadvantage women as a social and cultural group. Douglas relies in part for her evidence of the development and reproduction of social attitudes on a variety of popular media like film and television

that indicate how our society makes, and has historically made, contradictory demands on mothers. For example, the vast majority of mothers work, and for an increasing number of hours, yet particularly over the last 10 years the growth of the ideology of "intensive mothering" has demanded that an increasing number of hours be devoted to the tasks of childrearing. Many pages of popular culture lore are devoted to increasing guilt among those mothers who work for their inability to meet the demands of this mothering "speed up." Her book is a prime example of works which combine cultural analysis with other types of analysis and evidence. Together, these forms of analysis enable one to develop a critical perspective on an aspect of social activity in which women's work plays the major role. It is an extremely politically informed commentary on many aspects of our "culture of motherhood" in the contemporary US. Douglas supplements her cultural history with a running account of all the policy decisions affecting mothers that have been made by the US government over the last four decades – what she has dubbed the backlash era against feminism. Douglas's work stands as an interesting methodological example among books discussing the gendered aspects of our culture in that it addresses not only gender and culture, but the political issues and related policy debates that highlight their importance for our everyday lives.

Hays (1996) is similarly cultural in her level of explanation, yet is both more specific and even more historically framed. Hays interrogates our widespread cultural assumption that what she calls intensive mothering is necessary or even beneficial for children. Marshaling historical evidence, Hays examines the historical growth of this assumption and analyzes its relationship to our society's varying use of women as a reserve labor force, as women are pulled in to work when needed and pushed out with cries of child neglect when they are not. The argument is cultural throughout in that it challenges those who assert that women's biology accounts for their desire to mother according to the intensive style she describes. The cultural evidence Hays uses, then, is both historical and socioeconomic in nature.

Yet another cultural take on the study of mothering focuses on the representation of mothering as a gendered practice in a series of cultural artifacts like film, television, books, newspapers, etc. There has been much work on the intersection of gender and culture focused on the topic of mothering from this perspective. Kaplan (1992), for example, focuses on the representation of mothers in popular Hollywood film, identifying several prototypes typical of Hollywood's images and classifying a plethora of Hollywood works according to these prototypes. Many others have commented on various aspects of motherhood's filmic representation and its potential impact on women viewers, and on our cultural ideas about mothering generally (Geraghty 1991).

Press (1991) and Press and Cole (1999) and others discuss some aspects of the representation of mothering in television, and its impact on the viewers they researched. Press (1991) focuses generally on analyzing the representation of women and families in prime time television, and in particular discusses women's reactions to and interpretations of these representations. Many women interviewed for the study mentioned their reactions to the mothers and families depicted in the television they had watched. Some even described their own mothering styles, current or planned, in relation to these images. Press and Cole (1999) again discuss issues surrounding motherhood with women, this time in the context of broader dialogues on and off television about abortion. Discussion took place in groups and preceded or followed viewing of various prime time television treatments of the issue. While mothering itself was not the actual focus of the discussions, the topic was central to the abortion opinions expressed by many of the women in the study.

Many works (e.g., Walters 2001) discuss multiple types of cultural artifacts more directly, including films, entertainment, television, books, and news media, all from the perspective of how motherhood is represented in different ways and with what impact on society. These works all support the importance of cultural representations of gender in contributing to the reproduction of our gendered system and the inequalities inherent in it.

CONCLUSION

This brief discussion illustrates that the study of gender is intertwined with cultural concepts and factors. The definition of culture itself is difficult to pin down, and ranges from an amorphous notion encompassing many aspects of social existence, to one more specifically based on cultural artifacts and products. The sociology of gender cannot be imagined without a strong notion of the importance of culture and the ubiquity of cultural factors.

As the interdisciplinary study of gender has developed in a distinctive way, it has in turn influenced the sociology of gender to move in a more cultural direction. The recent influx of studies focusing on the gendered aspects of culture is a good example of the impact this has had on the sociology of gender. Press (2000) details three axes for recent work in the field of communication focusing on gender issues: technology, the body, and the public sphere. All of these topics have been taken up in recent work on the sociology of gender. The increasing tendency of the field to assimilate influences from interdisciplinary studies which have transformed the very nature of the field itself is good evidence that the cultural bent in gendered sociology is here to stay.

culture industries

Nicholas Garnham

Culture industries is a term which performs both a descriptive and conceptual function. It also has a history. Since the term was coined by Horkheimer and Adorno in their 1947 essay "The Culture Industry: Enlightenment as

Mass Deception," both what the term designates and its theoretical implications have undergone a number of shifts.

In its original Frankfurt School usage the term was a polemical intervention into the mass society/mass culture debate and a development of the Marxist theory of Ideology. On the one hand, the term culture referred to the superstructure – the social realm of meaning construction and circulation where symbolic forms of all types were produced and distributed – and to the German Idealist tradition of culture (or art) as a realm of freedom from material constraint and interests. Its linkage to the term industry (in the singular), on the other hand, was intended polemically to indicate the destruction of the relative autonomy of the superstructure and of the emancipatory possibilities of art by the economic dynamics of the base. The culture industry thus primarily referred to the industrialization and commodification of the process of symbolic production and circulation *in toto*. For Horkheimer and Adorno, the ideological domination of capitalism, and thus the suppression of revolutionary possibilities, was effected not by the overt content of cultural production, but by the deep structure of the cultural forms and the alienated relations between both producer (artist) and cultural work and between producers and audiences that the system of capitalist industrial cultural production produced. In this period this approach was counterposed to the wide spread sociopolitical concern with propaganda as a key element in the construction and maintenance of authoritarian regimes (fascism and Stalinism).

The use of the term industry referred (drawing on Marx) to the domination of the cultural realm by competitive and increasingly monopolistic corporations driven by the search for profit through the exchange of cultural commodities, thus necessarily alienating. It also referred (drawing on Weber) to a process of organizational rationalization, whereby cultural production and consumption were increasingly planned, thus suppressing cultural and political alternatives. Importantly, this approach placed the analysis of advertising and marketing at the center of a general process the purpose and effect of which was to hold the audience in thrall (the new opiate of the people).

This rationalization took place not just within the process of production, but within the cultural form. Cultural products were standardized and produced "pseudo individuality" in consumption.

Importantly, this vision and theoretical analysis were starkly opposed to Walter Benjamin's (1970) view of media technologies as emancipatory advances which shifted the relation between audience and art work from one of worship ("aura") to one of education and rational inquiry.

Through the 1950s and 1960s the term culture industry and its accompanying theoretical approach was largely forgotten in favor of a pluralist analysis of the mass media and their power (or lack of it). It was dismissed as the nostalgic and elitist response of exiled German intellectuals to US popular culture. The term reappeared, more usually in the form of cultural industries, in the late 1960s with the revival of theoretical Marxism and the New Left. It now drew on three developments: (1) the revival of a political economy of communications which returned to a serious analysis of the economics of the mass media in contrast to the ideological analysis of media content; (2) the turn to cultural studies, which shifted the emphasis in the wider analysis of and opposition to capitalist consumerist hegemony from economic to cultural structures and processes; (3) the revival of the Frankfurt School analysis of capitalism and its social and cultural effects in the form of a utopian, countercultural, anti-consumerist critique of capitalism as the society of the spectacle (deBord 1995) symbolized by the May 1968 events in France and by Marcuse's role as a guru of the US New Left (Marcuse 1991).

Now the use of the term signaled a shift away from a focus on the mass media, understood as the print publishing and broadcasting industries, and the overwhelming focus on the direct political effects of those media, to a focus on popular entertainment and, in particular, linked to a heightened sociological interest in youth culture, to a concern with the music and film industries.

It is important to note that in this new usage the cultural industries were no longer assumed to be alienated and repressive. On the contrary, the term could now be used positively in a

critique of the elitist implications of established public policies for the support of art and media (Garnham 1990). It was thus associated with a widespread positive evaluation, both within economics and cultural studies, of consumerism, and the discovery of the "empowered" consumer and audience.

At the same time the use of the term signaled a refusal to follow the "cultural turn" in rejecting economic determination. Those analyzing the cultural industries now drew not only on Marxist economics, but on developments in mainstream industrial and information economics, to make much more detailed and nuanced analyses of the economic structure and dynamics of the cultural industries than that of the Frankfurt School. The cultural industries were now analyzed in terms of the special nature of their products and markets. Indeed, the term industries in the plural was now used to indicate the existence of important economic differences between these industries. Stress was now placed on the particular nature of symbolic or immaterial products and services and the difficulties in commodifying them. Rejecting Frankfurt School notions of rationalization and planning, this new analysis emphasized the exceptionally risky and irrational nature of the production and distribution process stemming from the need for constant product innovation and the inherent uncertainty of demand. This created a "hit and flop" economy where a few super profitable, but inherently unpredictable, hits paid for the high percentage of losers. A distinction was drawn between the high sunk costs of production (so called first copy costs and more akin to R&D in classical material goods producing industries) and the low costs of reproduction and distribution which resulted in increased returns to scale and thus a powerful drive towards audience maximization and both sectoral and cross sectoral concentration of ownership and control. The structure and dynamics of the cultural sector were explained as the response of management under conditions of intercapitalist competition to these problems of realization.

On this basis the French school (Miege 1989; Flichy 1991) distinguished subsectors of the cultural industries (*les industries de l'imaginaire*) nature of their products, their relations of production, their relation to their markets,

and their relation to the underlying technologies of distribution and appropriation. These subsectors were, first, *editorial* (of which book publishing and records were the classic cases) where control over a catalog of products – and thus the ability to spread the investment risk – was strategically crucial. Here, production of the cultural products remained artisanal, was outsourced, and the key workforce was managed and subordinated through contract and intellectual property rights. The second subsector regarded *flow* (i.e., broadcasting in its various forms) where customer loyalty to a constantly replenished service and series of channels required control over distribution and the centralized planning of content production – and thus also the employment of content producers as wage workers in large industrial organizations. Here the commodity being sold was audiences to advertisers and a major share of value added was extracted not by the content producers but by the producers of consumer electronics (e.g., TV and radio sets, video recorders, DVD players, etc).

The cultural industries approach now developed in three distinct although not necessarily incompatible directions, and in so doing largely lost its original link to Marxism. First, the focus on distribution and the industries' links with the consumer electronics sector led to a focus on the impact of developments in ICTs (information and communication technologies) and related policy issues. Here the central argument was over the extent to which developments in the communication and cultural sectors were technologically determined and whether technological development was or was not broadly emancipatory (de Sola Pool 1984).

Secondly, the focus on the industrial economics of information led to a merger with the broader post Fordist analysis of the development of the capitalist economy, which saw the economy in general satisfying immaterial (and therefore cultural), rather than material, needs (Lash & Urry 1994). Here the distinction between cultural industries and other economic sectors is increasingly brought into question. These two developments have led to the absorption of the cultural industries analysis into a broader information sector, information economy, information society analysis.

Thirdly, the term cultural industries has given way to a range of terms such as entertainment industry, information sector, knowledge industries and, in particular, creative industries. Here, linked to a more general analysis of the knowledge economy (Castells 1999), itself a development of the concepts of the post industrial and service economies, the center of analysis is immateriality, the percentage of value added attributable to “knowledge,” the dependency on intellectual property. In particular, the role and formation of “knowledge” or “creative” workers becomes a matter of central concern. This development is largely policy driven. On the one hand, it is based on an argument that the cultural sector is a key growth sector globally and thus, as a response to deindustrialization, nations need to foster their “creative industries” in order to get a share of this market and the profits and export earnings that flow from it. On the other hand, “knowledge” creation generally is a condition for success in the new information economy and thus comparative advantage stems from creating conditions – educational, legal, and fiscal – to foster this creativity.

Analysis of and debates surrounding the cultural industries relate to two other important topics: the public sphere and intellectuals. Habermas's original formulation of his public sphere thesis stems directly from Adorno's analysis of the culture industries. It is the creation of the culture industries that destroys the public sphere as an arena for free discussion and deliberation upon which democracy is founded. Thus an analysis of the structure and dynamics of these industries is central to an understanding of the history and future possibilities of the public sphere.

Central to the culture industries tradition has been a concern with the socioeconomic position and role of cultural workers and the extent to which, as intellectuals, they can continue to exercise an autonomous and critical role in the development of knowledge and culture. The shift to a focus on creative industries and the information society places this concern with the relations of cultural production center stage.

culture jamming

Jay M. Handelman and Robert V. Kozinets

Culture jamming refers to an organized, social activist effort that aims to counter the bombardment of consumption oriented messages in the mass media. For Habermas (1985), an ideal speech situation is one in which all participants within a public space are empowered to reach consensus on issues of mutual importance through engagement in symmetrical discourse. Culture jammers see contemporary public space as filled with distorted communications, and seek to right the situation. These activists see fair and accessible public discourse as eroded by a mass media controlled by corporations, whose sponsored advertising has become the primary propagandist supporting the social logic of consumption culture. Culture jamming, then, is consumer culture jamming. The activists seek to break through the wall of corporate

controlled, distorted, asymmetrical public discourse, awakening people from the hegemonic culture where the logic of consumption permeates all aspects of their lived experience (Rumbo 2002).

The rationale for culture jamming is found in the writings of Frankfurt School theorists, perhaps most powerfully espoused by Horkheimer and Adorno (1996). The Frankfurt School's conceptual framework critiques social structures constructed under the guise of a capitalist ideology that come to define a culture of consumption. Here, corporations act as "cultural engineers" (Holt 2002) that define a limited set of socially acceptable human activities and identities, inherently limiting human potential and freedom. By controlling and permeating virtually all public spaces, corporations and their capitalist ideology serve as the groundwork for a hegemonic cultural logic of consumption. Ontologically, while this culture of consumption is socially constructed, it becomes reified as a "natural" social order, appearing concrete, objective, and void of competing worldviews and any alternative possibility for human expression.

Consistent with the underlying philosophy of the Frankfurt School, culture jamming involves at least three steps in its effort to break through this oppressive framework of social meaning. First, culture jamming tries to identify the contradictions buried beneath the apparently seamless barrage of capitalist messages. Advertising, the communication carrier of the capitalist cultural code, naturalizes consumption by interweaving consumer goods and the very fabric of social life (Leiss et al. 1990). Through advertising, consumption of consumer goods appears as the sole route to solving life's problems and achieving individual happiness. Culture jamming's first step is to unveil the economic, social, and environmental misery that hides beneath this happy exterior.

The second step in culture jamming involves achieving a type of reflexive resistance whereby consumers (i.e., the general public) become aware of the hidden contradictions underlying the cultural ideology of consumption. By revealing these otherwise hidden contradictions, culture jamming empowers consumers by enabling them not only to see the discrepancies lurking beneath capitalism's glossy

and seductive messages, but also to examine critically how the dominant capitalist ideology imposes constraints on human freedom. In achieving this, culture jamming sets the stage for the third step, which is emancipation. Here, consumers are changed – which is the culture jammers' ultimate objective. They are able to envision and act upon other cultural logics and alternative possibilities for social expression and individual happiness.

Culture jamming's perspective of omnipotent consumer culture that can only be broken by organized activists who heroically emancipate consumers has come under considerable scrutiny. At the axiological level, the culture jamming project inherently assumes that consumers are cultural dupes who have been hoodwinked by clever capitalists and are in dire need of emancipation by enlightened activists. Cultural studies of consumers have found that individual consumers can, on their own, be well aware of the contradictions that permeate a culture of consumption. These consumers come to see the contradictions in culture jamming itself as an attempt by yet another set of cultural elitists (social activists) to control the social agenda (Kozinets & Handelman 2004).

Ontologically, postmodern researchers view the erosion of a culture of consumption as occurring not through top down activist attempts at culture jamming, but via fragmented and self produced consumption whereby individual consumers produce their own system of cultural meanings (Holt 2002). With this type of resistance, consumers come to form their own patterns of social interaction and cultural meaning, which are organically produced not through consumption of mass produced products but by alternative methods of exchange, such as gift giving and sacrificial practices (Kozinets 2002).

Empirical research in this area lends itself best to interpretive (qualitative) techniques. As the issue of culture jamming is intricately tied with issues of cultural meaning, social movements, ideology, and the like, examining culture jamming and other forms of consumer resistance is best achieved by studying these activities embedded in their cultural context. Ongoing research in the area of culture jamming will grapple with the alternative axiological and ontological perspectives mentioned

above. On the one hand is the idea of consumer resistance such as culture jamming as occurring in the form of an organized, top down social activist attempt to break consumers free from a hegemonic capitalist ideology that sustains materialism as a central cultural value. On the other hand is a postmodern conceptualization of consumer resistance that advocates self directed agency towards consumer sovereignty (Thompson 2004).

culture, nature and

Chandra Mukerji

There is a movement among sociologists and social critics to include the built environment and physical bodies in social analysis, and to think seriously about the ways that locations

and creatures (including people) matter to group life. Part of this comes from anthropological leanings in sociology, and the tradition of thick description that includes discussions of chickens and back streets as well as group life. Part of it is motivated by feminist theory, and the determination to keep bodies and gender cultures in social analysis. Not only the settings for social life but also the human form itself is a cultural artifact made from natural materials. Part of the interest in cultures of nature also comes from Foucault. It is clear that power founded in the built environment provides an almost unnoticed but consequential regulatory mechanism.

Sociologists have had a long term interest in describing the physical forms and social effects of cultural relations to the natural world. While relatively few ethnographic sociologists have paid serious attention to the physical settings for social life, those who have done community studies have sometimes illustrated the centrality of cultures of nature to collective life. Kai Erikson in *Everything in its Path* (1976) describes the social devastation of the Buffalo Creek flood, and how the mining industry, in disposing of its wastes, set up the conditions for the flood. He makes clear that the physical locations where social relations play out matter, and that these are shaped through human hands as well as by natural forces. The book by John Walton (2001) about Carmel, California, again looks at history, environment, and community, showing the enduring value of community studies that focus on cultures of nature and the forms of life they sustain.

Urban sociologists have also written about nature, too – the persistence of natural forces in artificial worlds. Sharon Zukin (1995) describes cities as quasi natures of living creatures and supposedly inanimate structures that nonetheless settle and move. The city may seem to be the opposite of nature, but it is better understood as a culture of nature that seeks its control. Patrick Joyce (2003) looks at the meaning and forms of material control in two British cities, showing how political liberalism developed in the context of highly regulated material life. The compact between liberal, self governing individuals and the regimes of power they inhabit is partly written on the ground in the places they inhabit.

Ecofeminists write quite differently about cultural relations to nature, bringing gender critique to the patterns of seeing and using the physical world. They argue that gender domination has been both symbolically and practically played out on the earth. Carolyn Merchant (1980) describes the masculine gaze in science. She argues that longstanding popular respect for female deities or Mother Nature was undermined by the promotion of objectivity in modern science. The power that was gained this way and through the culture of stewardship helped to erode the quality of human life in spite of the rhetoric of improvement. Donna Haraway (2002), in quite a different move, looks at the companion species that live with human beings, sometimes known as pets, to meditate on domination of nature and the possibility of friendships with non human beings. She asks whether cross species companionship can be a model for human relations to the natural world.

Sociologists of science, after focusing most of their attention for years on epistemological issues, are now asking about cultural formations of nature, their connections to science, and their implications for power. Chandra Mukerji (1997) looks at the role of territoriality in state formation in France, asking not simply about land claims but also about the territorial engineering used to define and defend them. Patrick Carroll (2001) writes about the role of “engine science” or engineering in the British control of Ireland. Like Patrick Joyce (2003), he identifies the exercise of power with control of the built environment. But Carroll sees Ireland as a laboratory for the British to experiment with tools of colonial control that were exported to other parts of the empire.

Prakash (1999) documents some of the results of these British efforts at material domination. In *Another Reason*, he follows the tools of engineering from Britain to India. There western science confronted local intellectual elites, who tried to find ways to engage it. Some picked up western intellectual styles, and saw the colonial railroad and other engineering projects as ways to modernize India. Others tried to find ways to build intellectual links between traditional forms of Indian culture and the imported ones. British colonial

government established its hegemony through the environment, and brought face to face a utilitarian western reason and an indigenous one more deeply rooted in the subcontinent.

What makes work in this subfield so engaging is that it still takes materialism seriously even in this period when Marxist materialism has shown its intellectual failings. Human life remains embedded in the earth, and the landscapes people shape and inhabit. They regulate their bodies through material means, controlling diet, health, and habitations. In this period of globalization, when there are massive efforts to restructure relations to the natural world, this kind of social analysis has continued practical salience. And with the need to define a new materialism for the social sciences, studying the meeting places of nature and culture is intellectually vital as well.

culture, organizations and

Andrew Chan

Culture in organizations refers to the values, norms, and patterns of action that characterize the social relationships within formal organizations. Jaques (1951) first described the changing culture of a factory, defining it as the customary or traditional ways of doing things, which are shared to a greater or lesser extent by all members of the organization and which new members must learn and at least partially accept in order to be accepted into the service of the firm.

Turner (1971) defines culture and its importance for organizing. According to Turner, part of the effectiveness of organizations lies in the way in which they are able to bring together large numbers of people and imbue them for a sufficient time with a sufficient similarity of approach, outlook, and priorities to enable them to achieve collective, sustained responses which would be impossible if a group of unorganized individuals were to face the same problem. However, this very property also brings with it the dangers of a collective blindness that some vital factors may be left outside the bounds of organizational perception. Culture is the source of blind spots because sharedness in values, norms, and perceptions results in a similarity of approach, shared expectations among members of the group to bring certain assumptions to the task of decision making within the organization, and to operate with similar views of rationality. Culture is therefore a double edged sword.

INTELLECTUAL AND SOCIAL CONTEXT

Culture was primarily a central concern for anthropologists and sociologists throughout the twentieth century. Only more recently, in the 1980s, did it catch the attention of the structural contingency school of organization theorists and economists, as a result of a number of popular texts that advocated an optimistic, even

democratic view of the capacities of ordinary employees: *In Search of Excellence* (1982), *The Art of Japanese Management* (1982), *Theory Z* (1982), *The Winning Streak* (1984), and *Corporate Cultures* (1988) are some examples. These popular books reiterated and consolidated the insights of the human relations approach of industrial relations. These books also prefabricated alternative management theories, ones that capitalized on culture as a precursor of more effective production and less hierarchical arrangements. Rediscovering culture seemed to be a way of responding to economic recessions at that time, and especially the challenges coming from Japanese companies. Organizational culture became seen as a variable in the firm's success equation and ultimate performance. As Chan and Clegg (2002) observe, one consequence of these enthusiasms has been to reduce the culture concept to an effect, constituted as a (metaphorical) object of inquiry. In the realm of organizational research, culture therefore very often only refers to "organizational culture" – a term that came to the fore in a series of British and American popular management texts of the 1980s. However, research did not stop with this popular consensus. Existing chasms between functionalist and pluralist paradigms, modern and postmodern approaches, and science and contra science were reiterated in much of the research on organizational culture. Authors argued differences openly in a number of publications. A major axis of difference centered upon the definition of the construct per se (ontology), and upon the paradigms and methodologies used to apprehend it and to generate knowledge about it (epistemology).

MAJOR DIMENSIONS OF CULTURE

One dimension of culture was depicted by organizational anthropologists who pointed out that the organizational literature hijacked culture and used familiar concepts related to it (i.e., rituals, myths, taboos, and symbols) in disconcertingly unrecognizable ways (Marcus 1998). The displacement or transfer of the terms from anthropology to organization studies was inadequate and far from satisfying. Anthropologically and sociologically informed researchers considered that culture was not as

pliable as practitioners and managers seemed to think it should be (Meek 1988). For the latter, culture, as broadly construed by the organization and management literature, embodied consultant driven reform initiatives for corporations, as well as managers' own attempts to gain control of their organizations through influencing the value premises on which organizational members' behavior was based. With this dimension of organization culture, clearly the least deeply conceived, widespread interest and enthusiasm extolled its perceived potency; culture assumed the character of a panacea, one that, potentially, could solve many organizational ailments. The business community had no qualms about the seductiveness of cultural management techniques as they infiltrated management circles. The panacea attributes of culture became widely identified with and internalized by the practitioner and managerial community throughout the 1980s and 1990s, even while more fundamental research continued. Willmott (1993) provided a comprehensive review of this "corporate culturalism" phenomenon over that decade.

METHODOLOGICAL ISSUES

Martin (2002) used the metaphor of "culture war games" to describe the paradigm dissensus and struggle for intellectual dominance within culture research communities throughout the 1980s and 1990s. From the outset, the culture movement represented a promising alternative and even a counter initiative to functionalist and quantitative approaches in organization studies. The interest in culture in the 1980s gathered momentum amid a general discontent with quantitative approaches and structural contingency theories of organization that had already evolved from the systematic critique of normal organization science developed in the 1970s.

Administrative studies of culture favored quantitative techniques to provide functionalist accounts that lent themselves to the development of empirically based generalizations. Chatman (1991) and O'Reilly et al. (1991) were good examples. On the other hand, more pluralistic researchers had good reason to employ qualitative methodology and other

multi paradigmatic methodologies in developing context specific explanations of culture. Qualitative research on culture allowed multi perspective ethnographic methodologies to acquire legitimacy, representing an opportunity to break with the constraints of dominant quantitative and positivistic approaches.

The underpinnings of the two broad camps may be classified using Martin's (2002) "differentiation" perspective and its opposite, the "integrationist" genre of culture research. Research following a differentiation perspective, according to Martin, acknowledges inconsistencies in attitude. It sees consensus as occurring only within subcultural boundaries. It acknowledges conflicts of interest, for example, between top management and other employees, and within the top management team. These studies describe the inconsistencies and subcultural differences they find, so that inconsistency, subcultural consensus, and subcultural clarity become seen as the characteristic hallmarks of differentiation research.

The integrationist perspective drew from the managerially oriented and popular culture writings. Many quantitative studies depicted culture as an internally consistent package that fostered organization wide consensus, usually around some set of shared values. Aspects of change and reform in organizations were seen as an embodiment of organization wide cultural transformation, whereby either an old unity could be replaced (it was hoped by a new one) or unity forged out of difference. Some of the major themes that directed work undertaken in the integrationist framework were concerned with the management of meaning and various practices and devices through which managers attempt to bring off acceptable definitions of organizational reality as a basis for collective action, such as, for example, specific adoption of language, ritual, myth, story, legend, and narrative, etc., that were organizationally approved.

On one hand, the integrationist genre sees pragmatism, certainty, rationality, homogeneity, harmony, and a unified culture as an order of things that are both to be striven for and are achievable. Research in the integrationist genre conceptualized culture as a benign panacea, with properties that lent themselves to being pliable, at will, by managers. By contrast, the

differentiation perspective criticized integrationist social engineering and value management treatments of culture. The differentiation perspective developed a critical assortment of theories of organizations that opposed a seemingly scientific, variable based cultural theory of organization.

The bifurcation of cultural research into differentiation and integrationist camps was a result of resistance to the dominant integrationist and positivist approaches to organization theory and culture. The differentiation perspective argued that the existence of dissent and ambiguities, conflicts, and confusion in organizations, and the nature of the workers' passionate engagement in work, are glossed and rendered mute by the mainstream integrationist literature.

FUTURE DIRECTIONS

Between 1990 and 2001 three major handbooks were published: *Organizational Climate and Culture* (1990), *Handbook of Organizational Culture and Climate* (2000), and the *International Handbook of Organizational Culture and Climate* (2001). Additionally, economists such as Hermalin (2001) provided a comprehensive review of the relationship between economics and corporate culture. Administrative study of culture continues to thrive, emphasizing employee and company culture fit. Culture audit and organizational culture diagnosis tools continue to be refined mainly in company organizational development and applied settings that make use of such survey tools. More classically, future research in the differentiation tradition is likely to develop in the broad direction of studies of the hermeneutics of sense making and exploration of process philosophy views of culture.

The first view considers that material aspects of organizations are made real only by being given meaning. We make sense of the realities of our everyday world by invoking and bringing to bear prior experience and assumptions. When we observe culture, whether in an organization or in society at large, we are observing an evolved form of social practice that has been influenced by many complex interactions between people, events, situations, actions, and

general circumstances. The hermeneutic perspective is based on culture being constructed and accounted for through meaning giving and sensemaking.

The process philosophical perspective treats culture not as entity like structures but as instances that give meanings to actions and behaviors (Chia 2002). Culture is treated as a process of reality construction enabling people to understand certain events, action, things, and situations in distinctive ways. The treatment of culture as a fixed, unitary, bounded entity gives way to a sense of fluidity and permeability. It requires also that explanation of cultural forms be situated in a larger environment and a wider arena of different forces.

Future research on culture is likely to become more fruitful by returning to analysis of the social interactive processes through which actors create their world, via interpretive schemes. Deterministic models of culture are likely to give way to a reconsideration of culture as an inference making process, except perhaps where culture is conceived of as the subject of managerial tools and techniques.

culture of poverty

Kristina Wolff

The phrase culture of poverty was coined by Oscar Lewis (1965) to describe the combination of factors that perpetuate patterns of inequality and poverty in society. By focusing on the experiences of Puerto Ricans, Lewis illustrated how difficult it was for people to escape poverty due to the influence of cultural beliefs that support behaviors that contribute to people remaining in poverty. He described how the poor feel alienated in society. Because of their frustrations with their inability to transcend poverty, a culture develops which supports behaviors providing short term gratification and other conditions of poverty as "normal." This is largely due to the conviction that it is impossible to improve their lives. These beliefs and behaviors are then instilled from one generation to the next, which eventually develops into a culture of poverty.

This concept has been used as a rationale to both increase and decrease government support for the poor, ranging from individuals within the US to debates about developing nations and the amount of aid they "deserve" from industrialized nations. A liberal approach utilizes this theory as a means to examine the structural impediments that create barriers for people to move out of poverty. These include absence of jobs, poor transportation, and limited access to adequate education and health

care. Conservative interpretations of poverty use Lewis's concept as an illustration of the lack of motivation of individual poor people. Often drawing on stereotypes within popular culture, that people on welfare are "lazy," "hedonistic," or possessing questionable morals, a culture of poverty represents an individual's choice to remain dependent on the government instead of seeking gainful employment.

Sociologists have explored the relationships of ethnicity, race, and gender with various interpretations of the culture of poverty. By using this concept as a means to illustrate groups as having a "defective" culture, it becomes politically justifiable to limit support for the poor. For example, when the US restructured welfare programs in the 1990s, many argued in support of forced birth control or caps on the number of children women on public assistance could have and still receive government funds. Women and children constitute a large segment of the impoverished and proportionally more women of color are in poverty or are part of the working poor in US society. By focusing on individuals or specific populations as responsible for their impoverished state, social structures and practices that create barriers to success escape accountability.

culture, production of

Richard A. Peterson

The production of culture perspective focuses on the ways in which the content of symbolic elements of culture are significantly shaped by the systems within which they are created, distributed, evaluated, taught, and preserved. The initial focus was on the production of expressive symbols such as art works, scientific research reports, popular culture, religious practices, legal judgments, journalism, and other parts of the culture industries. Now the perspective is also applied to many situations where the manipulation of symbols is a byproduct rather than the purpose of the collective activity (Peterson 1976; Crane 1992, Peterson & Anand 2004).

In the 1970s, when the production of culture emerged as a self conscious perspective, it challenged the then dominant idea that culture values and social structure mirror each other, a view held by most Marxists and functionalists – among them Talcott Parsons. Breaking from the mirror view, the production perspective sees culture and social structure as elements in an ever changing patchwork (Peterson 1979). Research in the perspective draws freely on theories and methods developed in other branches of sociology. It is, however, distinctive in focusing on the consequences of social activities for the symbolic elements of culture (DiMaggio 2000).

Cultural production systems change slowly, but occasionally there is rapid change altering the aesthetic expression of a cultural expression. Such change is illustrated by the study that helped inspire the production perspective in culture, Howard and Cynthia White's 1965 study *Canvases and Careers*. It showed the transformation of the nineteenth century French art world and the consequent emergence of Impressionist art. Six production factors are identified as making possible rapid cultural change. These include changes in law and regulation, technology, industrial structure, organizational structure, occupational careers, and the consumer market. The workings of these facets should be considered together as part of an interdependent production network (Peterson & Anand 2004).

Technology provides the tools with which people and institutions augment their abilities to communicate, while changes in communication technology profoundly destabilize and create new opportunities in art and culture. Technological innovations including radio, phonograph records, movies, television, and digitalized communication transformed art and popular culture in the twentieth century. At the micro level, the electronic manipulation of guitar sounds transformed pop music, and digital communication media have facilitated the rapid globalization of culture (Waksman 1999; Goodall 2000).

Law and regulation create the ground rules which shape the ways in which creative fields develop. Changes in copyright law have influenced the kinds of fiction that gets published, and restrictive notions of intellectual property continue to inhibit cultural expressions. Censorship of the culture industries has shaped what can be produced, and federal restrictions on multiple ownership of newspapers, and TV and radio deregulation, have led to less diversity in points of view being expressed.

Industrial fields and organizational structures in creative industries tend to be structured in one of three ways. There may be many small competing firms producing a diversity of products, a few vertically integrated oligarchical firms that mass produce a few standardized products, or a more open system of oligarches with niche market targeted divisions plus a large number of small specialty service and market development firms, where the former produce the most lucrative products, while the latter produce the most innovative (Negus 1999; Caves 2000).

Occupational careers develop in each cultural field. The distribution of creative, craft, functional, and entrepreneurial occupations is determined largely by a field's structure, which in turn helps determine the symbolic output. Careers tend to be chaotic and foster cultural innovation, as creative people build careers by starting from the margins of existing professions and conventions (Becker 1982; Grazian 2003).

Markets are constructed by producers to render the welter of consumer tastes comprehensible. Once consumer tastes are reified as a market, those in the field tailor their actions

to create cultural goods like those currently most popular as measured with tools devised by producers (Turow 1992; Caves 2000).

The production perspective has proved a useful model for organizing ideas and research in five areas where the production of culture is itself not consciously sought. First, it has spawned the *culture industries* model in academic management research and become the prime model of post bureaucratic organization. Second, studies of the *autoproduction* of culture show that people produce identities and life styles for themselves from elements of traditional and mass mediated symbols. Third, studies show that *cultural omnivorousness* is replacing highbrow snobbery as people show their high status by consuming not only the fine arts but also appreciating many, if not all, forms of popular culture. Fourth, studies focused on *resistance and appropriation* show how young people take the products tendered to them by the culture industries and recombine them in unique ways to show their resistance to the dominant culture and to give expression to their own identities. Fifth, much of what is taken to be subcultural resistance is actually *fabricated* by the *consumer industry*. The contrast between the artifice of manufacture and the fan's experience of authenticity is arguably the most important unresolved paradox of cultural sociology (Negus 1999; Peterson & Anand 2004).

culture, social movements and

Rhys H. Williams

Culture is the symbolic and expressive dimensions of social life. This includes sets of symbols such as language, intangible, abstract “mental products” such as ideas, beliefs, values, and identity, and the meanings given to material objects such as clothing, decorations, art objects, buildings, and the like.

Social movements are sustained, more or less organized attempts at change. They may try to change individuals, group behaviors, government policies, or society’s cultural understandings. Social movements are generally thought to last longer and be more organized than a mob or a crowd, but are not as established or institutionalized as a political party or lobbying group.

Sociologists have studied culture and social movements with three basic sets of questions. First, many accounts of social movement emergence posit their basic causes as cultural. Second, when studying the processes and dynamics that allow social movements to function and maintain themselves, analysts have focused on cultural factors such as collective identity, ideological claims, emotions, and internal group norms, rituals, and practices. Third, scholars who study the impact that movements have on society have often focused on the cultural changes that are their goals for action (cf. Johnston & Klandermans 1995).

MOVEMENT EMERGENCE

Most of the sociological study of social movements since the end of World War II has sought to ascertain why social movements emerge. One way to categorize the answers is whether they put the basic cause of movement emergence in the social structural dimensions of society or in societal and group culture. Social structural causes include changing economic fortunes of particular classes, the formal political systems of society, or the resources (such as money, members, and organizations) that a group can mobilize in order to mount collective action. Cultural answers to the question of movement emergence have generally fallen within one of two categories: changes in the national or societal culture or changes in group subculture among those people involved in a social movement.

For example, both Gurr (1970) and Melucci (1989) basically claim that movements develop because large scale social and cultural changes result in a collective social psychological anomie or alienation among people experiencing these changes. Various types of cultural “strain” lead to breakdowns in normal routines and result in disruptive and innovative collective actions. European based “new social movements” of the 1970s and 1980s, such as the Greens, were theorized as the cultural response to late capitalism’s elevation of “lifestyle” concerns over redistributive economic politics (Scott 1990). Middle class cultural movements replaced labor as central collective actors. A more specific analysis of the role of group culture was Gusfield’s (1986) thesis that the US Prohibition Movement was led by people concerned about their declining social status. Their movement was a “symbolic crusade” to restore their cultural prestige.

At a more micro level perspective, scholars have focused on the language and “framing” work done by movement leaders. Analysts argue that many groups have the potential for collective action, but it takes the articulation of an ideology and a sense of collective identity for this potential to turn into an actual movement. Movements are thus “constructed” by the frames of movement leaders, who convince people to engage in collective action. Collective action frames interpret people’s life situations,

including such emotions as the anger and fear they may feel, by articulating them as grievances against an unjust system or enemy. Frames also tell people how they might change such situations, and try to convince them their own involvement will make a difference (see Benford & Snow 2000).

In all of these examples, it is something in culture – changes in the culture of a particular group, changes in the larger culture, or the use of cultural objects such as rhetoric, ideology, and identity – that is responsible for causing a social movement to emerge.

MOVEMENT DYNAMICS

Once a social movement has emerged, it needs to sustain collective action through mobilizing people repeatedly to action. This involves both cultural objects and processes that work cognitively, emotionally, and morally. Movement ideology is composed of language and non textual symbols directed at both movement members and the society the movement is trying to persuade. Other dimensions of culture, such as collective identity, group practices, and shared emotions and narratives, help people who are mobilized stay committed to their movement and their cause.

Social movements use ideological claims and symbolic messages to make their case for social change (Williams 1996; Platt & Williams 2002). Sometimes ideology is a straightforward articulation of the ideas that motivate the movement and include the visions of how society might be different. For example, Students for a Democratic Society drafted the *Port Huron Statement* that gave their rationale for action; similarly, Marx and Engel's *Communist Manifesto* was the ideological base for the international communist movement's plans for social change.

Movements experience some limitations in the ideological claims they can make (Williams 1995). While activists are free to formulate any argument they choose, many claims will not be effective in particular contexts. There is a "cultural repertoire" that puts boundaries on what a given society or historical period will consider legitimate ideas. These repertoires develop through the interaction of challenger claims and the reigning hegemonic ideology (Steinberg

1995). Movements face the challenge of articulating innovative calls for change, while using ideological claims and symbolic messages that are largely within the boundaries of the legitimate.

Movements' ideological messages are often reduced to easily remembered slogans, such as "Make Love, Not War," "God is Pro Life," or "No Blood for Oil." These slogans are a short hand that is only effective when the movement's fuller ideology is well enough known that audiences can fill in the potential ambiguity in content (e.g., a San Francisco bumper sticker, "I own a dog and I vote," only makes sense if one understands current land use issues in the Bay Area).

Another method of communicating the content of movement claims is to reduce them further to pictures or non textual figures. The pro choice movement consistently uses a drawing of a coat hanger with a line through it to symbolize the dangers of illegal abortions. Christian right organizations distribute bumper stickers with the word "vote" in which the "t" is elongated into a cross. Communist movements have used red stars historically, while white supremacist groups in the US and Europe resurrect the Nazi swastika. Non textual symbols provide even less information about specific issues, and yet make even broader political and social claims. They are often ambiguous enough that multiple groups use them, as in the Vietnam War era in the US when counterculture protesters stitched American flags on to the backs of their blue jean jackets at the same time that pro war blue collar workers were putting American flag decals on their hard hats. In such cases, the ideological message was not readable directly from the symbol used, but could only be understood within the context of a general presentation of self.

Movements must create and sustain a collective identity (e.g., Polletta & Jasper 2001). That is, people must feel that they share important characteristics with others in the movement, and that this identity is important enough to promote or protect through action. So, while slogans and non textual symbols articulate a social movement's ideas, the individuals and groups who display them are also making a statement about their personal and social identity. Symbolic displays mark those using them

as part of a particular movement, and encapsulate their basic attitudes and values.

The creation and nurturance of a shared collective identity produces a sense of “we-ness,” in such a way that it can become the basis for action. People may identify themselves as the victims of an injustice, experience anger or determination as a result of this, and organize to combat the injustice. Other times, the “we” becomes people who hold a certain set of values or interests (such as preserving wilderness areas) and feel both motivated and obligated to act. Sometimes the “we” seems obvious, as when it is built on a longstanding ethnic or religious identity.

Collective identity helps mobilize and sustain a movement (Fantasia 1988; Nepstad 2004). People must be willing to continue to contribute time and energy, and perhaps withstand risk, through both victories and setbacks. Spirits must be kept up, shared identities must be reaffirmed, and group solidarity must be cultivated. Songs, slogans, a particularized vocabulary, items of clothing or grooming, flags or pennants, all can contribute to this process – letting fellow movement members know who one is, and distinguishing movement “members” from others. Narratives and stories allow group members to frame a shared history and align their experiences, motives, emotions, and identities (Davis 2002).

Another dimension of movement culture is the discourse and practices used among movement members in the processes of internal debate, decision making, and interpersonal interaction. “Backstage” arguments among movement members are connected to the public ideology movements articulate, but they are often not identical (Kubal 1998). They may be dress rehearsals for later public positions, they may be quarrels among factions vying for control of the group’s message (Benford 1993), and they may be jokes, rationales, or beliefs purposely kept from public view. Movement members develop norms of etiquette (Polletta 2002) or styles of discourse (Hart 2001) that govern what types of arguments are allowed within group meetings, what types of relationships are considered the model for action, and what types of people movement members should want to try to be. These are cultural rules of action that help shape movement ideological

claims, group strategic decisions, and public collective identity.

MOVEMENT IMPACT

Almost all social movements have a variety of goals. Many want to change laws, or enact policy changes within institutions such as schools, churches, or hospitals. But many movements also seek changes in their wider societal culture (Epstein 1991; D’Anjou 1996). For example, the gay and lesbian liberation movement wants policy changes that will end discrimination against gays and lesbians, but it also wants to change the cultural values associated with homosexual orientations. Similarly, the women’s movement in the US and globally has worked at combating stereotypes about women (Naples & Desai 2002), while the vegetarian movement has tried to change people’s ideas (as well as habits) about food and non human animals (Maurer 2002). The Christian Right has sometimes been interested almost exclusively in symbolic change, as when it advocates putting the 10 Commandments in government buildings. Movement groups are often particularly interested in creating “activists”; that is, the change in which they are most interested is in the set of personal and collective identities found within groups of people (Lichterman 1996). Helping to transform individuals and groups into people who continue to agitate for sociocultural change is itself a form of cultural impact.

culture, the state and

Chandra Mukerji

Studies of culture and the state focus on a range of relationships between modern political regimes and patterns of symbolic and material life. They reveal the diverse ways that power works through culture, and provide means for a better understanding of how power is accumulated, organized, and deployed in or around state systems.

Much work in this subfield takes nationalism to be the fundamental culture of states, but most scholars working in this tradition do not make the mistake of treating national cultures as natural kinds. They try instead to understand how the processes involved in developing and shaping state power since the nineteenth century have generated distinctive national forms of political culture. Sociologists studying nationalism and its development have revealed the cultural techniques used in the creation of nationalist movements and identities. They have investigated the use of propaganda, the arts, gender relations, sexuality, storytelling, engineering, dress, and the media to establish taken for granted connections between populations and their governments.

Other scholars interested in culture and states have examined political processes like voting, policymaking, public advocacy, court procedures, and the use of violence, considering these activities as cultural performances or narrative devices, and following the complex rituals by which power is both exercised and legitimated. Among the students of American culture, there has also been broad interest in the moral dimensions of political participation and the practices of political activists. And Europeans have written with insight and precision about the cultures of bureaucracies, economic institutions, and educational systems that have helped to shape state based political life and national identities.

Studies of culture and the state in the US surprisingly had methodological roots in urban sociology, particularly work of the Chicago School with its fundamental interest in political culture. Fieldwork studies of urban political life and social movements made their cultural

forms evident. Scholars schooled in this tradition but caught up in the social activism and analytical Marxism of the 1960s and 1970s began to broaden the area of political concern, asking questions not only about cities but also about states and how they gain or lose authority. They were given tools for their analyses of politics by European sociologists such as members of the British School of Cultural Studies, and the French scholars working with Pierre Bourdieu. These analysts showed how seemingly innocent cultural practices, particularly education and popular culture, had effects on stratification and national identity. Unfortunately, scholars working in these schools generalized about "culture" from their own national traditions, as though there were no cultural differences or different uses of culture among states. This lack of attention to states and culture was criticized by Michele Lamont, and led to her work with Laurent Thevenot to compare class cultures in France and the US (Lamont & Thevenot 2000).

While techniques for analyzing political culture were developing among sociologists of culture in the mid twentieth century, theories of the state became a major area of sociological concern. This was motivated by some of the same historical conditions: the social activism of the 1960s and 1970s. By doing comparative research across countries and historical periods, students of the state hoped to see when and why political regimes failed or endured. Most of the work in the field was strictly structuralist, and explicitly so. Guided by the traditional Marxist theory of history, these scholars assumed that the political fates of regimes would be a consequence of structural processes, and dismissed culture and ideology as objects of analysis. Methodologically, they used the extant historical accounts of states and empires to compare their trajectories of power. Where they found states (as they often did) to be "semi autonomous," they could have asked questions about culture, but did not. Only in the last decade has there been a turn toward culture by theorists of the state. The results have been impressive, if different in method and implication. Tilly's (2003) elegant analysis of violence has revealed the unclear border between legitimate and illegitimate forms of collective violence. Charrad's (2001) award winning study

of the political cultures of gender in North African countries has shown how differently a common religion could be portrayed and used in political processes of state building.

Given the fundamental differences in theoretical orientation and methodology between macrosociology of state systems and microsociology of culture, it seemed unlikely between 1960 and 1990 that sociologists would have considered seriously cultural studies of states. But outside sociology, there were shifts in intellectual culture that pushed sociologists in this direction. One was strong interest in comparative cultural studies of states among anthropologists and historians who wrote influential pieces about the political cultures of these systems. Their empirical work made sense to sociologists working with similar methods and interested in comparable concerns. The other influence was more powerful and disconcerting to sociologists: the rapidly growing interdisciplinary interest in cultural studies and the writings of Foucault. Foucault argued that power did not primarily reside in institutions like the state, but rather in the processes of social classification that simultaneously organized knowledge and social relations.

Structural analyses like those developed by historical sociologists of the state, from this perspective, were fundamentally misguided. Even power (as legitimate violence) was not a monopoly of armies and police systems, but was a part of the discursive terrain that aligned power with knowledge. Cultural studies begged the question of whether there were any distinctive kinds of powers that states could wield to their advantage. It was a good question, so rather than destroying all efforts to study states, poststructuralism simply sent sociologists back to the historical record to see what could be learned about the cultural powers of states.

Foucault's early work on hospitals, clinics, and prisons had been easily folded into the sociology of deviance. But later poststructuralists' mantra like invocation of class, gender, and race and treatment of complex cultures as texts were more grating to sociologists. They seemed to provide humanists with prefabricated versions of social analysis, making even constructivist sociologists weary of this approach to culture. Some scholars in the field shared Foucault's interest in the politics of

language and labeling, but even these often remained advocates of fieldwork methods and more local ways of understanding stratification and power.

Studying culture, then, seemed more important than before, but the question was how to improve sociological analysis. Many sociologists simply did fieldwork to address questions raised by poststructuralists. But a substantial number of new works in historical sociology appeared, using subjects in political culture to address the workings of power itself. They rejected Foucault's aversion to traditional politics as an object of study, but embraced his project of seeking out neglected cultural practices of power. Michael Schudson (1992) and Barry Schwartz (2000) considered the powers of collective memory, while Joseph Gusfield (1981) and Robin Wagner Pacifici (1986) wrote on the performative aspects of political events. Meanwhile, Chandra Mukerji (1997) focused on material culture and the built environment, the ways that state power could be stabilized and materialized in maps, styles of dress, and places themselves.

In the 1990s, perhaps in response to the Reagan years in American politics, many new works on culture and the state appeared, focusing on nationalism, fascism, and the Holocaust. The question of why fascism gained power in the mid twentieth century had dominated critical theory and neo Marxism, bringing cultural issues to the heart of Marxist thought. Now the subject was being reexamined, using the tools of cultural sociology to explain the seductions of political imagery and identities that supported genocide (Berezin 1997; Falasca Zamponi 1997).

In the face of theoretical challenges from cultural studies and methodological ones from anthropology and history, sociologists interested in culture and the state have become better scholars. The push to produce a more richly nuanced cultural history of states has made it harder simply to skim off the secondary literature. At the same time, sociological understandings of states have matured, too. They are not automatically reduced to apparatuses (as structures) or nations (as a natural counterpart to states). They are analyzed as places of power, engineered to be politically identifiable

and materially managed territories, and sites of performances of power, linking people to places. States in the new sociology of culture are simultaneously imagined communities, narrowly organized sets of social relations, socially sanctioned ways of using the land, and elements in webs of violence and control. They exist as social institutions but exercise power not as some passive apparatus, but rather through politically nuanced and intentional practices of cultural domination through design.

cybercrime

Samuel Nunn

Cybercrime refers to the commission of criminal acts that target computers, use computers as an instrumentality to traditional crimes, or transmit illegal information using computer networks. One continuing form of cybercrime targets computers. So called hackers and crackers, through various means, gain access to closed computer networks in order to vandalize or otherwise damage databases or network software by introducing computer viruses or "denial of service" attacks. Denial of service refers to computer viruses or worms that create an overabundance of computer transactions, to the extent that entire systems will slow significantly or shut down completely.

Cybercrime comes in many guises. The objective of many early cybercrimes involving computer intrusions was to destroy data or interrupt the flow of computerized services. As the cybercrime concept evolved, it began to include similar break ins to protected computer networks, but instead of mischievous vandalism, theft and material gain were the motivation. Common cybercrimes now include the theft and subsequent sale or counterfeiting of debit and credit card numbers from the protected databases of private financial firms, as well as larceny involving intellectual property such as computer software, movies, digital videos, recorded music, or other items. The commission and camouflage of other traditional crimes such as child pornography are considered cybercrimes because of the widespread use of computer networks, digital photography, electronic mail, and encryption techniques to support the operation of globalized schemes. "Cyberstalking" involves the use of electronic communications to transmit threats of personal violence or kidnapping. The increasing creativity of terrorist attacks during the 1993–2004 period created the term "cyberterrorism" to describe criminal acts involving interference with the computer networks and automated operations of federally defined critical infrastructure such as banking, aviation, finance, power, gas, petroleum, transportation, and water networks.

As with other offenses, cybercrime involves the three traditional elements of crime: *actus reus*, *mens rea*, and concurrence. The *actus reus* usually involves the illegal entrance into protected computer systems and subsequent actions taken against or in pursuit of electronic properties. The *mens rea* of cybercrime is more complex. Destructive, larcenous, and other criminal acts using computerized resources are typically accompanied by varied motivations including power, greed, dominance, revenge, or satisfaction of prurient interest. Concurrence is also a complicated aspect of cybercrime. Many cybercrimes, such as computer break ins and intellectual property theft, might not be detected for long periods of time. Computer assisted identity theft might go on for months before victims become aware a crime has occurred.

The most common forms of cybercrime are credit or bank card fraud, child pornography, unauthorized access to a computer, identity theft, and cyberstalking. In the US, many cybercrimes are federal offenses because they involve use of computer networks that cross interstate boundaries. By 2004, the US criminal code included approximately two dozen chapters devoted to aspects of cybercrime. It is common for major law enforcement agencies to form computer forensics and other specialized squads to investigate cybercrime. Similar organizational strategies have been followed by international police agencies such as Interpol and Europol.

Criminal justice agencies face several challenges in their fight against cybercrime. Because computer networks are globalized, many cybercrimes raise questions regarding which jurisdictions have responsibility for investigation. Further, many cybercrimes are perpetrated by single individuals or small groups that nonetheless affect the computers or electronic property of hundreds or thousands of persons or organizations located in many different locales across the globe. For any single victim, the costs of these cybercrimes are often too low to warrant reporting formally, but taken in sum the costs of the crimes for all victims can be massive. Effective enforcement and adjudication of cybercrime law often requires interjurisdictional task forces, including cross national teams to conduct simultaneous investigations and arrests

in different countries across many different time zones.

cyberculture

David Bell

A neologism derived from a neologism, cyber culture welds together the “cyber” from cyberspace with “culture.” It is important to understand what happens when cyber and culture are brought together, and in order to work toward that understanding we need to begin by saying a few words about cyberspace (and some related things). The term cyberspace was famously coined by cyberpunk novelist William Gibson in his 1984 novel *Neuromancer*, to describe the imaginary “datascape” which his characters entered by “jacking in” – connecting their consciousness directly to networked computers. The well known and often quoted formulation in *Neuromancer* runs like this:

Cyberspace. A consensual hallucination experienced daily by millions of legitimate operators. . . . A graphic representation of data abstracted from the banks of every computer in the human system. Unthinkable complexity. Lines of light ranged in the nonspace of the mind, clusters and constellations of data. Like city lights, receding. (Gibson 1984: 67)

This vivid description offered a powerful fictional portent for the future, a future of unthinkable complexity and constellations of data. However, the computing science realities of what was then emerging as cyberspace were little known to Gibson; nevertheless, the term and the way cyberspace was depicted in *Neuromancer* have had a profound influence upon its development and its representation – an influence Gibson did not foresee when he cobbled the word together. As he put it:

Assembled word *cyberspace* from small and readily available components of language. Neologic spasm: the primal act of pop poetics. Preceded any concept whatever. Slick and hollow awaiting received meaning. All I did: folded words as taught. Now other words accrete in the interstices. (Gibson 1991: 27)

Other words have indeed accreted in the interstices of Gibson’s cyberspace – including cyberculture. Moreover, cyberspace came to be the preferred term for scholars writing about particular configurations of media and communications technologies, most especially the Internet (though others prefer an expanded definition that encompasses other realms of digital technology and digital culture; see Bell 2001). Cyberspace became a hot topic across a range of academic disciplines in the 1990s, as more and more researchers turned their attention to the many ways that the Internet was transforming ever greater parts of people’s lives. Through the course of the 1990s, research and writing on cyberspace began to branch and specialize, and there was something of a publishing boom. Aside from computer science research, a large body of work emerged which focused on the social and cultural aspects of cyberspace. These “cyberspace studies” have morphed over time, particularly as scholars have brought ideas and theories from other disciplines – psychology, sociology, cultural studies, or geography, for instance – into contact with the Internet and related technologies.

In terms of the subject area we might call “cyberculture studies,” David Silver (2000) has tracked the development of cyberculture as a field of study across the 1990s, identifying three distinct phases. His typology offers a useful way of introducing the trajectory of these diverse studies in this important decade,

during which the foundations of cyberculture studies were solidified. Silver names the first substantive phase “popular cyberculture,” characterized by journalistic writing, personal accounts of being online, popular history publications about the development of the Internet, and large numbers of “how to” books helping people make use of computers and networks. Accounts from this phase tend to be descriptive, often experiential, but are split in terms of how their authors view the impacts that the Internet is having on people’s lives. At the most extreme ends of this divide are what Silver calls techno-futurist writings, which tend to be overwhelmingly optimistic, even utopian, about the promises of online life. Journalists writing in new US magazines like *Wired* or *Mondo 2000* typify technofuturism for Silver, as do writers describing cyberspace as a new frontier ripe for pioneers to colonize (see, e.g., Rheingold 1993). Writing from a polar opposite, profoundly dystopian, perspective are the “Neo Luddites,” who see in cyberspace multiple threats to human existence (see, e.g., Sale 1995). Of course, most writing during this phase falls somewhere in between these “dystopian rants or utopian raves” (Silver 2000: 20). Nevertheless, this fundamental binary divide – is cyberspace good or bad? – continues to structure many scholars’ thinking; indeed, later periods in the development of cyberculture studies revisit this in their own terms, and rants and raves continue to appear from both sides. However, as the field of study has evolved, it has refined both the theoretical and methodological tools brought to analyze the Internet, as well as focusing in on more specific domains and effects of cyberspace.

The second phase of cyberculture scholarship is called by Silver simply “cyberculture studies,” in recognition of a shift away from populist accounts (though these continue to be published) toward a more scholarly approach to understanding the Internet. Crucially, two major focuses were brought center stage in this phase, both of which are concerned with the relationship between online and offline life: studies of community and studies of identity. Here we see one way in which cyber and culture are brought together: by exploring how some of the key concerns of cultural studies (such as identity or community) are transformed in cyberspace. Silver rightly identifies

the *ur texts* here as Rheingold’s *The Virtual Community* (1993) and Turkle’s *Life on the Screen* (1995) – these are the “twin pillars” of second phase cyberculture studies (Silver 2000: 23), hugely influential books whose impact can be felt to this day. Turkle’s book is an important illustration of the second way that cyber and culture are brought together in this phase: the use of cultural theory to think about cyberspace. In her exploration of online identity, Turkle draws heavily on psychoanalytic, poststructuralist, and postmodern theories of self identity, which help her to understand how online identities are fractured and multiple. Other scholars also began to bring their own favorite theories and theorists into cyberspace, leading to a productive period in which cyberculture studies diversified: sociologists brought social network approaches to understanding online communities, for example, while geographers brought theories of space and place into contact with cyberspace and feminist scholars introduced ideas of cyberfeminism (see, e.g., Plant 1997; Crang et al. 1999; Smith & Kollock 1999). At the same time, there was also a diversification in terms of research methods used to study cyberculture, as researchers brought their own methodological traditions and innovations into cyberspace: qualitative and quantitative methods, linguistic and textual techniques, and so on.

Silver notes that studies produced in this phase tend to be more positive and optimistic about cyberspace, seeing productive new possibilities for identity and community online. However, many accounts rest on a problematic separation of online and offline (sometimes called “real life” or “real world”) experiences – another dualism which continues to haunt many studies of cyberculture to this day. Nevertheless, this second phase marks a consolidation of academic cyberculture studies marked by diverse theories and methods, intersections with diverse disciplines, and a gathering momentum in terms of both volume and growing sophistication of published material. We could say that this phase marks the beginning of something of a discipline of cyberculture studies itself, in fact, as degree courses, conferences, and networks blossomed in academia.

In the latter part of the 1990s, a third phase is identified by Silver. This he labels “critical

cyberculture studies.” Marked by continuing growth and diversification, Silver tracks four themes which rose to dominance in this period (for an overview of the breadth of this phase, see Bell & Kennedy 2000). The first is in part a counter to the problematic online/offline split of phase two, and is concerned with contextualizing cyberspace and cyberculture, in terms of how economic, social, and cultural interactions occur simultaneously in cyberspace and in “real life.” Empirical work bridging online and offline field sites – such as Miller and Slater’s (2000) ethnographic study of Internet use in Trinidad – has been particularly important in bringing back together the two worlds split apart in earlier studies. Detailed empirical work has also performed a valuable hype busting function, replacing the rants and raves of earlier phases with more balanced, empirically grounded studies.

The second theme of critical cyberculture studies picked out by Silver focuses on discursive constructions of cyberspace – the stories we tell about it. This means unpacking the ways that cyberspace is imagined and represented across a wide range of cultural texts, from cyberpunk novels and movies to Internet service providers’ adverts or pop songs (see Bell 2001). It also involves exploring the dominant discourses via which the Internet is talked about, whether the frontier mythology mentioned earlier or the “gold rush” discourse that provoked and sustained the dot.com explosion. Thirdly, Silver notes an increasing emphasis on questions of access and inequality – another valuable dose of hype busting, since it replaces the discourse of information freedom and the Internet’s democratic “worldwideness” with studies highlighting patterns of uneven development, issues of marginalization, and barriers to access to technology at all levels, from the global to the individual. Access questions bring into focus the extent to which axes of social identity such as race, class, gender, and sexuality are either reproduced or challenged in cyberspace, with studies concluding both that cyberspace reinforces existing divides as well as bringing in new ones, and that it can provide space for new and productive kinds of identity work to take place (see, e.g., Nakamura 2002).

Finally, Silver notes an increase in studies exploring design and visual culture aspects of

cyberspace, particularly around the idea of the interface: how cyberspace is represented to us on the screens of our computers – a neat return to Gibson’s originary formulation. Work on interfaces has also returned to themes introduced in earlier phases, such as the role of web pages in expressing self identity, and the role of participatory design in facilitating online communities. Crucially for Silver, critical cyberculture studies finally acknowledges the messy commingling of online and offline life and experience: “cyberculture is best comprehended as a series of negotiations that take place both online and off. . . . In the new millennium, it is the task of cyberculture scholars to acknowledge, reveal and critique these negotiations to better understand what takes place within the wires” (Silver 2000: 30).

Having described Silver’s useful brief history of cyberculture studies, attention can now be turned to an essay which attempts to define a program for cultural studies of the Internet, Jonathan Sterne’s “Thinking the Internet: Cultural Studies versus the Millennium” (1999). This is an important article in that it attempts to lay out a specifically cultural studies approach to cyberspace, therefore productively exemplifying Silver’s critical cyberculture phase. It provides a road map of what cultural studies as a discipline uniquely brings to analysis of cyberspace, urging scholars to “move beyond the commonplaces and clichés of Internet scholarship and [to] reconceptualize it in intellectually challenging and politically vital terms” (Sterne 1999: 260). It is, perhaps, in the last part of that statement – about being politically vital – that Sterne’s essay is most insightful; he reminds scholars of the deep political commitment at the heart of the cultural studies project, arguing that if it is (or should be) about anything, then cultural studies is about culture and power. Any critical study of the Internet should therefore have at its heart an analysis of culture and power since, as Poster (2001: 2) suggests, “without a concept of culture, the study of new media incorporates by default the culture of the dominant institutions in society” – the state and the market.

To advance his argument, Sterne places emphasis on the need to understand and critically analyze the politics of knowledge production (asking what is at stake in studying the

Internet, and how new knowledge of cyber space can advance emancipatory politics), the need to be acutely aware of context (the manifold relationships between people, place, practices, and things), and the need to produce a theory of articulation (how things are connected together). Such a theory would have as its central concerns “(a) *what counts* in a cultural study of the Internet and (b) *how to think about* and represent the Internet” (Sterne 1999: 263, emphasis in original). Finally, and echoing points made earlier, Sterne reinforces the necessity of a commitment to theory as a way of finding new and more effective ways to describe and analyze cyberspace and cyberculture.

Making a point resonant with Silver’s discussion of critical cyberculture studies, Sterne calls for a move beyond the simplistic online/offline (or virtual/real) split which has for so long impaired analyses of cyberspace, toward a conceptualization that emphasizes understanding the place of the Internet in everyday life. Equally importantly, Sterne argues for the need to reconnect the Internet to other media, and to techniques of analyzing other media. This is particularly crucial in the current period, given the increasing convergence of new (and old) media. As new digital devices such as MP3 players and palm pilots become more and more ubiquitous, and as existing media are repurposed for the digital age (mobile phones, for example), so the idea of separating out the Internet as an object of study becomes redundant. At the same time, the uses to which we may now put our computers – from listening to the radio to editing home movies to shopping – calls for a broader rethinking of what it is we are studying when we are studying cyberculture.

This last point is worth exploring in a bit more detail. Some researchers have suggested that we need to track the myriad sites where we encounter digital culture beyond the narrow emphasis on the computer screen: cyberspace exists in all kinds of places, from CGI heavy movies to imaging technologies used in biomedicine (see Bell 2001). Moreover, the kinds of contact that we have with these new technologies is equally varied: we may be transformed into data and lodged in databases thanks to the manifold technologies of data collection that monitor our habits and routines (from our shopping practices to our workplace productivity);

equally, we may have particularly intimate relationships with devices that become part of our everyday lives, even part of our bodies – leading some scholars to theorize the body–technology interface by using ideas of the cyborg or the post human (see Gray 1995; Badmington 2000).

Cyberculture must be about critically analyzing all of these sites, and the discourses and representations that surround them. In part that means attending to the mundane interactions we have with technologies such as word processors or console games; but it also requires an awareness of the cutting edge of new and future technologies, such as nanotechnology, artificial life, and artificial intelligence. To fully encompass all that cyberculture means is no easy task, therefore. While some scholars have called for junking the term cyberculture studies in favor of newer, more inclusive terms like web studies or new media studies (or even new media cultures; see Marshall 2004), others continue to see valuable mileage in working with and through cyberculture as a “contested and evolving discourse [whose] discussants include activists, politicians, computer geeks, social scientists, science fiction writers, digital artists, etc., all of whom are involved in the creation of new concepts and ideas” (Bell et al. 2004: xiii). To that end, the concept is still very much alive, indeed teeming with life, and we need the open, even promiscuous, approach to theory and method, as well as the political commitment, of critical cyberculture studies to continue to engage creatively and critically with the past, present, and future of cyberculture.

cybersexualities and virtual sexuality

Ken Plummer

Just as when photography and film were first introduced they generated the pornographic photograph and film, so as soon as the newer information technologies appeared, an erotic

world of cybersex and intimacy appeared along side and embedded within it. New information technologies are used in ways that can facilitate new patterns of sexualities and intimacies. And this is no small world. Surfing the Internet gives access to a medium full of intimate words and images: from guidance pages on infertility (over a million sites on sperm banks), to sites engaged in bride mail ordering; from images of the most “extreme” sexual fetishes (“Extreme” is indeed the name given to one such site), to access to potentially endless partners on email. The sheer range, number, and intense flow of unregulated intimacy and erotica of all kinds that becomes available at the press of a button could never have happened before in history.

These new technologies have generated multiple new forms of intimacy: sex messaging, sex chat rooms, sex news groups and bulletin boards, email discussion groups, camcorder sex, new forms of porn, access to relationships of all kinds, new social movement campaigns around sexuality, even so called cyborg sex, teledildonics, virtual sex, and new approaches to the body and emergent “techno identities” and “techno cultures.” Along with this a new language has emerged that mirrors new forms of sexualities: cyberporn, cyberqueer, cyber stalking, cyberrape, cybervictim, cybersex. Although such new forms can result in people meeting in real space for “real sex,” there is also a great deal of masturbatory sex being generated through these media, as well as virtual sex taking place in these virtual spaces.

What this means is that in recent years many new sexual practices have unfolded along with an array of new issues. Sociologists are starting to provide critical ethnographic materials on their day to day workings, and are developing innovative theorizations of the whole field, clarifying and criticizing links to postmodern social theory and connecting these globally. Thus, Dennis Waskul in *Self Games and Body Play: Personhood in Online Chat and Cybersex* (2003) applies the theoretical work of Erving Goffman on self management and the presentation of self in sexual communications online. Aaron Ben Ze'ev has examined *Love Online* (2004), providing detailed accounts of how people meet online. Others have documented some of the pitfalls of cybersex – how it can generate infidelity, the growth and routinization of

pornography, the development of sexual harassment online, and the growth of "sexual addiction" on the Internet (e.g., Maheu and Subotnik's *Infidelity on the Internet*, 2001, and Patrick Carnes's *In the Shadow of the Net*, 2001). On a wider level, sociologists have suggested that moral panics and hysteria gather around such sexualities. Most prominently, there is the concern with pedophilia on the net, and the ways in which young people can be misled, "groomed," and ultimately seduced and abused (see Philip Jenkin's *Beyond Tolerance: Child Porn Online*, 2001).

Cybersexualities, then, are becoming increasingly an important means of sexual communication in the twenty first century. And they have both positive and negative impacts. They reveal changing spaces and boundaries for new forms of sexualities and suggest key shifts in public/private dimensions. Through both webcams and the global nature of communications the old boundaries in sexual relations break down. The body starts to change its contours – no longer simply fixed and corporeal, but fluid, boundary less and "virtual" (as with ideas of changing gender identity online raised by transgender activist Sandy Stone, 1995). Some have suggested that much of this leads to "posthumanism," a marker for the end of the human being as such and the discovery of tools for articulating the embodied human with intelligent machines (Hayles 1999; Hables Gray 2002). A new form of being – the cyborg – may be in the making. Yet we must be careful. Even though there are already new worlds of cybersex, the posthuman, and the cyborg, and even though these will probably grow and develop, talk of cyberworlds still makes little sense to large populations that do not yet even have access to basic water, medication, shelter, phone lines, or computers, let alone the Internet.

Cybersex opens up political and moral questions that are emerging around the control and regulation of such sites. Hamelink (2000)

suggests a wide array of ethical issues in web issues. For instance, how decent it is to post a picture of your ex partner on the web? How far is it infidelity to find partners on the web while concealing this from one's "real" partner? Should children's access to cyberspace be guarded? What dangers threaten your children when they surf the Internet? What should we do if we want free speech in cyberspace but also want to rid the Internet of child pornography and racism? Do we need a new morality for virtual reality?

Cybersex is a new phenomenon raising many new questions. At the start of the twenty first century, there are signs that sociologists are taking significant interest in it.

D

daily life pollution

Koichi Hasegawa

Daily life pollution refers to the type of environmental contamination caused by the everyday life activities of ordinary citizens and consumers. In contrast with main pollution caused by industrial production processes, daily life pollution includes detergent pollution in rivers, lakes, or the ocean caused by washing clothes and landfill and incineration pollution caused by excess household garbage. Although the individual impact each citizen has on the environment is negligible, cumulatively their behavior can create severe environmental and social problems.

The cumulative effect of about 70 million households (in the US) or about 40 million households (in Japan) resembles the old proverb, "Many drops make a flood." "The ecological footprint" data of each country show the respective ecological impact per capita. In many countries the ecological impact exceeds the available biologically productive area of the country (Chambers et al. 2001), clearly showing this agglomeration effect for one environment. Theoretically, the "tragedy of the commons" by Hardin (1968) and subsequent studies of the "social dilemma" neatly model this mechanism. The social dilemma is defined as a dilemma or conflict between collectively and individually rational action, where the action required for achieving the collectively best outcome or goal is in conflict with the action required for achieving the individually best outcome (Yamagishi 1995).

For instance, a well organized garbage collection system that separates various kinds of garbage can reduce the whole amount of daily garbage and the whole amount of the related

municipal expenditure (collective best outcome). However, citizens may feel that separating their garbage takes too much attention and too many minutes. To save time, some of them may violate the rules by merging organic waste and non organic waste (individual "best outcome"). Every citizen has a similar temptation. As a result, the separated garbage collection system may not work as planned. The malfunctioning of the separated collection system discourages other citizens from obeying the regulations, finally causing the collection system to disappear. Garbage may flood the streets and parks and citizens must pay more tax to collect it (collective worst outcome). Thus, the ordinary citizen can easily be both the perpetrator and the victim of this vicious cycle of pollution.

Spiked tire pollution is another good example. Spiked tires have metal studs embedded to prevent cars from slipping on icy roads. They are highly effective, and unlike chains do not require any effort to put on or take off. In the 1970s they rapidly came into wide use, especially in snowy northern Japan. But when used on dry roads, they tear up the road surface and create dust. Thus in the late 1970s and early 1980s, spiked tires brought serious air pollution in major cities such as Sendai and Sapporo. In Sendai, a broad movement to encourage voluntary restraint in the use of spiked tires developed, including cooperation between public authorities, the mass media, residents' groups, and the local lawyers' association. In 1985, Miyagi prefecture including Sendai as its prefectural capital first enacted restrictive ordinances at the prefectural level. Similar ordinances were subsequently enacted by Sapporo and other prefectures. This led to nationwide legislation in 1990 that prohibited the use of spiked tires altogether. In other cases, public administration officials have taken the lead,

working with residents' groups to sometimes promote or sometimes discourage the use of certain products, such as the movement that started in 1975 around Lake Biwa to abstain from using phosphorous synthetic detergents and instead use soap powder.

In these cases, the possibility of resolving the issue through the use of alternative technologies or alternative products was high, and the concerned industries were not antagonistic to these movements. From a relatively early stage the industries endeavored to develop and market alternative products (e.g., studless tires, four wheel drive vehicles, and non phosphorous synthetic detergents). In situations where the perpetrators are also the victims and the movement is not facing a powerful adversary, it is relatively easy to reach a social consensus (although not necessarily an adequate solution – for example, the introduction of non phosphorous detergents did not entirely resolve the problem of detergent pollution, merely the issue of phosphorous pollution). This relatively uncontested consensus making process makes it easier for politicians and public officials to take the initiative.

In many cases of daily life pollution, the effects appear directly and visibly for ordinary citizens in a relatively limited geographical range. But daily life pollution, such as in driving automobiles, also contributes to much more widespread problems as global warming. In its basic logic, the issue of global warming closely resembles the “tragedy of the commons” or social dilemma process of local daily life pollution. But in the global warming case, the effect goes to the global level and pushes the most severe effects of the degradation on to future generations. In addition, the consensus building process has to occur among sovereign states, not local groups, making it more difficult.

Although ordinary citizens and general consumers are responsible for daily life pollution, this does not discharge producers, industries, and administrators of their responsibilities. Especially in mass consumption society, big industries strongly influence the market and consumers through advertising, stimulating customers' needs or desires as a “dependent effect” (Galbraith 1958). In the purchasing decisions of ordinary citizens, the image or package stimulated by advertising can become

more important than the utility value of the goods.

The case of spiked tires shows that appropriate regulation can work effectively to solve the problems of daily life pollution. It may be the only way to overcome the “social dilemma.” That means the government is responsible for solving this kind of problem. The government should prohibit the use of harmful commodities by legislative policy or administrative regulation. European countries first prohibited the use of spiked tires in the late 1970s because they tore up and damaged roads. Tire producers, car industries, legislators, and government administrators in other regions could have prevented spiked tire pollution in their own countries by paying attention to these foreign examples. On this point they were responsible.

Daily life pollution varies by domestic class structure, ethnic and racial differences, and global differences in wealth and poverty. These factors create serious gaps in consumption levels producing daily life pollution as well as in exposure to the resulting hazards. For instance, environmental racism can lead to the placement of waste disposal facilities near minority communities (Bullard 1994). At all levels, from community to the globe, richer people and countries consume more and produce more ecological damage than poorer or minority people. When we think of solutions to daily life pollution that involve reducing consumption, we have to remember that the poor of the world often do not yet have enough to meet basic needs. Given these disparities, wealthy people and nations have to take the initiative to adopt more eco friendly consumption patterns that reduce daily life pollution while meeting needs. These new consumption models will then diffuse to the poorer populations.

dangerousness

Christian Debuyt

The term dangerousness is a neologism, invented in the context of the Italian positivist school of criminology and especially attributed to Garofalo, who, in the framework of his bio-psychological approach to the criminal, considered taking into account the essential element of *temibilità*, or the constant and active perversity of the criminal and the extent to which one is afraid of him based on this characteristic (Garofalo 1905; see also Kinberg 1959: 44-5). Garafalo replaced this older term with the concept of *periculosità*, which means dangerousness, and reformulated its definition: the capacity of an individual to adapt, or to resist adapting, to social demands. In this definition the American criminologist F. A. Allen (1960) perceived the fundamental objective of Garafalo: the elimination from society of those who, because of a moral abnormality, are not capable of making social adjustments.

Another meaning of the concept of dangerousness is found in the definitions of the terms dangerous populations and dangerous mental state. The former term appeared first in European and Latin American discourses of the eighteenth century and concerned subjects whose style of living was considered dangerous: vagabonds, beggars, etc. The term dangerous classes appeared in discourses of the nineteenth century and referred to the poor and the working classes. Also falling into the category of those from whom society must be protected were persons with mental deficiencies, who

(especially around the year 1920) were considered to be incapable of resisting their genetically inscribed impulses. Sexual deviants have historically been viewed in a similar way and portrayed as sick people to be imprisoned and sometimes as psychopaths, from whom it is also important to protect society. A similar concept of dangerousness is used nowadays in the US in connection with recidivists and the so called "three strikes and you're out" laws, under which criminals who have been convicted of three felonies are sentenced to life terms in prison.

The Italian positivist school found its starting point in Darwin's theory of evolution. According to the positivists, some individuals by nature cannot adapt to the complex demands of society. In this context, and in opposition to the views of the classical school of criminology, crime is not defined in legal terms, but as an expression of personality which results in a direct threat to society. Whereas the classical school defended the notion of free decision making, the positivist school emphasized the biological, psychological, and social determinism of human actions. From the perspective of the classical school, it follows that punishment would be effective as a deterrent to criminal acts, whereas from the positivists' point of view punishment should be replaced by scientific treatment as a better way of protecting society.

One reason for the development of the positivist perspective, especially in Western Europe, was rising crime rates which could not be efficiently handled by penal policy based on the classical model. In the same manner, other scientific approaches to dealing with crime were developed when the International Union of Penal Law was founded in 1889 and integrated into its program the idea of "social defense." For the US, the situation seems to have been different; under pressure from the media and from what Becker (1997) called "moral entrepreneurs," certain categories of persons (recidivists, psychopaths, sexual delinquents) and specific scandalized events gave rise to a single and concentrated change in legislation.

The first problem concerning the application of the concept of dangerousness is that of diagnostics and prognosis. Such critiques have

always accompanied the ideas of the Italian positivists. However, there have been some efforts to systematize the concept. In 1935, for instance, Kinberg introduced the differentiated view of dangerousness as “habitual” and caused by “temporal circumstances” (see also Megargee 1969). Clinical diagnostics done by psychiatrists seem mostly to overestimate the dangerousness of individuals, and the use of prediction tables as a basis of decision (at least between 1925 and 1960) always produced a great volume of falsely positive and falsely negative results. As a consequence of this, decisions about dangerousness are mostly based on the type and nature of offenses committed in the past.

Another critique is aimed at the theoretical basis of dangerousness, especially the concept of “criminal personality.” Social psychological theory and empirical research emphasize that behavior is always a product of situational conditions and more stable factors of personality. Other critiques apply a more sociopolitical perspective by emphasizing that giving too much significance to personality leaves aside more important aspects of social problems which the actors are confronted with. The same can be said of the types of offenses commonly taken into consideration when talking about dangerousness; these notions always leave aside other offenses that can arguably cause more harm to society, like white collar crime, political crime, or delinquency connected to drug trafficking. These critiques underscore the fact that the concept of dangerousness is marked by differences in ideology (Debuyst & Tulkens 1981).

Many psychologists and sociologists have criticized the notion of determinism, but in two different directions. On the one hand, it is argued that the notion of determinism denies the idea of personal responsibility, which is the basis of both penal law and the classical school of criminology. On the other hand, there are some critiques that enlarge the concept of responsibility to include the idea of society and social reactions, emphasizing that violent offenses and individuals in society who are called dangerous reflect conditions of social exclusion in which acts of violence can seem to be a rational reaction (Crawford 2002).

Davis, Kingsley (1908–97)

Donald J. Hernandez

Kingsley Davis, one of the most influential and eminent sociologists of the twentieth century, made major contributions to sociology, anthropology, and demography. A pioneer of sociological theory as it emerged during the 1930s and 1940s, he published prominent papers on the social and normative foundations of legitimate and illicit sexual behavior, marriage and divorce in contemporary societies, intermarriage in caste societies, and the place of children in the family and the broader social structure. Concerned with issues central to the structure and functioning of society, and therefore ideologically, morally, and emotionally charged, Davis's analyses were illuminating, but often perforce subject to extensive debate and

controversy, sometimes the focus of challenge from conservatives and other times confounding liberals.

A grandnephew of Confederate President Jefferson Davis, and born in Tuxedo, Texas on August 20, 1908, Kingsley Davis earned a BA in English in 1930 from the University of Texas, where he edited the campus literary magazine, and where he continued with graduate study in philosophy, economics, and sociology, earning an MA in philosophy in 1932. He then enrolled at Harvard University, studying with Talcott Parsons, Pitrim Sorokin, W. Lloyd Warner, and Carle Zimmerman, and he taught at Smith College from 1934 to 1936. Davis also was central in the prominent discussion group led by Talcott Parsons, who was then writing *The Structure of Social Action* (published in 1937). After receiving his PhD in 1936 with a dissertation titled “A Structural Analysis of Kinship,” Davis taught at Clark University (1936–7) and then Pennsylvania State University (1937–44), while also pursuing studies in statistics, mathematics, and demography as a Social Science Research Council post doctoral fellow at the University of Chicago with Samuel Stouffer and at the US Census Bureau.

Beyond his contributions to family sociology during the 1940s, Davis published (with Wilbert Moore in 1945) the most systematic and fully developed functional theory of social stratification, explaining the inequality found across social positions in all societies as the necessary consequence of their diverse positive contributions to the survival of the larger social system. Fierce debate followed as some critics took the theory to be an attack on the value position that equality is a virtue. They chafed against the idea that social inequality is necessary for a society to survive, and argued that the theory ignored the potentially dysfunctional effects of too much inequality, overstated the amount of social mobility occurring in actual societies, and did not address the issue of social conflict. Thus, opponents highlighted limits of the theory, effectively widening its scope, but the original underlying paradigm for analyzing relationships that link social positions, their incumbents, and social institutions has remained central to sociology. Important subsequent contributions advancing theoretical

sociology were his lucid synthesis in *Human Society* (1949) of fundamental sociological concepts and principles using ethnographic data, and his controversial presidential address to the American Sociological Association (1959) arguing that sociological analysis cannot be distinguished from functional analysis.

Davis’s seminal theoretical and empirical contributions to social demography began in the 1930s, with a provocative article on “Reproductive Institutions and the Pressure for Population.” Moving to Princeton University (1942–8), where he founded the department of sociology and anthropology, he wrote an extremely influential article, “The World Demographic Transition,” in 1945, as well as his first empirical research on cities, *Urbanization in Latin America* (with Ana Casis in 1946). Davis’s prominence as a demographer grew at Columbia University (1949–55) with the publication of *The Population of India and Pakistan* (1951), which stands as the classic work on the topic for 1880–1940, but also an exemplar of social demography for how to analyze and interpret the fertility, mortality, migration, family, education, and religion of a nation, and with his penetrating critique (1955) of Malthus’s work as a scientific theory of fertility.

At the University of California at Berkeley (1955–77), Davis continued to lead the theoretical development of social demography, first by conceiving (with Judith Blake, his wife) the analytic framework for studying intermediate variables through which social structure can affect fertility (1956). His subsequent presidential address to the Population Association of America in 1963, “The Theory of Response and Change in Modern Demographic History,” offered an integrated understanding of the central role that individual motivations for social and economic success played in the multiphasic response of populations in all developed countries, not only in reducing fertility in response to declining mortality, but also by changing marital behaviors, and fostering migration out of agriculture and beyond national borders.

With characteristic incisiveness, Davis ignited a long running controversy with the publication of a logical, theoretical, and empirical critique in *Science* (1967) of family planning programs as a policy for reducing rapid population growth in third world countries. The

article argued that a policy of simply making contraception available to women will not be successful because fertility will decline substantially only if there are fundamental changes in features of social organization that determine the motivation to bear children. The article was lauded by conservatives and berated by liberals, despite the explicitly stated corollary, and essentially feminist argument, that achieving the goal of sharply reduced fertility would better be achieved by policies making educational, occupational, and income opportunities for women equal to those of men. Davis continued to contribute to understanding changes in the family, economy, and women's roles at the University of Southern California (1977–92), most notably in “Wives and Work: The Sex Role Revolution and its Consequences” (1984).

Davis's early interest in cities and urbanization also was abiding. Prominent among his contributions were “The Origin and Growth of Urbanization in the World” (1955), “Colonial Expansion and Urban Diffusion in the Americas” (1960), “World Urbanization 1950–1970” (V. 1, 1969; V. 2, 1972), *Cities: Their Origin, Growth, and Human Impact* (1973), and “Asia's Cities: Problems and Options” (1975). In the final years of his career at the Hoover Institution (from 1981 until his death on February 27, 1997), Davis organized conferences and edited books addressing causes, consequences, and policies for below replacement fertility in industrial societies (1987) and the connections linking resources, environment, and population change (1991).

Davis's creativity and the breadth of his influence in academia, in the Washington policy community, and the discourse of the general public are reflected in the terms *demographic transition*, *population explosion*, and *zero population growth* which he coined, and in the honor bestowed upon him as the first sociologist to be elected to the US National Academy of Sciences. As one of the giants among twentieth century social scientists, Kingsley Davis's legacy to scholarly and public discourse will endure for generations to come.

death and dying

Deborah Carr

Sociology of death and dying is the study of the ways that values, beliefs, behavior, and institutional arrangements concerning death are structured by social environments and contexts. Although death is a universal human experience, societal responses to death vary according to cultural attitudes toward death, as well as contextual factors including the primary causes of death, and normative age at which death occurs.

Conceptualizations of and practices surrounding death in the United States have come full circle over the past two centuries. In the eighteenth century, death was public and visible. Death tended to occur at a relatively young age, at home, and due to infectious diseases that could not be “cured.” The loss of a loved one was expressed by dramatic displays of grief among survivors, and elaborate efforts to memorialize the deceased (Ariès 1981). Throughout the late nineteenth and most of the twentieth

centuries, death became “invisible” (Ariès 1981) and “bureaucratized” (Blauner 1966). Physicians and hospitals assumed control over dying, death and mourning became private, the handling of dead bodies and funeral rites were transferred from private homes to funeral parlors, and people were encouraged to deny death and believe in medical technologies (Blauner 1966). Treating dying persons in isolation was believed to help smooth the transition beyond death; reducing the social status of those who were about to die would minimize disruption of ongoing social and economic relationships.

The epidemiology of death also changed dramatically (Omran 1971). In the nineteenth and early twentieth centuries deaths occurred primarily due to infectious diseases, which were not stratified by social class or gender. Men and women, rich and poor, were equally likely to become ill and die, and death often occurred relatively quickly after the initial onset of symptoms. Death during the latter half of the twentieth and early twenty first centuries, in contrast, occurs overwhelmingly due to chronic diseases, including cancer and heart disease. These diseases tend to strike older rather than younger adults, men more so than women, and persons with fewer rather than richer economic resources. Death typically occurs at the end of a long, often debilitating, and painful illness where the dying patients’ final days are spent in a hospital or nursing home, and where life sustaining technologies are used.

In the late twentieth and early twenty first centuries, death is again becoming visible and managed by the dying and their families. Patients’ and care providers’ recognition that dying is often a socially isolated, physician controlled experience has triggered a number of political and social movements with the explicit goal of placing control of the dying process in the hands of patients and their families. The Patient Self Determination Act, passed by Congress in 1990, requires all government funded health providers to give patients the opportunity to complete an advance directive (or living will) when they are admitted to a hospital. The hospice movement, which began in the United States in the early 1970s to promote palliative care at the end of life, also has grown in popularity. Hospice care, whether in hospital or at home, provides an alternative

to the medical, scientific model of dying. Pain management, open communication among family, patient, and care providers, and a peaceful accepted death are core goals.

As the context of death and dying has changed, research foci also have shifted. In the 1950s and early 1960s, research and theory were guided by the assumption that the United States was a death denying society (Gorer 1955). Influential works included an examination of the problems associated with transferring death and funeral rites from private homes to professional funeral homes, and explorations of the ways that health care providers, dying patients, and their family members mutually ignore and shield one another from their knowledge that the patient is dying (Glaser & Straus 1965).

In the late 1960s and 1970s, the “death awareness” movement guided research and theory. Key scholarly works of this era offered important advancements in conceptualizing the dying process. Barney Glaser and Anselm Straus (1968) proposed that dying tends to follow one of three trajectories: lingering, expected quick, and unexpected quick. The latter was considered most distressing for both health care providers and surviving family members. Elizabeth Kubler Ross (1969) delineated the emotional and cognitive stages that dying persons pass through, before reaching the final stage of “acceptance.” The interdisciplinary field of death studies and the two leading scholarly journals of death and dying also were launched in the 1970s: *Omega: The Journal of Death and Dying* debuted in 1970, while *Death Studies* has been published since 1977.

In the late twentieth and early twenty first centuries, research on death and dying has flourished (for an excellent and comprehensive compendium, see Bryant 2003). Scholarly and public concern about death reflects two broad social patterns. First, increasingly large numbers of older adults are living longer than ever before, with most suffering from at least one chronic and terminal disease at the end of life. Second, technological innovations to extend life, including life support systems, organ transplants, and advances in cancer treatment, extend the life span, but also raise important questions about the meaning of life and death.

Despite dramatic growth in death related research, the claim by William Faunce and Robert Fulton (1958) that the sociology of death is "a neglected area" remains at least partially true. The development of broad and unifying theoretical perspectives on the sociology of death and dying has not occurred alongside the explosion of empirical work (Marshall 1980; George 2002). Rather, subdisciplines of sociology have each claimed distinct – and seldom overlapping – topics of study pertaining to death and dying.

For example, demographers study the timing and social patterning of mortality. Social gerontologists investigate a broad array of issues pertaining to death, dying, and end of life, but their analyses focus nearly exclusively on persons age 65 and older. Sociologists of culture examine the ways that death is depicted in humor, art, literature, and other forms of media, cross cultural differences in death rites and rituals, and public discourses about controversial issues related to death and dying, including euthanasia and the death penalty. Medical sociologists investigate interactions between patients, family members, and their physicians at the end of life, as well as ethical, social, and financial issues pertaining to life extending technologies and practices. Sociologists of law focus on legal definitions of death, and the implications and problems created by such definitions for heroic medical efforts, transplantation, inheritance, and insurance. Sociologists of religion focus on rites and rituals at the end of life, the impact of religion and spirituality on beliefs about life and death, and changes in religious attitudes and practices as individuals manage their own dying process and the deaths of family members. Sociologists of deviance investigate deaths that violate traditional norms, such as murder and suicide, as well as reactions to death that are considered deviant, such as anniversary suicides.

Despite the absence of an overarching theoretical framework, one broad theme that underlies much current research is the importance of personal control and agency, among both dying persons and their survivors. Two specific lines of inquiry which have developed over the past ten years are personal control over practical aspects of the dying process, and active

"meaning making" among the dying and bereaved.

Mounting research explores how dying persons and their families make decisions about the type, site, and duration of care they want to receive at the end of life. Sociologists' key contributions have included identifying the cognitive, emotional, and structural factors that may enable or prevent individuals from receiving the type of care they hope to receive. Recent research reveals that patients and their family members seldom have sufficient information about their illness trajectory and future life span so that they can make informed decisions. Nicholas Christakis (1999) argues persuasively that physicians are extremely poor at prognosis, or projecting how much longer a dying patient has to live, and they often convey an unrealistically optimistic picture of their patient's future.

A second area of inquiry that has attracted renewed scholarly attention is meaning making among both the dying and their loved ones following loss. This concept was first set forth in *Death and Identity*, where Fulton (1965) argued that "preserving rather than losing . . . personal identity" was a critical aspect of the dying process. Victor Marshall (1980) proposed that heightened awareness of one's impending death triggers increased self reflection, reminiscence, and the conscious construction of a coherent personal history. More recently, Edwin Schneidman (1995) proposed that dying persons actively construct a "post self" or a lasting image of the self that will persist after their death.

The ways that bereaved survivors actively find meaning in death was articulated early on by Herman Feifel (1977: 9), who observed that the mourning period following loss provides a time for the bereaved to "redefine and integrate oneself into life." Current research explores the ways that active meaning making among the newly bereaved helps to reestablish predictability and one's sense of security. Other goals for the bereaved include personal growth, an adaptive broadening of philosophical perspectives, and an increased appreciation of other interpersonal relations.

Scholars of death and dying face several important methodological challenges. First, bereavement research focuses nearly exclusively

on the loss of a spouse, children, and parents; few studies investigate personal responses to the deaths of friends, siblings, or unmarried romantic partners, including gay and lesbian partners. A further limitation is that studies vary widely in their operationalization of "dying." Common measures include one's current illness diagnosis, combinations of diagnoses, symptom expression, and functional capacity (see George 2002 for a review). Although rich conceptual models of dying trajectories have been developed, formal operationalizations need further refinement. Finally, although most conceptual models of the dying process and bereavement are dynamic, such as the stage theory of dying (Kubler Ross 1969), most empirical studies still rely on single point in time evaluations that retrospectively recall the dying and bereavement process.

In the future, the research agenda may focus increasingly on positive aspects of dying, including psychological resilience in the face of loss, and the characteristics of and pathways to a "good death." Important research goals include pinpointing modifiable factors of social contexts and relationships that may help ensure a smooth transition to death and bereavement. Early theories of loss proposed that persons who were not depressed following the loss of a loved one were "pathological." Researchers now are documenting that the non depressed bereaved may experience "resilience" rather than pathological "absent grief" (Bonanno 2004).

Research on the "good death" also is accumulating. A good death is characterized as one where medical treatments minimize avoidable pain and match patients' and family members' preferences. A "good death" also encompasses important social, psychological, and philosophical elements, such as accepting one's impending death and not feeling like a burden to loved ones. However, as norms for the "good death" are solidified, a fruitful line of inquiry may be the consequences for bereaved family members and health care providers when a death occurs under conditions that fail to meet the widely accepted ideal. Failure to achieve the "good death" may reflect enduring social and structural obstacles. For example, family member (or caregiver) involvement is essential to a patient's participation in hospice; few studies have explored the extent to which unmarried or

childless people rely on hospice. Such inquiries may further reveal the ways that the experience of death reflects persistent social inequalities.

death penalty as a social problem

Evi Girling

The death penalty (also known as capital punishment) is the sentencing of offenders to death after conviction following due process of law. The practice of the death penalty has undergone two key transformations in modern times. The first one is an unremitting restriction on the kinds of crimes and categories of offender on whom the death penalty could be applied, leading to its eventual abolition in the majority of jurisdictions. The second shift is its transformation from brutal public displays of excess (famously depicted by Foucault in *Discipline and Punish*, 1977) to private, detached, and medicalized executions where pain and the body is elided, where execution is rendered a non event. Within the sociology of punishment these shifts have been mostly explained either by the cultural dynamic of the privatization of disturbing events or by the transformation in technologies of power from punishment as a public and violent spectacle inflicting pain on the body to the emergence of disciplinary power and the surveillance of the soul.

The death penalty can be traced to antiquity from the Lex Talionis of the Code of Hamurabi (1750 BCE) to the laws of Draco in ancient Greece (seventh century BCE) and its prescription by Roman Law (fifth century BCE). It also has established provenance in some of the world's major religions, such as Christianity, Judaism, and Islam, all of which have at times provided justification or condoned the practice. Its widespread use during the middle ages was defended during the Renaissance and Reformation by many Enlightenment thinkers such as Hobbes, Locke, and Rousseau. It was however during this same period that the first seeds of at least partial abolitionism began to emerge. The Italian criminologist Cesare Beccaria in his work *Dei Delitti, et delle Pene* (1764) argued for the abolition of the death penalty and became influential in the development of the modern abolitionist movement. Abolitionism grew in the nineteenth century through the work of the jurists Jeremy Bentham and Samuel Rommilly.

By the end of the 1920s several European countries had eradicated the death penalty for peacetime offenses. This momentum was reversed with the rise of authoritarian regimes and the reinstatement and expansion of the practice in jurisdictions such as Italy and Germany.

The end of World War II proved a turning point in the development of international sensibilities and legal instruments to regulate punishment by death. A number of international and regional treaties that restricted or provided for the abolition of the death penalty were put in place. The transformation has been at its most dramatic in Europe, where from the 1960s onwards increasing numbers of states abolished the use of the death penalty. In 1986 Protocol No. 6 to the European Convention of Human Rights came into force, abolishing the death penalty in peacetime. Since 1998 a condition for entry to the European Union has been the abolition of the death penalty. Beyond Europe the Universal Declaration of Human Rights (1948) recognized each person's right to life and states that "No one shall be subjected to torture or to cruel, inhuman, or degrading treatment or punishment." Opponents of the death penalty argue that the death penalty violates these rights both at the point of execution and in the length, conditions, and experience of prisoners in death row. Article 6 of the International Covenant on Civil and Political Rights (1989) proclaims the right to life, but precognizes capital punishment as a permissible exception. It also sets out procedural safeguards for its application and significantly prohibits the execution of juveniles and pregnant women. The Second Optional Protocol to the International Covenant on Civil and Political Rights (1989) provides for the total abolition of the death penalty, but allows states to retain the death penalty for the most serious crimes if they make a reservation to that effect at the time of ratifying or acceding to the protocol. The International Criminal Court (1998) excluded the death penalty from the punishments which it is authorized to impose. A similar stance has been taken by the International Criminal Tribunal for the Former Yugoslavia (1993) and the International Criminal Tribunal for Rwanda (1994).

Yet the abolitionist movement cannot claim global success. According to Amnesty

International, by 2005 121 countries had abolished the death penalty either in law or in practice, 86 countries had abolished the death penalty for all crimes, 11 had retained the death penalty only for exceptional crimes, and 24 countries retain the death penalty in law but have not carried out executions for the last 10 years. According to the best estimates during 2004, at least 3,797 people were executed in 25 countries and at least 7,395 people were sentenced to death in 64 countries. A small number of countries are responsible for the vast majority of executions: 97 percent of all known executions took place in China, Iran, Vietnam, and the US (Amnesty International 2005). Within this group the People's Republic of China is estimated to have carried out 3,400 (9 out of 10 executions).

Support and opposition to the death penalty rest on the fine balancing between philosophical questions about its justice or morality and pragmatic questions about its usefulness, its possible discriminatory or capricious distribution among the guilty, and the inherent risk of executing the innocent.

Arguments in support of the death penalty usually evoke the principle of retribution or the principle of deterrence. Arguments against the death penalty challenge retribution and construct the death penalty as an extreme form of torture that violates the sanctity of life in particular and human rights in general. The deterrent justification is the one most often deployed by retentionist states and rests on the extent to which the death penalty stops other offenders from committing the same offense, thus saving innocent lives. Supporters of capital punishment argue that it has a deterrent effect on potentially violent offenders, especially where the threat of imprisonment is not a sufficient restraint, for example those already serving life imprisonment. Studies in the 1970s and 1980s (e.g., Ehrlich 1975) showed support for the deterrent effect of execution. Such studies have been subject to extensive methodological criticism and other studies using similar data refuted the deterrent effect of executions. Bowers and Pierce (1980) have found that rather than a deterrent effect, executions appear to contribute to an increase in the number of homicides. There is at the moment no conclusive and undisputed evidence that executing

offenders is more effective deterrence than life imprisonment.

In jurisdictions which take into account mitigating and aggravating factors in sentencing to death, capital punishment is only inflicted in a relatively small proportion of those legally eligible, raising questions of possible arbitrariness and discrimination. One of the most striking disparities is in the geographical distribution of capital sentences and executions both within and across individual states. In the 1970s the US Supreme Court suspended the use of the death penalty (*Furman v. Georgia* 1972), accepting the argument that the death penalty was applied in an arbitrary and capricious manner and that members of racial minorities were unfairly treated. After that decision many states introduced new laws structuring the use of discretion at the sentencing stage and the death penalty was reinstated in 1976 after the decision in *Gregg v. Georgia* (1976). Subsequent attempts to present to the Supreme Court social scientific evidence of discrimination in the application of the death penalty have failed. In *McCleskey v. Kemp* (1987) the Supreme Court agreed that evidence of discrimination in death penalty cases in general was disturbing, but it held that discretion was essential to the criminal justice process and the standard of proof for its abuse must be set high and the petitioner had to prove discriminatory intent in their particular case. This is a fine balancing between individualization and equality. Since the 1990s numerous studies have sought to establish whether the death penalty is applied in a discriminatory way according to race, sex, and wealth. For example, a study by Paternoster and Brame (2003) in Maryland found that discrimination permeates every stage of case handling in capital cases, echoing similar findings by researchers in other US states. One of the most consistent findings of such studies has been that offenders who kill white victims, especially if the offender is black, are significantly and substantially more likely to be charged with a capital crime than if both the victim and defendant are black.

In 1997 the American Bar Association responded to a growing concern about the reliability of the death penalty and the risk of executing innocent people by calling for a national moratorium on all executions, in part

to “minimize the risk that innocent persons may be executed.” In a study of every death penalty appeal from 1973 through 1995 it was found that of all the thousands of cases that had completed the appeals process, 68 percent were found to contain errors serious enough for a retrial or a new sentencing trial. The study highlighted the need to maintain what has been termed super due process in capital cases safeguarding the appeal process, which had come under attack in the 1990s for its cost and the delay. In the beginning of the twenty first century a series of miscarriages of justice led to a moratorium on executions in Illinois and many states have enacted legislation to allow evidence from DNA testing to be considered after the normal appeals in capital cases have concluded.

It could be argued that the risks of error, arbitrariness, and discrimination are endemic in even the most sophisticated legislation and for all kinds of sanctions. Capital punishment is not in that respect a special case, yet the risk of mistake in capital cases is often used to challenge the legitimacy of this sanction. Zimring (2003) argues that this may be because the punishment is irreversible, because its application is incompatible with substantial error, and because unlike imprisonment the usefulness of executions can be more readily challenged.

death of the sociology of deviance?

Erich Goode

Over the past decade or so, the claim that the sociology of deviance is “dead” has become increasingly vocal. Colin Sumner (1994), advocating an outspoken leftist agenda, dates the field’s “death” to 1975. Unfortunately for his argument, he offers aphorisms, plays on words, and polemical assertions about the field’s role in the political economy, but no empirical evidence to test his proposition.

Miller et al. (2001) demonstrate that works in the sociology of deviance published in the 1990s cite criminologists more often than recognized deviance specialists; and among the most frequently cited works of recognized deviance figures, only two were published after 1975. These findings, they argue, offer an “empirical test” of the “declining influence of scholarship in the sociology of deviance” (p. 43). In spite of the possible methodological limitations of the authors’ measurements, the tests of Miller et al. do suggest the field’s declining theoretical vitality, although they do not support Sumner’s “death” claim.

Hendershott (2002) agrees with Sumner that the sociology of deviance is “dead.” She argues

that “few sociologists want to teach” courses on deviance, that the subject is “being eliminated” from sociology’s curriculum. The field of deviance studies “died,” she claims, because of its relativistic stance; increasingly, she asserts, Americans are rejecting the field’s neutral, amoral, relativistic cloak because it justifies immoral behaviors that deserve to be stigmatized and vilified. It is time, she says, to return to “common sense” and “natural law.” In short, it is time to redefine deviance as behavior that is inherently, intrinsically, and objectively bad, wrong, harmful, disruptive, and subversive, rather than a mere social construction, as the sociologists of deviance have claimed. Her agenda, she says, is to engage in “remoralizing” America.

In a balanced argument, Joel Best (2004) traces the “trajectory” of sociological studies of deviance from the late 1950s into the 1990s. He argues that the field “has come to occupy an insecure, even precarious, place in sociology.” His conclusion is that the sociology of deviance “no longer plays as prominent a role in sociology’s thinking as it once did.” This is documented by a decline in the citation count of articles using the word “deviance” published in sociology’s three most prominent journals between the 1970s and the 1990s. As Best points out, the field of deviance may not be dead, “but neither does it seem to be thriving.”

Goode (2003) found that just under two thirds (16) of the sociology departments in the 25 leading US institutions of higher learning offer a deviance course. Enrollment figures for deviance courses in the 17 departments examined were found to be as robust today as they were in the 1970s. In short, Hendershott’s charges – not endorsed by Best – that no one wants to teach the course, and that it is being eliminated from sociology’s curriculum, are contradicted by the available evidence. While Best (2004) dismisses the notion that undergraduate enrollments and textbook sales indicate the field’s continued intellectual vitality, Goode (1997) disagrees by demonstrating that the major deviance textbooks generate a substantial number of citations from the field as a whole. This, according to Goode, indicates their continued intellectual utility. A tabulation of the more than 1,700 scholarly articles located by the Social Science Citation Index

(1957–2004) that bore “deviance” or “deviant” in their titles indicates that the 1980s was the field’s peak year for scholarly productivity, and that the 1990s was more productive than the 1970s; expressed as a yearly average, the 2000s (2000–3) were only slightly less productive than the 1990s. Hence, the field’s scholarly productivity seems to be as strong as it was during a decade (the 1970s) its critics claim was its peak productive era.

Not one of these claims or tests compares deviance with any other subfield of sociology; it is possible that other subfields are no different from deviance in this respect. Indeed, evidence indicates that the field of sociology, taken as a whole, is less conceptually and theoretically innovative than it was in the past. Still, nearly all indicators point to the fact that the productivity, conceptual and theoretical creativity, and influence of the sociology of deviance have declined somewhat since the 1980s. It is possible that the field’s split from criminology is responsible for this decline. However, to adequately test the hypothesis, the productivity and vitality of other fields – and sociology generally – would have to be compared with deviance to determine whether the latter is exceptional in this respect. By no measure, however, can the sociology of deviance be said to be “dead.” Evidence suggests that the charge is empirically false and, in all likelihood, politically motivated, energized, on both the political left and right, by a dread of the field’s foundational assumption: social and cultural relativism.

Debord, Guy (1931–94)

David Redmon

The *Situationist Internationale* extended French avant garde social movements by identifying how the spectacle replaced the commodity as the dominating mode of social life. Guy Debord was perhaps the foremost thinker in this group of French intellectuals who were influenced by Dadaism, Surrealism, and the sociologist Henri Lefebvre. Debord was not an academic, yet citations of his works are included in numerous sociological texts. Debord never graduated from college, barely graduated high school, and lived the majority of his life as a drifter who roamed to and from different urban locations. He eventually settled down in a rural village where he committed suicide by shooting himself in the heart at the age of 62 (Merrifield 2005).

Debord is most famous for his polemic “Society of the Spectacle” – a montage of theoretical writings which analyzed the transformation from a society organized around production to one organized around the consumption of “an immense accumulation of spectacles.” According to Best and Kellner (1997: 81), Debord sought to update the Marxian emphasis on class struggle and factory work with a project focused on the transformation of the city and liberating subjectivity from the hegemonic integration of media and consumer culture which manufactures a spectacular society. Spectacular society, Debord explained, was an apparatus of fabricated social relations in which institutions socialized people through relationships with images; it is a reified world where consumers and producers are alienated from each other and can only experience their social world through the accumulation of spectacles. Debord (1994) writes: “The spectacle is

the moment when the commodity has attained the total occupation of social life. The relation to the commodity is not only visible, but one no longer sees anything but it: the world one sees is its world.” All that remains from the spectacle are representations of life.

In spectacular society represented life is reduced to a hegemonic network of consumer gadgets, leisure is reduced to shopping, and the logo or brand becomes the dominating category of status and prestige for people. The apparatus of surface appearances effectively controls people precisely because they unite into a coherent glossy image that renders the rational techniques that manufactured them invisible; all that remains is the desire to possess the signifier of the sign. Therefore, the spectacle does not socially control its subjects by force, but through the pacification of creativity and the consensus of collective desire. The spectacle extends its subtle forms of normalization and domination by constituting the desires of subjects to conform to the glossy images in magazines, advertisements, commercials, and movies. “The spectacle,” Debord notes, “is the moment when the commodity has attained the total occupation of social life” (Thesis 42). The spectacle is a chain of images that flattens and reduces landscapes into a vacuum of TGI Fridays, Apple bees, GAP, Abercrombie and Finch, glistening billboards, and Starbucks located next to fast food restaurants and chain hotels.

Debord is adamant in pointing out, however, that spectacular society is socially constructed by an apparatus of modern men and women: advertisers, city council planners, international financial institutions, corporations, special economic zones, architects, fashion designers, and so on. Therefore, he claims, it is imperative to understand that the spectacle is vulnerable to disruption and eventual eradication. The concept he applies to this possible transformation is *détournement*. *Détournement* is a conceptual and physical tactic employed by opponents of the spectacle who desire to alter, destroy, and replace it with a more humane alternative, one that advances creativity and the ability to fully participate in the creation of their everyday lives. Examples of *détournement* include squatting in abandoned spaces; resignifying or inverting the intended meaning of advertisements through graffiti or street art; reclaiming

streets, parks, or abandoned gardens so that the public can participate in them through actions such as growing organic food, playing with children, creating music, or participating in games, chess, soccer, or carnivals. Pleasure, passion, and organic relationships based on difference and self creativity are the values upon which the Situationists attempted to transform everyday life.

These intentional revolts were meant to influence everyday people to create their own *détournement* actions. May 1968 provided the defining moment of Situationism in that the historical rupture could not be attributed directly to a crisis in the economy. Perhaps the most controversial organization that emerged in Paris out of May 1968, and influenced by the Situationists, was the Angry Brigade. The Angry Brigade was a marginal yet influential organization of anonymous activists who set off more than 20 bombings. None of the bombs, however, were designed to kill or maim anyone (and no one was ever killed or maimed). Instead, their bombing targets were identified for their symbolic value. Consider one statement from their communiqué: "Life is so boring, there's nothing to do except spend all our wages on the latest skirt or shirt. Brothers and sisters, what are your real desires?"

Contemporary examples of *détournement* include international social movements against global capitalism and neoliberalism: Critical Mass and Reclaim the Streets. The twentieth century birth of these contemporary movements is marked by the 1989 uprisings in Venezuela against the International Monetary Fund. The mainstream media visualized them on January 1, 1994, when the Zapatistas rose up against neoliberalism and for humanity. They erupted in Seattle, WA against the World Trade Organization on November 30, 1999 – exactly 5 years after Debord's suicide. Appropriately, masked anarchists were invited to join local activists and citizens to damage the spectacle. Targets included the spectacular images that Debord sought to eradicate, the pillars of the global spectacle themselves: McDonald's, Starbucks, Niketown, and banks were all vandalized, windows were smashed, and graffiti was painted, "Fuck the WTO," "Stop sweat shops," and perhaps most famously, "We are winning!"

Individuals who employ Black Bloc tactics are made up of decentralized affinity groups who employ a diversity of tactics in reclaiming streets, desires, and autonomy. In regard to the destruction of corporate property in Seattle during the World Trade Organization meetings, for example, groups who employed "Black Bloc tactics" circulated a communiqué influenced by the writings of Debord. In true Debordian style, these groups explained that they "took on an offensive role regarding the conscious destruction of capitalist private property. Here, affinity groups within the Bloc would facilitate the smashing of windows, spray painting of revolutionary messages and trashing of police and/or military vehicles. Of course, all such activity was clearly directed against capitalist targets ... In short, the demonstration here begins to assume its own identity free of the social spectacle of the commodified consumer culture, and begins to move in a more fluid, self defining manner" (Green Mountain Anarchist Collective). The Black Bloc papers go on to provide a comprehensive critique of the "society of the spectacle" and the international financial institutions through a critical analysis in which Debord is quoted in several passages.

decision-making

Lois A. Vitt

Decision making is the process by which individuals and groups identify, combine, and integrate information in order to choose one of

several possible courses of action. In social psychology, research traditions involve the cognition, affect, and behavior that drive both *individual* decision making (including attitudes, beliefs, values, and actions) and *group* decision making (including group formation, group preference, performance and influence, social decision schemes, straw poll, social comparison, and groupthink).

Although some social psychologists have taken up decision making as a focused research interest, social psychology generally is seen as informing the emerging interdisciplinary areas of the decision sciences. As a topic area within social psychology, decision making is not guided by a single theoretical framework that researchers use to organize and guide their work. Rather, a number of theories in which decision making is either explicit or implicit can be found within symbolic interactionism, exchange theory, rational choice, cognitive consistency theories, and other research on attitudes, beliefs, values, and behaviors. Dissonance theory, for instance, is a comprehensive framework that describes cognition and behavior before, during, and after people make decisions. It is based upon the general proposition that inconsistent cognitions arouse an unpleasant subjective state, which leads to behaviors designed to reduce dissonance and achieve consistency, a satisfactory subject state. People feel discomfort in virtually all unresolved decision situations – the more important the decision, the greater the dissonance.

Historically, the heading of “judgment and decision research” is broad and work has been conducted over many years using differing methods within and across disciplines. Since the 1940s and 1950s, such research generally has followed two lines of inquiry. One group of researchers set out to learn how people decide on a particular course of action. How do people choose what to do next? Are their decisions rational? If not, by what processes do they make choices? A second group of researchers was motivated by people’s perceptions. Do people integrate conflicting thoughts and ideas, arrive at an understanding of the situation they are facing, and then make a judgment? Does their judgment improve with experience? How does human judgment compare with actuarial prediction?

From the first set of inquiries a formal modeling approach evolved, which has most commonly been used in economics and organization management. It typically compares the cost or utility of alternatives, characterizes choice as the maximization of value, and assumes that rational, self interested persons make the correct, most efficient choice on the basis of available information. Rational decision making involves sufficiently reducing uncertainty so as to allow a reasonable choice to be made from among alternatives. This classical approach has contributed illuminating tools of thought and substance to the social sciences, but it also has been seen as both too strong and too weak: too strong because it sets impractical – if not impossible – standards and too weak because it fails to capture the subtleties of human concerns (Bacharach 1994). Sharir and his colleagues (1997), for example, have argued that rational models do not deal with significant aspects of actual deliberations, which are essentially subjective and can be experienced, and appear to others, as vague.

Evidence is accumulating in economics, particularly behavioral economics, and organization management that decision making requires persons, individually or in groups, to expend cognitive effort, and more often than not, feeling effort as well when identifying alternatives and choosing among them. Choice is a motivational condition that arouses both cognition and emotion and affects decision making behavior. Argyris (2001) argues that in order to be effective in group decision making, it is necessary to understand interpersonal factors during the decision process itself. According to Hayashi (2001), effective decision making involves having the ability to intuit, or “trust your gut.”

A second set of inquiries involving judgment can be found in the scholarship on history, politics, and the law, where quantitative modeling and cost analysis can be difficult or implausible to apply. Using a reason based approach to decision making, this perspective identifies reasons and arguments that influence decisions and explains choice in terms of the balance of for and against alternatives. One school within this perspective sees judgments and decisions reached by groups through sets of relatively simple rules known as “social decision schemes.”

Rules within social decision schemes relate the initial distribution of members' views or preferences to the group's final decisions. A *majority wins* rule suggests that a group will decide according to whatever position is initially supported by most of its members. Other social decision schemes involve the familiar *two thirds majority* rule in use by some juries and other decision making groups, and an alternative known as a *first shift* rule, in which groups tend to adopt a decision consistent with the direction of the first shift in opinion shown by any members. In contrast, a fourth alternative is the *truth wins* rule, which indicates that a decision will be reached by members' recognition of the "correctness" of a solution. The results of many studies indicate that these straightforward social decision schemes underlie, and are successful in predicting (up to 80 percent of), even complex group decisions.

Although some scholars have contributed to both choice and judgment areas of decision research, controversy over which approach is superior and efforts to integrate the two are still ongoing. For instance, one review of some 20 studies found that intuitive ("clinical") judgments are less accurate than a simple statistical combination of the same information available to the judge (Goldstein & Hogarth 1997). A third historical or meta approach called deciding how to decide is used to compare and explain the selection of one decision strategy over another, depending upon the conditions involved.

Recent developments in the field of judgment and decision making include the emergence of a formal interdisciplinary field of decision science, which seeks to understand and improve judgment and decision making of individuals, groups, and organizations. Theories that provide the core for decision science draw on insights from a diverse set of disciplines, including social psychology as well as cognitive psychology, economics, statistics, neurology, and philosophy. Applications of decision making research are being used to improve decision capabilities of fields as diverse as medicine, military science, law, organization management, and consumer finance.

At one end of the field, judgment and decision researchers now include higher order thought processes, thus blurring the line between decision research and cognitive

psychology. Researchers cite and conduct studies that involve memory, mood, and motivation, learning and language, attention and attitude, reasoning and representation, problem solving and perception, expertise and explanatory coherence. At the other end of the field, researchers are conducting intensive study of the social aspects of decision making, thereby blurring lines between parts of social psychology, sociology, economics, political science, and anthropology. These areas of judgment and decision research are moving forward rapidly. However, another discipline exists that has long incorporated an understanding of the subjective nature of decision making – the field of market research that supports commercial advertising and consumer decision making.

Among the tools of market researchers are concepts originally developed by social psychologists and sociologists. Some market researchers, for instance, hold that human values inform the processes of preference, choice, and purchase decisions. Targeted efforts often are designed to tap into what is known about consumer values in order to sell them products and services. The idea that individuals or groups of individuals prefer and choose among what they value most is not new to social psychology. Although discussions about values and how values function at personal levels have occurred over centuries and can be found in all fields of the social sciences (and in law, the physical sciences, education, philosophy, and religion), it was social psychologist Milton Rokeach who may be best known for his work on the nature of human values and value systems. Rokeach argued that values drove decisions and although difficult to accomplish, changes in human values have the power to change even entrenched behaviors.

Other behavioral and social scientists (and philosophers) have used the term values to refer to ideals in the world toward which people are oriented and to what is regarded as personally desirable. Individuals hold beliefs and attitudes about the way things are, make judgments about the way things should be, make tradeoffs among choices, then choose and take action according to what they value. Although the study of human values in sociology has more or less languished (perhaps for want of better measurement tools), in

Value Focused Thinking decision researcher Ralph Keeney (1996) argues that values drive the best decisions of both individuals and businesses. New theoretical frameworks are being introduced into the values and decision making research literature in order to reenergize thinking in that research area, and also to present explanations of consumers' financial and health care decision making behaviors (e.g., Vitt 2004).

Decision making based on values alone, however, is not without controversy. Not much is known, for example, about the links between consumers' stated values and their sometimes inconsistent decision behavior. A better understanding of values awaits further research in social psychology and the decision sciences. How and why these inconsistencies operate in health care, purchase behaviors, savings and investment behaviors, and environmental choices could improve understanding of both individual and group judgment and decision making in these and other areas in society.

In addition to links to human values in decision making, connections have been made to the attitude literature, exchange theory, literature on the self, role and identity, and many other social psychological conceptualizations. Meanings elaborated in decision making also have importance beyond the task of rendering decisions. Decision making and the activities that surround it have symbolic significance as well. Decision makers develop and communicate meaning not only about decisions, but also about what is happening in the world and why. They define morally important issues, create understandings, and impact events, actions, policies, and even cultures. They allocate resources that define who is powerful, who is smart, who is prosperous, and who is virtuous. Thus, the process of judgment and decision making affects individual, organizational, and societal esteem and standing. It helps to create and sustain a social order of relationships, trust and distrust. It builds bridges to disciplines of study, both basic and applied.

The reality is that individual and group decisions result in outcomes as significant as life and death, war and peace, prosperity and impoverishment, social justice, foreign relations and the domestic policies of nations. Organizations can succeed or fail as a consequence of the decision making skills, mindsets, and practices of

managers. The theories and research of social psychologists have contributed to the vast decision sciences and will undoubtedly continue to fit into and work within this growing network, helping to improve knowledge about judgment and decision making by individuals and groups.

decolonization

Julian Go

Decolonization typically refers to a shift in a society's political status from colony to autonomous state or independent nation. It can also

refer to a shift from colonial status to full incorporation into the dominant polity such that it is no longer subordinate to the latter. While decolonization has occurred in many different places and times, typical usage of the term in the modern period refers to the decolonization by western colonial powers of dependencies in Asia, Africa, or the Americas. It is strongly associated with the fall of modern empires and the spread of nationalism and the nation state around the world. Decolonization has also been used to refer to a cultural or psychological process that may or may not correlate with formal political decolonization.

The first major period of decolonization in the modern era occurred in the late eighteenth and early nineteenth centuries. In this period, colonies of England, France, Portugal, and Spain emerged as independent nations. The period began with the revolution of Britain's continental colonies and the formation of the United States and the emergence of independent Haiti, formerly the French colony of Saint Domingue. Thereafter, in the early nineteenth century, colonies of Spain and Portugal in Latin America obtained independence in the wake of the occupation of Spain by Napoleon in 1808. The second major era of decolonization occurred in the mid twentieth century. This period saw a far reaching, global spread of decolonization. Most colonies in the Indian subcontinent, the Pacific, Southeast Asia, Africa, the Caribbean, and the Middle East obtained independence. The process began after World War I but was accelerated after World War II. From 1945 to 1981, approximately 105 new nations emerged as a direct or indirect result of decolonization. Most of these nations then joined the United Nations, such that the number of members in the United Nations expanded from 56 members to 156 in this period.

The two periods of decolonization differ in several respects, in part due to the character of the colonies involved. In the first period, decolonization was led by revolts among creoles and settlers who sought independence from their former mother country. In the second period, decolonization was led by indigenous groups rather than settlers or creoles. Furthermore, decolonization in the Americas during the late eighteenth and nineteenth centuries was

localized in the western hemisphere. By contrast, decolonization in the second period was global in scope, covering nearly all colonies. While a handful of countries remained dependencies of western powers after World War II, decolonization in this period is typically associated with the end of the western empires and the concomitant diffusion of the nation state ideal around the globe. Finally, decolonization in the first period was typically initiated by anti colonial revolutions. In North America, Central and South America, and Haiti, independence was won through war (the exception is the independence of Brazil from Portugal). In contrast, decolonization in the twentieth century most often occurred without violence. Except for Algeria, Angola, Indonesia, and Vietnam, colonies won their independence after initial signs of discontent were expressed and as imperial powers decided to let them become independent.

There is little consensus on the causes of decolonization, but several classes of causation can be discerned. One includes factors internal to the colony, such as the emergence of nationalism among local populations and associated resistance to the metropolitan power. A second includes the relative capacity or willingness on the part of metropolitan powers. The third includes larger systemic factors in the global system of international politics, which might in turn shape the metropolitan powers' willingness to decolonize. Some theories suggest, for example, that when an imperial state is "hegemonic" in the world system, it prefers global free trade and therefore becomes more supportive of decolonization. A related factor is global political culture. After World War II, for example, colonial empires began to lose legitimacy and the ideal of the nation state became most pronounced, in part because the United States lent support to anti colonial sentiment.

The results of decolonization in the twentieth century have been complex. While decolonization was heralded by national elites as the first step toward modernization and economic growth, modeled after the development of their former imperial rulers, these developmental dreams proved difficult to realize even in the absence of direct political control by outside rulers. The effects of colonialism upon local socioeconomic structures were difficult to cast

off and neocolonialism or relations of dependency continued with western powers. Many decolonized countries saw an influx of foreign capital that, as some studies argued, slowed if not impeded economic growth. They also became subject to the policies of global institutions such as the World Bank or International Monetary Fund. Political legacies were also strong, as postcolonial nations created governments often modeled after the government of their former ruler. The global diffusion of western political forms such as constitutions can partly be attributed to decolonization.

One of the most significant consequences of decolonization, however, is the emergence of the nation state as the dominant form for organizing societies and the related realization of the modern interstate system around the world. After decolonization in the twentieth century, empires have become illegitimate in the eyes of the international community, and few territories have become recolonized. Decolonization has meant that empire, a major form for organizing peoples for centuries, has ended. Whether this legacy of decolonization will persist, or whether a new era of empires will emerge, remains to be seen.

deconstruction

George Pavlich

At first blush, placing a term like deconstruction in a sociology encyclopedia seems entirely incongruous. The word *encyclopedia* derives from the Greek prefix *en* (in) and *kúklos* with *paideiā*, connoting education (Ayto 1990: 201). Together, the implication is this: encyclopedias encircle education by gathering general, but definitive, discussions on particular topics between the covers of one reference work. This activity undoubtedly runs contrary to the spirit of deconstructive practices that expressly involve undoing language where it gathers itself into closed circles – especially when it purports to reflect the necessary, essential, absolute, or fixed. By contrast, the prospect of reinventing encyclopedic traditions from within is certainly not counter to deconstructive thought. Without clinging to the *en*, one could, for instance, allude to the deconstructive potential of generally circling around educative meaning horizons.

Associated with the French writer Jacques Derrida, deconstruction appears alongside several neologisms he initially created to read, yet reach beyond, the Platonic auspices of western metaphysics. Key among those auspices are oppositions that distinguish between appearance and reality, matter and form, temporal manifestation and essential principle (Derrida 1976, 1979, 1981). As well, metaphysical writing privileges logical arguments (*logocentrism*), formulating them as the center and marginalizing all other aspects of the text (Derrida 1982). So, the real, formal, and essential is assumed to be apodictic; logic within language faithfully represents, names, or classifies what is already there. Heidegger, who cast himself as among the first post metaphysical thinkers, sought to undo such thinking, appealing at times to nostalgic strategies of remembrance that recall “authentic” forms of Being ignored by metaphysical languages. Although markedly influenced by Heidegger’s work, Derrida offers a rather different, non nostalgic tack.

His now famous adage suggests that language may be approached as constitutive in its own right, without assuming the external

existence of its referents: “*There is nothing outside the text*” (Derrida 1976: 158; emphasis in original). Contextually sanctioned arrangements of words compose not only the entities enunciated through language (e.g., subjects, objects, things, transcendental ideas), but also the very concept of existence. Consequently, metaphysics’ primordial suppositions about being as that which is present, or indeed its emphasis on such oppositions as appearance–reality, are the products of language usage in given locales. For Derrida, anything said to exist or deemed present always achieves that status by virtue of specific iterations of language use. For instance, Being is enunciated as presence because of the way signs are locally deployed in relation to one another, and its meaning emerges from particular patterns of deferral. Consider another example. If asked “what does the word air plane mean?” a language user must respond by deferring to other words, signs with which that word is internally related in a given context – “it is a machine that flies,” “it is not a ground vehicle,” and so on. Dictionaries and encyclopedias also provide good examples of the ways meaning arises through deferral. Derrida (1976, 1981) famously explored this “play of differences” and coined the term *différance* (which in French can connote both “to differ” and “to defer”) to indicate how meaning, presence, and referents are generated by deferment to other signs. Such deferrals are not inconsequential; they literally shape both identities and how these live.

Moreover, language systems are governed by historically situated rules and conventions whose authority is premised on absence, rupture, aporia, and paradox. Patterns of *différance* are therefore never stable, necessary, fixed, or closed; they always can be – by virtue of their contingent, aporetic structure – disrupted, dispersed, opened, and dissociated to make way for new deferral patterns, meaning horizons, and existences. Disruptions to language formations have potentially vast consequences for the everyday meanings subjects use to encompass being at any given point in history. If that reflects Derrida’s direct relevance to ethical questions of how to be with others, it also suggests how deconstructing given

organizations of *différance* is ultimately about incipient ways of existing.

But what precisely is deconstruction? Although this question is not unproblematic in context, one might say that deconstruction has to do with opening up given linguistic arrangements to the mostly silent, background suppositions and aporias that enable their particular patterns of deferral. Its opening gambit, “guardrail,” is to read a classic text closely (never abandoning it or rejecting it out of hand), surveying especially what it eclipses, ignores, rejects, expels, dismisses, marginalizes, renders supplemental, excludes, and eliminates. Deconstruction pores over these delegitimated elements of a text to make room for alternate interpretations that open up a reading to what is completely unforeseeable from the vantage of its meaning horizons. Through such openings, deconstruction seeks to reorganize a given language use by realigning conventional oppositions, creating space for unexpected linguistic possibilities and being. Like the host, perhaps, it offers an unconditional welcome to the arrival of what is strange, unfamiliar, and other (Derrida 1997b, 1999, 2001; Derrida & Dufourmantelle 2000).

From here, the waters get muddy for those in search of singular definitions that expect one to decide definitively about deconstruction. The very question “what is ...?” poses a unique problem: while it appears to open discussion, the *is* commits respondents to the existence of the very thing placed in question. Yet, as Derrida (1995, 1997) repeatedly indicates, deconstruction is not a finite being (a presence) that can be defined universally, once and for all. Indeed, formulating an essential, fixed definition of deconstruction would replicate the very “metaphysics of presence” that he challenges. Instead, a different approach to language is required, and one that immediately faces a definitional intricacy: the word “deconstruction” cannot be defined once and for all, with any fixed unity, because any meaning or feature attributed to it is always, in its turn, deconstructable (see Derrida 1988: 4).

Several further things may be said about deconstructive analysis. Each such analysis is, as noted in the above quotation, subject to further deconstruction – the process is

unending and without final decision. There is never a point at which deconstruction ends, for every emergent meaning horizon is traced through deconstructible grammars. Moreover, attempts at deconstruction do not approximate a sustained method, methodology, procedure, or unified strategy. Rather, their emergence is as diverse as the contexts in which they are located, and in each case a close familiarity with the analyzed text is required. Its contingent path is, however, never determined or predictable. As Derrida insists: "Deconstruction is not a method or some tool that you apply to something from the outside. Deconstruction is something which happens and which happens inside" (Derrida 1997a: 9). It is not an intentional act that produces predictable results – it emerges by happening, if at all. And that happening is pleasurable, structurally desirable, and playful. Derrida (in Kearney 1984: 126) even suggests that deconstructing a text entails revealing how it "functions as desire," how the quest to render present, to secure a stable plenitude, is always deferred. The reader engages this "desire of language" through his or her own desire to appropriate in the text an absence, or something that is other to the self who reads.

In addition, since deconstruction is always located as somewhat of a "double gesture" that both reads and exceeds given texts, it never breaks fully with the past: "I do not believe in decisive ruptures, in an unequivocal 'epistemological break,' as it is called today. Breaks are always, and fatally, reinscribed in an old cloth that must continually, interminably be undone" (Derrida 1981: 24).

So, deconstruction takes place, or not as the case may be, through particular instances where attempts are made to open (dissociate) given arrangements of language to other possible arrangements. It attends closely to the unspoken elements that enable the central, or privileged, theses of a given meaning formation; it transpires by working with the lowly, unstable, contingent, and aporetic foundations upon which any open system of *différance* resides.

While the emphasis on language may appear to render deconstruction particularly well suited to literary and philosophical discourses, its effects have reverberated through many

discourses, including socio legal studies, women's studies, cultural studies, anthropology, religious studies, politics, criminology, and so on. Within the context of sociology, specifically, deconstruction's ethical pursuit of how to be with others is directly pertinent. But it also strikes a potentially rich chord in several other ways.

First, to the extent that deconstruction privileges dissociation over "gathering," opening over closure, it dovetails with inaugurating strands of sociological thought that viewed social formations as contingent, changeable, and amenable to historically situated openings. In later musings on the idea of deconstruction, Derrida (1997a: 13) tells us his focus has always been on "heterogeneity" and "dissociation" rather than practices that privilege "gathering" and unified formulations of concepts like "community" or even "society." He senses in such unities potentially dangerous closures that direct responsibility from members and fail to recognize basic ethical commitments to excluded others, the absences which render possible intimations of identity. Deconstruction is a way to keep open such unities and to prevent them from closing themselves off as necessary, inevitable, or the like.

If this concern with contingent, heterogeneous openings echoes elements of sociology, deconstruction assuredly does not endorse the latter's Eurocentric visions of social progress, or any quests to engineer absolute social or communal formations (see Pavlich 2001). At most, its call is to keep associative patterns interminably open, to spring into play precisely where discourses try to sign themselves off as necessary, unavoidable, unquestionably just, and so on.

Second, Derrida explicitly engages with seemingly canonical sociological texts, including his discussions of Rousseau and Marx (Derrida 1976, 1994, 2002b). His *Specters of Marx* recovers the significance of Marx by reading key texts deconstructively, making place for the idea that – despite talk to the contrary – we continue to be heirs to diverse Marxist legacies. Marx's multiple intellectual ghosts still haunt our times. One of these, often portrayed as his chief bequest, addresses the essential ontology (laws, processes, effects) of

capitalist societies. Yet Derrida argues that this somewhat anachronistic ontology is not Marx's most enduring legacy. The memory of Marx also continues to surface, for example, in the personal suffering, exploitation, and inequalities that persist on a global scale. Derrida deconstructively quarries the margins of texts like Marx and Engels's *Communist Manifesto*, or *The German Ideology*, to disclose still other specters. He surfaces with Marx's emphasis on radical, historically placed self critique that opens up to what is to come, and which strives for what cannot be known from within present possibilities. While Derrida (1994: 89) may worry about Marx's ontological formulations, he tells us he is not prepared to relinquish the critical, probing "spirit" of Marxism; but even more than this, he remains committed to the promise of emancipation and even to the "messianic" pledge to deliver new ways of being, new events that usher in new collective associations. Marx's legacy here is to have alluded to the experience of a "messianic affirmation," without a messianism, that welcomes unconditionally the promise of existence beyond current social relations.

Finally, much of sociological thinking has been undertaken in the name of various conceptions of social justice; similarly, Derrida (2002a: 243) insists that deconstruction is a language of justice, and even more forcefully proclaims that it *is* justice. For him, justice appears as a promise, beyond law, and is itself incalculable, infinite, and undeconstructable. This is not to say that deconstruction pursues the *telos* of a known justice; rather, he asserts that justice is radically unknowable, infinite, undetermined, and incalculable. Yet for all that, we are required to calculate justice, and we do so through finite calculations that find expression in law. He therefore locates deconstruction in the "interval" between law (which is deconstructible) and justice (which is not). By relentlessly opening the law (rule, grammar), refusing to allow any finite calculation to close itself off as necessary, deconstruction perpetually opens up to a limitless promise of justice that is always to come, that never fully arrives. And it is precisely in the name of that promise that both deconstruction and sociology, commendably, proceed.

deference

Paul T. Munroe

Deference refers to the granting of influence, esteem, or simply the "right of way" from one person to another person, persons, or impersonal entities. When one defers, the interest is in the other with whom one is interacting. Deference is a necessary element of a status relation, and deference often characterizes a large portion of the interaction among close personal friends, intimates, and family members.

Deference is a pivotal concept in the status characteristics and expectation states research program initiated by Berger, Cohen, and Zelditch in the mid 1960s. Groups of people who are working collectively toward the best solution to a task behave in ways that, if viewed externally, look very much like a hierarchy. Some people talk more than others, are listened to more, and are more influential than others. However, viewed from within the group, people are often unaware of the inequality. Group members can be remarkably satisfied with their interactions and not unhappy about the inequality at all. Deference is a key factor here. People look to the group members whom they think have the best ideas and defer to them.

The trouble with this process is that often the reason for deferring has to do with status characteristics like age, sex, or race rather than actual ability. So the relations are often unfair and inefficient, regardless of the group members' sense of ease within the group process.

Deference is the most frequent dependent variable measure in status characteristics research. The standardized experiment compares the proportion of times a subject chooses to stay with their own choice or to defer to a partner's choice. The higher the status of the other person relative to oneself, the more likely one is to defer to that person.

For Kemper (2000), deference is what distinguishes status from power relations in interaction. In status relations, lower status persons defer to the higher status person(s). In power or coercive relations, the low power actor responds to the high power actor because they

have to do so. Scheff (1988) argues that conformity is prevalent in much of interaction, leading to a state of normative control, because people defer to the norms and expectations of others to avoid the feeling of shame.

Goffman's "interaction rituals" often involve deference behaviors. Interactions among those who are familiar or wish to be so are made smooth and disruptions are minimized by a pattern of each person offering deference to the other. This comes in the form of interest in the point of view of the other, looking at the other while listening, nodding, "back channeling" (saying "mm hmm," "ah yes," and so on), and overt statements of agreement. All these examples of deference facilitate interaction.

Deference can only be shown by people, individually or in groups, but the *object* of the deference can be another person, an object, idea, or imagined entity. One can show deference to another person, the law, God, or symbols such as the flag of one's country. Behavioral examples include removing one's hat in a courtroom, kneeling before an altar, or observing a moment of silence in memory of some person or event. Deference, viewed in these terms, is the key process that leads to social solidarity.

definition of the situation

J. I. (Hans) Bakker

The term "definition of the situation" has come to signify the "Thomas theorem," the idea expressed by W. I. Thomas as follows: "If men define situations as real, they are real in their consequences" (Thomas & Thomas 1928: 571–2). That is, when the phrase is used, it usually carries with it the connotation of the whole theorem. However, the phrase "definition of the situation" predates Thomas's famous theorem. The more general conceptualization seems to be closely related to the concept of norms and culture. The interpretation of collective norms is important for all social action. It is only in certain situations where the agent chooses to redefine the norms. Park and Burgess (1921: 763–9) cite a Carnegie study (1919) where the term is used to discuss the topic of assimilation to American society, especially in terms of "Americanization": "common participation in common activities implies a common 'definition of the situation.' In fact, every single act, and eventually all moral life, is dependent upon the definition of the situation. A definition of the situation precedes and limits any possible action, and a redefinition of the situation changes the character of the action." Clearly the theorem, as it is often interpreted, applies more to the "redefinition" of a situation than to the norms defined by the collectivity. There is confusion concerning the history of the idea. Park worked with Thomas on the Americanization Studies series sponsored by Carnegie, but Thomas's name did not appear as the lead author of the book they wrote with Herbert Miller until 30 years later (Thomas et al. 1951 [1921]). Hence, the first clear and contemporaneously recognized use by Thomas of the phrase can be said to be chapter 2 of *The Unadjusted Girl* (Thomas 1923: 41–69): "Preliminary to any self determined act of behavior there is always a stage of examination and deliberation which we may call the *definition of the situation*. And actually not only concrete acts are dependent on the definition of the situation, but gradually a whole life policy and the personality of the individual himself would follow from a series of such definitions." He

cites examples from the ethical code of the Russian *mir* as instances of the definition of the situation "by the community as a whole," which indicates that it is not just individuals who do the defining. Merton (1995) examines the publishing history of the concept in detail and argues that the "Thomas theorem" was first articulated in Thomas and Thomas (1928: 571–2) but that Dorothy Swain Thomas apparently had relatively little to do with the theoretical idea since she mainly contributed to the statistical argument. Maines (2001: 244–6) argues that Thomas's "definition of the situation" has been falsely perceived by many sociologists as "subjectivistic" in contrast to Merton's (1948) notion of "self fulfilling prophecies" as pertaining to objective social structures. To bolster that claim, Maines cites Thomas (1937: 8–9), where Thomas discusses "definitions" giving rise to "patterns." But the later usage seems to be scarcely distinguishable from cultural norms and values. Merton's self fulfilling prophecy focuses on the false definition of the situation which evokes behavior that then makes the original false belief seem true, as in a teacher believing a student has a low IQ and therefore not helping that student learn. In that way, the self fulfilling prophecy is a subset of the definition of the situation, not the other way around, as is often held. The Thomas theorem is frequently viewed as specific to symbolic interactionism and irrelevant to other research paradigms, but it can also be interpreted as a contribution to general sociology. Thomas clearly did not mean that all human choice is limited to social constructions that may lack objectivity; there is an "obdurate" reality and many definitions are real due to group pressures as manifested, for example, in gossip. The beliefs of members of a collectivity can create a positive feedback loop (e.g., Black is Beautiful). The "Protestant ethic" may be a definition of the situation that put social action on a new track. A more refined statement of the Thomas theorem might be: if human beings, individually or collectively, define a situation or set of situations as real, such social constructs can sometimes be real in their consequences, for better or for worse. However, that statement would not have the same punch. The extent to which "situation" is limited to small groups and communities rather than nation states remains problematic.

Is a situation the same as a frame? But Thomas's contribution is valuable as a reminder that there are indeed times when the objective consequences of holding a false belief can be very real and yet not be exactly equivalent to a self-fulfilling prophecy. Moreover, his ideas are not restricted to symbolic interaction or even just interpretive approaches to interaction generally; his sociological and anthropological "social psychological" interest in cognition and motivation overlaps with other approaches in disciplines such as cognitive neuroscience, psychology, and psychoanalysis (e.g., Langman 1998).

deindustrialization

Nicole Flynn

Deindustrialization is a general term used to describe the shift in production from manufacturing to services beginning in the United States in the mid to late 1960s. Although the transformation of the economy in terms of output is primary, the collateral changes are nearly impossible to separate. Changes in skills required for work and changes in the location of work stemming from the shift in output are often included as part of the concept of deindustrialization. Deindustrialization, or more optimistically industrial restructuring, is an expected development of advanced capitalism and a globalized economy. The implications of it, for both workers and industry, are debated by social scientists and economists.

The expansion and investment of capital, combined with wartime needs, drove the development of the manufacturing sector. As early as the Civil War, when manufacturing provided a more robust economy for the North than the agrarian South, the building of goods was recognized as providing both jobs for workers and goods for market. Cities developed around centers of manufacturing, and the spatial concentration of capital, both human and financial, created diverse and thriving communities. Chicago and New York are early examples of manufacturing cities, along with Philadelphia, Detroit, and Pittsburgh.

Following World War II, the population of the United States expanded and shifted, notably with the growth of the middle class. With this expansion, the demand for goods and services increased. Technology developed that made automation possible and increased both the effectiveness of manufacturing and the potential of the service sector. Expanding

service sector industries included health and health care, education, social services, personal services, and more recently financial, insurance, and real estate services, and hospitality/tourism. The increased demand for goods was accompanied by a push for cheaper production, which was made possible through automation, lower rents or land costs, and less expensive labor. The increased demand for services occurred during a time of increases in educational attainment, increases in female labor force participation, and increases in civil rights.

Both land and labor were cheaper in more rural areas, so initially deindustrialization meant a move from traditional manufacturing centers in the Northeast and Midwest, also known as the Frostbelt, to the South or the Sunbelt. Geographically, land was also cheaper outside cities, so when manufacturing plants relocated, they did so in more rural areas. Because of urban growth and residential patterns, less skilled workers were generally concentrated in the older areas of cities and towns. More affluent families and skilled labor lived in the suburban fringe. In former manufacturing cities, when service industries did expand and enter into urban areas, they brought jobs that required skills urban residents lacked. Lower skilled services and the remaining manufacturing jobs relocated or developed in the suburbs. The result is often referred to as "spatial skills mismatch" (Kain 1968; Kasarda 1995).

The decline in unionization is also a consideration in deindustrialization. As labor became less powerful and capital more concentrated, there was less potential for resistance when manufacturing reduced jobs or relocated. Traditional blue collar jobs, with high levels of unionization, were slowly disappearing. The diverse service sector, dominated by white collar and pink collar jobs, has yet to develop strong union representation.

As manufacturing left for cheaper markets, the service sector expanded. Production of services had advantages not available to goods producing industries. First, horizontal space was less important. Skyscrapers provided an effective way for industry to grow in space without having to purchase large tracts of expensive land. Office buildings rose in the air, and large cities became centers of financial

and legal services, information processing, and hospitality/tourism.

Demand for skilled labor in the service sector was very different from traditional manufacturing jobs. While most management manufacturing jobs did not require extensive formal schooling, service sector expansion increased the demand for more highly educated labor and workers skilled in specific areas such as medicine, the law, and technology. It also provided a share of lower skilled and lower paid positions that were often supervised by the more educated workers.

The expansion of the service sector and the bifurcation of skills and rewards associated with employment in these industries contributed to a shift in the class structure. Many blue collar jobs that paid living wages were relocated and the remaining options for workers with less education were lower skilled and lower paid service positions. The expansion of higher skilled services also ensured employment for the increasing number of college graduates and persons with professional and postgraduate training. A related outcome was increases in low wage earners and an expanding upper wage class, with fewer workers earning middle income wages. This shift has implications for class, race, and gender inequality.

In general, white men and women are more likely to benefit from these industrial changes than other race and ethnic groups. Workers with more access to higher education were initially best served by deindustrialization. As the service sector expanded, more women, especially white women, also entered and completed college and professional schooling. Their rise in educational levels, later age at first marriage and childbearing, and increasing presence in the labor force all coincided with the increasing availability of jobs in areas that were long accustomed to hiring women. Black women, a group with a long history of labor force participation and increasing levels of education, also stood to benefit from expansion of educational opportunities. Black men and immigrants with less education, a group that relied on low skilled manufacturing jobs, were most disadvantaged. The decline in unions that occurred with deindustrialization was an important factor explaining the wage gap between black and white men.

Recent research critically examines globalization as it shapes the context of deindustrialization. The ability to communicate and move both capital and people around the world makes possible an economy situated in a global labor market. World systems theory describes the interdependencies of advanced capitalist countries, developing nations, and countries rich in either labor, raw materials, or both. Goods producing industries dependent on unskilled labor search the rest of the world for cheaper locations for labor and land. Increasingly, less skilled service jobs are also relocated to countries with a surplus of inexpensive workers. Policy that encourages multinational corporations through tax benefits and exemptions further stimulates this movement of capital outflow and inflow of foreign investment.

Some researchers argue that deindustrialization is merely a feature of advanced capitalist economies, and that eventually the expansion of services will increase the standard of living for all persons in these post industrial countries. Post industrialists, as they are sometimes called, link any increases in inequality with the transition process or with qualities of the population, not the labor market. Others view the shift as a more permanent imbalance in the economy, one that will eventually not only increase inequality but also result in reductions in competitiveness and a decline in quality of output. The work of Bluestone, Harrison, Wilson, and others points toward a permanent change in the class structure, into one more reminiscent of pre industrialization characterized by a large class of poor workers and a class of wealthy persons, with little variation in between. The long term consequences of deindustrialization are still being debated. However, the transition of the United States economy from manufacturing to service production is a major transformation that clearly affects relationships between groups and shifts the structure of social institutions.

deinstitutionalization

Raymond M. Weinstein

In 1955 there were 559,000 patients in public mental hospitals in the United States, the highest there had ever been. At that time, patients were largely committed involuntarily and had long hospital stays. For more than a century, the number of patients at state institutions, historically the primary facilities for the treatment of psychiatric disorders, had been rising steadily. By 1980, however, this number had declined to just over 132,000, despite the fact that the national population grew considerably.

In 2003, fewer than 53,000 remained. The 93 percent drop in the resident census of state hospitals was accompanied by the growth of outpatient clinics and community mental health centers as primary care facilities, the sharp reduction in patients' average length of hospitalization, and the shift to policies emphasizing more voluntary admissions.

These statistics, however, did not reflect a precipitous reduction in the number of seriously mentally ill persons. What took place, especially from 1965 to 1980, was a *transfer* of patients from state institutions to a range of institutional settings such as nursing homes, board and care facilities, halfway houses, and community treatment centers. This massive and unprecedented patient relocation from hospital to community, termed "deinstitutionalization" by both social scientists and the mass media, was supported by certain ideologies and political actions. Deinstitutionalization was the most important social movement in the second half of the twentieth century, one that affected the lives of millions of mental patients, their families, community residents, and health care workers.

Changes in the locus of patient care were part of a psychiatric revolution that swept the country. A number of forces extant in society have been identified as causes. First, the introduction of psychotropic drugs in the mid 1950s – remarkable in their ability to attenuate flagrant symptoms and reduce the frequency of psychotic episodes – permitted psychiatrists to treat patients in the community rather than simply institutionalize them for indefinite periods of time. Second, the growth of new forms of psychotherapy in the 1960s (dealing with alcoholism, drug addiction, developmental disorders, and sexual dysfunctions) greatly expanded the definition of mental illness and its treatment on an outpatient basis. A third force for change was the new legislation in 1963 that provided funds for the construction and operation of non hospital patient care facilities. The idea of community based care of the mentally ill was not new, but the decades old vision was not realized until John F. Kennedy (president of the United States 1961–3) made a historic initiative and there was strong political support for it. Fourth, the deinstitutionalization movement was hastened by the call for

patients' rights from both inside and outside the mental health professions. A series of court decisions in the late 1960s and 1970s affirmed a patient's right to refuse treatment and to due process in commitment proceedings. Finally, the rising cost of inpatient care to state governments in the 1970s and 1980s coupled with increased federal support for community care was a powerful incentive for states to shift their financial burden to Washington. The payment structure and matched funding allowances of Medicare and Medicaid, as well as the expansion of federal welfare disability programs, encouraged the transfer of elderly and poor chronically ill patients from state supported hospitals to privately run nursing homes.

The process of deinstitutionalization involved two other goals aside from the release of hospital patients. It likewise entailed the use of alternative facilities to treat those with first time psychiatric disorders. Before the policy and practice of deinstitutionalization, these persons would have simply been placed in mental hospitals without any clear treatment plans or discharge dates. In addition, an important objective, arguably the most difficult of the three to achieve, was the development of community based mental health and social support services to maintain a non hospital patient population.

Deinstitutionalization had a distinctive social philosophy. In the post World War II period, the idea that state hospitals were inhumane warehouses and anti therapeutic environments for the mentally ill was featured prominently in the mass media as well as in scientific literature. Former patients wrote personal accounts about the negative effects of institutionalization. Journalists, at times playing the role of pseudopatient, published scathing exposés. Social scientists, via participant observation, researched large mental hospitals and documented the widespread patient abuse, staff incompetence, deplorable living conditions, and poor treatment. The post war era was also dominated by optimism that positive action could change social conditions. The Civil Rights Movement of the 1950s and 1960s encouraged the notion that hospitalized patients were a disenfranchised class and doors should be opened for them as well. The deinstitutionalization movement, characterized by a strong conviction that

community based care was more cost effective than institutional treatment, wedded social reformers and fiscal conservatives.

Important political actions hastened the process of deinstitutionalization. In 1963, under the provision of what is now called Supplemental Security Income, the mentally ill living in the community became eligible for federal financial assistance. This enabled patients who otherwise would be in state hospitals to stay at home, in board and care facilities, or in apartment hotels. Entrepreneurs, not always skilled in the management of psychiatric disorders, converted old houses and buildings into residential facilities for former patients. The passage of the Community Mental Health Centers Act the same year provided large scale funding for community based programs to treat released hospital patients and those with first time psychiatric disorders. Both pieces of legislation and their amendments provided much of the financial underpinning for deinstitutionalization. Later changes in state commitment laws tightened the criteria for admission and retention and also furthered the shift from hospital to community treatment. Lastly, a 1975 landmark Supreme Court case, which ruled that non dangerous patients who were not receiving treatment should be released if they could survive outside the mental hospital, accelerated the move toward community care.

The era of deinstitutionalization succeeded in gaining the release of a substantial proportion of hospitalized patients and in significantly reducing psychiatric admissions. However, the development of a full array of community based mental health and social services sufficient to maintain a non hospital patient population is the one goal that has not been realized. Various problems related to service delivery account for this. To begin with, achieving continuity of care for chronic patients outside of hospitals was inherently problematic. Treatment programs often focused on patients' immediate needs with little or no attention given to future requirements. In the early years, many proponents of deinstitutionalization believed chronicity would be abated once the negative effects of institutional living were removed. Second, the treatment needs of the mentally ill living in the community could not always be met. Before deinstitutionalization,

most hospital patients stayed for long periods of time, the rest of their lives in many cases, and there was little variation in the treatments afforded them. Today, the non hospital population is fragmented; patients have varying degrees of chronicity, some are shuttled in and out of hospitals, many mentally disturbed are in jail, others become homeless. Few communities have been able to service the treatment needs of patients who varied greatly in diagnosis, symptomatology, functional level, and family support.

A third problem of service delivery was the difficulty of providing comprehensive care. In the hospital, psychiatric, medical, social, rehabilitative, and vocational services were offered within a single physical setting. In the community, the locus and authority for such human services were typically divided among different public and private agencies that seldom achieved effective coordination. Fourth, the most disturbed persons in the community were frequently least likely to receive psychiatric treatment. Deinstitutionalization clearly intended that the new mental health programs would serve those most severely ill. However, many agencies, both intentionally and unintentionally, selected patients for treatment who were less disturbed or disabled. Persons least likely to secure psychiatric services on their own were left to do just that. Finally, community based care was lacking in effective measures of program outcome. Mental health administrators and clinicians seldom had reliable information concerning patient populations to be served and the effectiveness of treatments actually delivered. The statistical analysis used for program evaluation was more often than not irrelevant for the disjointed system of care that prevailed in most communities.

Aside from the problems related to service delivery, an important question is *why* community based care or aftercare programs failed to meet the objectives of deinstitutionalization. One important reason pertains to public attitudes toward the mentally ill. Research has consistently shown that most people do not want to associate with former mental patients or the mentally ill and that these negative attitudes have changed little over the years. Opportunities for discharged patients to find satisfactory employment and housing in the

community are thus limited by the public's prejudices. Deinstitutionalization occurred as a result of ideological, political, and legal forces in society, not public pressure to reintegrate former patients into communities. The public has been more willing to accept deinstitutionalization as a means of social control than treatment or rehabilitation. Former patients in nursing homes, jails, or halfway houses and board and care facilities in marginal neighborhoods are tolerated more than next door or at work.

A second explanation for the failure of aftercare programs deals with organizational processes within the mental health system. Sociologists have discovered that human service organizations are confronted with operational problems and compromising choices related to the establishment of priorities, acquisition of resources, adjustment of expectations, development of interorganizational networks, and rationalization of activities. Thus, state mental hospitals, which faced reduced resources in the era of deinstitutionalization, gave priority to inpatient care rather than discharge planning, and became more concerned with the number of patients discharged than their later quality of life in the community. Community mental health centers, in order to control costs and justify their effectiveness, chose to devote more of their resources to the non chronically ill and to enroll only the best patients for their vocational rehabilitation and substance abuse programs. Chronic patients were mainly treated with medications, their need for more comprehensive services ignored. Public and private social service agencies saw the chronically ill as outside the scope of their mission and refused to treat them. The lack of continuity of care between hospitals and community agencies reflected the role adaptations professional staff workers made adjusting idealistic goals to realistic accomplishments.

The inadequacy of community based care for the mentally ill is likewise explained through a political economy perspective. Mental patients, especially those with long term disabilities, are part of the so called underclass in American society, a growing army of unemployed persons, unskilled laborers, drug addicts, alcoholics, welfare recipients, illegal aliens, poorly educated racial minorities, and other incompetent or disreputable groups. Members of the underclass

lack sufficient power or resources to change social conditions that affect their lives. Thus, mental patients in hospitals, nursing homes, jails, on the streets, or in community halfway houses and board and care homes are unlikely to effectively organize and lobby the government for changes in the mental health laws or policies. Mental patients were decidedly *not* involved in the deinstitutionalization movement that sought to help them. Community housing for the mentally ill flourished only when there was an economic incentive to provide such services to this downtrodden group.

Despite its problems and failures, deinstitutionalization has been an integral part of mental health policy in the United States for almost half a century. Its ideology of concern for the well being of mental patients combined with the pragmatism of its promise of cost savings have probably sustained the movement over the years, often in the face of harsh criticism. Today, even with the experience of some notable program deficiencies, it is still widely assumed that community based care for the mentally ill is intrinsically more humane and more therapeutic than hospital treatment. Support for deinstitutionalization, however, has not resulted in corresponding increases in public monies for community mental health programs. Economy minded state officials have been willing to close state hospitals but are less willing to put the money saved into community programs for the patients they released. Advocates of deinstitutionalization have argued that dumping patients into neighborhoods ill prepared to deal with their needs does not constitute community treatment, and that the movement has not had a fair chance to demonstrate its merits since adequate public funding and program planning were lacking from the start.

The early history of deinstitutionalization offered promise to patients with chronic disorders: freedom from the sometimes inhumane conditions of public mental hospitals, reintegration with family and friends, management of their illness in community facilities. There was also hope that the new treatment programs would cure existing disorders in less chronic patients and prevent the occurrence of future illnesses among those who experience first time psychiatric episodes. Caregivers and service

providers, however, often did not distinguish between those with severe or lifelong conditions and those with less serious or intermittent disorders. Service programs during the early years were mainly designed for the latter group whose needs could be met with brief therapy and crisis interventions. The deinstitutionalization that took place failed to attend to the needs of the most severely ill and efforts at prevention failed to reduce the incidence of the most serious mental disorders. The very patients whom the movement was supposed to help, those forced out of state and county hospitals, fell through the cracks of the inadequate community service system.

In the 1980s and 1990s, one of the most important unintended consequences of deinstitutionalization was the dramatic increase in the homeless population. Inexpensive housing in large cities was unavailable and many discharged mental patients simply had no place to go and ended up living on the streets, in alley ways, or in subway caverns with other homeless people. Unable to make decisions for themselves or follow a consistent program of treatment, these novice outpatients suffered badly from a well meaning but poorly implemented social policy. Some discharged patients no doubt benefited from community care, but others found themselves bereft of adequate food, clothing, shelter, medical care, and psychiatric treatment, the very necessities and services formerly provided to them by the hospital. As early as 1984, the American Psychiatric Association proclaimed that deinstitutionalization was a failure and a major social tragedy.

By the close of the twentieth century, more than 90 percent of the state psychiatric hospital beds that existed in 1960 were eliminated. Thanks to lawsuits by civil liberties attorneys, it is now virtually impossible to treat severely mentally ill individuals involuntarily in the hospital or the community until they commit some overt criminal act. Increasingly, state mental health officials have been abdicating their responsibility to care for disturbed persons, preferring instead to hand them over to for profit health maintenance organizations (HMOs), who in turn eschew paying the \$400 a month per patient it would take for the newest antipsychotic medications. The outcome has been predictable: a significant rise

in criminal homicide. Deinstitutionalization has turned deadly, as approximately 1,000 homicides are committed each year nationwide by untreated mentally disturbed persons.

In recent years, the philosophical bases of deinstitutionalization have been reassessed. It is now generally recognized that the initial ideology of reform for hospitalized mental patients and conviction that substantial cost savings could be realized with community based treatment were misguided. Although it is unlikely that states will ever go back to a system of care based almost totally on hospital treatment, it is apparent that state hospitals continue to perform important functions for society. Such institutions serve as backup facilities for patients who cannot be treated effectively in outpatient clinics or nursing homes. Because of their size, hospitals are able to offer specialized services unavailable in community based programs. Decades of experience with deinstitutionalization have demonstrated that it is just as costly to provide effective and comprehensive care to mental patients with long term disabilities in the community as in state hospitals, equally as dear for that care to be provided by public institutions as by contracts with private facilities or practitioners. Current advocates of the policy stress that humane concern for the mentally ill, not presupposed cost advantages, should motivate society in its allocation of per capita treatment expenditures.

Deinstitutionalization never realized its promise or potential because it was largely a political rather than a clinical solution to the problem of chronic mental illness. Research has shown that the lives of patients can be improved by transferring them from large institutional settings to various neighborhood residences, provided that appropriate treatment and service programs are available to them in the community. The question is whether twenty first century politicians will be willing to commit the necessary financial resources to clinics and outpatient facilities their twentieth century counterparts did not.

Deleuze, Gilles (1925–95)

Sam Binkley

Gilles Deleuze was a significant twentieth century philosopher whose critiques of essentialism and rationalism made important

contributions to theories of postmodernity and poststructuralism. The philosophical standpoint he elaborated was one which emphasized the immanent possibilities for change manifested in things themselves. Bodies, objects, ideas, and social formations all possessed potentials for difference and deviation inherent in themselves. This view contradicted that of his chief philosophical interlocutor, Hegel (and all those upholding a Hegelian dialectical tradition), in which change was viewed as the result of external encounters or “negations” imposed from without. Deleuze’s philosophical project followed that of Nietzsche in emphasizing the affirmative property of things, and linking the agent with the act itself, denying traditional philosophical concepts of causality, will, and intention. Indeed, his philosophical oeuvre is defined by interrogations of the philosophical canon ranging from Plato to Nietzsche, Spinoza, Bergson, and Hume for conceptions of the world that emphasized such immanent properties of becoming and change.

These themes were developed and applied more broadly to a range of political and social arenas through books co authored with his longtime writing partner Félix Guattari. Most notably it was through a two part investigation of the contemporary social, cultural, and psychological nexus he termed “capitalism and schizophrenia” that Deleuzian conceptions of immanent difference were thematized and exported to other fields (Deleuze & Guattari 1977, 1987). Here Deleuze developed an identifiable nomenclature and rhetorical style whose influence extended to fields such as sociology, cultural studies, media studies, and throughout the humanities and social sciences more broadly.

Defined by Michel Foucault in the book’s opening pages as an introduction to anti fascism (not the fascism of the political state but the fascism of the mind which we as members of capitalist societies carry within us), *Anti Oedipus* (Deleuze & Guattari 1977) provides a critique of capitalist political economy that weds post Freudian psychoanalysis with Deleuze’s thesis on the generative capacity of things. It offers an overview of desire not as a reactive (as dictated by the law of Oedipal desire) but as an active and productive capacity, capable of affirming new differences and

investing new objects. Deleuze and Guattari discuss capitalism's success in denying desire its creative and affirmative quality through its incorporation into flows and chains of production governed by abstract systems (money), divorced entirely from the contexts and bodies in which they are generated. Against these limitations the book prescribes different flows of desire and production whose pattern escapes the Oedipalizing effects of capital through non linear and schizoid lines of flight: heading off in multiple directions, refusing to remain the same, escaping capture by slipping between dominant categories which threaten to consign desire to specific territories and purposes. *Thousand Plateaus* (Deleuze & Guattari 1987) continues this interrogation, adding the phrase that has become the most widely associated with Deleuze's contribution: the *rhizome*, a root or branch that twists, knots, splits, and grows in unpredictable, non linear directions (like a ginger root, as opposed to the linear structure of a carrot), serving as a metaphor for paths of desire, for modes of production, and movements of populations.

While his turgid and eccentric philosophic prose has drawn criticism from many sociological readers, Deleuzian thought has been influential in several areas, including postmodern social theory, where non linear, non teleological processes are considered as alternatives to modernization narratives of progress, social differentiation, and change (Delanda 1997). They have also been significant in theories of globalization, virtuality and the Internet, and in alternative conceptions of resistance to those provided by traditional Marxism (Hardt & Negri 2000).

democracy

Stephen K. Sanderson

It is only within the past two centuries – and mostly within the past century – that genuinely democratic governments have flourished. What is democracy? Rueschemeyer et al. (1992) identify four main characteristics of the most fully developed democracies:

- Parliamentary or congressional bodies with a power base independent of presidents or prime ministers.
- The regular, free, and fair election of government officials, with the entire adult population having the right to vote.
- Responsibility of other divisions of government to the parliament or legislature.
- Individual rights and freedoms pertaining to the entire population and their general honoring.

It is important to distinguish between *formal* democracies, in which the formal apparatus of democracy exists but democratic principles are usually not upheld in practice, and *substantive* democracies, which have not only the formal machinery of democratic government, but generally consistently implement this machinery. Another important distinction is that between *restricted* democracies, or those in which the right to vote is limited to certain segments of the adult population (such as men, property owners, or whites), and *unrestricted* democracies, or those in which the entire adult population has the right to vote.

Democracy is not an all or none process, but rather a matter of degree. The modern democracies of North America and Western Europe are today unrestricted and substantive democracies, but all started out as restricted and,

to some extent, formal democracies. The earliest modern democracies developed in the most developed societies of Western Europe and the settler colonies that hived off from Great Britain. The US was the first democracy, established in 1776. It was followed in order by Norway (1815), France (1815), Belgium (1831), the UK (1832), Germany (1848), Switzerland (1848), the Netherlands (1849), Denmark (1849), Italy (1861), Sweden (1866), and Japan (1889) (Flora 1983). Democracy has taken much longer to come to the less developed world, much of which is still today under the control of highly autocratic and often brutally repressive regimes. However, a major new wave of democratization swept through many third world countries beginning in the 1980s (Markoff 1996; Schaeffer 1997; Kurzman 1998; Green 1999; Doorenspleet 2000). Most third world democracies, however, are still not full substantive democracies, and it may be several more decades before that is achieved.

It has long been noted that democratic government and economic development are closely linked. In an early study, Lipset (1959) used a small sample of countries and found a strong relationship between a country's level of democratization and its levels of wealth, industrialization, education, and urbanization. Later, Cutright (1963), studying 77 countries, found high positive correlations between an index of democracy and indexes of levels of communication, urbanization, and education, and a high negative correlation between democracy and the percentage of the labor force working in agriculture.

Bollen and Jackman (1985), using a sample of 100 countries, looked at the effects of the level of economic development along with several other independent variables: the degree of ethnolinguistic pluralism, percentage of the population that was Protestant, British colonial experience, and a New Nation effect (independence obtained between 1958 and 1962). Regression results showed that all five independent variables explained 58 percent of the variance in the level of democracy, but that economic development alone explained 46 percent.

Lipset et al. (1993), using a large cross national sample, looked at the effects of several independent variables on the level of

democratization: per capita GNP, British versus French colonization, political mobilization (the annual sum of protests, riots, and strikes), regime coerciveness (the ratio of military expenditure to GNP), and trade dependence (the ratio of total trade to GNP). Results showed that economic development was clearly the best predictor.

Diamond (1992) found that economic development was closely related to democracy, whether measured by per capita GNP or by the World Bank's Human Development Index (an unweighted average of literacy, life expectancy, and per capita GNP). The HDI was a somewhat better predictor. Of 17 countries at the highest level of the HDI, all 17 had governments that Diamond classified as liberal democracies. Of 11 countries at the lowest level of the HDI, all 11 had what Diamond called closed state hegemonic regimes. Diamond also reported the results of earlier regression analyses conducted with Lipset and Seong. These showed that the most powerful predictive variable was the Physical Quality of Life Index, a composite of infant mortality, life expectancy at age 1, and adult literacy.

Why should greater economic development be closely associated with democracy? At least three lines of thinking can be discerned. Marxian scholars (e.g., Szymanski 1978) have argued that democracy has been promoted by rising capitalist classes because it is the form of government most suited to their economic interests. Capitalists want, above all else, freedom of economic action, and democracy is an ideal system for promoting such freedom. The problem with this argument, however, is that the historical evidence shows that capitalists have actually been quite hostile to democracy in the form of mass suffrage because they have feared the consequences of giving the working class the vote (Rueschemeyer et al. 1992). Capitalists have generally favored *parliamentary* government, especially because they or their representatives have constituted the most prominent members of parliaments. But parliamentary government alone is a far cry from true democracy.

A second line of thinking, endorsed by such thinkers as Lipset and Diamond, is a type of modernization theory. Education and literacy promote beliefs in the importance of

democratic norms. An ideology of "secular reformist gradualism," highly favorable to the development of democracy, emerges, largely as the result of higher living standards. As lower social strata become better off and better educated, they are less likely to be receptive to extremist ideologies. Economic development leads to the formation of a sizable middle class, much of which tends to work to moderate political conflict.

A third strand of thought emphasizes the resource balance between political elites and the rest of the population. Bollen (1983) notes that economic development creates a more educated and literate population that can gain access to the mass media of communication, thus allowing for increasing understanding of the political processes of their society. This increased understanding tends to generate greater demands for political representation. By the same token, a workforce that is better educated can become better organized and mobilized. In Bollen's mind the key issue is the general population's acquisition of resources that can be used to pressure political elites to accede to their demands for democracy. Tilly (2000, 2004) has taken a similar view.

In an exceptionally detailed cross national study of democracy using 172 countries and covering the entire period from 1850 to the early 1990s, Vanhanen (1997) based his analysis on the kind of balance of resources argument discussed above. Vanhanen argues that democracy emerges when the large mass of the population acquires resources it can use to force autocratic states to open themselves up to mass suffrage and political rights. Vanhanen identifies six types of resources that contribute to democratization: size of the nonagricultural population, size of the urban population, the degree to which farms are owned by independent families, the literacy rate, the enrollment rate in higher education, and the deconcentration of nonagricultural economic resources. Vanhanen measured all of these variables for most decades between 1850 and the early 1990s, combined them into a comprehensive supervariable called the Index of Power Resources, and then correlated this index with an index of democracy. The average correlation of the Index of Power Resources

with the level of democracy for three different years (1991, 1992, and 1993) was $r = .786$. Correlations for earlier years were not as strong, but were still very high. Vanhanen assumed that the correlation is causal in the sense that the acquisition of power resources preceded and brought about changes in the level of democracy.

Vanhanen stopped with simple correlations, failing to control for any other variables. He also assumed that all of the six subvariables within his Index of Power Resources were of equal significance in producing democracy. Sanderson (2004) reanalyzed Vanhanen's data by looking at his six subcomponents separately. He consistently found that the best predictor of the level of democratization was the literacy rate, with the deconcentration of nonagricultural resources an important secondary predictor. Size of the nonagricultural population and size of the urban population turned out to be essentially unproductive.

These last findings seem to contradict the conclusions of the best comparative historical (nonquantitative) study of democracy ever undertaken, that of Rueschemeyer et al. (1992). They found that the factor most critical to democracy was the level of industrialization and thus the size of the working class, which became an organized political force that struggled to establish democratic institutions, especially the right to vote. Democracy developed earliest and most fully in those societies with the largest working classes and latest and least in those societies with the smallest working classes. In these latter societies the landlord class was still powerful and the peasantry politically weak. Landlords were vehemently opposed to democracy because the key to their economic success was labor repressive agriculture, which democracy would obviously undermine. However, with industrialization, the role of the landlord class in society declined and the role of industrialists and workers increased, thus removing a major barrier to democratization. In the third world today, landlords still play a major economic role in many societies, which is perhaps the main reason that democracy has advanced only little in many of these societies.

Sanderson (2004) suggests that his findings are, in fact, not incompatible with those of

Rueschemeyer et al. (1992). Indeed, they are complementary; it is just that the latter authors have omitted a crucial variable. Industrialization and working class formation were crucial to democracy, Sanderson argues, but workers have to be made politically aware and ready to engage in political action. Literacy – itself largely a product of the development of mass primary education – provided the key. Literate workers could read newspapers and political pamphlets and could communicate with each other about what they read. This seemed to be critical to the working class's struggle for political incorporation.

In the most recent cross national study of democracy, which spanned the entire period between 1800 and 1999, Wejnert (2005) compared the relative roles of internal social and economic development and diffusionary effects coming from other societies. Regression results showed that diffusionary effects, especially the location of a country within a world region packed with democratic countries and the degree of participation of a country in economic and political networks containing largely democratic countries, were much greater than internal developmental forces. However, it is not clear what to make of these findings, since Wejnert's study is one of the first to take diffusionary effects into account and her findings have not yet been replicated. Moreover, her finding that literacy was unrelated to democracy is extremely curious in light of Sanderson's (2004) finding that it was the most important predictor of democratization.

What is clear is that democracy has historically been closely tied to economic development and that it has been steadily expanding on a global scale. Whether democracy is promoted more by a country's internal economic and social development or by its connections to other democratic countries (or some combination of the two), it seems reasonable to predict that democratization will be a continuing, if not continuous, trend.

democracy and organizations

David Courpasson

Still a controversial issue, the idea that the “civilian” world might be becoming more democratic is juxtaposed with an opposite trend with respect to the organizational world. As Rousseau and Rivero, among others, put it: “Although we are increasingly likely to be governed by democratic political systems, our workplaces are seldom democratic” (2003: 116). The increasingly dominant corporate power (Bernstein 2000), the persistence and refurbishment of hierarchy and bureaucratic systems (Courpasson & Reed 2004), the endless reproduction of corporate elite (Ocasio 1994; Courpasson 2004; Davis et al. 2003) are all trends highlighting the fact that the post bureaucratic dream of decentralized power and of people’s participation in the political decisions within organizations might be gone.

The supposedly post September 11 shift in the global power balance does not explain by itself the apparently legitimate use of strong central powers in the political structures of most western countries. In other words, the emergence of a “culture” of threat and terror is not exclusively the product of late modern patterns of civilization or of tragic and unprecedented events. Likewise, in the business world, the concentration of power is an old phenomenon (see, for instance, in Ocasio 1994) which is not exclusively related to the threatening and hectic movements of markets and the dynamics of capitalism. The wavering balance between democratic and oligarchic

tendencies is one of the most ancient political features of societies.

Addressing the complex issue of democracy in the context of organizations requires us to go beyond these partial accounts in order to make the connection between organizational models and the functioning of contemporary democratic societies. There are important questions relating to the elective affinities between the meaning of democracy and its diverse facets, and government as a complex and intermingled set of values and mechanisms.

THE MEANING AND MEANINGS OF DEMOCRACY

There are scores of available and relatively acceptable definitions of the concept of democracy. So numerous are they that the concept itself is in danger of becoming one of the most popular “buzzwords” of organization studies. As a means of clarifying this conceptual “hod gepodge,” we suggest adopting a twofold approach to understanding democracy: a political version and a competitive version.

Usually, democracy is defined as both a form of rule (the sovereignty of the people) and a symbolic framework within which this rule is exercised (such as individual liberty) (Mouffe 2000). This pertains to the well known duality within studies on democracy: the *liberal tradition*, according to which what counts is the rule of law and the respect of individual freedom encompassed in democratic regimes, and the *democratic tradition*, which privileges the notion of equality and the identity between governors and the governed. These traditions, when confronted, unveil the unassailable tension between liberty and equality. Dahl reminds us that for Tocqueville, the major phenomenon threatening democracy is that equality will crush liberty, that political equality is likely to destroy liberty, “because equality facilitates majority despotism, it threatens liberty” (1985: 9).

Therefore, the *political* definition of democracy leads to envisaging democratic politics not as the search for an unreachable consensus, but as an “agonistic confrontation” (Mouffe 2000: 9), necessitating the creation of a pluralistic body of actors. According to Mouffe, the main question of democratic politics “becomes then

not how to eliminate power, but how to constitute forms of power which are compatible with democratic values" (2000: 22). In short, the political perspective on democracy argues that democracy is not the absence of domination and the mere diffusion of social powers in the (organizational) body, but the genuine attempt to establish institutions which can limit and eventually contest domination. Dahl (1971) proposes to analyze the concrete forms of democracy through the notion of "polyarchy." Polyarchy is an approximation of democracy, where a permanent activity of institutional design and "engineering" (Poggi 1972) helps contestation to take roots within the social body.

The political perspective of democracy also implies that equality is not automatically taken for granted. It cannot exist without inequality, without exclusion. As Mouffe puts it, democratic equality "requires the political moment of discrimination between 'us' and 'them'" (2000: 44). Obviously, this view of democracy rejects the idea of "deliberative democracy" which can be found extensively in the organizational literature, especially under the auspices of the "managerial revolution" or of "post bureaucratic" management. The underlying argument of this latter perspective is that politics is identified with the exchange of arguments "among reasonable persons guided by the principle of impartiality" (Mouffe 2000: 86), which obliterates the possibility of legitimate struggles and debates between "adversaries."

For the *competitive* approach to democracy, a key characteristic of democratic regimes is the existence of a permissible opposition. This regards public contestation and political contestation (Dahl 1971: 4) as natural features of the system. Democracy is therefore a competitive regime. Ultimately, Dahl and the whole Tocquevillean tradition of which he is a part conceptualize democracy as being constituted by at least two dimensions: public contestation and the right to participate, i.e. the "inclusiveness" of the political regime. In that perspective, Dahl (1971: 8) defines polyarchy as a "highly inclusive" and an "extensively open to public contestation" regime, the closest to the concrete expressions of democracy.

The contribution of the competitive explanation is to clearly separate the generation of democratic regimes at the national level with the

circumstances of the organizational level. As Dahl (1971: 13) puts it, "while polyarchies may be competitive at the national level, a great many of the subnational organizations, particularly private associations, are hegemonic or oligarchic."

Wilde (1978) completes this definition by adding a more "procedural" nuance to the competitive aspect of bureaucracies. Democracies are, according to him, largely defined by "those rules that allow (though they do not necessarily bring about) genuine competition for authoritative political roles. No effective political office should be excluded from such competition, nor should opposition be suppressed by force" (p. 29). The corollary of this view is that organizations could be considered as democracies insofar as they develop "infra democratic" systems (p. 33), i.e., structural ingredients (comprising the distribution of power, specific political institutions, and social structure) which render democracy practically possible. But they are also "experiential" systems, characterized by the commitment of people to these very rules of competition and consent. We are clearly close to the seminal view of Montesquieu, when in *The Spirit of the Laws* he defines a political regime through the expectations and perceptions of individuals toward the governors, and through the degree to which power is concentrated.

Behind the scenes of the competitive framework lurks the notion of equality. This derives from Tocqueville's analyses on the tendency of equality to contribute to the degenerative process of democracy: "In democracies, not only are servants equal among themselves; one can say that they are in a way the equals of their masters" (2000: 549). This is the result of the credible potential for anybody (including the servant) to become a master himself. Democracy as competition is therefore connected to a vision of the temporary character of social hierarchies. But simultaneously, it requires from governors to invest constantly in the social fabric of their legitimation. As Tocqueville puts it, "servants are not sure that they should not be the masters and they are disposed to consider whoever commands them as the unjust usurper of their right" (p. 553).

Tocqueville's concerns go to the heart of the debate between bureaucratic and post bureaucratic models. The design of the latter model

aims explicitly to shatter the bureaucratic image of the unassailable bureaucratic hierarchy (Heckscher 1994). But once again, Tocqueville's reminder is timely: this type of hierarchical relationship, generating rivalries and endless struggles, necessitates the design of a constraining administration stipulating to each "what he is, what he can do, or what he should do" (Tocqueville 2000: 553). A rejuvenated bureaucracy, freshly legitimized by the requirement to "close the debates," arises from the very functioning and core values of democracy.

At the same time, both the political and competitive definitions of democracy offer another alternative. By saying that, we put forward the idea that organizations could be theorized as fundamentally antagonistic places, where a plurality of values and interests is never solved through a rational consensus (a notion dear to liberal democratic theories of management; see, e.g., Osborne & Gaebler 1992), nor through a pure domination or hegemony. It might be thought of as a complex and hybrid oligarchy, permanently producing acts of power and constituting itself as a political community through these very acts of power. A complex oligarchy is a political order of organizations based on certain forms of precarious and contestable dominations, always vulnerable and striving relentlessly to solidify themselves. It is precisely because of this precariousness that organizations can be seen partly as (very imperfect) democracies, "competitive oligarchies" to take Dahl's expression.

THE DEMOCRATIC PROBLEM: OLIGARCHIC DRIFT AND THE PRODUCTION OF INTERMEDIATE BODIES

At least since Tocqueville, we know democracy faces two major problems. First, the development of despotic/oligarchic trends spawned by the "circular" nature of democracy. Second, the consecutive necessity for democratic regimes to develop an institutional design likely to keep government from transmogrifying into despotism.

No principle, no procedural requirements, nor "absolute rights can prevent tyranny from emerging" (Dahl 1985: 18). In other words, any

governing body, majority or minority, may use democratic processes to destroy democracy itself. Democratic regimes are prone to self destruction (Linz & Stepan 1978). As Poggi (1972: 49) puts it, despotism is a degeneration of the inertial tendencies of democracy and not an intentional and implicit goal of a governing elite. To Tocqueville, oligarchy reproduces itself through the processes of democratization, what Poggi calls the circularity of democracy. As individual concerns are increasingly "privatized," the leaders must take powerful decisions in order to move away from despotic tendencies. In other words, oligarchs sustain their power by developing democratic principles and peculiar intermediate groups of political actors. But it is the central power which determines and delineates the type of groups, their prerogative and who, within these groups, is likely to reach the "inner circles" (Useem 1984).

According to Tocqueville, the very dynamics of equality might turn democracy into a new species of tyranny, a "breeding ground for mass despotism" (in Dahl 1985: 31). The Tocquevillian perspective outlines three major dangers to which democracies are prone: the atomization of societies into isolated individuals; the emergence of authoritarian regimes; and the support by people of these centralized forms of administration. Democratic collapse arises from the sometimes amazingly overwhelming public support toward authoritarian regimes. Moreover, the ascent of dictatorial forms of government stems often more from the persistence of inequalities than from an excess of equality, fragmenting the citizenry into hostile camps and enhancing confidence for a dictatorship (Dahl 1985).

Mild despotism emerges therefore from two parallel mechanisms. First, the illusions generated by the consensual vision of deliberative governments. In other words, consensus might be the very expression of hegemony and "the crystallization of [asymmetric] power relations" (Mouffe 2000: 49). The reconciliatory move observable in the post bureaucratic school of thought (Heckscher 1994), by insisting on the necessary initialization of debates, on the importance of speech acts (Benhabib 1996: 9), on symmetry, equality, and consensus, obliterates the fact that democratic politics in organizations is mostly about the negotiation of

paradoxes and the articulation of precarious solutions to these paradoxes (Mouffe 1999). Consensus is necessary but it must be accompanied by dissent, otherwise hegemonic regimes are likely to appear. This possible drift is also due to the fact that the very competitive essence of democracy implies a high degree of insecurity for those in governing positions. As Lipset et al. (1956: 10) put it, "the more truly democratic the governing system, the greater the insecurity." In other words, what Poggi (1972) terms "status insecurity" supposes that organizations need to be combined with oligarchic modes of selection. Oligarchic principles provide arguments to justify discrepancies between individuals, the "us and them" principle in Mouffe's terms. For Tocqueville, any mass of equals and atomized individuals needs an oligarchy to avoid being permanently threatened by anarchy. Under a tutelary oligarchy, people feel the obligation to cooperate, at least because they share similar concerns, fears, and weaknesses. Dresner (1968: 6–7) adds his voice by arguing that democracies should be defined as limited egalitarian ideologies. This presupposes certain inequalities and authority–obedience relationships as "necessary inequalities within general equality." Dresner, using the Tocquevillean framework, insists upon the influence of the emergence of a "politically disinterested individualism" arising from a democratic appeal to "material interests"; as a consequence, the danger of drifting toward despotic regimes comes not mostly from the "tyranny of the majority" but from the "apathy of the masses" (p. 42).

In sum, any concrete democratic structure must define whether the central government should be arbitrary or moderate, i.e., does it "oppose or allow the existence of nongovernmental centers of power" (Poggi 1972: 41). This leads us to our second point: the production of intermediate political bodies.

As Rousseau and Rivero (2003: 119) suggest, it might seem easier to promote democratic practices in organizations than in broader social bodies; consensus regarding tasks and purposes, socialization capacities, educational systems, and the focus on work provide cultural "cornerstones" in most organizations, whatever their size. Through recent corporate post-bureaucratic upheavals, new forces sustaining

democratic values and practices have appeared. These include the decentralization of organizing and information, the transformation of certain bases of power distribution, the broadening of the array of stakeholders, and the concomitant awareness of broader interdependencies and mutual impact of acts of power in "network organizations." But democracy has also to struggle with the persistence of hierarchy. The egalitarian aspects of democracy are hampered by the overwhelming competition among individuals, and with the contradictory effects of mobility on the organizational cohesiveness necessary to collective decision making and deliberative systems (Dahl 1985; Rousseau & Rivero 2003).

From these contradictory forces arises the absolute necessity for organizations to invent certain forms of "institutional engineering" (Poggi 1972) likely to tip the balance in the democratic direction. The idea is to counter the effects of the emergence of a "consumerist view of politics" (p. 45), which is the major threat to democracy as it facilitates the political monopoly of a specific oligarchy. Institutional engineering implies the creation of intermediate groups that prevent the displacement of social ties by more transitory relationships. For Tocqueville, intermediate groupings aim to create local powers that act as a counterbalance to the political concentration at the top of organizations and societies. They also aim to intensify individual commitments and enhance the construction of strong, efficient, and reliable internal elites. This institutional differentiation in the political system rests upon a "constitutional design" creating a distinction between a relatively small set of stable laws and an extensive set of peripheral laws subject to contestation, modification, or abolition. What rules are to become steady is a crucial issue for democracies to perpetuate. It implies that going further into the distinction between governmental and administrative issues, the former will affect the interests of the organization as a whole, the latter will affect primarily locally individuals.

The interest for organizations in installing local intermediate powers is especially important in times of economic deprivation which affect large numbers of people. In the context of societies, we know that under difficult conditions, individuals can be subject to

the seductive appeals of politically cynical leaders, without the will to take a hand in governmental affairs (Poggi 1972). For bitterness, feelings of insecurity or injustice, they could renounce any ambition and commitment, or withdraw exclusively into the private sphere, which could shatter social ties and make the social body collapse. Intermediate bodies are also a means for leaders to shed light on the benefits and interests of the collective body in times when individuals could prefer to neglect shared values and common political and cultural frames to step into the chilling dynamics of despotism. In the context of organizations, the political indifference or apathy, and the resulting focus on self fulfillment that one can observe (which is largely a result of the threatening and competitive "spirit" of contemporary liberal organizations; see Courpasson 2005), could lead to this type of dynamic: brushing off the ethical side of leaders' legitimacies, people could prefer to depend politically on strong and efficient centers of power, distributing the fruits of economic success, whatever the means used. The possibility of a political professionalization of leadership, foreshadowed a long time ago by Michels, might therefore doom the political aspirations of the forthcoming generation of workers and executives. Tocqueville's prophesy would then prove to be right. The urgent necessity of establishing strong intermediate (professional) powers could prevent organizations from becoming slowly and unobtrusively apolitical entities where the democratic idea would be restricted to the upbeat discourses of utopian thinkers and scholars.

CORPORATE ELITE PRODUCTION AND THE DYNAMICS OF DEMOCRACY

We have adopted a political framework to make sense of the dynamics of organizational regimes: the structures of power, the organization of coercion, the formation of coalitions and the production of political elites provide, in this perspective, the most relevant guides to the explanation of these dynamics (Tilly 1973: 447).

More particularly, understanding the emergence and production of a political regime supposes to focus on "the incumbents and their actions, their formulation of the agenda for the regime, their way of defining problems and

their capacity to solve them, the ability of the pro regime forces to maintain sufficient cohesion to govern" (Linz & Stepan 1978: 40). We suggest now that this has important implications for understanding the stability of political structures of organizations. Such factors are likely to inform both the definitions of democracy and the accounts regarding the evolution of democratic regimes toward oligarchy.

As Lipset et al. (1956) remind us, the insecurity of leadership status is one of the corner stones of democracies. However, a broad range of literature suggests firmly that contemporary corporate elites are perpetuating themselves relatively smoothly. This poses an interesting counterfactual for the supposed "circulation of power" or "circulation of control" put forward by some authors (Ocasio 1994; Ocasio & Kim 1999).

Two major phenomena might help account for the apparently seamless reproduction of corporate elites. First, the social fabric of a "class wide" principle (Useem 1984), according to which a certain number of mechanisms, especially interlocking directorates (Mizruchi 1996), facilitate the production of both cohesiveness among elite members and educational ingredients helping the selection and the socialization of coopted individuals, according to the well known "small world" phenomenon (Davis et al. 2003). In that view, a corporate elite can be represented as a powerful network of powerful individuals sustaining strategies of "power entrenchment" through the very management of the interlocks and friendship ties (Ingram & Roberts 2000). Second, the permanence of an "upper class" principle (Useem 1984), according to which the major ingredient of elite stability is its embeddedness in a specific social milieu of established wealthy families, "sharing a distinct culture, occupying a common social status, and unified through intermarriage and common experience in exclusive settings" (p. 13). At the corporate level, the power of social closeness and similarity has been pinpointed as a strong determinant of CEO succession and appointment (Westphal & Zajac 1995). Other studies have suggested that intra organizational mechanisms were also likely to produce endogenously an elite body through selective education and socializing mechanisms, as well as through the production of specific internal professions (Courpasson 2004).

If we follow Allen (1974), we could easily argue that the conjunction of these external and internal mechanisms is downright anti democratic, as it generates an “increasingly pervasive and integrated structure of elite cooptation among major corporations” (p. 404), restraining per se the quality of the competition and the principle of elite insecurity which has been put forward as the pillar of democratic regimes.

We have argued that the relationship between democracy and organizations is extremely ambivalent. A certain number of contemporary forces are clearly promoting democracy in the workplace. Others are clearly hampering any possibility of implementing true participation, contestation, and inclusiveness within organizations. When related to democracy, organizations appear more and more as regimes, i.e., “political forms ordering symbolically and structurally a set of social relations” (Mouffe 2000), organizing human coexistence and managing inequality between people and their relations of subordination. In organizations, “the stability of any democracy depends not on imposing a single unitary loyalty and viewpoint but on maintaining conflicting loyalties and viewpoints in a state of tension” (Crossman 1956). According to this general political definition of organizations, three major lines of inquiry may be suggested to better understand the relationship between democracy and the organizational world.

First, the study of the paradoxical roles played by contemporary oligarchies in the shaping of future organizations should be developed. Under a theory of political pluralism, it becomes urgent to understand that, in contemporary organizations, democracy and oligarchy are not necessarily opposite models. Oligarchy can become the very ferment of the production of a fragmentation of the complex social body. This can enable people not only to be related to the larger organization, but also to be affiliated with or loyal to subgroups within the organization (Lipset et al. 1956: 15), and therefore, to keep a close hand on their own fates and decisions. Contemporary processes such as the (re)emergence of professions and collegial forms in organizations (Lazega 2000) suggest undoubtedly that organizations could be politically shaped in a “polycratic” fashion, to take Weber’s expression.

Second the study of democracy in/for organizations cannot neglect the determination of political regimes by the specific profiles of business leaders. For instance, does the development of global corporations serve to develop a “global corporate elite”? In contrast, do the stiff competition and the uncertainties deriving from the growing multiplicity of stakeholders necessitate the generation of a more “parochial elite” deeply committed to the interests of individual companies but not fulfilling the political dimensions of the “managerial class”? At any rate, studying leadership as a profession, as some seminal studies have shown (Selznick 1957), more than as a practice could help scholars to better understand the very reasons why, maybe, key stakeholders do not consider developing democracy is in their interest.

Third, it is obviously crucial for organizational scholars to keep on studying the dynamics of authority within organizations, especially to understand why, while most people consider organizations have too much power over their members, very few think the latter should exercise more power in the workplace (Rousseau & Rivero 2003: 130). In other words, is democracy “thin” or “weak” because of a shared vision of legitimate authority within organizations? If yes, business leaders would have achieved a political tour de force. If not, we should give more attention to why the apparent zone of indifference (Barnard 1938) might be larger than ever in the contemporary workplace.

Other issues are of great importance, such as the link between the rise of the knowledge economy and the increasingly differential treatment of knowledge workers. The greater individual employability of these workers requires a rethinking of assumptions of the latent power asymmetry between firms and employees, and to what extent this dynamic has the capacity to enhance democratic practices or whether it forecloses any possibility of the development of a durable commitment of workers in the political affairs of the organizations for whom they work and in which they live.

CONCLUSION

We have argued that the current political dynamics of organizations and of surrounding

societies bear the seeds of mild despotic regimes, as Tocqueville predicted two centuries ago. At the same time, we have suggested that the incumbent economic leaders cannot brush aside the effects of recent corporate scandals in the engineering of the power structures of organizations. Moreover, recent investigations suggest that some deeply rooted patterns of corporate elite production could have been shattered for at least two decades (Cappelli & Hamori 2004).

Without envisaging that democratic organizations could miraculously emerge out of the shadows of corporate scandals, we think the quest for accountability and responsibility could be one of the political touchstones of organizations of the twenty first century. The constitution of a notion of *political performance* (Eckstein 1969) applied to organizations could help to find a new equilibrium for the excessive dominance of economic variables in the contemporary notion of survival. A politically efficient government is not necessarily the most democratic, but that which is capable of sharing out what is produced by a collective endeavor.

Organization studies on democracy are influenced by the post war optimism about the durability of democracies, once established. They are mostly grappling with the eternal question of why organizations are not democratic. We think organizational scholars should leave this question to jump to two complementary questions: (1) How far is democracy necessary to the functioning of organizations? (2) What are the contemporary concrete hybrids which are shaping the political structures of tomorrow's organizations? It is by understanding the complexity and fragility of these political hybrids that organizational scholars will be able to help future business elites to avoid some mistakes of the past.

demographic data: censuses, registers, surveys

Mark Mather

Population censuses, registers, and surveys are the primary sources of demographic data, including information about the size, composition, and

characteristics of a population or population subgroups. A census is an enumeration of all households in a well defined territory at a given point in time. Population registers are systems of continuous registration, maintained by certain countries, to keep demographic records of individuals. Surveys are used to collect detailed data on a particular subject from a sample or subset of the population. All three sources of data – censuses, registers, and surveys – are often used to monitor changes in population size and composition.

CENSUSES

For hundreds of years, censuses have been used to collect demographic, social, and economic information about individuals and households. The first modern census was conducted in Quebec in 1666, but there are much earlier references to census taking in the Bible and in early civilizations in China, Egypt, India, and Rome. The first US census was conducted in 1790, followed by the United Kingdom and France in 1801.

After World War II, the United Nations encouraged all countries to conduct national censuses, and today, more than 90 percent of the world's population is covered by a census enumeration. Recent censuses conducted in China and India – arguably the most ambitious censuses ever taken – together counted more than 2 billion people. The rich data from population censuses are used not only to monitor demographic changes within countries, but also to keep track of global changes in the size and characteristics of the world's population. In the United States, data from the decennial census are used to apportion Congressional seats in the US House of Representatives, draw new boundaries for legislative districts, and allocate billions of dollars in federal funds to states and local areas. Census data are also widely used by researchers, business groups, and local planners, who use them to monitor population trends, the demand for goods and services, and social and economic inequalities between groups.

Conducting a high quality, nationwide census is a complex and expensive process – depending on the size, geographical distribution, and level of cooperation of the population – and often

requires years of planning. Census administrators need to develop an address list, prepare detailed maps, prepare for advertising or outreach efforts, develop questionnaires (often in multiple languages), conduct tests of questionnaire items, and recruit and train census enumerators. Once the demographic data have been collected, the census staff need to analyze the data and prepare data products and reports for public use.

Census data can be collected through mail out questionnaires, by telephone, or through personal interviews. In the US census, which is conducted every 10 years, a questionnaire is mailed to every household in the United States. Census enumerators follow up with households that do not return their forms by telephone or with personal interviews. In the United States and in many other countries, census response rates have declined in recent decades because of growing concerns about privacy and confidentiality. The Netherlands has not conducted a national census since 1971 because of growing concerns among Dutch citizens about privacy and rights violations. Today, the Netherlands relies on a combination of surveys and administrative registers (see "Registers," below) to collect demographic data.

No census is wholly accurate. One source of error relates to the difficulty in counting every household and resident in a population. Residents who fear the government or outsiders, speak non native languages, or live in mobile or complex households are the most likely to be missed in a census. In the United States, past censuses have also overlooked a disproportionate share of children and minorities, resulting in an undercount of those groups. In developing countries, census counts tend to be less accurate for populations with low levels of literacy and poor transportation networks. Other errors in census data can result from respondents' inability or unwillingness to provide correct information or errors made in data collection or processing. In a few countries, census figures have been manipulated to bolster the numbers of a specific ethnic group or region.

In order to test the accuracy of census results, the US Census Bureau conducted special post enumeration surveys (see "Surveys," below) after the 1990 and 2000 Censuses. Census population counts were compared with

independent estimates from these surveys for different geographical areas and for subgroups of the population. Census counts were also compared with 2000 population estimates derived through analyses of birth, death, and migration records. These comparisons have been useful in evaluating census undercounts, particularly for minority groups.

Census questionnaires are typically completed by the household head or "reference" person and may include questions about age, gender, marital status, place of birth, relationship, educational level, occupation, religion, race/ethnicity, or other demographic characteristics. Information is collected for each member of the household. There are two methods used to conduct a census: in a "de facto" enumeration, people are counted at their actual place of residence at the time the census is conducted. In a "de jure" enumeration, residents are assigned to their "usual place of residence." The United Kingdom counts people using the de facto method, while Canada, Mexico, and the United States use a de jure approach.

REGISTERS

Countries with national population registers keep records of individuals from the time of birth (or immigration) to death (or emigration) and update the record over time with life events. In general, population registers are used to record four basic demographic events: births, deaths, marriages, and migration. However, registers vary in the type of demographic data that are collected and how those data are used. The earliest registration systems were maintained by parishes and date back to the 1300s. National population registers were first established in Europe during the fourteenth and fifteenth centuries. Today, the most complete population registers can be found in Denmark, Finland, Japan, the Netherlands, Norway, and Sweden. What distinguishes these countries from most others is that they collect and store information about demographic events in a central government office, instead of using separate systems of birth, death, and marriage registration.

Bryan (2004) notes that these "universal" registers are less common than "partial"

registers that are set up for specific administrative purposes. For example, several US agencies, including the Social Security Administration, the Department of Homeland Security, and the Internal Revenue Service, maintain large administrative data files that can be considered partial registers.

Population registers are most often used for government administrative purposes, but can also be used to monitor changes in a country's population size and composition, keep track of trends in fertility and mortality, or select random samples of individuals from the population. Data from pre industrial registers in Europe have been used for historical demographic research on family structure, fertility, and mortality. Population registers can also be used as a substitute to conducting a national census. The main advantage of a national register is timeliness; demographic events are recorded on a continuous basis, rather than once every 5 or 10 years.

Population registers are expensive to maintain, however, and require a high level of cooperation in order to produce high quality data. Universal registers are probably not feasible in a country like the United States, where there is growing public concern about invasion of privacy and protecting confidentiality.

VITAL REGISTRATION SYSTEMS

Like population registers, vital registration systems collect data on a continuous basis, but are generally limited to information about births, deaths, marriages, and divorces. Data on vital events are drawn from birth certificates and other forms that are completed at the time the events occur. Most developed countries have fairly complete vital registration systems, while developing countries are more likely to rely on surveys to collect the information. Along with basic statistics about the number of vital events that occur in a given month or year, vital registration systems often collect more detailed information on age, racial and ethnic composition, marital status, and other characteristics.

In the United States, the National Center for Health Statistics (NCHS) compiles and disseminates information about vital events based on data received from state health departments.

NCHS data are often used in combination with census or survey data to produce demographic rates and ratios (e.g., fertility and mortality rates) and to monitor national, state, and local demographic trends.

SURVEYS

Unlike censuses and registers, which enumerate the entire population, a survey is conducted for a sample or subset of the population. Surveys are generally used to collect detailed information about a specific topic, such as labor force participation, health, economic status, religious affiliation, or life course events. Surveys can also be used as a primary or supplemental source of demographic data in countries without a regular, high quality national census, population register, or vital registration system. While most census data are collected by the government, surveys are collected by a variety of governmental and private organizations.

The quality of survey data is dependent on many of the same factors that affect census data quality – response rates, respondents' knowledge and level of cooperation, and errors made in data collection or processing – but survey data quality is also linked to the size and design of the sample. Surveys are often administered using a “probability” or random sample of the population, so that findings can be generalized to the population as a whole. Data based on a probability sample are subject to “sampling error,” which indicates the extent to which sample estimates might differ from actual population characteristics.

Modern surveys were first introduced in the Gallup Poll in the 1930s, and were focused on measuring public opinion. The US Current Population Survey (CPS) dates back to the mid 1940s and was the first survey to collect detailed social, demographic, and economic information about the US population. In the 1950s and 1960s many countries conducted “knowledge, attitudes, and practice” (KAP) surveys to measure contraceptive use. The World Fertility Survey (WFS) revolutionized demographic analysis during the 1970s and 1980s with detailed surveys of women's fertility and contraceptive use in over 60 countries.

Today, the Demographic and Health Survey (DHS), modeled after the WFS, asks detailed questions about fertility, family planning, infant mortality, and maternal and child health.

Surveys are generally divided into two types: cross sectional and longitudinal. Cross sectional surveys, like the CPS and DHS surveys, collect information from a cross section of the population at a given point in time. Cross sectional surveys provide a snapshot of the population and are best for descriptive analyses, while longitudinal surveys ask questions of people at two points in time and are more suitable for measuring causal relationships between variables.

Worldwide, one of the largest surveys is the US decennial census "long form." While the census "short form" is mailed to every household in the United States, the long form questionnaire is mailed to approximately one out of every six households – about 5 million households nationwide. The long form includes detailed questions about social and economic characteristics of the population, while the census short form includes only a subset of questions on age, gender, race, ethnicity, and household tenure.

The United States is conducting a new survey called the American Community Survey (ACS), designed to replace the census long form in 2010. Instead of having to wait 10 years for long form data, the ACS will provide demographic estimates for the American population each year. The ACS is the first US survey to provide continuous data on social, economic, and demographic characteristics for states and local areas.

demographic techniques: decomposition and standardization

Prithwis Das Gupta

Demographers are often interested in comparing rates (e.g., birth rates, mortality rates) in populations cross nationally and/or over time. Interpreting difference between rates requires an understanding of the various factors that comprise that rate. Crude birth rates, for example, depend not just on the fertility of women of childbearing age, but also the proportion of the population that consists of such women. In such cases, in which the overall rate of a phenomenon for a population depends on a number of factors, a detailed comparison of two such rates from two different populations can be made in two distinctly different but closely related ways. One way is to see how the overall rates would change if one of the factors varied as it did in the two populations, while the other factors were kept at the same levels. The rates obtained in this way are called the standardized rates with respect to the unchanged factors, and the process is called *standardization*. The other way of comparing the two overall rates is to break the difference between these two rates into additive components constituting

the effects of the factors involved. The effects of the factors obtained in this way are called the decomposed effects and the process is called *decomposition*. These two processes of standardization and decomposition are closely linked because, if they are developed correctly, the difference between the two standardized rates from the two populations corresponding to the only factor that has changed should be equal to the effect of the same factor in the decomposition process. Authors who have contributed to this subject include Kitagawa (1955), Cho and Retherford (1973), Das Gupta (1978, 1991, 1993), and Kim and Strobino (1984)

AN EXAMPLE: THE RATE AS THE PRODUCT OF TWO FACTORS

This example illustrates the use of standardization and decomposition by examining the respective roles that two factors play in constituting a rate. The Crude Birth Rate (CBR) is defined as the number of live births per 1,000 members of the population. In 1981, Austria had a CBR of 12.512 and Chile had a CBR of 32.845. The difference between the two rates is a substantial 20.333.

However, the CBR can also be calculated by multiplying the General Fertility Rate (GFR: the number of births per 1,000 women aged 15–49), which is represented by α in this example, by the proportion of women aged 15–49 in the total population, represented by β , so that:

$$\text{CBR} = \alpha\beta.$$

In 1981, Austria had a GFR (α) of 51.767 and the proportion of women aged 15–49 in the population (β) was .24170. For Chile, the numbers were $\alpha = 84.905$ and $\beta = .38684$.

The CBRs for Austria and Chile can be standardized on the β factor (i.e., the proportion of the population that is made up of women aged 15–49). This is done by multiplying the average of the two countries' β s by the respective α . The β standardized rates for Austria and Chile are:

$$\begin{aligned} \beta \text{ standardized CBR (Austria)} \\ &= .5 * (\beta(\text{Chile}) + \beta(\text{Austria})) * \alpha(\text{Austria}) \\ &= .5 * (.38684 + .24170) * 51.767 \\ &= 16.269 \end{aligned}$$

$$\begin{aligned} \beta \text{ standardized CBR (Chile)} \\ &= .5 * (\beta(\text{Chile}) + \beta(\text{Austria})) * \alpha(\text{Chile}) \\ &= .5 * (.38684 + .24170) * 84.905 \\ &= 26.684 \end{aligned}$$

The α effect – the amount of the difference between CBRs that is attributable to differences in GFRs – is the difference between the two β standardized CBRs: $26.684 - 16.269 = 10.415$.

Similarly, the α standardized rates for Austria and Chile are, respectively,

$$\begin{aligned} \alpha \text{ standardized CBR (Austria)} \\ &= .5 * (\alpha(\text{Chile}) + \alpha(\text{Austria})) * \beta(\text{Austria}) \\ &= 16.517 \\ \alpha \text{ standardized CBR (Chile)} \\ &= .5 * (\alpha(\text{Chile}) + \alpha(\text{Austria})) * \beta(\text{Chile}) \\ &= 26.435 \end{aligned}$$

$$\text{The } \beta \text{ effect} = 26.435 - 16.517 = 9.918$$

The α effect (10.415) is 51.2 percent of the total difference in CBRs (20.333), and the β effect (9.918) is 48.8 percent of the total. These standardized rates demonstrate that 51.2 percent of the difference between the CBRs of Austria and Chile for 1981 can be attributed to the difference in their general fertility rates and the remaining 48.8 percent can be attributed to the difference in their proportions of women aged 15–49 in the total population. Although Austria and Chile had quite different crude birth rates in 1981, standardizing the rates shows that almost half of this difference is due to the different age structures in the two countries.

This technique can similarly be extended to the *product* of three or more factors (Das Gupta 1991, 1993).

OTHER FORMS OF RATES

Standardization and decomposition can also be used to analyze rates that are *functions of two factors*. For example, the General Fertility Rate (GFR) per woman aged 15–44 can be thought of as a function of two factors, viz., the number of births per married woman aged 15–44 (α) and the ratio of single to married women in the age group 15–44 (β). In this case, the GFR can

be written not as a simple multiplication of two factors, but as a function

$$\text{GFR} = \alpha / (1 + \beta)$$

of the two factors. Still, the technique is similar to that used for standardized rates that are the product of two factors; for example, β standardized GFR is computed by averaging two GFRs using the same α and different β s. This technique can be extended to functions of more than two factors (Das Gupta 1991, 1993).

In many situations, a factor may be represented by several numbers. For example, in a crude birth rate, seven age specific fertility rates together may be considered one factor (α) and seven numbers of women in the age groups as proportions of the total population the other factor (β). Such factors may be called *vector factors* (as opposed to scalar factors). Standardization and decomposition techniques can be applied to vector factors. For example, β standardized crude birth rate is computed by the sum of the products of all the age specific fertility rates and the average proportions of the population in that age range for the two populations.

Most of the papers on standardization and decomposition published so far perform standardization and decomposition techniques on *cross classified data* involving one or more factors. Unlike the situations in the preceding examples, the decomposition in this case involves the effect of the differences in the cell specific rates, called the rate effect, in addition to the effects of the factors. This might be done to compare subgroups of the population. For example, standardizing the age structure of two groups of women – those with one child and those with four or more – allows a more meaningful comparison of expressed future fertility preferences. When this is done as a one factor cross classified case with a single factor effect and rate effect, it is very similar to the case of two vector factors. However, the treatment of cross classified data with two or more factors is very different, and is discussed in Das Gupta (1991, 1993).

CONCLUSION

The four broad categories of decomposition – product of two or more factors, function of two

or more factors, function of two or more vector factors, and rates from cross classified data – should cover virtually all cases of decomposition of the difference between two rates for any number of factors. In the absence of general methods of decomposition to be used under various circumstances, social scientists have devised in the past their own ad hoc methods to handle their respective problems. Although their approaches have produced meaningful results, sometimes they have been less than satisfactory in terms of mathematical rigor and elegance.

The problem of decomposition is different from the problem of regression analysis. In the decomposition problem with cross classified data, the rate effect may not always decrease (it may even increase) with the addition of a new factor, whereas in the regression analysis the addition of each independent variable to the equation increasingly explains the variation in the dependent variable. For example, it is very likely that, in a regression analysis, poverty status would be explained significantly by race, but that the difference in the race composition in two years would not be an important factor in explaining the difference in the poverty rates in those years.

The decomposition problem can also be handled using statistical modeling approaches such as log linear analysis and the purging method involving errors (Clogg & Eliason 1988; Liao 1989) instead of the above mathematical approaches of solving unknowns from algebraic equations. The modeling approach is handicapped by the fact that it is often too complicated to be of any practical use even for data involving only two factors. Also, this approach leads to several widely different sets of results depending on the type of purging used and it is not clear how to justify choosing one set over all others.

Unlike the statistical modeling approach, the method presented decomposes the difference between two rates into additive main effects and does not involve any interaction effects. This elegance is achieved not by ignoring the parts in the total difference that other models might label interactions, but by fully accounting for the total difference in terms of main effects, and thereby distributing the so called interactions among the main effects. This

distribution does not change the conclusions about the relative importance of the factors, it only simplifies the picture.

The effects of factors do not necessarily imply any causal relationships. They simply indicate the nature of the association of the factors with the phenomenon being measured. There might be some hidden forces behind the factors that are actually responsible for the numbers we allocate to different factors as effects, but identifying those forces is beyond the scope of the decomposition analysis.

When there are more than two populations to be compared, the decompositions can be carried out more than once by taking two populations at a time. However, this procedure may lead to internally inconsistent results. For example, the effects of the factor α in the comparison of populations 1 and 2, and of populations 2 and 3, may not add up to the α effect when populations 1 and 3 are compared. A unique way of achieving consistency in the effects based on the multiple populations being compared, without bringing in an exogenous population as standard, is provided in Das Gupta (1991, 1993).

demographic techniques: event history methods

Steven Martin

Event history analysis is a term used in sociology for numerous statistical methods that use information about *whether* and *when* an individual experiences an event. Almost any social phenomenon can be thought of as an event that happens to an individual, whether that individual is (for example) a woman having a third child, a city experiencing a race riot, or a state legislature passing women's suffrage. It is not surprising, then, that as computer software has made event history techniques easier to use since the 1980s, researchers have found many imaginative applications for these techniques.

Sociologists use the term event history analysis to describe models for duration data, but similar models are used in other disciplines with different names and slightly different terminologies. For example, models for duration data are called survival analysis by health scientists, duration analysis by economists, and failure time analysis by engineers. Many of the original and ongoing developments in duration modeling come from the health sciences, and some of the terms used in event history analysis (such as *risk* and *hazard*) reflect this heritage.

EVENT HISTORY DATA

Event history data generally require three pieces of information. These are *whether* an

individual experienced an event, *when* an individual who experienced an event experienced that event, and *when* the last valid observation came for an individual who was “censored” – that is, for an individual who had not yet experienced the event when the last observation was made.

Data for event history analysis can be collected and assembled in a variety of ways. In survey research, event history data are usually obtained by asking respondents to remember when events occurred in their lives. Traditionally, such retrospective data come from standard lists of survey questions. Examples would be: “Have you ever been married?” and “What year did your first marriage begin?” Increasingly, however, survey researchers have found that respondents do better at recalling long past events or difficult to remember events using *event history calendars* that allow the respondents to map several timelines at once (cf. Belli et al. 2001). For example, a welfare history calendar could include timelines for landmark events, residence changes, changes in family structure, employment changes, and use of entitlement programs. The increased use of event history calendars in survey research is one indication of the growing range of social questions being addressed through event history analysis.

AN EVENT HISTORY MODEL

Once the event history data have been organized, there are a number of event history models to analyze the results in a familiar regression style framework. Commonly used models include proportional hazard models for continuous time data. In such models, the outcome variable is the *hazard* or *rate* of the event of interest. The hazard is defined as the conditional probability that an event occurs in a given time interval (given that it has not already occurred), divided by the length of the time interval. An example would be a rate (or “hazard”) of .03 per month hazard of returning to welfare for single mothers who have just left welfare.

For continuous time data, the conditional probability of an event in a given time interval is $P(t, t + \Delta t)$, where t is the start of a time

interval and $t + \Delta t$ is the end of the time interval. The time interval Δt is defined to be vanishingly small, and the hazard function takes the following form:

$$h(t) = \lim_{\Delta t \rightarrow 0} \frac{P(t, t + \Delta t)}{\Delta t}$$

Besides $h(t)$, other commonly used symbols for the hazard function include $r(t)$ and $\lambda(t)$.

The general form of the proportional hazard model is as follows:

$$h(t) = \exp(\gamma(t) + \beta_1 x_1 + K + \beta_k x_k),$$

where $\gamma(t)$ is some function that describes how the rate of the event changes over time (the “duration dependence”), x_i are a set of explanatory variables, and β_i are a set of coefficients to describe how the explanatory variables predict differences in the hazard rate.

A proportional hazard model differs from a standard regression model in three notable respects. The first difference is that the coefficients are all exponentiated, so the explanatory variables are defined to have multiplicative rather than additive effects on the hazard. Second is the inclusion of $\gamma(t)$ to allow the hazard to vary as a function of time. The notion that the hazard is a function of time forces the researcher (usually) to choose a functional form for the duration dependence based on theoretical criteria or simple observed patterns. The duration dependency also forces the researcher to define a starting time t_0 . In many hazard models t_0 is implicitly obvious, but in other hazard models t_0 can be quite arbitrary. The last notable difference between a standard regression model and a proportional hazard model is the lack of an error term in a proportional hazard model; hazard models are estimated by maximum likelihood procedures rather than least squares procedures.

Continuous time event history models bear a strong resemblance to logistic regression models, which examine *whether* an individual experiences an event. Because a hazard model adds information on *when* events occur, the explicit time dimension makes it possible to determine the order of changes in explanatory variables and changes in the outcome variable. Establishing the time order of events is

critical to building causal interpretations from observed social patterns. Another advantage of hazard models is the full use they make of the available data. Event history models allow one to distinguish between two events that happened at different durations. A final advantage of event history models over traditional logistic regression models is that event history models enable the researcher to draw some information from individuals who could only be observed for part of the time they were at risk of the event ("censored" cases).

Event history models also have unique weaknesses. One is the problem of unmeasured heterogeneity. Any control variables left out of an event history model will distort the baseline duration function $\gamma(t)$ and bias the coefficients for the key explanatory variables to some extent. Many researchers have developed complex estimation procedures to correct for problems of unmeasured heterogeneity, but the statistical fixes themselves often rest on tenuous assumptions. For a description of problems of unmeasured heterogeneity see Vaupel and Yashin (1985). Another problem is that of non proportional hazards. The proportional hazard model assumes that covariates have the same effect on the outcome variable across all possible durations of exposure, and this is simply not the case for many social phenomena. The problem of non proportional hazards can be remedied fairly easily by interacting the covariate of interest with the duration function.

AN EXAMPLE

One example of an application of event history analysis comes from demography. The subsequent fertility of teen mothers has been a topic of social interest due to concerns that early births may lead to rapid repeat births, a particular social concern when the teen mothers are not married. One can test for such a difference using data from the June 1995 Current Population Survey (CPS), with a sample of 2,952 US women born in the years 1965 to 1970. Standard life table procedures indicate that 23.5 percent of teen mothers in the sample had a second birth within 24 months of the first birth, compared to only 19 percent of mothers with a first birth at age 20 or older. An application of a proportional

hazard model can show whether this difference is statistically significant, and whether this difference is evident at all birth intervals or only at short birth intervals.

A popular variant of the proportional hazard model is the Cox regression model, in which the duration function $\gamma(t)$ is not estimated directly (Cox 1972). The Cox model implicitly controls for duration since the first birth, with rates of second births very low immediately after a first birth, rising rapidly to a peak rate at about 3 years postpartum, and declining thereafter. In Cox regression models, the researcher need not specify a baseline duration function. The model controls for race and ethnicity, and includes a dichotomous variable that identifies women with a teen first birth. Finally, to identify possible non proportional effects of time, a series of interactions between a teen first birth and duration since first birth are also added in Model 2.

Results using the Stata statistical package are shown in Table 1. The first model shows coefficients for age at first birth, averaged across all durations since the first birth, plus controls for race/ethnicity. In the first model, the coefficient for a teen first birth is small (.08) and not statistically significant. This coefficient shows the *overall* effect of a teen first birth on the rate of a subsequent birth, but the effect may not be even (or proportional) across time (or duration) since the first birth. For non proportional results, look to the second model. The "main effect" of a teen first birth is essentially zero (.00); this coefficient refers to the comparison durations of the third to sixth years postpartum. However, there is a statistically significant *non proportional interaction* effect in the second year postpartum, indicating that the monthly hazard of a subsequent birth increases by a factor of $\exp(.28) = 1.32$ times in the second year after a first birth. This means that teen mothers' second birth rates are much higher in the second year postpartum than we would expect from teen mothers' second birth rates at longer durations. Note also the marginally statistically significant *negative interaction* for teen mothers in the seventh and later years postpartum, perhaps indicating very low second birth rates at long durations.

From this analysis one can infer that the overall rate of second births is similar for teen and

non teen mothers, but the exact timing of those second births might be much sooner for teen mothers than non teen mothers. Hence, the techniques of event history modeling provide some justification to social concerns about closely spaced second births among teen mothers.

OTHER EVENT HISTORY MODELS

There is a large and growing number of variants on event history models. The Cox proportional hazard model represents only one type of proportional hazard model; there are many other proportional hazard models that explicitly define the duration dependency $\gamma(t)$. Furthermore, the expanded use of event history models has led to increased use of models for repeated events, events with more than one possible outcome, and events with more than one possible origin. Such complicated event patterns often arise in analyses of political events (Box Steffensmeier & Zorn 2002) and life course studies (Wu 2003).

There are also types of event history models that are not based on the hazard function.

Whereas proportional hazard models use as an outcome the hazard of an event, *accelerated failure time* models use as an outcome the expected time to the event. A set of methods called *discrete time* methods are useful when event times are measured in large units such as years. The issue of long time intervals in event history data is important because commonly used surveys increasingly suppress information about the month and day of events to protect the privacy of survey respondents.

To learn more about the variety of event history models and their uses, the reader should refer to specialized texts on the subject. Useful treatments for social scientists can be found in Yamaguchi (1991) and Blossfeld and Rohwer (2002), and a more general treatment can be found in Kalbfleisch and Prentice (2002). Many readily available software packages have modules for estimating basic to moderately complicated event history models, including the Cox regression model. Allison (1995) describes in detail various techniques for event history analysis in SAS. Other popular programs include SPSS, Stata, and S Plus. Researchers have also developed a number of statistical

packages for estimation of non standard event history models of various sorts, including CTM (Yi et al. 1987), TDA (Blossfeld et al. 1989), and aML (Lillard & Panis 2000). As event history analysis continues to develop and evolve, researchers will no doubt continue to write new programs and expand the capabilities of the existing programs.

demographic techniques: life-table methods

Robert Schoen

A life table describes the survival of a hypothetical group of persons from birth, through successive ages, to the death of the last member. In doing so, it shows the implications of a set of mortality rates for the probability of surviving from one age to another, and provides useful summary measures such as the expectation of life at birth. Beyond its wide use in studies of mortality, the life table has been used in analyses of marriage, divorce, contraceptive use, and many other topics where it is valuable to examine how rates of decrement reduce the number of persons in a closed group.

The life table dates back to the seventeenth century. In 1662, John Graunt advanced the first, rather crude, table based on English experience. In 1694, Edmund Halley (of comet fame) constructed a life table for Breslau (now Wrocław, Poland), adding actuarial functions to facilitate the calculation of life annuities. Life tables are now available for nearly all countries, and are routinely produced by government statistical offices, insurance companies, and academic demographers. Life tables describe the mortality experience of a population, facilitate population projections, and are central to calculating the costs of life insurance and life annuities.

Mortality (death) rates are the basis of most life tables. Demographers typically use death rates of the form

$$M(x, n) = D(x, n)/P(x, n) \quad (1)$$

where age specific death rate $M(x, n)$ reflects mortality between ages x and $x + n$ (or more precisely from exact age x to the instant before the attainment of exact age $x + n$), $D(x, n)$ gives the number of deaths in the population between the ages of x and $x + n$, and $P(x, n)$ is the number of persons in the population between the ages of x and $x + n$. Rates in the form of equation (1) are known as occurrence exposure rates, because they relate the number of deaths (occurrences) to the number of

persons at risk of dying (i.e., the exposed population). Death rates are generally calculated separately by sex, as male and female mortality patterns differ. Complete life tables show age in single years up to some high age (100 or over), but most life tables are “abridged,” and show ages 0, 1, and every fifth year from 5 to at least 85. Age 1 is shown because mortality at age 0 is very different from mortality at ages 1 to 5. Given contemporary survivorship, many recent abridged life tables go to age 90 (or higher).

To start the life table, a “radix” value is chosen to establish the size of the life table cohort, where that cohort is the hypothetical group of persons, closed to migration, whose survivorship is described by the table. Denoting the number of persons in the life table cohort who survive to exact age x by $l(x)$, the radix value, represented by $l(0)$, is generally set at 100,000. Essentially that radix indicates that the data are considered reliable to about five significant digits. Life tables based on small datasets sometimes start with a radix of 1,000, while insurance company life tables, based on extensive and detailed data, have used radix values of 10,000,000.

The central problem in life table construction is to transform death rates into probabilities of dying, and thus generate the number of survivors to each age in the table. Let us define $d(x, n)$ as the number of deaths in the life table cohort between the ages of x and $x + n$. Because the life table cohort is a closed group, we have

$$l(x + n) = l(x) - d(x, n) \quad (2)$$

or that the number surviving to exact age $x + n$ is the number surviving to exact age x less the number of deaths between those ages. Using equation (2), we can write the probability of dying between ages x and $x + n$, $q(x, n)$, as:

$$q(x, n) = d(x, n)/l(x) \quad (3)$$

In terms of life table functions, the death rate in equation (1) can be written:

$$M(x, n) = d(x, n)/L(x, n) \quad (4)$$

where $L(x, n)$ is the number of person years lived by the life table cohort between the ages

of x and $x + n$. (A person year is one year lived by one person.) Finding death probabilities from rates is thus equivalent to finding the number of person years lived in an interval in terms of the number of survivors to different exact ages.

Many ways of transforming rates to probabilities have been used in life table construction. One simple approach is to assume that the survivorship function, $l(x)$, is linear between ages x and $x + n$. That yields the solution:

$$q(x, n) = nM(x, n)/[1 + (n/2)M(x, n)] \quad (5)$$

A second approach is to assume that the survivorship function is exponential within each age interval. In that case,

$$q(x, n) = 1 - e^{-nM(x, n)} \quad (6)$$

While the linear assumption in equation (5) is usually accurate for 5 year age intervals in a mortality only life table, the exponential assumption in equation (6) is not. However, the frequently used Reed–Merrell modification, that is:

$$q(x, 5) = 1 - \exp[-5M(x, 5) - \{M(x, 5)\}^2] \quad (7)$$

generally yields an acceptably accurate abridged life table.

Two other life table functions are commonly encountered. $T(x)$ is the total number of person years lived above exact age x , and is thus the sum of the L values from age x through the highest age in the table. The life expectancy at age x , $e(x)$, is given by:

$$e(x) = T(x)/l(x) \quad (8)$$

The average number of years a person age x will live is the total number of years lived above age x by the life table cohort divided by the number of persons in the cohort who survive to age x .

Given a method for relating rates and probabilities, survivorship [$l(x)$] values can be found for all ages from equations (2) and (3), and person year [$L(x, n)$] values can be found from equation (4). The $T(x)$ and $e(x)$ values follow

from the $L(x, n)$ and from equation (8). Special procedures are needed at ages under 5 and to close out the table. Readers interested in making a life table are referred to the discussions in Preston et al. (2001) and Schoen (1988).

Table 1 shows a life table for US females, 1996. It is a period life table, in that it is based on rates observed during a single year (or period). Cohort life tables, which follow the experience of actual birth cohorts, have been calculated, but are much less common because they require data over a long time interval. The $M(x)$ column is not shown in the table, but the age specific life table death rates can readily be found using equation (4).

As is commonly the case, there are 100,000 persons in the life table cohort. Life expectancy at birth is 79.1 years. Since 659 persons die at age 0, the probability of dying before attaining age 1 is .00659. Some 90,317 persons survive to attain age 60 where, on average, they will live another 22.9 years. At age 85, only 41,813 persons remain alive. Their probability of dying is 1, but on average they will live another 6.4 years.

The mortality patterns shown in the table are rather typical of contemporary low mortality populations. Japanese females, the population that currently has the lowest known mortality, have an expectation of life at birth approaching 85 years, and some select subpopulations have

been found with even longer life expectancies. Longevity in low mortality populations has been steadily increasing in recent years, and no limiting life expectancy is in sight.

The life table can be seen as a population model that goes beyond the experience of a single birth cohort. Consider a long series of birth cohorts, each of $l(0)$ births uniformly distributed over the year, exposed to an unchanging regime of age specific death rates. After 120 or so years, a stationary population will result, one that is constant in both size and age composition. Each year there are $l(0)$ deaths in the stationary population, $d(x, n)$ of them between the ages of x and $x + n$. There are $l(x)$ persons attaining every age x , $L(x, n)$ person years lived between ages x and $x + n$ and, at any time, $L(x, n)$ persons between the ages of x and $x + n$. The $L(x, n)$ function thus has two distinct interpretations: the number of person years lived by each cohort between the ages of x and $x + n$, and the number of persons in that segment of the stationary population. The total number of persons in the stationary population is $T(0)$, and its crude death rate is always $l(0)/T(0)$ or $1/e(0)$. Each year, behavior in the stationary population reproduces the lifetime experience of one life table birth cohort.

The basic life table model has been generalized in a number of ways. The table need not follow a birth cohort – any closed group will do. For example, numerous analyses have been done examining attrition in a marriage cohort, where time is represented by duration of marriage rather than age.

A common extension is to recognize more than one cause of exit (or decrement) from the life table cohort. Multiple causes of death are probably the most common example. However, studies have also been made of birth cohorts subject to the risks of mortality and first marriage, marriage cohorts subject to mortality and divorce, and many other subjects. Multiple causes of decrement are easily recognized. The total life table decrement function, $d(x, n)$, is simply apportioned to the different causes in the same proportion as observed decrements. A cause of death life table can reflect the probability of ever dying from a specified cause.

A further extension is the “cause eliminated” or “associated single decrement” life table. This model considers the hypothetical question

of what survivorship would be if a particular cause of decrement were eliminated. The simplest way to calculate such tables is to assume that age-cause specific rates (not probabilities) of decrements remain unchanged, though caution is in order because hypothetical rather than actual behavior is being described. Age specific probabilities of death for the remaining cause(s) always increase, because the population at risk of decrement to those causes must increase. The most common application is to cause of death life tables, where one can estimate the addition to life expectancy that would follow the elimination of a particular cause of death. The model is also useful in a number of other instances, for example to eliminate the possibly distorting effects of mortality from nuptiality mortality double decrement life tables.

An important generalization recognizes more than one living state in the life table model, and follows persons as they move between model states. Such multistate or increment-decrement life tables have been applied to numerous situations, especially studies of marriage, divorce, and remarriage; migration between geographical regions; changes in parity (i.e., a woman's number of live births); health status; and labor force status. Numerous useful summary measures can be found from such models. For example, a marital status life table recognizing the four living states of “Never Married,” “Presently Married,” “Widowed,” and “Divorced” can yield the probability of ever marrying, the proportion of life lived married, the probability a marriage will end in divorce, and the average duration of a marriage.

Multistate life tables can be constructed from a set of age specific rates of decrement using techniques analogous to those used for the basic life table, though multiple equations (or matrices) are needed. Conceptually, multistate models introduce important new distinctions. In calculating probabilities, one must be clear whether the starting population consists of all persons of a given age or just persons in a specific state at that age. The same is true with respect to life expectancies. The number of years a man age 60 can expect to live widowed depends substantially on his marital status at age 60.

It is commonplace – and analytically useful – to talk about measures such as life expectancy that do not refer to actual people but to the

experience of a life table cohort. The life table model remains a basic tool in demography because it shows the cumulative implications of a set of behavioral rates, and thus summarizes long term (and possibly complex) behavior.

demographic techniques: population projections and estimates

John F. Long

Population projections and estimates constitute a core focus of demographic techniques. Both activities calculate the size and often the demographic characteristics of a given population in the absence of complete data such as might be available from a population census. Population projections and estimates play an important role in analysis of societal trends and in planning and policy decisions.

Population projections and estimates are sometimes distinguished from each other by the statement that population estimates refer to current or past dates while population

projections refer to future dates. A better distinction would be based on the time period of the input data relative to the output data. Population projections take the data on trends in population size and/or in the components of population change (births, deaths, and migration) and use mathematical models to extrapolate these trends into a time period not covered by the data. Usually, but not always, projections are done for some point in the future that is not only beyond the last date of the input data but also beyond the date that the projection is actually prepared.

Population estimates relate to a past time period for which population counts are not available (such as the years after the most recent population census). In contrast to population projections, population estimates take advantage of actual measurements of indicator variables related to population size or to the components of population change.

COMPONENT BASED PROJECTIONS

Population projections use a wide variety of methods, but the methods that are most commonly used take advantage of knowledge of the ways populations change. These methods, known as component methods, use information on the size and demographic characteristics of the beginning population (often measured by a census) and then add measures, extrapolations, or assumptions about the components of population change – births, deaths, and migration. In the most general form, the component method reduces to a basic accounting equation for population change.

$$P_{i,t} = P_{i,0} + (B_i - D_i + I_i - O_i) \quad (1)$$

where $P_{i,t}$ = population of area i at time t , $P_{i,0}$ = population in area i at beginning of period, B_i = births in area i since beginning of period, D_i = deaths in area i since beginning of period, I_i = immigration to area i , and O_i = outmigration from area i during the period.

If we add to this basic formulation information about the size of the population in each age group and the age specific probabilities of giving birth, dying, or moving, the resulting methodology is known as the cohort component

method. This method is the basis for many population projections since it has the advantage of using data on a known population age composition from the last decennial census to determine the future momentum of the population. For instance, populations with younger age structures are more likely to have higher growth rates due to a larger number of births and fewer deaths, while populations with an older beginning population will show the opposite trends.

The art in population projections comes from the choices made to predict the changes in the age specific birth, death, and migration rates. Many methods have been used ranging from holding previous rates constant, building in a time trend either from simple extrapolation or time series models, setting ultimate assumptions and interpolating to get to those results, or predicting future change with multivariate models. Each of the components of population change requires decisions about a number of issues as future rates are constructed.

Fertility rates have varied markedly over time, with a long term decline occasionally interrupted by major deviations like the post World War II baby boom in North America and many European countries. More recently, the rapid decline of fertility toward replacement or below in the developing world and the dramatic fall of fertility to well below replacement levels in much of Europe has made forecasting fertility much more difficult. Early uses of birth expectations data to forecast the short term future of fertility behavior achieved mixed success as many women's actual experiences failed to match their initial expectations. Time series analysis of the distribution of age specific fertility rates, sometimes taking into account the number of children already born to a woman (parity), has proved useful where there is a well behaved change in fertility patterns. Often, the approach has been to use expert judgment to assume an ultimate level of fertility – often related to the level of fertility needed to replace the population (roughly 2.1 children per woman). The assumption of this replacement level fertility level has been highly debated and there seems to be no agreement that future fertility for a given society needs to be near replacement.

Future trends in death rates have gone through similar discussions. Fortunately, the

basic mechanics of population projections are closely related to the construction of a life table and age specific mortality rates can be cumulated into life expectancies. The difficulty here is assessing medical and public health improvements that offer the possibility of substantially improved life expectancies and estimating the speed at which progress to those higher life expectancies can be made. There is no agreement as to whether there is an ultimate limit to the life span and hence to the improvement in life expectancies. As with fertility, not all changes are monotonic and declines in life expectancies have been noted in several countries over specific periods of time (e.g., in Russia since the disintegration of the Soviet Union). Typically, time series and extrapolation models set ultimate assumptions based on levels reached by other societies that are further along in achieving higher life expectancies.

Dealing with migration brings its own set of problems. Unlike births or deaths, migration can be in two directions. Moreover, the probability models based on current population of an area that work for births and deaths might work for outmigration but the population at risk of immigrating is not the current population of an area. For these reasons migration is often handled as exogenous to the system with assumptions made about the level rather than the rate of immigration. Alternatively, migration can be handled in a multistate model where the populations of various areas are projected jointly and the outmigration flows from one area become the immigration flows for other areas. Again, one has the problem of projecting future rates and often the origin destination rates are held constant and the major dynamic in migration flows become the shifting size of the populations of origin.

COMPONENT BASED ESTIMATES

Although population estimates can be produced based only on trends in the growth of the population as a whole, the more sophisticated methods use component based techniques similar to those used for population projections. However, rather than developing methods to forecast these components into the future, the task of population estimation methods is to measure the size of each component since the

last census or – lacking a direct measure – to find an indicator that can be used to model the level of that component. An indicator variable can be any measured characteristic that varies regularly with the component being estimated.

Direct measurement is possible for some of the components of population change. Births and deaths are often well measured by a vital statistics registration system. International migration is something of a mixed picture, with administrative data measuring most of the legal immigration into the country but often providing little or no information on emigration or illegal immigration. Unmeasured migration across international borders requires the use of assumptions about the quantity and characteristics of the population flows missed and is a major cause of estimation error.

The other major aspect of migration, domestic or internal migration between subareas of a country, is the focus of much effort in population estimation procedures. There is seldom a direct measure of internal migration, so it must be estimated using an indicator variable based on an alternative data source devised for another purpose. One method for estimating the internal migration rate uses administrative data that provide addresses for individuals at two different points in time (usually a year apart). Such data provide approximate information on immigration, outmigration, and even area to area flows. While there are several potential sources of these administrative data – changes in postal addresses, drivers' license records, tax returns, and health insurance information – the problem is to find a source that provides representative coverage and consistency in reporting and tabulation.

The US Census Bureau uses an administrative records method that compares tax returns from the Internal Revenue Service (IRS) for changes in filing addresses between two consecutive annual tax filings. In the estimation process, tax returns from one year are matched with those from previous years by matching Social Security numbers of the filers. For persons with a new address, the new mailing address is coded to state, place, and county. If the state, place, or county is different from the previous year, the filer and all exemptions are classified as migrants. These data are then used to construct net migration rates for each county

and place as an input to the population estimation formula. An estimate of the rate of net migration is calculated by dividing the net flow of exemptions (the tax filer plus his or her dependents) moving into the area by the number of exemptions filed in the area.

$$\mu_i = \frac{\sum_j (T_{ji} - T_{ij})}{T_i} \quad (2)$$

where T_{ij} = flow of tax exemptions from area i to j and T_i = total number of matched tax exemptions living in area i at the beginning of the period. This net migration rate (μ_i) is then multiplied by the initial population to get the estimated net internal migration for the period.

A critical assumption in this method is that the population not covered by the administrative dataset moves similarly to the population covered or that the uncovered population is too small to affect the results markedly. Since this assumption is especially inappropriate for the population over 65 and for certain military and institutionalized populations, those populations are handled separately. Other potential problems include the difficulty of coding addresses to geography, changes in administrative coverage over time, and the elimination of administrative data sources as governmental programs change. Despite these limitations, the population estimates made using this indicator model have repeatedly proven better than extrapolations of trends in these components based on data from previous time periods.

MODELING UNCERTAINTY IN PROJECTIONS AND ESTIMATES

Population projections and estimates have substantial uncertainty due to the approximations to reality made in specifying a model and in the unexpected events that inevitably arise as we go further into the future. Unlike sampling theory, there is no set model or series of models that can be used to determine future forecast error. One approach often used is to develop several different series of population projections that might represent reasonable high and low future levels of each component and create a set of alternative assumptions based on each assumed level. More recently, there has been increased interest in a

more formalized procedure for producing stochastic forecasts. These forecasts begin not with a single trajectory for the rates of each component of change but with a distribution of future fertility levels based on statistical time series analysis of past trends. These distributions are then used to develop simulations of future growth paths in which each year's value for each of the age specific rates is randomly selected from the distribution and the resulting forecast trajectory is calculated. This process is repeated for a large number of simulations giving a resulting distribution of forecast values of each component and for each age for all years of the projection period. Population estimates also have a substantial level of uncertainty, although probably not as much as projections, given the shorter time frame and the fact that they are based on actual measures.

demographic techniques: population pyramids and age/sex structure

Joan R. Kahn

Age and sex are among the most fundamental demographic characteristics of individuals. Viewed in the aggregate, age/sex composition

forms the basic structure of human populations. It tells us the relative numbers of young and old as well as the balance of men and women at different ages. By characterizing the "raw materials" of human populations, the age/sex structure indicates the numbers of people "at risk" or "available" to engage in a wide range of behaviors that vary by age (e.g., going to school, getting a job, committing a crime, getting married, starting a family, buying a home, getting divorced, retiring, getting sick and dying). By itself, it does not tell us who will engage in any of these behaviors, yet it does help determine overall patterns and trends.

Population aging is one of the most universal demographic trends characterizing early twenty first century populations. The age of a population simply refers to the relative numbers of people in different age groups. Populations around the world vary from being quite youthful (e.g., Uganda, where 51 percent of the population is under age 15 as of 2004), to being much older on average (e.g., Germany, where only 15 percent of the population is under age 15). The trend toward increasingly older populations is directly linked to declines in both fertility and mortality. With fewer births, the proportion of children declines, thereby raising the proportions at older ages; similarly, declines in adult mortality imply greater longevity and hence a larger proportion surviving to older ages. Trends in population aging are most evident in the more industrialized countries of Europe, North America, and Japan, where the percentage of population over age 65 is projected to surpass 20 percent by 2030. However, a great many less developed countries can also anticipate rapid population aging in the near future as a result of their recent steep declines in both fertility and mortality.

As can be seen from the demographic causes of population aging, the age structure is dynamic and can change as a result of shifting demographic patterns. It is also a major determinant of the demographic patterns themselves. Because vital events do not occur equally to people of all ages and both sexes, the numbers of births, deaths, and moves also depend on the numbers of men and women at different ages (i.e., the age/sex structure). For example, if population size and fertility rates are held constant, a more youthful population (with

relatively large numbers of people in the child bearing ages) will produce more births than an older one. Thus, very young populations have built in potential for rapid population growth even after fertility rates start to decline. This phenomenon is often referred to as "population momentum." Conversely, an older population will have relatively more deaths and disabled persons than a younger population of similar size. Hence, understanding the age/sex structure of a population is vital to explaining social trends and planning for the future.

The most common measure of the sex composition of a population is the sex ratio, which is simply the ratio of males to females (multiplied by 100). In a few countries, such as India, government agencies calculate the sex ratio as the number of females for every 100 males. It is often assumed that populations are fairly balanced between men and women, but in most countries women outnumber men overall, though not necessarily at all ages. The sex ratio often declines with age because of progressively higher male than female mortality rates at older ages. In the US, for example, the overall sex ratio is about 95 males for every 100 females; however, at birth, there are about 105 males for every 100 females, and by ages 85 and over, there are only about 40 males for every 100 females.

Of course, not all countries follow this pattern; in places characterized by high levels of gender inequality and higher female than male mortality (e.g., India, Afghanistan), it is not unusual to find an excess of males at every age. High sex ratios may also reflect underreporting of females, as with the large number of "missing daughters" in China, who are thought to have been given up for adoption and not reported as live births (Tien et al. 1992, cited in Rowland 2003). Similarly, the growing popularity and availability of sex selective abortion in countries with strong preferences for sons has driven up the sex ratio in countries such as India and China.

DEPENDENCY RATIOS

The dependency ratio is a summary measure of the age structure and is typically defined as the ratio of economically inactive to

economically active persons. Since the economically inactive tend to be the young and the old, the dependency ratio is simply measured as the ratio of age groups (i.e., (Children + Elderly) / Working Ages). The precise ages used depends on the population being studied as well as the availability of data broken down by specific ages. In the US for example, the dependency ratio is often measured as the ratio of "persons under age 15 and over age 65" to "persons of ages 15–64." While it is recognized that many persons over age 15 are not yet economically active, and many persons over age 65 are still economically active, the dependency ratio approximates the number of inactive persons whom each active person must support. Given the different needs of children and elders, it is often useful to look separately at the child dependency ratio (Children / Working Ages) and the aged dependency ratio (Elderly / Working Ages).

Data on age/sex structure are typically presented graphically in the form of an age pyramid, also known as a population pyramid. The pyramid can be thought of as two histograms placed on their sides and facing back to back, showing the age distributions for males on the left and females on the right. The vertical axis is age, coded in single years, or in 5 year age categories, with the youngest at the bottom. Each bar of the pyramid shows either the number or proportion of the population who are males or females in a given age group. The size of each bar reflects past patterns of fertility, mortality, and migration. For example, the number of people in age group X reflects the survivors of the births that occurred X years earlier, plus or minus the migrants from the same birth cohort who entered or departed the population during the intervening years.

Since each bar is determined by past demographic patterns, it follows that the overall shape of the pyramid does as well. Rapidly growing populations, in which births far exceed deaths, are typically characterized by a wide base and a classic "pyramid like" shape (i.e., each new cohort is larger than the previous one). In contrast, a population which is neither growing nor declining has a more rectangular shape whereby each new cohort entering at the bottom is roughly the same size as the preceding cohort. A population which is

declining due to an excess of deaths over births would have an age pyramid which is narrower at the base than at older ages.

In addition to reflecting population growth patterns, the shape of an age pyramid can also serve as a kind of historical record of past events that may have affected fertility, mortality, or migration. For example, one of the most obvious demographic consequences of war is the large numbers of deaths to young adult males. However, there are also brief declines in the numbers of births, either because spouses are separated or because couples choose to postpone getting pregnant until the war is over. In either case, the demographic impact would be unusually narrow bars in the pyramid representing small cohorts of males in their twenties and also newborns of either sex. As these cohorts grow older, their narrow size remains with them as they move up the pyramid.

After wars end, there is often a surge in births as couples reunite and attempt to make up for lost time. The post World War II baby boom is perhaps the defining demographic event for the United States in the second half of the twentieth century. The surge in births between 1946 and 1964 (the cohorts aged 35–55 in 2000) was unprecedented and unexpected, especially given the low fertility of American women prior to World War II. Every US age pyramid after 1960 shows the progression of the unusually large baby boom cohorts (and the smaller baby bust cohorts which followed in the 1970s) as they move through the life course. The visual impact of an age pyramid showing the baby boomers approaching retirement ages starting in the year 2010 helped to stimulate the policy debate on the future of Social Security and Medicare.

demographic techniques: time use

Sara Raley

Time is a scarce, some would say increasingly scarce, resource. However, unlike other resources, time is equally distributed because everyone faces the same 24 hour constraint as they make decisions about how to allocate their limited time to various and often competing commitments. Despite its apparent equality, time allocation is a major indicator of social differentiation and stratification. For example, people with high levels of human capital may be better able to afford to trade paid work time for leisure time as well as purchase time saving goods and services (such as prepared meals and house cleaning) than people with lower levels of human capital.

Further, the choices people make about their time use has important implications for their health, financial security, and general life satisfaction. In addition to people's personal preferences, myriad norms (and even laws) govern how people should use their time – how much time is appropriate to spend at work, how much time is needed to care for family, and even how much time one should spend brushing one's teeth each night. Thus, at the social level, people's time use patterns reflect how societies value categories such as work, family, and leisure.

MEASUREMENT

There are three primary ways to measure people's time use: (1) asking respondents to indicate on questionnaires how much time they spend in various activities; (2) observing people in their daily routines; and (3) prompting respondents to recount their day in a time diary. Of these three methods, the time diary has become the preferred methodology because

of its accuracy relative to estimates based on questionnaires and cost effectiveness relative to observational methods.

Estimating weekly hours spent in certain activities is difficult because people do not spend their time in clearly delineated time frames. A person may go to the office at 9 a.m. and return at 5 p.m., but it does not necessarily mean she worked an 8 hour day. She may have taken a 1 hour lunch break, left the office for an hour and a half for a doctor's appointment, and spent 30 minutes in the afternoon talking on the phone with a child. Once home, the respondent may engage in a series of activities simultaneously (e.g., put in two loads of laundry, start cooking dinner, and answer a work related telephone call), making it extremely difficult to add up the exact minutes of the day spent in each activity. Further, there are some activities, like childcare, that are deemed more socially desirable than others, like television viewing. Thus, when asked about their time use, people may be more inclined to overestimate their time with their children and underestimate time spent watching television.

One way of getting around the biases inherent in people's estimates of their time use is to follow them around and keep track of their activities for them. This is likely to produce more accurate measures of time use, is a method often used by anthropologists, but is extremely costly. The high cost associated with this methodology means that only a few cases can be observed, making it difficult to draw representative samples and make practical comparisons between groups. People may also be reluctant to have researchers follow them around, particularly when they engage in behaviors requiring privacy like changing clothes and engaging in sexual activity.

Time diary methodology gets around some of these issues by asking respondents to provide an account of one or more of their days, or even a week. Because respondents are constrained to a 24 hour period in each day and must recount their activities sequentially (i.e., in the order they occurred throughout the day), it is more difficult to exaggerate time expenditures. It is less mentally taxing than responding to survey questions that ask respondents to quickly add up time in various activities. Respondents go

through their day's activities, which prompts them to remember things more precisely than if they are asked to sum all time spent in a single activity, like market work, in a day. Time diaries also capture the complexity of time use. They indicate multitasking, or when people engage in more than one activity simultaneously, as well as the location and people present for each reported activity. At the same time, diaries are not perfect measures of time use as people may be reluctant to report socially deviant or embarrassing behaviors.

HISTORY OF TIME USE DATA COLLECTION

Although the history of time diary methodology extends back to the mid 1920s, the most comprehensive and well known time diary study is the 1965 Multinational Comparative Time Budget Research Project. In this study, 2,000 respondents from each of 12 different countries completed single day diaries. The sampling procedure, diary format, and data collection procedures of this landmark study set the standard for several subsequent international time diary collections. In addition, several of the countries in the original 1965 collection replicated their studies in later years. The Harmonized European Time Use Study was developed between 1996 and 1998 and captured time use data on 20 countries. To date, time diary studies have been administered in over 60 countries spanning North America, South America, Europe, Australia, Africa, and Asia.

In the US, a series of cross sectional time diary studies based out of the Universities of Michigan and Maryland have been conducted at roughly 10 year intervals since the 1960s. Whereas most of these studies focus on the time use of adult men and women, smaller scale studies of adolescents and children were administered in the 1980s and 1990s. In 1997, the Panel Study of Income Dynamics (PSID) survey added time diaries for 3,000 children aged 3 to 12 as part of the Child Development Supplement (CDS). These children were followed up and asked to complete another diary in 2003, making this one of the few longitudinal diary collections. The study is particularly innovative not only because it is longitudinal,

but also because the time diary data in the CDS can be linked to the respondent's detailed income histories in the PSID.

Time diary methodology has become so popular that in January 2003, the Bureau of Labor Statistics launched the American Time Use Survey, which is now the largest time use survey ever conducted in the world. This nationally representative data collection makes it possible to make more detailed comparisons of time use across groups by such indicators as age, race, employment status, gender, and income.

TRENDS IN WORK AND LEISURE TIME

The time harried American trying to squeeze in time for market work, household labor, exercise, a healthy diet, family, sleep, and, of course, leisure is a common image in the popular media. Particularly in light of technological advances like beepers, pagers, cell phones, email, and instant messaging, it seems that everyone is on the go. In the context of this fast paced lifestyle, changes in work and leisure time are of central concern, with the prevailing viewpoint being that work time has increased greatly and leisure time is on the decline.

This perspective was underscored and popularized by Juliet Schor, author of the *Overworked American: The Unexpected Decline of Leisure* and *The Overspent American: Upscaling, Downshifting, and the New Consumer*, who argues the nature of work and consumption have changed so dramatically in the US that people are working longer hours than ever before so they can earn enough money to buy and accumulate large numbers of consumer durables. Relying heavily on government survey data as well as newspaper articles, she made the astonishing assertion that between 1979 and 1987, working hours increased by the equivalent of a month, or 163 hours, a year. Her arguments were echoed by Arlie Hochschild (1997), who claims the increased commitment to market work has moved society to an age where work has become home and home has become work.

In stark contrast to those who argue work hours are rapidly encroaching on quality leisure time are scholars like John Robinson and Geoffrey Godbey (1999), whose analysis of

time diary data on Americans' time since the mid 1960s argues that leisure time, if anything, increased in recent decades. Their estimates showed gains in free time activities (all those outside of market work, non market work, and childcare) amounted to an additional month and a half of *vacation* between 1965 and 1985. Others also pointed out that the average work week has changed little over the last few decades (Rones et al. 1997). Hence, the dramatic decline in leisure may be more a perception than a reality.

Both sides bring to bear convincing evidence on this issue, so it seems impossible that *both* work and leisure time could be simultaneously increasing. Jacobs and Gerson (2001) suggest, however, that even though the two sides *seem* thoroughly at odds, they may not necessarily be mutually exclusive trends. First, if the unit of analysis is shifted from individuals to families, where the once normative male breadwinner, female homemaker household has been replaced by dual earner and single parent families, it becomes clear that the combined working hours of families have skyrocketed. With the increase in women, particularly married mothers, in the labor force, far fewer families have a member available to focus exclusively on non market work. Second, changes in the distribution in the population might make averages across the population seem misleading. For example, the universe of people who are of working age has shifted. People are entering the workforce later in their lives because of increased educational attainment and exiting the labor market earlier as retirement ages decline. Thus, it is possible that people may be working more when they are in the prime working ages, but working less over the life course as a whole.

FUTURE DIRECTIONS: SUBJECTIVE FEELINGS ABOUT TIME

Time use data capture the objective measures of people's time use: what they are doing, where they are doing it, who is accompanying them, and how long they are engaging in their various activities. However, the sense of pressure and anxiety associated with daily activities is not a major component of most time diary collections. Who feels responsibility for the

family caretaking and the added stress that comes along with this responsibility is not captured by time use data. Further, the extent to which people enjoy the activities they engage in regularly is not measured in most time use studies. For example, some people enjoy spending 40 hours a week at work while others may find 40 hours of market work stressful. Hence, the field is moving to incorporate methodologies that evaluate the subjective as well as the objective dimensions of time use.

In experiential sampling studies, or “beeper” studies, respondents are randomly “beeped” and asked to report not only what they are doing, but how they feel about their selected activity. A major strength of this approach is that it provides a broad set of information about how daily life is experienced by capturing both the quantity and quality of time use. Further, it avoids the problems associated with the intrusive observer, which is particularly useful for interviewing self-conscious adolescents reluctant to be followed by an outside observer. Like the diary method, it also avoids the pitfalls of recall bias because respondents report their feelings as they experience them. Procedures of this kind were used as far back as the 1940s, but did not gain popularity among researchers until the 1980s when the term “experiential sampling method” was coined.

Since that time, several projects utilizing this methodology have been conducted, focusing primarily on adolescents, children, and families. These studies shed light on how adolescents and families organize their time, what activities they find the most enjoyable, what activities they find the most stressful, and how adolescents and their parents experience their interactions. Future studies can be used to better understand how men, women, and children experience time expenditures differently as well as how families collectively experience phenomena like work–family conflict. This is particularly significant in light of rising concern popularized by Juliet Schor that the time pressed nature of modern society is increasingly putting people’s physical and mental health at risk.

demographic transition theory

John R. Weeks

Although it dominated demographic thinking in the latter half of the twentieth century, demographic transition theory actually began as only a description of the demographic changes that had taken place over time in the advanced nations. In particular, it described the transition from high birth and death rates to low birth and death rates, with an interstitial spurt in growth rates leading to a larger population at the end of the transition than there had been at the start. The idea emerged in 1929, when Warren Thompson gathered data from “certain countries” for the period 1908–27 and showed that the countries fell into three main groups, according to their patterns of population growth: (1) Northern and Western Europe and the United States had gone from high rates of natural increase to very low rates of natural increase, and were on the verge of depopulating at that time; (2) Italy, Spain, and the “Slavic” peoples of Central Europe showed

some evidence of a decline in both birth rates and death rates but it seemed likely that the birth rates would remain higher than the death rates for some time to come; and (3) the rest of the world, where there was little evidence of control over either births or deaths. The populations of these latter countries, comprising about 75 percent of the world's population at the time, were living at subsistence levels and would likely increase in size if economic conditions improved enough for death rates to decline a bit.

In 1945, following the end of World War II, there was a growing concern about population growth. Frank Notestein (1945) picked up the threads of Thompson's thesis and provided labels for the three types of growth patterns. Notestein labeled the first "incipient decline," the second "transitional growth," and the third "high growth potential." By reversing Thompson's order, one could describe the transition from high birth and death rates to a transitional drop in death rates followed by a drop in birth rates, and finally to a stage where both are low. That same year, Kingsley Davis (1945) edited a volume of the *Annals of the American Academy of Political and Social Sciences* titled *World Population in Transition*, and in the lead article (titled "The World Demographic Transition") he noted that the world's population had been analogous for a long time to a powder fuse burning slowly toward the charge, but now it was about to reach that charge and explode. The term population explosion, alluded to by Davis, refers to the phase that Notestein called transitional growth. Thus in 1945 was born the term *demographic transition*.

At this point in the 1940s, the demographic transition was merely a picture of demographic change, not a theory, but each new country studied fit into the picture, and it seemed as though some new universal law of population growth – an evolutionary scheme – was being developed. Between the mid 1940s and the late 1960s rapid population growth became a world wide concern, and demographers devoted a great deal of time to the demographic transition perspective. Explanations were developed for why and how countries pass through the transition. These explanations tended to be derived from the modernization theory, which is based on the idea that in premodern times human

society was generally governed by "tradition," and that the massive economic changes wrought by industrialization forced societies to alter traditional institutions. In traditional societies fertility and mortality rates are high, whereas in modern societies the birth and death rates are low. Spanning these two extremes is the demographic transition. In the process, behavior has changed and the world has been permanently transformed. It is a macro level theory that sees human actors as being buffeted by changing social institutions. Thus, individuals did not deliberately lower their risk of death to precipitate the modern decline in mortality. Rather, society wide increases in income and improved public health infrastructure brought about this change. Similarly, people did not just decide to move from the farm to town to take a job in a factory. Economic changes took place that created those higher wage urban jobs while eliminating many agricultural jobs. These same economic forces improved transportation and communication and made it possible for individuals to migrate in previously unheard of numbers.

Modernization theory provided the vehicle that allowed the demographic transition to move from a mere description of events to a demographic perspective. In its initial formulations this perspective was expressed by sentiments such as "take care of the people and population will take care of itself" or "development is the best contraceptive" (Teitelbaum 1975). The theory drew on the available data for most countries that had gone through the transition. Death rates declined as the standard of living improved, and birth rates almost always declined a few decades later, eventually dropping to low levels, although rarely as low as the death rate. It was argued that the decline in the birth rate typically lagged behind the decline in the death rate because it takes time for a population to adjust to the fact that mortality really is lower, and because the social and economic institutions that favored high fertility require time to adjust to new norms of lower fertility that are more consistent with the lower levels of mortality. Since most people value the prolongation of life, it is not hard to lower mortality, but the reduction of fertility is contrary to the established norms of societies that have required high birth rates to keep pace with

high death rates. Such norms are not easily changed, even in the face of poverty.

Birth rates eventually declined, it was argued, as the importance of family life was diminished by industrial and urban life, thus weakening the pressure for large families. Large families are presumed to have been desired because they provided parents with a built-in labor pool, and because children provided old-age security for parents. The same economic development that lowered mortality is theorized to transform a society into an urban industrial state in which compulsory education lowers the value of children by removing them from the labor force, and people come to realize that lower infant mortality means that fewer children need to be born to achieve a certain number of surviving children. Finally, as a consequence of the many alterations in social institutions, people feel less pressure to have children and the idea of consciously controlling fertility begins to take hold.

Over time it has become obvious that the demographic transition is too complex to be explained by simple reference to the modernization theory. One of the most important social scientific endeavors to cast doubt on the classic explanation was the European Fertility Project, directed by Ansley Coale at Princeton University. In the 1960s, researchers at Princeton began looking at changes over time in marriage and fertility patterns in various European provinces. They quickly discovered that cultural factors such as language and religion were important predictors of fertility patterns, even when controlling for economic variables. Economic development emerges, then, as a sufficient cause of fertility decline, though not a necessary one. For example, many provinces of Europe experienced a rapid drop in the birth rate even though they were not very urban, infant mortality rates were high, and a low percentage of the population was in industrial occupations. The data suggest that one of the more common similarities in those areas that have undergone fertility declines is the rapid spread of secularization, which often spreads quickly, being diffused through social networks as people imitate the behavior of others to whom they look for clues to proper and appropriate conduct.

The work of the European Fertility Project focused on explaining regional differences in

fertility declines. This was a very important theoretical development, but not a comprehensive one because it only partially dealt with a central issue of the demographic transition theory: How (and under what conditions) can a mortality decline lead to a fertility decline? To answer that question, Kingsley Davis (1963) asked what happens to individuals when mortality declines. The answer, which came to be known as the *theory of demographic change and response*, is that more children survive through adulthood, putting greater pressure on family resources, and people have to reorganize their lives in an attempt to relieve that pressure; that is, people respond to the demographic change. But Davis argued that their response will be in terms of personal goals, not national goals. It rarely matters what a government wants. If individual members of a society do not stand to gain by behaving in a particular way, they probably will not behave that way. Davis believed that the response that individuals make to the population pressure created by more members joining their ranks is determined by the means available to them. A first response, non-demographic in nature, is to try to increase resources by working harder. If that is not sufficient or there are no such opportunities, then migration of some family members (typically, unmarried sons or daughters) is the easiest demographic response. But what will be the response of that second generation, the children who now have survived when previously they would not have, and who have thus put the pressure on resources? Davis argued that if there is in fact a chance for social or economic improvement, then people will try to take advantage of those opportunities by avoiding the large families that caused problems for their parents. Davis suggested that the most powerful motive for family limitation is not fear of poverty or avoidance of pain; rather, it is the prospect of rising prosperity that will most often motivate people to find the means to limit the number of children they have.

A shortcoming of all of the explanations of the demographic transition has been that they have focused largely on the causes of the mortality and fertility declines, without paying close attention to the other changes that are predictably put into motion as the rate of natural increase changes in a society. Interaction

between population change and societal change is, in fact, at the heart of the realization that the demographic transition is really a whole set of transitions, rather than simply being one big transition. These transitions include the mortality (also known as the epidemiological) transition, the fertility transition, the age transition, the migration transition, the urban transition, and the family and household transition.

Usually (although not always), the first transition to occur is the mortality transition – the shift from deaths at younger ages due to communicable disease to deaths at older ages due to degenerative diseases. This process is brought about by changes in society that improve the health of people and thus their ability to resist disease, and by scientific advances that prevent premature death. However, death rates do not decline evenly by age; rather, it is the very youngest and the very oldest – but especially the youngest – whose lives are most likely to be saved by improved life expectancy. Thus, the initial impact of the mortality transition is to increase the number of young people who are alive, ballooning the bottom end of the age structure in a manner that looks just like an increase in the birth rate. This typically sets all the other transitions in motion.

The fertility transition is the shift from natural (and high) to controlled (and low) fertility, typically in a delayed response to the mortality transition. Although it can begin without a decline in mortality (as happened in France), in nearly all places in the world it is the decline in mortality, leading to greater survival of children, that eventually motivates people to think about limiting the number of children they are having. Throughout most of human history the average woman had two children who survived to adulthood. The decline in mortality, however, obviously increases that number and thereby threatens the very foundation of the household economy. At the community or societal level, the increasing number of young people creates multiple pressures to change, often leading to peer pressure to conform to new standards of behavior, including the deliberate control of reproduction. Another extremely important change that occurs in the context of mortality transition is that the scope of life expands for women as they, too, live longer. They are increasingly empowered to delay

childbearing and to have fewer children because they begin to realize that most of their children will survive to adulthood and they themselves will survive beyond the reproductive ages, beyond their children's arrival into adulthood. This new demographic freedom offers the promise of vastly greater opportunities than ever before in human history to do something with their lives besides bearing and raising children. This realization may be a genuine tipping point in the fertility transition, leading to an almost irreversible decline.

The predictable changes in the age structure (the age transition) brought about by the mortality and fertility transitions produce social and economic reactions as societies adjust to constantly changing age distributions. The age transition is the “master” transition in that the changing number of people at each age that occurs with the decline in mortality and then the decline in fertility presents the most obvious demographic pressure for social change. When both mortality and fertility are high, the age structure is quite young, but the decline in mortality makes it even younger by disproportionately increasing the number of young people. Then, as fertility declines, the youngest ages are obviously again affected first, since births occur only at age 0, so a fertility decline shows up first as simply fewer young children than before. However, as the bulge of young people born prior to the fertility decline pushes into the older ages while fertility begins to decline, the age structure moves into a stage that can be very beneficial to economic development in a society – a large fraction of the population is composed of young adults of working age who are having fewer children as dependents at the same time that the older population has not yet increased in size enough to create problems of dependency in old age. This phase in the age transition is often associated with a golden age of advancement in the standard of living. That golden age can be transitory, however, if a society has not planned for the next phase of the age transition, when the older population begins to increase more rapidly than the younger population. The baby bulge created by the initial declines in mortality reaches old age at a time when fertility has likely declined, and so the age structure has a much greater number and a higher fraction of older people than ever before. We are only now

learning how societies will respond to this challenge of an increasingly older population.

The rapid growth of the population occasioned by the pattern of mortality declining sooner and more rapidly than fertility almost always leads to overpopulation of rural areas, producing the migration transition, especially toward urban areas, which in turn creates the urban transition. In rural areas, where most of the population lived for most of human history, the growth in the number of young people will lead to an oversupply of young people looking for jobs, which will encourage people to go elsewhere in search of economic opportunity, producing an inevitable flow of migrants out of rapidly growing rural areas.

With all good agricultural land being accounted for, migrants from the countryside in the world today have no place to go but to cities, and cities have historically tended to flourish by absorbing labor from rural areas. A majority of humans now live in cities, and the fraction is steadily increasing. The urban transition thus begins with migration from rural to urban areas, but then becomes the urban “evolution” as most humans wind up being born, living, and dying in cities. The complexity of human existence is played out in the cities, leading us to expect a constant dynamism of urban places for most of the rest of human history. Because urban places are historically associated with lower levels of fertility than rural areas, as the world’s population becomes increasingly urban we can anticipate that this will be a major factor in bringing and keeping fertility levels down all over the world.

The family and household transition is occasioned by the massive structural changes that accompany longer life, lower fertility, an older age structure, and urban instead of rural residence – all of which are part and parcel of the demographic transition. These changes occurred first in Europe, leading van de Kaa (1987) to talk about the “second demographic transition.” A demographic centerpiece of this change in the richer countries has been a fall in fertility to below replacement levels, but van de Kaa suggested that the change was less about just not having babies than it was about the personal freedom to do what one wanted, especially among women. So, rather than grow up, marry, and have children, this transition is

associated with a postponement of marriage, a rise in single living, cohabitation, and prolonged residence in the parental household. There has also been an increasing lack of permanence in family relationships, leading to higher divorce rates and instability in cohabiting relationships. Furthermore, when families do reconstitute, it is increasingly likely that it will involve cohabitation rather than remarriage. It is reasonable to think, however, that this transition in family and household structure is not so much a second transition as it is another set of transitions within the broader framework of the demographic transition. The family and household transition is influenced by all of the previously mentioned transitions. The mortality transition is pivotal because it gives women (and men, too, of course) the dramatically greater number of years to live in general, and more specifically the greater number of years that do not need to be devoted to children. Low mortality reduces the pressure for a woman to marry early and start bearing children while she is young enough for her body to handle that stress. Furthermore, when mortality was high, marriages had a high probability of ending in widowhood when one of the partners was still reasonably young, and families routinely were reconstituted as widows and widowers remarried. But low mortality leads to a much longer time that married couples will be alive together before one partner dies, and this alone is related to part of the increase in divorce rates.

The age transition plays a role at the societal level as well, because over time the increasingly similar number of people at all ages – as opposed to a majority of people being very young – means that any society is bound to be composed of a greater array of family and household arrangements. Diversity in families and households is also encouraged by migration (which breaks up and reconstitutes families) and by the urban transition, especially since urban places tend to be more tolerant of diversity than are smaller rural communities.

demography

Vanessa R. Wight

Demography is the scientific study of human population. The discipline uses empirical investigation to analyze populations and its processes. This includes the study of fertility, mortality, and migration and how these factors

change over time and affect population size, growth, structure, and composition.

The field of demography typically has been thought of in terms of two strands of scholarship. *Formal demography* focuses on the conceptualization and measurement of population processes. This area within the field emphasizes the methods by which to measure fertility, mortality, and migration, how these processes operate across different populations and within the same population over time, and mathematical modeling for estimating population growth and structure. Yet demography is also interested in the relationship between demographic behavior and the larger social context. Thus *social demography* not only measures and quantifies population processes, but it also seeks to understand more broadly the context within which demographic behavior takes place, how this context influences demographic patterns, and the relationship between this behavior and subsequent social, economic, and biological processes. Hence, family and labor force patterns that are related to key demographic events, such as union formation and dissolution, household transitions and living arrangements, intergenerational relationships and exchanges, and employment status, become important objects of consideration.

Finally, demography has long been interested in the effect of demographic processes on the natural environment. It is perhaps here where demography gained its popularity. Concern over runaway population growth or “population explosion” and subsequent increases in the level of consumption of scarce resources has historically fueled doomsday reports of the expiration of human society. However, despite the general indictment that population growth is one of the main culprits of environmental degradation, others would argue that it is the bedrock of technological innovation, economic expansion, and efficient markets – all of which are, for the most part, considered beneficial to social welfare.

POPULATION CHANGE AND DEMOGRAPHIC PROCESSES

Populations change under a limited number of conditions (Hinde 1998). That is, the change

observed in any given population over a period of time (e.g., from time t to $t + 1$) is a function of the difference in the number of births ($B_{(t)}$) and deaths ($D_{(t)}$) experienced by a population plus the difference in the number of people moving in to ($IM_{(t)}$) and out of ($OM_{(t)}$) the population. Thus, population change over time can be expressed in the following *basic demographic equation*:

$$P_{(t+1)} = P_{(t)} + B_{(t)} - D_{(t)} + IM_{(t)} - OM_{(t)}$$

The main demographic processes that account for population change are *fertility*, *mortality*, and *migration*. Fertility refers to actual reproduction (e.g., number of births), which is substantively different from fecundity or the capacity of an individual to bear children. Fertility can be measured by estimating a crude birth rate (CBR), which is the number of births per 1,000 people in the population. However, this rate includes people who cannot bear children, such as men, girls, and older women. Therefore, using a crude birth rate can result in an underestimation of fertility at a particular point in time. Thus, age specific fertility rates (ASFR) and the total fertility rate (TFR) are generally used to estimate fertility behavior. The ASFR is the number of births to women of a specific age per 1,000 women who are that age. The TFR is estimated using a life table, which is a method widely used by demographers to calculate variation in such vital events as births and deaths, as well as migration. Life table estimates are derived by subjecting a birth cohort to a set of fixed age specific rates. It is a mathematical exercise that allows demographers to make inferences about future demographic behavior in a given population (e.g., the probability that a childless woman at age 30 will have a child by age 35 or the number of years a child born in 2000 can expect to live). The total fertility rate, thus, is a measure of completed fertility and represents the average total number of births a woman can expect to have provided the age specific fertility rates remain constant over her reproductive lifespan. It is derived by summing the age specific fertility rates. The various fertility rates can be expressed as:

$$CBR = \frac{\# \text{ of births}}{\text{Total Pop}} \times 1,000$$

$$ASFR = \frac{\# \text{ of births } W_i}{\text{Total } W_i} \times 1,000$$

$$TFR = \sum ASFR$$

Mortality is the study of deaths within a population. Like fertility, the extent of mortality can be estimated using a crude death rate (i.e., the number of deaths per 1,000 people in a given population at a particular point in time). However, because the risk of death can vary by age, demographers typically use age specific death rates to estimate mortality. As discussed above, age specific rates provide the number of events, in this case deaths, to people of an exact age or age group per 1,000 people who are of the exact age or age group. A commonly used age specific death rate among demographers is the infant mortality rate (IMR). The IMR is an estimate of the number of deaths to children less than 1 year old per 1,000 live births at a particular point in time. It is expressed as:

$$IMR = \frac{\# \text{ of deaths to children under age 1 in a given year}}{\# \text{ of live births in the given year}} \times 1,000$$

Life expectancy is also commonly used to assess the degree of mortality within a particular population. Like the total fertility rate, life expectancy is estimated using a life table and the measure represents the average number of years, typically measured at birth, that a person can be expected to live, assuming that the rate of mortality at each age remains fixed.

Demographers who study *migration* focus on the movement of people. The effect of migration on societies (both senders and receivers) can be positive or negative. On the positive side, migration can act as a safety valve, alleviating social and economic pressures associated with overpopulation. People can also benefit from remittances received from family members who have migrated. Furthermore, migration can help some countries meet labor shortages that may be the result of declines in fertility. However, out migration can also lead to labor shortages. Furthermore, some of the

loss in labor can be among the most highly skilled (i.e., a brain drain). The challenges to studying migration are tremendous and most of this is related to the paucity of data available on the global movement of people. Thus, migration is typically estimated using an intercensal component method. That is, if the size of the population at two points in time is known, as well as the number of births and deaths occurring during this time period, then the amount of net migration can be estimated as the residual. Thus,

$$\begin{aligned} \text{if } P_{(t+1)} &= P_{(t)} + B_{(t)} - D_{(t)} + IM_{(t)} - OM_{(t)}; \\ \text{then Net Migration } (IM_{(t)} - OM_{(t)}) &= \\ P_{(t+1)} - P_{(t)} - B_{(t)} - D_{(t)} \end{aligned}$$

SOURCES OF DEMOGRAPHIC INFORMATION

In order to analyze a particular population, it is necessary to measure the number of people currently alive, the number of births and deaths, and how many people move in and out of the population. One source of basic demographic information is a population count or census. Population counts provide demographers with the number of people in a given area, such as the world, nation, or state, at a given period of time. Another source of demographic information is a vital register. The registration of vital events documents processes that most closely come to bear on population change, such as births, deaths, migration, marriages, and divorce. Sample surveys are another source of demographic information. They are good sources of data for two primary reasons. First, most surveys offer additional information beyond the enumeration of people and vital events that can be helpful in assessing the relationship between demographic behavior and broader social and economic change. Second, sample surveys can provide demographic information for estimating fertility, mortality, and migration in places where census counts or vital registration systems are poor or nonexistent. The Demographic and Health Surveys (DHS) are a good example of this. Originally known as the World Fertility Survey (WFS) and the Contraceptive Prevalence Surveys (CPS), DHS is a worldwide research project offering data on

population, health, and the nutritional status of women and children in developing countries. Over time, the DHS has been adopted and widely used as an important source for estimating demographic rates of change.

DEMOGRAPHIC PERSPECTIVES: THEORIES OF POPULATION CHANGE

The study of human population size and growth has captured the popular imagination of societies for centuries (see Weeks 2004 for discussion). The field of demography has enjoyed a long history of exchange and debate over the theories that seek to explain the causes of population change, the conditions under which vital events such as mortality and fertility change, and the consequences of these changes for society.

The Malthusian Perspective

Perhaps one of the most influential arguments on the dangers of population growth, and certainly one of the longest standing, is that proposed by Thomas Malthus. In his *Essay on the Principle of Population* (1798), Malthus argued that “population, when unchecked, increases in a geometrical ratio. Subsistence increases only in an arithmetical ratio” (p. 4). According to Malthus, the world was expected to expand at a rate that could not be supported by the environment – population growth was projected to outstrip the earth’s resources.

Continued growth on a global scale over the last two centuries without a complete depletion of the earth’s resources has led some critics to suggest that Malthus’s theory of population growth may have been flawed. Demographic evidence today indicates that the world has not experienced the geometric growth rate in the population that he originally proposed. Furthermore, global society has managed to make progress in producing food at a tempo far above that projected by Malthus (Weeks 2004). This is evidenced by the presence today of large agricultural conglomerates whose aim is to develop technology based food production enabling people to better process food crops as well as renewable sources of fuel – something Malthus did not foresee. In short, Malthus assumed that food would continue to

be produced in the same manner in which it was produced in his lifetime. He did not consider humans' capacity for innovation as a protective agent against dangers of rampant population growth.

Despite the shortcomings of his perspective, we still see evidence today of the Malthusian tension between population growth and resources. In 1968, Paul Ehrlich garnered popular support and critical attention with his book *The Population Bomb*. Characterized by some as a modern version of Thomas Malthus, Ehrlich predicted widespread famine and economic devastation as the result of overpopulation. However, unlike Malthus, Ehrlich also emphasized increasing environmental degradation. According to Ehrlich, food security could not be sustained indefinitely. Ultimately, unchecked population growth would outstrip the nutritional carrying capacity or "the maximum number of people that can be provided with adequate diets at any given time without undermining the planet's capacity to support people in the future" (Ehrlich et al. 1993). Ehrlich's solution, like Malthus's, was to limit population growth by moral restraint or, if this failed, by contraceptive use.

Classic Demographic Transition Theory

More than a century after Malthus the field of demography was the proving ground for yet another theory of population growth – that of the theory of demographic transition. The first formulation of the theory was a description of demographic processes that evolved into a typology of a group of countries that by today's standards would be considered developed (Thompson 1929). Additional expansion on the themes originally advanced by Thompson launched the inculcation of the demographic transition theory – a broad framework that has been a predominant influence on demographers and their preoccupation with the determinants of population change (Kirk 1996; Weeks 2004). The theory argued that societies typically moved through three stages of growth patterns. First, societies were characterized by levels of high mortality and high fertility and exhibited either stable or low rates of population growth. Under this demographic regime, high levels of

mortality were instrumental in promoting high levels of fertility. As economic organization in pretransitional societies was largely structured around the family, the survival of it was essential to the long term functioning of society (Coale 1973). Thus high levels of fertility were necessary to balance high rates of mortality.

During the second stage, mortality declined as the standard of living improved. Declines in fertility typically lagged behind declines in mortality and this was thought to be the case because fertility behavior was largely determined by social norms and values that supported higher levels of fertility in the presence of high levels of mortality. It also took people time to recognize that more children were living longer and that the need to hoard them for insurance against old age was no longer necessary. In short, it took a while for norms and values to recalibrate to a level more consistent with low mortality.

The third stage of the transition was marked by declines in fertility. Industrialization and urbanization were thought to change parents' conscious calculus about having children. For example, the value of children changed as education requirements removed children from families' labor supply. Decreases in infant mortality meant that fewer births were necessary in order to achieve a desired family size. Hence, fertility declines were the result of an increasing economic advantage to limiting family size (Coale 1973; Kirk 1996; Weeks 2004).

Reformulations of the Demographic Transition Theory

The subtle assumption of demographic transition theory was that economic development created the necessary preconditions for declines in mortality and subsequent declines in fertility. Findings from the European Fertility Project organized by Ansley Coale in 1963 challenged this theory. Reexamination of fertility and mortality declines in approximately 600 administrative divisions in Europe revealed a high level of regional variation in *when* fertility declined. As Coale (1973) stated, "the demographic transition correctly ... predicted that mortality would decline before fertility ... In neither instance does it specify ... the circumstances under

which the decline of fertility begins." In short, the demographic transition theory could not reliably identify a threshold at which fertility declined. The evidence suggested that economic development was important. However, given variation across regions in the timing of fertility declines, critics argued that economic development was not enough.

Thus began a series of reformulations aimed at explaining the conditions under which fertility fell in the wake of declines in mortality. The somewhat ethnocentric nature of theory, in that it was postulated entirely by and about people in developed countries, and its economic determinism spawned a series of reformulations in which cultural and social context were thought to moderate the economic factors that influence fertility.

For example, some critics argued that despite the increasing importance of material conditions in explaining fertility decline, ideational components that give meaning to the various costs and benefits of children are also important. In other words, the examination of fertility behavior should consider both the decision making process (the cost benefit framework) and the context within which fertility decisions are made (Lesthaeghe 1983; Lesthaeghe & Surkyn 1988). Similarly, Caldwell (1976) argued that what mattered was what people thought about children – both the economic and social value placed on having them.

Central to Caldwell's restatement of the demographic transition theory was the idea that fertility would not decline until the flow of wealth, which had typically been from children to parents, was reversed. In the process of modernization, large family networks collapsed and were replaced by smaller families that were both economically and emotionally independent and self sufficient. In the midst of familial and emotional nucleation, wealth flows from children to parents changed direction. As a result, ideas and attitudes about children changed. The economic value of children declined as they became the financial beneficiaries of family life – thereby increasing the cost to parents of having them. Therefore fertility declined as families decreased their family size to adjust to change in wealth flows. Yet, Caldwell argued the economically rational behavior

influencing fertility decisions was determined by non economic factors, such as social and cultural conditions that exist in societies. It is these conditions that influence the social value of children and prevent fertility in societies from falling below replacement level, even when this may be at odds with the economic benefits of remaining childfree (van de Kaa 1996).

In a further elaboration, and in response to demography's failure to foresee the high levels of fertility resulting in the baby boom birth cohort of the 1950s and early 1960s, Robert Easterlin argued that economic well being was an important factor in explaining fertility declines (Easterlin 1978; Weeks 2004). Specifically, Easterlin argued that the standard of living experienced as children becomes the foundation or "yardstick" by which current economic well being as adults is measured. Therefore, if individuals are able to achieve a level of economic well being similar to their parents', they will marry earlier and exhibit higher birth rates. If, however, economic prospects appear bleak and adults perceive it to be more difficult to achieve a standard of living similar to what they experienced as a child, they may delay marriage and childbearing.

According to Easterlin (1978), how the age structure of a population interacts with the economy influences the degree to which adults face economic prosperity. Thus, if the number and proportion of people entering working age are small in the presence of a burgeoning economy, their labor will most likely be in high demand and well compensated. If this compensation can afford individuals a lifestyle similar to what they experienced as children, this will exert an upward pressure on fertility. People will feel comfortable assuming the increased financial burden of having children. If, however, there is a glut in the number of young adults entering the labor force, regardless of the state of the economy, their overabundance will increase the competition for jobs and lower wage rates. This makes it more difficult for individuals to achieve the standard of living comparable to that of their parents at the same age and will thus exert a downward pressure on fertility. In short, people will be reluctant to have children, or at least a large number of them (Easterlin 1978; Weeks 2004).

The Second Demographic Transition

Many of the aforementioned theories on population change were preoccupied with either high fertility or the transition from high to low fertility. Recent trends, however, suggest that we are witnessing a deceleration in population growth on a global scale and most of this is due to widespread declines in fertility rates. So while the level of fertility still remains high in some areas of the world, the average number of children born to women has declined, resulting in a reduction in the overall rate of growth (see below). This has led many in the field to shift their focus from an overwhelming concern about high fertility to a concern about low fertility. Some have argued that these demographic changes since the 1960s warrant the label "second demographic transition" (Lesthaeghe 1995). Like the first, this transition was also described in three stages. The first stage, which took place between 1955 and 1970, was characterized by an acceleration in divorce rates, the end of the baby boom, and an increase in the age of marriage. During the second stage, around 1975–80, cohabitation and childbearing outside of marriage increased. In the third stage, which marks the mid 1980s and onwards, divorce rates flattened, remarriage was largely replaced with cohabitation, and delays in fertility characteristic at younger ages were recouped after age 30 (Lesthaeghe 1995). However, unlike the first, the motivations for the second demographic transition were notably different. While fertility declines in the first transition were linked to economic development and changes in the value of children with an increased focus on child quality, the second demographic transition was inspired by an increase in secularization or rising individualism and an increased focus on the quality of adult relationships. In short, fertility behavior, such as low or below replacement fertility, under the new demographic regime is linked to delays in marriage and increases in contraception and the motivation of this shift in behavior is thought to be more a function of increasing individual autonomy, a move toward gender symmetry, and a greater focus on the relationship between adult partners than had previously been the case.

Developed and Developing Countries Compared

Many of the theories originally aimed at explaining changes in fertility focused largely on developed countries. The fertility behavior and demographic transitions of developing countries, however, differed somewhat from their developed counterparts. While the timing of the transition from high to lower fertility was compatible with theories of economic development, the pace of transition was much faster than what had been observed in other countries, suggesting that other factors related to fertility behavior were at play (Watkins 1987). Some demographers argued that the importance of institutional change, such as the control and distribution over family planning funds and methods, as well as of ideational change was missing from theories seeking to explain fertility behavior. For example, diffusion such as the exchange of ideas about family size and family limiting practices was thought to be an important and powerful solvent of traditional fertility behavior – explaining the pace with which developing countries moved through the transition (Watkins 2000). Others went further to argue that *what* was being diffused was important. That is, the diffusion of westernized family values, which typically accompanied modernization, was thought to be one of the most important social exports to developing countries (Caldwell 1976). With its emphasis on smaller, emotionally nucleated families and increased attention and expenditures on children, the export and diffusion of westernized social values, according to Caldwell, eclipsed the role of economic modernization in explaining fertility change.

POPULATION PROFILE IN THE BEGINNING OF THE TWENTY FIRST CENTURY

Apart from the ebbs and flows in fertility and the theories that seek to explain population change, the profile of the world's population today is marked by a deceleration in growth. In 2002, the annual average growth rate of the world's population was approximately 1.2

percent, compared to 2.2 percent approximately 40 years before (US Census Bureau 2004). Considering the long history of fertility decline and the theories attempting to explain it, a decreasing growth rate may not be much of a surprise. Indeed, most of the deceleration in population growth can be traced to fertility decline. In 2002, women globally were averaging about one half more of a child than necessary to maintain levels of population replacement. In response to relatively high, albeit declining, global fertility combined with moderate levels of mortality, the largest share of the world's population are the very young under age 15. The distribution of women and men is approximately equal. China with a population of approximately 1.3 billion, India with 1.0 billion, and the United States with 298 million hold the top three spots as the most populous countries. However, in 2002 developing countries constituted the remainder of the top ten ranking (US Census Bureau 2004).

In 2002, the overall life expectancy at birth was 63.8 years. That is, assuming that the rate of mortality remained constant across each age group, a person born in 2002 was expected to survive an average of 63.8 years. There is considerable variation in life expectancy across countries. European and North American countries had the highest levels of life expectancy – upwards of 70 to 79 years – while Sub Saharan Africa had the lowest – ranging from approximately 50 years or less. This variation is due, in part, to the HIV/AIDS pandemic which has taken its largest toll on the African continent (US Census Bureau 2004). In 2002, the effect of migration flows on population change was not large. Approximately 3 million people were estimated to cross national boundaries. Mexico was the largest sender of people, followed by China and Tanzania. The top three receivers were the United States, followed by Afghanistan and Canada (US Census Bureau 2004).

It is important to note that the onset of HIV/AIDS has important implications for the study of demography, particularly demographic trends in developing countries that face the highest rates of infection and disease. The full demographic impact of the disease has yet to be realized. However, the nature of the disease, such as how it is transmitted (i.e., by horizontal

transmission from partner to partner or by vertical transmission from mother to child), as well as where mortality is concentrated in the population, can already be observed in the declines in life expectancy, declines in the growth rate, and the distortions in the age structure among the hardest hit regions of the world.

demography: historical

Etienne van de Walle

The history of population has long been of interest to historians and demographers. Historical writings were used to estimate the population of the Roman Empire, of China, and of the world over time. Local historians used monthly numbers of burials and baptisms in parish records to ascertain the effect of epidemics or food crises. Starting in the mid 1950s, the work of the French demographer Louis Henry is generally credited for initiating a new discipline, historical demography, based this time not only on the careful accounting of

vital events at the aggregate level, but also on the nominal linking of records. This became an essential tool of historians, and the appellation “historical demography” is often reserved for that auxiliary branch of history that deals with the quantitative aspects of past populations, whereas “demographic history” deals with more substantive aspects.

Adopting a more inclusive definition, historical demography is the discipline that studies the structure and the evolution of populations of the past for which written sources exist, and the determinants and consequences of population trends over time, both at the individual and at the aggregate level. This definition is broad enough to encompass literary sources or historical accounts (e.g., on the history of contraception), or medical or epidemiological evidence (e.g., on the history of disease). “The past” as used in the definition will depend on the situation and the use of the data; historical demography commonly uses sources in ways for which these sources were not meant at the time they were collected (as in the nominal use of census records) or applies new techniques to old data sets (as in regression analysis of population registers).

The field has focused heavily on methodological procedures meant to avoid the biases inherent in the data. The geographical coverage of its sources is spotty and they privilege certain individuals (e.g., the more stable and rural families) and typically only part of their life (e.g., the time they were observed in village records). Moreover, the quantitative data include a limited number of variables. Qualitative data derived from contemporary accounts or from literary, medical, and judicial sources are normative in nature, may reflect a written tradition rather than actual behavior, and are socially biased toward the upper classes; they provide insight, but must be used critically.

Louis Henry (1970) perfected the method of family reconstitution, which consists in linking all the information concerning individual couples and their children found in the registers kept by local church or civil authorities. The technique was applied to parish records of villages, and served first to investigate the fertility of individual married couples in eighteenth century rural France. Other researchers have followed his lead to study parish records in

various European countries, most notably England, and in Canada. Similar techniques can be used with already reconstituted families, as accessible through genealogies or population registers. Such registers that provide information on both the population and its vital events have existed in Sweden since 1750, and in several European countries during the nineteenth century. Akira Hayami (1979) initiated the study of the Japanese population registers of the Tokugawa era (the religious faith investigation registers); population registers and genealogies from Taiwan and mainland China have also yielded information on non western populations.

Henry's initial interest was the decomposition of the biology of fertility. He was searching past records for examples of "natural fertility," i.e., the marital fertility that would prevail in the absence of family limitation. The family reconstitution method proved useful to investigate additional characteristics of the demography of the old regime, such as infant and child mortality. The focus here was microdemographic. Henry also laid down a plan to study a representative sample of rural French parishes using non nominal counts of vital events, to study such topics as their seasonality, illegitimacy, marriage patterns (age at marriage, permanent celibacy, widowhood), and even literacy (ability to sign a marriage certificate). He also pioneered the technique of population reconstruction, the macrodemographic analysis of parish records over time to establish the age and sex distribution of a population as well as its fertility, nuptiality, and mortality trends.

Historical demography was widely accepted by historians because the study of common village people fitted well in the "serial" history of the Annales School (as opposed to "evential" history that focused on major events and figures). It contributed to an understanding of underlying structures and trends over the long term. The demographic system of past societies became the trunk on which other studies of the socioeconomic structure could be grafted. The methodology was extended to larger units, e.g., cities, regions, whole countries, where social differences between individuals and groups were more marked than in rural parishes. It was applied to large samples where the results could be extrapolated to rural France (Séguy

2001), England (Wrigley & Schofield 1981), Germany (Knodel 1988), Canada (Charbonneau et al. 1993), and the pioneer trail to Utah (Bean et al. 1990).

Parallel developments in historical demography involved the use of censuses, either alone or in combination with vital registration. At the aggregate level, they are used to compute long series of fertility and mortality indices to shed light on major demographic changes at the secular level. The European fertility project (Coale & Watkins 1986) produced standardized measures of fertility and nuptiality for a comparative study of the demographic transition in Europe. At the individual level, nominal listings of inhabitants are used to investigate household structure in the past (Laslett & Wall 1972). In the United States, the study of historical censuses has been facilitated by the systematic conservation of census lists. The interest in microdata from censuses stems in part from the new availability of computers facilitating the manipulation of large stores of data and from the development of analytical methods that did not exist at the time the information was collected. These include information on the occupational and ethnic composition of the population and on infant and child mortality (Watkins 1994) at the time of a particular census. Equally important in the eyes of social historians is the creation of historical series of comparable structural data where the evolution of social phenomena can be followed though time.

From a sociologist's point of view, historical demography provides insights into individual behavior and the complex social life of communities. Data from the past have served as a store of comparative materials on which hypotheses on human behavior can be tested and models of demographic evolution can be derived and applied to populations of the developing world with inadequate statistics. Theories about the demographic past have been regrouped in a series of general explanatory frameworks or models, which remain controversial and serve as battlefields for dissenting researchers. The most important of these models relate to fertility, mortality and health, and marriage and household formation. The long term study of fertility change is subsumed in the model of the fertility transition. Fertility transition is

interpreted as a change from natural fertility to deliberate control of childbearing. In natural fertility regimes, the duration of birth intervals within marriage is the result of involuntary behavior determined by social norms (e.g., on abstinence or breastfeeding), by health, and by environmental variables. After the fertility transition, the deliberate action of the spouses to limit their births is a function of their desire for children. The model posits that there is a clear divide between demographic regimes where couples had no precise reproductive targets, and regimes where they attempted to stop childbearing upon reaching certain parity and to replace deceased children. This fundamental change in behavior has been variously explained as an adaptation to socioeconomic change or as the result of the diffusion of new ideas, norms, and techniques (e.g., birth control).

The dominant model accounting for the decline of mortality in the western world has received the name of epidemiologic transition. Historical demography produced estimates of steadily declining mortality from the middle of the eighteenth century onward (Schofield et al. 1991). The decline reflects the progressive transition from a stage dominated by food crises and infectious diseases to a situation where most people die in old age from chronic diseases. The main explanations of the change have ranged from exogenous (the effect of climatic or epidemiological factors, and later the diffusion of medical knowledge) to endogenous causes (the high mortality resulting from population pressure and low standards of living giving way, under the influence of economic development, to better nutrition and a better control of the environment).

A third important model relates to nuptiality and household formation. John Hajnal (1965) pointed out the singularity of the Western European pattern of marriage characterized by a late age at onset and extensive celibacy. He associated it with a pattern of household formation where men had to defer marriage until they could establish sufficient livelihood to support a family. The study of household structure in European census lists confirmed that the conjugal family unit had long constituted the basic residential pattern. Extended family households appear to have been rare in Western Europe for several centuries, whereas they dominate in

many other contexts. If economic circumstances allow or prevent the contracting of marriages and the establishment of households, a feedback mechanism will link fertility population increase to economic growth. British historians have demonstrated the effectiveness of nuptiality as a long term regulator of population growth, and have adopted a Malthusian paradigm.

From its beginnings in the study of the fertility and mortality of individuals, historical demography has evolved toward the consideration of demographic systems and their dynamics in the historical context of specific economy and societies. In the process, it has grown increasingly comparative. The opening up of new data sources with historical depth in Japan and China has allowed a comparative approach that has often challenged the generalizations derived from the study of western countries (Bengtsson et al. 2004). It has been argued, for example, that the Chinese demographic system was more preoccupied than the European one with lineage perpetuation, and resorted more to adoption and to infanticide to attain that goal (Lee & Wang 1999). An attraction of historical demography is the opportunity it provides to analyze other data sets, other cultures, and other social and epidemiological contexts.

denationalization

Saskia Sassen

Denationalization is an emerging category for analysis that aims at capturing a specific set of components in today's major global transformations for which the typical terms in

use – globalization, postnationalism, and transnationalism – are inadequate. These three terms all point to locations for change that lie outside the nation state. The effort behind developing a fourth category – denationalization – arises out of an as yet small but growing body of research showing that critical components of today's major transformations actually take place inside the nation state. The actual processes that constitute the transformation in this case have the effect of denationalizing what has historically been constructed as national. These processes are partial, often highly specialized and obscure. Further, they frequently continue to be coded, represented, and experienced in the vocabulary of the national, and hence can remain unrecognized and undetected. Thus this new category for analysis opens up a vast research and theorization agenda connected to global trends but focused on the nation state. Sociology is particularly well situated to develop this agenda because its theories, methods, and data sets have to a large extent been shaped by the fact of nation states. But while this new agenda can use and benefit from sociology's existing resources, it will require new interpretive instruments and framings.

The ongoing development of categories for analysis is today shaped in good part by the fact of cross border processes such as economic, political, and cultural globalization and the resulting theoretical and methodological challenges they pose. Such challenges arise out of the fact that the global – whether an institution, a process, a discursive practice, or an imaginary – simultaneously transcends the exclusive framing of national states yet partly inhabits national territories and institutions. Seen this way, globalization is more than the common notion of growing interdependence of the world generally and the formation of global institutions. It also includes subnational locations.

When the term globalization is used, it tends to cover the presence and further formation of explicitly global institutions and processes, such as the World Trade Organization, global financial markets, the new cosmopolitanism, and the War Crimes Tribunals. The practices and organizational forms through which these dynamics operate constitute what is typically thought of as global. Although they are partly

enacted at the national scale, they are to a very large extent novel and self evident global formations.

But there are processes that do not necessarily scale at the global level as such, yet are part of large global changes. These processes take place deep inside territories and institutional domains that have largely been constructed in national terms in much, though by no means all, of the world. Although localized in national, indeed, subnational settings, these processes are part of globalization in that they involve trans boundary networks and entities connecting multiple local or “national” processes and actors. Among these are included, for instance, cross border networks of activists engaged in specific localized struggles with an explicit or implicit global agenda, as is the case with many human rights and environmental organizations; particular aspects of the work of states, e.g., certain monetary and fiscal policies being implemented in a growing number of countries, often with enormous pressure from the IMF and the US, because they are critical to the constitution of global financial markets; the fact that national courts are now using international instruments – whether human rights, international environmental standards, or WTO regulations – to address issues where before they would have used national instruments. It also includes more elusive emergent conditions, such as forms of politics and imaginaries which are focused on localized issues and struggles, yet are part of global lateral networks containing other similar issues and struggles, with all participants increasingly aware of this and connecting around their shared local issues; these can be thought of as non cosmopolitan forms of globality.

But if the global partly inhabits the national, it becomes evident that globalization in its many different forms directly engages two key assumptions in the social sciences generally, and in sociology in particular. The first is the explicit or implicit assumption about the nation state as the container of social process. The other is the implied correspondence of national territory with the national, i.e., if a process or condition is located in a national institution or in national territory, it must be national. Both assumptions describe conditions that have held, though never fully, throughout

much of the history of the modern state, especially since World War I, and to some extent continue to do so. What is different today is that these conditions are now partly but actively being unbundled. Different also is the scope of this unbundling.

Conceiving of globalization not simply in terms of interdependence and global institutions but also as inhabiting the national opens up a vast field for study that remains largely unaddressed within the globalization and related scholarships. The assumptions about the nation state as container of social process continue to work well for many of the subjects studied in the social sciences, and have indeed allowed social scientists to develop powerful methods of analysis and the requisite data sets. Further, these same assumptions are typically also present in much of the scholarship on globalization, transnationalism, and postnationalism, from where come definitions of globalization as growing interdependence and the global as exogenous to the national. But these assumptions are not helpful in elucidating questions about how today’s global, transnational, and postnational processes and formations are constituted partly inside the national, and are not merely exogenous forces that “attack” the national.

Theories based on the assumption that the nation state is a closed unit, that the state has exclusive authority over its territory, and hence that what takes place inside the nation state is national cannot fully accommodate the series of instances that the category “denationalization” seeks to capture. We might formulate this effort as follows. We need to recognize that the fact that a process or entity is located within the territory of a sovereign state does not necessarily mean it is a national process or entity; it might be a localization of the global. While most such entities and processes are likely to be national, there is a growing need for empirical research to establish this for what is in turn a growing range of localizations of the global. Much of what we continue to code as national today may well be precisely such a localization – whether endogenous to the national or an insertion from the outside.

Developing the theoretical and empirical specifications that allow us to accommodate such conditions is a difficult and collective effort.

However, some of the empirical knowledge on subnational processes and conditions – especially in sociology, anthropology, and political science – can be of use, as can the methods used to produce such knowledge. Including the national allows us to use many of the existing research techniques and data sets in sociology developed with national and subnational settings in mind. But we will still need to use and develop new conceptual frameworks for interpreting findings – frameworks that do not assume the national is a closed system and one that excludes the global. Surveys of factories that are part of global commodity chains, in depth interviews that decipher individual imaginaries about globality, and ethnographies of national financial centers all focus on national settings and thereby expand the analytic terrain for understanding global processes. Denationalization is an analytic category that provides a potentially much encompassing conceptual architecture for this type of work.

Using (and developing) the category denationalization for studying these processes means mapping an analytic terrain for the study of globalization that moves inside the national. It includes but also moves beyond understandings of globalization that focus on growing interdependence and self evident global institutions. Thus part of the research work entails detecting the presence of globalizing dynamics in thick social environments which mix national and non national elements. Structurations of the global inside the national produce a partial, typically highly specialized, and specific denationalization of particular components of the national.

If we conceive of it narrowly, the research literature on denationalization is still small but growing rapidly. In the 1980s, Zorn did some initial work on the subject, and in the 1990s Sassen (1996) began a serious effort to develop the term into a category for analysis. The work of Gereffi and Korzeniewicz (1994) contains critical elements for this effort. There have been other efforts, notably Bosniak (2000), but a careful reading shows that denationalization is there used as equivalent to postnationalism. Closer to the mark is the type of analysis found in Rubenstein and Adler (2000), Koh (1997), and Jacobson and Ruffer (2006). Ulrich Beck (e.g., 2006) has for years developed a critique of

methodological nationalism that is a key ingredient for an elaboration of the category denationalization. The most developed treatment, and perhaps the book that introduces the category formally, is Sassen (2006). This book also examines a large body of contemporary work in all the social sciences (e.g., on global cities, on translocal households, on the incorporation of human rights norms in national law, on the reorientation of state policy toward global agendas) that has done a type of research we might see as fitting but has done so without knowingly developing this particular category for analysis, and hence would not be right to cite here. The most developed of these bodies of scholarship is that on global cities (e.g., Taylor 2004). In the last few years we have seen a significant increase in the number and kinds of studies wherein the critical organizing variable is the subnational constitution of global processes. This research ranges from studies focused on markets for global trading that have only one location, such as the Gold Fix in London, to particular types of ghettos that are becoming part of cross border networks of ghettos, often through cultural practices, most notably rapping. Multi scalar analytics are one framing that is critical in this effort, especially as a heuristic (Jones 1998).

denomination

William H. Swatos, Jr.

The term denomination was innovated in the late seventeenth century by those groups of Christians in England who dissented from the established Church of England, but considered themselves loyal to the British state and recognized the monarch as having rights with respect to the Church of England. In 1702, specifically, Presbyterian, Baptist, and Congregationalist clergy formed “the body of the Dissenting Ministers of the Three Denominations in and about the City of London.” The term was introduced to counter the pejorative term sect, which in popular usage carried a sense not only of deviant or undesirable practices, but also, as sectaries, implied political radicalism. *Denomination* is now used in pluralist societies for those forms of organized religious expression that generally support the established social order and are mutually tolerant of each other’s practices.

TYPOLOGY

The term denominationalism was significantly introduced into the literature of the sociology of religion by H. Richard Niebuhr in his book *The Social Sources of Denominationalism* (1929). The central thesis of this work is that new religious organizations (“sects”) begin among

the socially “disinherited” within a population, but in the US, as these groups attain to higher social status, their religious expressions become more “respectable” or socially accepted; thus, there is a movement across generations from sectarian to denominational religious life – or else the sectarian group dies out. This strongly evolutionary view of religious innovation and organizational development has been considerably modified today. A particularly important contribution to the study of denominationalism was David Martin’s seminal article “The Denomination” (1962), wherein he argued for a reconsideration of this structural form as a historically and culturally specific type of religious organization, rather than as a stage on a quasi evolutionary continuum.

A standard current definition of the denomination has been provided by Wilson (1959: 4–5), who writes that the denomination is “a voluntary association” that “accepts adherents without imposition of traditional prerequisites of entry,” such as belonging to a particular ethnic or national group, or sectarian testimonies of spiritual regeneration. “Breadth and tolerance are emphasized . . . Its self conception is unclear and its doctrinal position unstressed . . . One movement among many . . . it accepts the standards and values of the prevailing culture . . . Individual commitment is not very intense; the denomination accepts the values of the secular society and the state.”

Furthermore, and most significantly, individuals in a denomination coalesce around a notably open view of their religious purpose. The elusive goal of a denomination’s members is to build and maintain a particular identity as believers without losing sight of all that, at the roots, unites religious groups and their purposes in a free society.

The association between religious denominationalism and sociocultural pluralism is crucial to its organizational success. In pluralism one may belong to any denomination or none at all. Religion is pigeonholed and privatized. It is a voluntary activity undertaken or dismissed at the discretion of the individual. The denomination is thus marked most significantly by this voluntarism of support coupled to mutual respect and forbearance of all other competing religious groups. It is indeed this quality of *competition* that is the unique hallmark of the

pluralistic religious situation; acceptance of the “free market” of religious ideas is the critical operating principle of denominationalism as an ideology. Denominations are the organizational forms that dominant religious traditions assume in a pluralistic culture. The distinction between monopolistic and pluralistic societies in typological differentiation between the church and the denomination appears particularly in Swatos’s (1979, 1981) church sect model.

Although denominationalism is now characteristic of virtually all western societies, it reaches its quintessential expression in the US; that is, American denominationalism has been the model for religious pluralism throughout the world. (Andrew Greeley, for example, titled a text on American religious life *The Denominational Society*, 1972.) The particular effect this had on American religious development up to the 1950s is chronicled in Will Herberg’s benchmark volume *Protestant–Catholic–Jew* (1955). Although, strictly speaking, denominationalism is a Protestant dynamic, it has become fully accepted in principle by all major religious groups in the US; in fact, one could say that the denominationalizing process represents the *Americanizing* of a religious tradition, which is at the same time and in the same measure a *relativizing* process. Religious groups that too strongly resist this process are likely eventually to face run ins with the legal system. Since the 1940s, social scientists have been particularly interested in the relationship between denomination and both social stratification and sociopolitical variables; the term *class church* was first applied as an equivalent to denomination by J. Milton Yinger in the 1940s.

Although some religious groups have made specific efforts to eschew the term as a label, denomination nevertheless has been the most neutral and general term used to identify religious organizations in the US. Denominationalism is an institutional pattern that both governs relations among religious groups and organizes contact between them and the wider community. Such common phrases in sociological research as organized religion and religious affiliation anticipate denominationalism as the dominant religious expression in society. Religious belief and action “work together” with the sociocultural system to develop a legitimization system as a result of mutual interdependence.

Denominationalism is a structure that allowed Americans to resolve religious differences peacefully. A concomitant result was to create a context for both a deemphasis on and eventual discrediting of theology as a source for authoritative knowledge in American civil society.

DENOMINATIONS TODAY

Since the 1980s, and particularly with the publication of Robert Wuthnow’s *The Restructuring of American Religion* in 1988, there has been considerable debate within the sociology of religion over the current significance of denominationalism in American society. This debate was presaged by a distinction drawn by the church historian Martin Marty in *Righteous Empire* (1970) between two “parties” in American religion. According to Wuthnow’s elaboration of this view, each denomination is now divided between the two parties (roughly, liberals and conservatives) on critical sociopolitical issues, reflecting in turn the relative rise in importance of “the state” as a sociocultural actor since the 1940s, whereas prior to that time the state’s field was largely limited to the political economic sphere. The ecclesiastical “party” with which people identify as a part of their cultural lifestyle hence is more important to both their spiritual and their moral lives than is a particular denominational label, according to this theory.

This realignment involves two related changes in the structure of American religion. First, official denominationalism, even that of the broadest sort analyzed by Herberg, appears to some analysts to be waning. They claim less and less distinctive information is conveyed by denominational labels, while more and more these organizations have been reaping distrust and alienation from members. Second, in their place hosts of movements with narrower objectives have emerged, ordinarily ones that cluster loosely around items from either conservative or liberal political agendas.

Attention has thus turned away from interdenominational ecumenical activity, for example, not because the churches themselves deem it to be unimportant, but because there is no need to negotiate peace among noncombatants. “The primary axis defining religious and

cultural pluralism in American life has shifted. The important divisions are no longer ecclesiastical but rather ‘cosmological’” (Hunter 1988: 22). They no longer revolve around specific doctrinal issues or styles of religious practice and organization, but rather around fundamental assumptions about values, purpose, truth, freedom, and collective identity. (Thus the most heated controversies swirl around such issues as abortion and sexual orientation rather than whether people kneel or stand or sit to receive Holy Communion or have or have not been confirmed by a bishop in apostolic succession. The growth of “nondenominational” and “para church” organizations is seen as part of this process.)

Others argue that this view is historically shortsighted and needs modification. Swatos, for example, uses the local–cosmopolitan distinction elaborated specifically in the sociology of religion by Wade Clark Roof to argue that denominationalism in the context of American voluntarism is preeminently a *local* dynamic, providing people “place” in a specific setting, and that this dynamic operates as much as it ever did to the extent that cosmopolitan elaborations (e.g., denominational agency structures) can be discounted from analyses. Cosmopolitan denominational bureaucracies are not, according to this thesis, the crucial social dynamic of the typology, but a specific, transitory development. In addition, intradenominational debates have created more internally consistent denominational worldviews – conservatives now dominate the Southern Baptists, while liberals have won the day among Episcopalians and the United Church of Christ. James Davidson and colleagues have also shown that the various denominations continue to remain significantly disproportionately represented among elites in the US across the twentieth century, with corrections required only to accommodate specific immigration effects. Reform Jews, for example, are now also significantly over represented among elites, along with Episcopalians, Unitarians, and Presbyterians; Roman Catholics have achieved approximate parity with their share of the general population. On the other hand, conservative Protestants generally remain significantly under represented among American elites, which may explain their attempts to

achieve greater political visibility, hence to influence both economic and cultural policies.

An often overlooked historical dimension of American denominationalism is the role women played in maintaining the life of the different denominations and in the social ranking system that they may have implied – again, particularly at the local level. The decline of membership in some mainline denominations (e.g., Methodists, Presbyterians, Episcopalians, Congregationalists [United Church of Christ]) is at least partially due to the increased presence of women in the workforce, which has resulted in a corresponding absence of women to undertake volunteer activities. Women in these denominations are also more likely to be in the professional classes and thus to have job responsibilities that do not end with the workday. Denominations that have declined in membership directly correspond to those that have most endorsed gender equality, while those that have gained membership are more gender differentiated. They also tend to attract membership from the working stratum, where even women working outside the home are, relatively speaking, more likely to be able to devote more of their discretionary time to church activities and are less likely to experience role redefinition in the home.

Regardless of which side of the debate on the significance of denominationalism is ultimately vindicated, both perspectives emphasize the crucial role of the congregation as the place where religious ideology and the lived experience of the people who wear a particular denominational label meet. This points to a crucial dialectic in American religiosity between organization and action: denominationalism is not now nor has it ever been realized except through the life of specific local units or congregations.

CONGREGATIONALISM

Used in three interconnected senses, the term congregationalism emphasizes the role of lay persons (or the laity, as contrasted to ordained, set apart clergy) within a religious organization. While congregationalism is especially important to understanding religion in the US, it is characteristic of denominationalism globally. Congregational religiosity may be contrasted to

both historic state church monopolies and to shrine or pilgrimage religion where a group of resident devotees maintains a shrine to which the public comes either for festivals or for specific clientelistic needs (funerals, weddings, healing services, fortune telling, etc.). Religious congregations in the US form the largest and most significant community group that weaves through American society, but at the same time their diversity on crucial sociopolitical, socio-economic, and sociomoral issues diffuses their potential impact on the larger society, as outsiders tend to see these cleavages in central values as diluting confidence in the authority of the stance of any specific group.

One sense of the term is to refer to a specific denomination of Christians, once called the Congregational Church – since a 1950s merger with the Evangelical and Reformed Church now formally titled the United Church of Christ (UCC). This body is the inheritor of the established church of New England formed through a Pilgrim–Puritan alliance in the early seventeenth century, shortly after immigration from England. In England today, historically Congregational churches are now part of the United Reformed Church; in Canada, most Congregational churches merged into the United Church of Canada in the 1920s; one group of Congregational churches in the US that did not join the UCC merger is now known as Congregational Christian Churches. New England Congregationalism spawned a number of offshoots, including Unitarianism and virtually all Baptist churches.

The name Congregational Church is taken from the fact that this denomination vests authority in the local congregation; that is, it has a congregational polity, or organizational structure. Other forms of polity are presbyterian, where authority is vested in the regional clergy associations, and episcopal, where authority is vested in a singular regional head, known in Christian traditions as a bishop. These forms of polity historically have named the major streams of American Protestant Christianity. (The United Methodist Church, for example, was originally named the Methodist Episcopal Church, contrasting it with the Protestant Episcopal Church, now known simply as the Episcopal Church in the US, the Anglican Church in most

of the rest of the world.) Both the presbyterian and episcopal forms in actual practice in the US, however, are modified significantly by congregationalism. In strict usage, however, the core principle of congregationalism is that the local congregation *is* the church; that is, no other earthly institution can claim religious authority over the corporate worship of believers. It hires (“calls”) its own minister (and can fire him or her as well). It also decides acceptable forms of doctrinal profession, worship style, and so on, and decides on what forms of “fellowship” it will accept with other churches – for example, whether it will allow members who belong to a different congregation to receive various sacramental ministrations, particularly Holy Communion, and the terms on which it will allow individuals who have belonged to some other congregation to join its congregation. The congregation also normally corporately owns the property on which any facilities it uses are located (e.g., the worship building, education facilities, and offices).

As a form of polity, congregationalism descends from the Jewish synagogue tradition (synagogue is a Greek word for “gathering together”), where in Orthodox practice a synagogue is created whenever 10 men gather together for prayer. In its modern usage, however, congregationalism has come to symbolize a greater principle – namely, the religious *voluntarism* of denominationalism. The upshot of modern western political ideology is that religion is an entirely voluntary activity: one may not only go to whatever church one chooses, but one may also go or stay home whenever one chooses, and one does not have to go to or join any church at all. Furthermore, the church is largely seen as serving the needs of its congregation, rather than the reverse. The greater the extent to which, as in the US, support for the church is on an entirely voluntary basis as well, rather than through some tax scheme, the role of the congregation is correspondingly increasingly magnified. In this sense all churches in the US and other nations which lack either an explicit or covert system of government subsidization are congregationalist in a radical way: unless a church has been extremely well endowed by prior generations, if the congregation leaves, the church must be closed. This is very different,

for example, from some Scandinavian countries, where state support ensures that a regular program of activities will go on, even though only a tiny percentage of the population attends church. By the same token, persons from these traditions may find offensive the practice of passing and offering (collection) plate or basket during worship – perhaps the one common worship experience that cuts across virtually all religious traditions in the US.

Steeped deeply in the Pilgrim myth and Puritan culture, the worldview of the Protestant ethic, the voluntaristic principle that is inherent in congregationalism colors all religion in the US, not simply the Congregational Church or even Protestantism or even Judeo Christianity. Buddhist, Islamic, Roman Catholic, and national Orthodox groups in the US all must adjust to aspects of this organizational norm in order to survive. Similarly, the missionary activity of European Protestants throughout much of the Southern hemisphere and Far East has made congregationalism normative at least as far as Christian congregations are concerned. There was also a Catholic version of congregationalism in the US (called trusteeism) in the early years of the American experiment, but it was officially discontinued in the nineteenth century. Several recent studies of American Catholics, however, have emphasized continued popular attachment to a local parish as distinct from a hierarchical structure. Indeed, although the observation is most often credited to G. K. Chesterton, more than one commentator has remarked that in America even the Catholics are Protestants!

Americans can and do worship as well as vote with their feet and their pocketbooks. A degree of accommodation to this aspect of the “American way of life” is structured into virtually all corporate religious practice. By the same token, Americans are more likely to see “religion,” whether they value it positively or negatively, as a congregational activity (“belonging to a church,” or sometimes “organized religion”), and in recent usage to distinguish this from personal religiosity by referring to the latter as spirituality. Denominationalism, expressed through congregational religious life, provides definition for a sociocultural space in societies as they create institutional subsystems

that attempt to differentiate public and private worlds. In historically monarchical societies religious and political lines were certainly blurred and possibly obliterated. To hold a religious opinion contrary to the official church was to be disloyal to state and society. The move toward a measure of separation between worlds of public obedience and private opinion began in the British Isles, but was almost immediately exported to the American colonies, where it grew far more rapidly and produced more abundantly.

GLOBALIZATION

From both American and British missionaries the public/private distinction lying behind denominationalism was widely exported and has become internationally recognized as a normative principle for political-religious relations and articulations of religious freedom. At the same time, however, specific denominational traditions in Anglo America have at times had to face up to global realities in ways they did not necessarily expect. While on the one hand denominations in the mother countries gradually came to support an end to “colonialism” both in practice and in the ideology that lay behind it, they often were surprised that the doctrinal seeds they sewed would bloom as profusely as they have. For example, the largest number of Anglicans now reside in sub-Saharan Africa, and from a number of those countries they are being taken to task by their coreligionists for what are perceived by those whom they evangelized as betrayals of the basic tenets of the Christian faith, particularly with respect to human sexuality. This is also true for the southern cone of South America and parts of Asia. A similar situation exists among African Methodists. Some denominations of specifically American origin, such as the Church of Jesus Christ of Latter day Saints (Mormons) and Seventh day Adventists, have also globalized so successfully that their majority constituencies lie outside the US. In short, the denominational principle has been exported as a political solution but not necessarily as an ecclesiastical value of compromise to a set of standards that is not characteristic of the

indigenous population's appropriation of the moral values of Christianity.

In Europe, by contrast, the denominational principle has been appropriated in terms of a gradual disestablishment of specific religious expressions, but not necessarily of state support. Thus, it remains the case that "denominational" churches that have had historical state church ties remain largely the province of small numbers of attendees, with clergy salaries and building maintenance underwritten from state or parastate agencies. Potentially the most interesting cases for the future of denominationalism are in the countries of the former Soviet Union, where religious monopolies (primarily either Orthodox Christian or Islamic) vie with challenges from religious groups of primarily western denominational origin (e.g., Baptists and Pentecostals, and to a lesser extent New Religious Movements). In Greece as well, the issue of European Union pluralism versus historic Orthodox primacy has arisen, primarily in respect to the inclusion of "religion" on passports and identity cards in contravention of EU standards, but also with regard to the treatment of adherents to such "marginal" denominations as Jehovah's Witnesses.

department store

Wendy A. Wiedenhoft

Department stores by definition offer a large variety of merchandise organized into specialty departments under one roof. The first department stores were unique not simply because of the variety of goods they offered, but also because their policies were "consumercentric." Department stores instituted fixed prices – often advertised in newspapers – so consumers would not have to engage in the time consuming practice of haggling over the cost of the goods that they purchased. Catering to the whims of consumers, department stores established the "no questions asked" policy of merchandise exchanges and refunds, money back guarantees on purchased products, and free delivery. The first department stores offered cooking and knitting classes; some became "Saturday bankers," cashing checks when banks were closed. Other consumercentric policies included personal attention by sales clerks and clothing alterations. These policies engendered consumer loyalty and trust, as did the participation by department store owners in local civic life (Rosenberg 1985; Leach 1993).

Aristide Boucicaut opened the first department store, Bon Marché, in Paris in 1852. It did not take long for retail merchants in the United States to institutionalize the department store as a fixture of the urban landscape. Alexander Turney Stewart has been credited with opening the first department store in New York City in 1862. Named the Cast Iron Palace, it contained 19 departments from silks to toys. Other cast iron department stores were established near Stewart's store on lower Broadway between 8th and 23rd, popularly known as "Ladies' Mile," including Lord & Taylor, Siegel Cooper, Stern Brothers, LeBoutellier, James McCreery, and Simpson Crawford. John Wanamaker, the "Merchant Prince," opened the Grand Depot in Philadelphia in 1876. It became the largest single floor department store in the world with 129 concentric counters surrounding a central ballroom of female fashions. Marshall Field built the largest department store in the world on State Street in Chicago when he added a 20 story men's store in 1917 across the street from his existing 12 story structure erected in 1907. Macy's department store soon took over this title when it came to occupy an entire city block and stand 30 stories tall in 1924.

THE DEMOCRATIZATION OF DESIRE

Department stores created a "dream world" (Williams 1982) for consumers with extravagant displays and spectacular atriums that encouraged them to browse and fantasize about current and future purchases and identities. However, these dream worlds would have been impossible without technological and organizational advances in mass production and consumption and business management (Leach 1993). The sensational array of goods displayed at department stores depended upon the mass production of consumer goods, especially ready to wear clothing. Reliable distribution methods were necessary to continually stock merchandise. This was particularly important because many of the first department stores sold food products. Elevators and escalators were installed to provide comfort and convenience as well as to methodically navigate consumers through different departments. Pneumatic tube systems were used

to efficiently handle the high volume of cash transactions until credit. Installment payment plans were established to tempt consumers to immediately gratify their desires. Thus, a hidden, formally rationalized system supported the enchanting façade of the department store (Ritzer 2005).

Although department stores catered to an overwhelmingly bourgeois consumer base, they did not close their doors to working class consumers who wanted a glimpse of luxury. Members of all classes were encouraged to spend hours walking through these vast emporiums, wandering from department to department, fantasizing about the novel array of consumer goods on display – all without having to spend any money at all. Marshall Field even tried to tempt consumers from the city sidewalk, installing spectacular window displays to create desire. According to Leach (1993: 63), glass was used by department stores to democratize desire while "dedemocratizing access to goods." Displaying goods under the protection of glass allowed all consumers to gaze at luxurious products, even if they could not physically touch them or financially afford them. While department stores may have democratized consumer desire by inviting all individuals to enter their dream worlds, most stores were privy to the fact that working class consumers could not afford many of the goods they offered. To solve this dilemma some department stores created bargain basements with marked down goods and cheap imitations of products for sale on the upper levels (Leach 1993).

A PRIVILEGED SPACE FOR WOMEN

One may question the democratic nature of this desire because it was primarily directed at one group: women (Reekie 1993). Although men certainly consumed goods, they were viewed as too rational to be tempted into buying something they did not really need. Store managers did not think that most men had the time to waste spending hours wandering through a variety of departments; conventional wisdom held that most men would be uncomfortable walking through women's departments. Women, on the other hand, were stereotypically viewed as not only having the time to shop, but also possessing

an irrationality that could be managed through created desire. The department store became the female public sphere, replacing, in the words of Émile Zola, the church. According to Zola, the department store “marches to the religion of the cash desk, of beauty, of coquetry, and fashion. [Women] go there to pass the hours as they used to go to church” (cited in Miller 1981: 19). Like the church, the department store was a place where middle class women could legitimately be alone in the city. Their access to this part of the public sphere was a consequence of their domestic duty to take care of the private sphere. While women could fantasize about the latest fashions, much of their shopping revolved around purchasing items for their households.

Women, however, were not just shopping at the department store but were also working as sales clerks within them. Furthermore, men were not entirely absent from this female public sphere as they owned and managed most department stores (Benson 1986). Thus, a sexual division of labor and a class division of shopping existed as a concrete reality in these dream worlds. Young, unmarried female sales clerks were overworked and underpaid, yet they were still expected to look and act professional. Female shoppers were not ignorant of this exploitation. During the Progressive era middle and upper class female shoppers formed a consumers’ league to help ameliorate the working conditions of female sales clerks in New York City, publishing a “white list” of department stores that treated their female sales clerks fairly. Interestingly, the success of securing shorter working days for sales clerks came at the expense of working class women, who did not have the leisure to shop during what became regular department store hours.

THE DEPARTMENT STORE AND THE SHOPPING MALL

The rise of the enclosed, suburban shopping mall in the post war era marked both the success and the eventual downfall of the traditional department store. The original grand emporiums remained in the city center, but when department stores began creating national chains they lost much of their distinctiveness. Mall developers courted the large department

stores to anchor their shopping centers. Most mall developers provided either low or no rent from department stores because they knew that they brought in prized foot traffic. Early shopping malls mimicked a “dumb bell” architectural model with department stores as the anchors to force consumers to walk through the interior of the mall and hopefully be tempted to shop at smaller, specialty shops. However, smaller specialty shops began to rob the department store of its actual departments. Consumers could now shop at Victoria’s Secret for lingerie or Footlocker for athletic apparel instead of searching for these departments at Macy’s or Bloomingdale’s.

No longer rooted in a local city culture, chain department stores became increasingly rationalized or “McDonaldized” (Ritzer 2004). The physical architecture of the stores lost their enchantment. The homogeneous products they offered for sale did little to distinguish one department store chain from another. Prices remained low, but at the expense of personal service. Mergers have been one of the primary causes of this disenchantment. Mergers, of course, are not a recent development. The first significant department store mergers occurred in the 1920s, culminating in the creation of Federated Department Stores in 1929. In 2005 Federated Department Stores spent \$11 billion to acquire May Department Stores Company. This mega merger of about 950 department stores has resulted in many May department stores, such as Lazarus, Rich’s, Hecht’s, and Kaufman’s, being renamed Federated’s most popular chain, Macy’s.

THE DEATH OF THE DEPARTMENT STORE?

In recent years the department store has been in a state of decline with the rise of “big box” stores, such as Home Depot, Office Max, and PetSmart. Big box stores are free standing spaces that specialize in selling large quantities of a distinct category of merchandise at low prices. Dubbed “category killers” (Spector 2005), big box stores seek to monopolize the market of a specific category at the expense of both local retail stores and department stores. Essentially, big box stores have taken the

“departments” out of the department store. Charles Lazarus, the founder of Toys R Us, institutionalized the modern big box store. Department stores dominated the market for toys until this category killer was established. Department stores have steadily decreased their number of departments since the birth of the big box stores, including home furnishings, home goods, and electronics.

The initial success of big box stores was built upon discount prices, convenience, and self service. Unlike the department store, big box stores did not seek customer loyalty or offer personal services. Instead, they sought to attract the bargain hunter who was willing to sacrifice the dream world quality of the department store for low prices. Indeed, the mentality of these consumers rests upon the notion that self service in a warehouse like setting keeps prices low. Over the years big box stores have gone through a transformation from low maintenance warehouses to lifestyle centers. Interestingly, they have come to incorporate many of the elements that once made department stores so enchanting to consumers. Some provide resting areas, cafés, day care facilities, and lavish displays; customer service is improving at many of them. Many big box stores have attempted to enchant their disenchanted spaces through implosion (Ritzer 2005). Although most of these stores are popular because they appear differentiated, many implode distinct categories or departments under one roof. For example, Barnes and Noble is not simply a book store, it is also a music store, a video store, a gift store, and a coffee shop.

Big box stores have not been the only competition that the traditional department store has faced. Discount department stores, like Wal Mart and Target, have also taken over their share of the retail market. The creation of the “festival marketplace” (Hannigan 1998) has also hurt department stores. These open air, Main Street style marketplaces combine eating, entertainment, and shopping. Unlike the enclosed shopping mall, most do not need, or want, department stores as anchors. While the festival marketplace began in the city, many are opening in the suburbs and threatening the vitality of the enclosed shopping mall. Enclosed shopping mall owners are trying to

compete with the festival marketplaces by courting big box stores, like Old Navy, Target, and Costco, to become new anchors and by creating open air wings. In order to survive, some department stores have begun to imitate big box stores, building free standing stores and abandoning the traditional anchor spaces they used to occupy in the shopping mall. The question remains, however, whether the department store can be sustained in an artificial space independent of either the city or the shopping mall.

dependency and world-systems theories

Christopher Chase Dunn

Dependency approaches emerged out of Latin America in the 1960s in reaction to modernization theories of development. *Dependentistas* attributed the difficulties of development in the global South to the legacies of the long history of colonialism as well as contemporary international power relations. This approach suggested that international inequalities were socially structured and that hierarchy is a central feature of the global system of societies.

The world systems perspective is a strategy for explaining social change that focuses on whole intersocietal systems rather than single societies. The main insight is that important interaction networks (trade, information flows, alliances, and fighting) have woven polities and cultures together since the beginning of human social evolution. Explanations of social change need to take intersocietal systems (world systems) as the units that evolve. However, intersocietal interaction networks were rather small when transportation was mainly a matter of hiking with a pack. Globalization, in the sense of the expansion and intensification of larger interaction networks, has been increasing for millennia, albeit unevenly and in waves.

The intellectual history of world systems theory has roots in classical sociology, Marxian political economy, and the thinking of the *dependentistas*. But in explicit form the world systems perspective emerged only in the 1970s when Samir Amin, André Gunder Frank, and Immanuel Wallerstein began to formulate the concepts and to narrate the analytic history of the modern world system.

The idea of the *whole system* ought to mean that all the human interaction networks, small and large, from the household to global trade, constitute the world system. It is not just a matter of "international relations" or global scale institutions such as the World Bank. Rather, at the present time, the world system is all the people of the earth and all their cultural, economic, and political institutions and the interactions and connections among

them. The world systems perspective looks at human institutions over long periods of time and employs the spatial scales that are required for comprehending these whole interaction systems.

The modern world system can be understood structurally as a stratification system composed of economically, culturally, and militarily dominant core societies (themselves in competition with one another), and dependent peripheral and semiperipheral regions. Some dependent regions have been successful in improving their positions in the larger core/periphery hierarchy, while most have simply maintained their peripheral and semiperipheral positions. This structural perspective on world history allows us to analyze the cyclical features of social change and the long term patterns of development in historical and comparative perspective. We can see the development of the modern world system as driven primarily by capitalist accumulation and geopolitics in which businesses and states compete with one another for power and wealth. Competition among states and capitals is conditioned by the dynamics of struggle among classes and by the resistance of peripheral and semiperipheral peoples to domination and exploitation from the core. In the modern world system, the semiperiphery is composed of large and powerful countries in the third world (e.g., Mexico, India, Brazil, China) as well as smaller countries that have intermediate levels of economic development (e.g., the newly industrializing countries of East Asia). It is not possible to understand the history of social change without taking into account both the strategies and technologies of the winners, and the strategies and forms of struggle of those who have resisted domination and exploitation.

It is also difficult to understand why and where innovative social change emerges with out a conceptualization of the world system as a whole. New organizational forms that transform institutions and that lead to upward mobility most often emerge from societies in semiperipheral locations. Thus all the countries that became dominant core states in the modern system had formerly been semiperipheral (the Dutch, the British, and the United States). This is a continuation of a long term pattern of social evolution that Chase Dunn and Hall

(1997) have called "semiperipheral development." Semiperipheral marcher states and semi peripheral capitalist city states had acted as the main agents of empire formation and commercialization for millennia. This phenomenon arguably also includes organizational innovations in contemporary semiperipheral countries (e.g., Mexico, India, South Korea, Brazil) that may transform the now global system.

This approach requires that we think structurally. We must be able to abstract from the particularities of the game of musical chairs that constitutes uneven development in the system to see the structural continuities. The core/periphery hierarchy remains, though some countries have moved up or down. The interstate system remains, though the internationalization of capital has further constrained the abilities of states to structure national economies. States have always been subjected to larger geopolitical and economic forces in the world system, and as is still the case, some have been more successful at exploiting opportunities and protecting themselves from liabilities than others.

In this perspective many of the phenomena that have been called "globalization" correspond to recently expanded international trade, financial flows, and foreign investment by transnational corporations and banks. Much of the globalization discourse assumes that until recently there were separate national societies and economies, and that these have now been superseded by an expansion of international integration driven by information and transportation technologies. Rather than a wholly unique and new phenomenon, globalization is primarily international economic integration, and as such it is a feature of the world system that has been oscillating as well as increasing for centuries. Recent research comparing the nineteenth and twentieth centuries has shown that trade globalization is both a cycle and a trend.

The Great Chartered Companies of the seventeenth century were already playing an important role in shaping the development of world regions. Certainly, the transnational corporations of the present are much more important players, but the point is that "foreign investment" is not an institution that only became important since 1970 (nor since World War II). Arrighi (1994) has shown that finance

capital has been a central component of the commanding heights of the world system since the fourteenth century. The current floods and ebbs of world money are typical of the late phase of very long "systemic cycles of accumulation."

Most world systems scholars contend that leaving out the core/periphery dimension or treating the periphery as inert are grave mistakes, not only for reasons of completeness, but also because the ability of core capitalists and their states to exploit peripheral resources and labor has been a major factor in deciding the winners of the competition among core contenders. And the resistance to exploitation and domination mounted by peripheral peoples has played a powerful role in shaping the historical development of world orders. Thus world history cannot be properly understood without attention to the core/periphery hierarchy.

McMichael (2000) has studied the "globalization project" – the abandoning of Keynesian models of national development and a new (or renewed) emphasis on deregulation and opening national commodity and financial markets to foreign trade and investment. This approach focuses on the political and ideological aspects of the recent wave of international integration. The term many prefer for this turn in global discourse is "neoliberalism," but it has also been called "Reaganism/Thatcherism" and the "Washington Consensus." The worldwide decline of the political left predated the revolutions of 1989 and the demise of the Soviet Union, but it was certainly also accelerated by these events. The structural basis of the rise of the globalization project is the new level of integration reached by the global capitalist class. The internationalization of capital has long been an important part of the trend toward economic globalization, and there have been many claims to represent the general interests of business before. Indeed, every modern dominant state has made this claim. But the real integration of the interests of capitalists all over the world has very likely reached a level greater than at the peak of the nineteenth century wave of globalization.

This is the part of the theory of a global stage of capitalism that must be taken most seriously, though it can certainly be overdone. The world system has now reached a point at which the old interstate system based on

separate national capitalist classes exists simultaneously with new institutions representing the global interests of capital, and both are powerful forces. In this light each country can be seen to have an important ruling class faction that is allied with the transnational capitalist class. The big question is whether or not this new level of transnational integration will be strong enough to prevent competition among states for world hegemony from turning into warfare, as it has always done in the past, during a period in which a dominant state (now the United States) is declining.

The insight that capitalist globalization has occurred in waves, and that these waves of integration are followed by periods of globalization backlash, has important implications for the future. Capitalist globalization increased both intranational and international inequalities in the nineteenth century and it has done the same thing in the late twentieth century (O'Rourke & Williamson 2000). Those countries and groups that are left out of the "beautiful époque" either mobilize to challenge the status of the powerful or they retreat into self reliance, or both.

Globalization protests emerged in the non core with the anti IMF riots of the 1980s. The several transnational social movements that participated in the 1999 protest in Seattle brought globalization protest to the attention of observers in the core, and this resistance to capitalist globalization has continued and grown despite the setback that occurred in response to the terrorist attacks on New York and Washington in 2001.

There is an apparent tension between, on the one hand, those who advocate deglobalization and delinking from the global capitalist economy and the building of stronger, more cooperative and self reliant social relations in the periphery and semiperiphery and, on the other hand, those who seek to mobilize support for new, or reformed, institutions of democratic global governance. Self reliance by itself, though an understandable reaction to exploitation, is not likely to solve the problems of humanity in the long run. The great challenge of the twenty first century will be the building of a democratic and collectively rational global commonwealth. World systems theory can be an important contributor to this effort.

Derrida, Jacques (1930–2005)

Michael Lipscomb

Jacques Derrida was an Algerian born philosopher remembered for his development of deconstruction, an approach to thinking that seeks carefully to analyze signifying objects in terms of the differences that are constitutive of those objects. Typically, this deconstructive approach proceeds through a close analysis of the ambivalent and marginal terms that help secure the bounded understanding of a text,

concept, or phenomenon, but which cannot be reduced to a final, stable meaning intended by the author or by orthodox interpretation.

Derrida's writing has been attacked for both its difficulty and its supposedly nihilistic implications. Regarding the first charge, his work certainly reflects the density and complexity of the philosophical tradition from which it emerges, but there are numerous places in his later work and his published interviews that offer fairly straightforward summaries of his thinking. Regarding the second charge, Derrida worked hard to counter the common conception that deconstruction entails a kind of textual free play that inevitably leads to a moral and intellectual relativism. In fact, his work represents a scrupulous commitment to the practice of carefully reading any text (written or otherwise), which, above all, respects the probity of the text under consideration. Thus, though his work offers a general strategy for thinking about conditions of knowledge and representation, the power of that approach is derived from its attentiveness to how those conditions are manifested in specific contexts. Throughout his long and prolific career, Derrida brought this practice of close reading to bear on examinations of an impressive variety of subjects, ranging across considerations of major figures in the western philosophical canon (e.g., Plato, Kant, Hegel, Husserl, Heidegger, Nietzsche, and Freud), literary productions (including the works of Ponge, Genet, Joyce, and Malarmé), and a wide array of social and political themes (education, internationalism, telecommunications, political economy, and the death penalty, to offer a partial list).

Throughout the breadth of this output, and despite repeated criticisms to the contrary, Derrida's efforts were not aimed against the possibility of coherent interpretations; instead, he sought to show how the possible coherence of any interpretation, the very possibility of communicative meaning, is derived within a specific semantic code and is thus premised upon the possibility of repeating that code, its "iterability." In the temporal and spatial movement of a repetition, there is always the possibility of slippage, and thus the recurring possibility of the new and the unforeseen, the possibility that any text might be grafted into new contexts that would begin to reshape its

meaning. For Derrida, this iterative inevitability suggests a certain continuity and stability, but it also points to the inherently open ended status of any text, phenomenon, or representation. On the one hand, Derrida decidedly does not seek to reduce all phenomena to a literary text; rather, his famous declaration that "there is nothing outside of the text" (Derrida 1974) points to the ways in which texts are unendingly opened by the very terms that mark the bounded field of meaning that makes any immediate understanding possible. On the other hand, Derrida's thinking does not seek to destroy the conceptual traditions from which it emerges (they are, in fact, its very condition of possibility); rather, it seeks to solicit them in a way that denaturalizes that which might otherwise seem natural and already decided.

Derrida's approach to reading, therefore, has both epistemological and ethical implications, linking an insistence on careful descriptive work with an always present normative orientation. Descriptively, this line of thinking has helped complicate working concepts within a broad range of intellectual disciplines, opening those concepts to an ongoing reconsideration and thus stressing a kind of scientific and intellectual practice that remains open to new perspectives and events. To take but one example, Derrida's work has provided tools for productively troubling liberal, Marxist, structuralist, feminist, and psychoanalytic understandings of the "human subject" and its relation to its social environment. Normatively, Derrida's general approach emphasizes a respect for the "other" that comes from outside of our previously consecrated and currently present understandings, resisting the tendency to reduce that which is different to the interpretive grids that we have inherited. Deconstruction, then, carries an ethical imperative that productively complicates our other regarding orientations, and it is in this sense that Derrida would insist that deconstruction is always, in the very movement of its critical posture, an affirmative gesture that is capable of saying "yes" to that which is yet to come.

descriptive statistics

Karen Lahm

Descriptive statistics, also known as univariate statistics, are most often used to describe the distribution of a variable or variables in a sample. A distribution of a variable can be thought of as all of the individual scores or categories of a variable contained in a sample or population. For example, if the variable being measured in a sample of 100 people is age, then the distribution for the age variable would be all of the 100 separate ages of the people contained in the sample.

The most common examples of descriptive statistics are the mean, median, mode, range, standard deviation, and variance. It is important to note that one can obtain descriptive statistics for a sample or a population. However, in the population these values would be referred to as parameters, not statistics. So, when the term descriptive statistics is used to describe a variable or variables, the researcher is referring to a sample, not a population.

When taken together, the mode, median, and mean are most often referred to as measures of central tendency. They are used to describe the

center of a distribution of a variable. The mode is the most frequently occurring category or score in the distribution of a variable. For example, if one had a sample of eight test scores – 80, 50, 72, 65, 80, 80, 99, and 90 – then the mode would be the score of 80 because it is the score that is repeated most often. Even though the mode is considered a measure of central tendency, the mode is not the exact center of the distribution. It is just the most frequently reported score or category.

The exact center of a distribution of a variable is the median. Half of the sample lies above the value of the median and half lies below. The median can also be described as a value or category that lies at the 50 percentile of the distribution. Using a sample of five test scores – 50, 60, 70, 80, and 90 – in order to obtain the median one would first have to order the scores from lowest to highest. Using the formula for the median $[(n + 1)/2]$ with n being sample size of five, the formula would give us the placeholder of the median. Thus, in this example, the placeholder of the median is the third score and that is 70. Thus, two scores lie above 70 and two below. No matter how many scores are in a distribution, or the values of those scores, the median is always the exact center score.

The final measure of central tendency is the mean. The mean is simply the average score in the distribution of a variable. Adding up all of the observed scores of a variable in a sample and then dividing that summed value by the sample size (n) will result in the mean of that variable. Thus, if one had five scores in a sample – 60, 75, 82, 88, and 90 – one would add up those five scores and divide by five to get the mean ($395/5 = 79$).

The mean acts like a teeter totter by balancing all of the values of the scores in the distribution of a variable. As a result, the mean may not be, and usually is not, the exact center of a distribution. One reason for this is because the mean is highly affected by extreme scores (i.e., outliers) in a sample of scores. Extreme scores can be either very high or low scores when compared to the other scores in the distribution. For example, if one had a sample of seven test scores – 15, 65, 70, 72, 85, 90, 96 – the outlier in this case may be the 15. More over, because the score of 15 is so low, the

mean is actually pulled toward it, thus deflating the actual center score. This gives an inaccurate picture of the real center of the distribution of scores. So, when one has a sample containing outliers, it is often called a skewed distribution. Extreme caution should be used when examining the mean in a skewed distribution because it is often not the best representation of the center of that distribution. Rather, the median should be used as the best measure of central tendency for any skewed distributions.

Three other very important descriptive statistics are the range, variance, and standard deviation. These descriptive statistics are often called measures of dispersion because they typically describe the variation of the observed scores of a variable around the mean. The range is simply the difference between the lowest (i.e., minimum) and highest score (i.e., maximum) in the distribution.

The variance is the average squared difference of scores from the mean. Since the variance is measured in squared units (e.g., years squared, dollars squared, etc.) it is commonly not discussed as much as other measures of dispersion. A more frequently examined measure of dispersion is the standard deviation. Mathematically, the standard deviation is found by taking the square root of the variance. Thus, standard deviation can be interpreted as the average difference of scores from the mean.

Some samples have a wide variety of scores (i.e., heterogeneous samples) and some have observed scores that are very similar or close to one another (i.e., homogeneous samples). For example, if a sample of 100 people were all the same age then the measures of dispersion would both be zero because there is no variation in the ages of the sample respondents. Moreover, heterogeneous samples (i.e., having a wide variety of scores) would have high values for the variance and standard deviation, while homogeneous samples (i.e., very little variation in the scores) would have lower values for the variance and standard deviation. There is no commonly accepted value indicating a high or low measure of dispersion because variables can be represented in a wide array of units. For example, a standard deviation of six can represent a high measure of dispersion for a variable, such as number of children. However, that same

standard deviation of six can also actually be a very small measure of dispersion for a variable such as income.

deterrence theory

Mark Stafford and Gini Deibert

Deterrence theory can be traced to such early utilitarians as Cesare Beccaria and Jeremy Bentham (Johnson & Wolfe 2003). The underlying idea is that people will commit crimes to the extent they are more pleasurable than painful. Certain, severe, and swift legal punishments increase the pain for crimes and, thereby, can deter people from committing them.

Neither Beccaria nor Bentham systematically defined *deterrence*. However, Gibbs's (1975) definition is conventional: deterrence is the omission or curtailment of a crime from fear of legal punishment. The terms "omission" and "curtailment" identify two possibilities: (1) people may refrain entirely from committing a crime from fear of legal punishment, or (2) they may only curtail or restrict their commission of it (e.g., a motorist may speed only occasionally in the belief that repetitive speeding eventually will result in a fine).

No single version of deterrence theory is accepted universally. However, any version

is likely to include something like this proposition:

Proposition 1: The greater the certainty, severity, and celerity of legal punishment for a type of crime, the less the rate of that crime.

Certainty refers to the likelihood (e.g., probability) of legal punishment; severity refers to the punishment's magnitude; and celerity refers to its swiftness. A high certainty of legal punishment has been considered a more effective deterrent than either high severity or high celerity, and consequently it has been the principal variable in deterrence theory and research (Gibbs 1975; Nagin 1998).

There are two ways to consider legal punishments. The first is to consider them as *objectively given*. For example, for a particular time and place, the objective certainty of imprisonment for a type of crime could be estimated by taking the number of persons imprisoned for that crime, divided by the number of such crimes; and the objective severity of imprisonment for the crime could be estimated by the average number of years in prison people actually served for it. The second way to consider legal punishments is *perceptually*. For example, people could be asked about their perceptions of the certainty and severity of imprisonment for a type of crime. The distinction between objective and perceived punishments is reflected in these three deterrence propositions:

Proposition 2: The greater the objective certainty, severity, and celerity of legal punishment for a type of crime (OP), the less the rate of that crime (CR).

Proposition 3: The greater the objective certainty, severity, and celerity of legal punishment for a type of crime (OP), the greater the perceived certainty, severity, and celerity of legal punishment for that crime (PP).

Proposition 4: The greater the perceived certainty, severity, and celerity of legal punishment for a type of crime (PP), the less the rate of that crime (CR).

Or, combining and expressing the three propositions diagrammatically:

$$OP \longrightarrow PP \longleftarrow CR$$

where \longrightarrow denotes a positive relation and \longleftarrow denotes a negative relation.

Prior to 1980, most deterrence research focused on Proposition 2. For example, Gibbs (1968) found a negative association among US states between the objective certainty and severity of imprisonment for homicide and the homicide rate.

Both Beccaria and Bentham posited a positive relationship between objective and perceived legal punishments, which is stated as Proposition 3, and policymakers agree in expecting to increase people's perceptions of punishment by increasing the levels of objective punishments (e.g., by increasing the objective certainty of arrest for crimes). Despite that expectation, most of the relevant findings have been contrary to it. For example, Erickson and Gibbs (1978) found only a moderately strong positive association among 10 types of crimes between the objective and perceived certainty of arrest. Moreover, they found no support for a central implication of Propositions 2–4 "that the objective certainty of punishment is related to crime rates *through* the perception of punishment" (p. 263).

Doubts about the relationship between objective and perceived legal punishments have led deterrence researchers more recently to focus on Proposition 4 that perceived punishments (e.g., perceptions of the certainty of punishment) for a type of crime are negatively related to the rate of that crime (Nagin 1998). That focus is justified because Proposition 4 comes closer than the others in capturing the element of fear that is integral to the definition of deterrence (see above). Scores of studies over the past several decades have found that "perceptions of ... [the certainty of] punishment have negative, deterrent like associations with ... offending" (Nagin 1998: 13). This is not the case with the perceptions of the severity of punishment, "but when individual assessments of the cost of ... sanctions are taken into account ... significant negative associations ... emerge" (ibid.).

Many "non deterrence" variables are related to rates of crime, which makes deterrence theory more complex than the foregoing propositions suggest. For example, while crime rates are related to perceived punishments (Proposition 4), they also are related to threats of *extralegal* punishments, such as stigma, divorce,

and loss of job. Extralegal punishments are relevant for deterrence theory in at least three ways. First, legal and extralegal punishments may have independent effects on crime rates. Second, legal punishments may prevent people from committing crimes *through* their effects on extralegal punishments (e.g., people may refrain from crime for fear of job loss if arrested). Finally, legal and extralegal punishments may have interactive effects on crime rates (e.g., people may be deterred by fear of legal punishment *only if* they believe they will suffer an extralegal punishment, such as divorce).

development: political economy

Manuela Boatcă

The emergence of the idea of development in western culture is closely linked to the evolutionary worldview that began to gain ground in Europe in the eighteenth century and has as such also been constitutive for sociology as a discipline. Like evolution, development has

taken on a variety of meanings, the common denominator of which can be seen in the idea of continuous, orderly social change usually proceeding in several, clearly demarcated stages and entailing an improvement of living conditions. However, as will be shown in the following, while most evolutionary theories implicitly are theories of development, the reverse does not apply.

In contrast to the relative social stability and the deterministic outlook characteristic of previous centuries, such major political upheavals of the eighteenth and nineteenth centuries as the French Revolution, the American Revolutionary War, and the South American Wars of Independence, along with the rise in social mobility that accompanied the spread of industrialization, gradually imposed the notion that social and political change, rather than being exceptional, was the norm. Modern society, and with it western civilization, were increasingly seen as the product of progress in which such constant change had resulted. Viewed in turn as static, undifferentiated, and lacking in complexity, traditional societies were relegated to an earlier stage in the course of human development. The theological explanation according to which the "savages" and "barbarians" of the non European world had hitherto been considered less than human was consequently replaced by a historicist interpretation that perceived them as (merely) less developed. An evolutionary perspective postulating the unidirectionality and inherent progressiveness of human history thus became central to both western sociology and anthropology, as disciplines whose institutionalization in the nineteenth century was intimately linked to the European project of civilizing the world. Their task therefore consisted of identifying the different stages of development and the corresponding laws of social evolution through which each society must pass in order to reach the western standard of civilization. Classical political economy, best illustrated within sociology by Marx's theory of historical materialism, concurred in this view by conceiving of modes of production as chronologically structured and nationally determined. In this classical understanding, development thus represented the outcome of an immanent historical process to be traversed by individual social organisms on their

way to maturity – the equivalent of modern society.

Massive criticism directed at evolutionism in the first half of the twentieth century, ultimately leading to its temporary discrediting as an academic endeavor, prevented a resumption of the issue of development until the post war era. During the 1950s, development again became central to both social scientific concerns and policymaking. The bipolar geopolitical structure characterizing the aftermath of World War II, as well as the simultaneous process of decolonization of European empires in Asia, Africa, and Latin America that resulted in the emergence of an array of new nation states in the so called third world, accordingly led to a competition for potential economic and political spheres of influence between the US and the Soviet Union. In response to the need to discredit the communist model as a viable alternative for the new nations, the multidisciplinary US modernization school identified the problem of third world countries in their traditionalism and viewed the solution to it in modernization, understood as a stage by stage replication of the economic development of Western Europe and North America. Drawing on evolutionary as well as functionalist assumptions, modernization theory saw societies as becoming increasingly similar in the course of a slowly operating process of social change considered unidirectional, progressive, and irreversible. It thus revived basic premises of nineteenth century evolutionary theory, such as the stage theory of development and the clear cut distinction between traditional and modern societies. At the same time, it replaced the notion of development as a byproduct of an immanent historical process with the one of development strategy, deliberately triggered and controlled by political actors with the help of state led policies. In *The Stages of Economic Growth*, one of the most widely debated works of the modernization school, W. W. Rostow (1960) identified the lack of productive investment as the main problem of third world societies and was among the first to suggest that the obvious solution was to provide US aid to these countries – understood in terms of capital, technology, and expertise. It can thus be said that the models brought forth by the modernization school were neither evolutionary nor

functionalist large scale *theories of social change*, but *theories of development* of limited spatial and temporal scope. They were born out of an attempt to solve the issue of development of particular regions of the world with respect to other particular regions at a specific moment in history – although researchers often extrapolated both across time periods and geographical locations. In this modern variant, development therefore became coterminous with planned economic growth and political modernization, to be implemented with the help of development agencies and foreign aid projects especially created for the purpose.

Rejecting both the main theoretical assumptions and the policy implications of the modernization school with respect to development, the largely neo Marxist dependency theory focused instead on underdevelopment (and is therefore sometimes referred to as underdevelopment theory). Arising in Latin America in the early 1960s in reaction to the failure of the United Nations' economic program to promote development, and the modernization school's inability to explain the ensuing economic stagnation in the region, the dependency school claimed that modernization was an ideology used in order to justify US intervention in third world affairs. In the wake of Lenin's and J. A. Hobson's theories of "imperialism," dependency theorists characterized modern capitalism as a center-periphery (i.e., asymmetrical) relationship between the developed, industrialized West and the underdeveloped, agricultural third world. Rejecting the theoretical division between "traditional" and "modern" society, which modernization policies were meant to bridge, dependency theorists claimed that the modern world's center-periphery structure mirrored an underlying international division of labor, established during the European colonial expansion and still maintained in the present through mechanisms of economic domination. In this view, the economies of the colonized regions had been reorganized so as to meet the needs of the colonizer countries, and ended up producing raw materials that served the latter's interests. Hence, in sharp contrast to modernization theory, the dependency school did not view underdevelopment as a "stage" previous to development, but as a distinct historical process

that industrialized economies have not experienced. For dependency theorists, therefore, just as center and periphery are relational notions, existing only simultaneously, development and underdevelopment are only different aspects of the same phenomenon, not different stages in an evolutionary continuum. Moreover, in their view, underdevelopment is not the natural condition the modernization school liked to presuppose, but an artifact created by the long history of colonial domination in third world countries, and as such a process of “development of underdevelopment” (Frank 1967). Accordingly, studying individual societies, as modernization theories did, meant leaving all exogenous factors of change out of the analysis and thus could not lead to a valid explanation of social change. Since the development of the US and Western Europe had been based on the underdevelopment of the third world, foreign aid policies could only result in the latter falling further and further behind. Consequently, dependency theorists saw the only concrete solution to the termination of dependency situations in third world countries in severing the ties with the core and choosing a socialist path of autonomous development, on the model of China and Cuba. In response to mounting criticism pointing out the economic success of other former colonies such as South Korea or Taiwan, a modified version of the theory later combined the notions of dependency and development into “associated dependent development” (Cardoso 1973). This approach postulated that the industrial capital invested by multinational corporations in peripheral countries could induce some amount of development and as such constituted a viable alternative for the states that did not want to take the chance of a socialist revolution.

World systems analysis expanded on the basis of the criticism that the dependency school had directed at the methodology of modernization studies. It claimed that the developmentalist view of social change which modernization theorists shared had a flawed logic. In a world economy such as the one represented by the current capitalist world system, it was the world system as a whole, and not individual societies, that should constitute the basic unit of analysis. Reifying political cultural units (i.e., states) into autonomously evolving entities, as

most theories of social change commonly did, led to ahistorical models of social transformation, as in the “traditional” vs. “modern” distinction. For world systems analysis, as for dependency theory, underdevelopment was not an earlier stage in the transition to development, but the necessary result of the international division of labor underlying the capitalist world economy. Although the world systems model advanced by Immanuel Wallerstein included an additional structural position, the semiperiphery, as well as a historical account of the evolution of the entire structural hierarchy since the sixteenth century, upward mobility within the capitalist division of labor (e.g., a semiperiphery’s rise to core status) was not considered development (since it was achieved at the expense of other regions), but merely successful expropriation of world surplus. While the dependency school, unlike world systems analysis, did not advance a general evolutionary theory, but one of social change in the periphery, both approaches retained a notion of development in which progress was represented by the – however uncertain – transition to (world) socialism.

The long term result of the neo Marxist critiques of the notion of development espoused by modernization theories was growing skepticism toward classical development theory, as well as added attention being devoted to the issue of underdevelopment both by scholars and policymakers. By the end of the twentieth century, development as a theme of academic research was largely considered outdated and treatment of the political and economic factors affecting macrostructural social change increasingly occurred within the more neutral, but less specifically defined, theoretical framework of globalization. In conceptual terms, this translated into a shift in the process of development from nationally to globally managed economic growth (McMichael 2005). Especially after the demise of communism in Eastern Europe and the end of the Cold War, global tendencies toward a withering away of the state as an agent of development on the one hand and toward a strengthening of the self regulating global market on the other were accompanied on the political level by the advance of neoliberalism and a corresponding trend toward privatization and anti statism. At the same time, the

language of globalization, whether in terms of the liberalization of market economies, democratization, or transition from the second to the first world, revealed the same teleological understanding of world history on which nineteenth century evolutionary models were premised, while adhering to a similar progressivist logic as the one inherent in the successive western models of "development" represented by Christianization, the civilizing mission, or modernization (Mignolo 2000). Questioning the extent to which the evolutionist outlook central to the self definition of the modern world is complicitous with a model of global economic growth responsible for excluding the great majority of the world's population from the development process while depleting the world's natural resources has, therefore, raised more than once the issue of available alternatives and their respective scope. The answers have, on the one hand, often entailed the search for alternative developments – whether an "ethnodevelopment" focusing on indigenous peoples and ethnic minorities, a "sustainable development" targeting the preservation of resources, or a feminist development economics centered on gender sensitive development policies. However, dissatisfaction with the inherent limitations of the development paradigm as such has on the other hand prompted increasing demands for alternatives to development (Escobar 1995) that would fundamentally question the principle of economic growth and the model of modernity that has been based on it.

developmental stages

Cynthia Schellenbach

The developmental stage approach refers to the socially or developmentally defined, age related sequence of stages individuals experience from birth through death. The assumption underlying the stage theories is that each stage represents a qualitatively unique period of development, indicating that the type of development is completely different and not reducible to earlier forms. That is, the developmental process occurs in an invariant sequence. The stage theory assumes that development is cumulative in nature and that development is based on each preceding step. It is expected that development proceeds toward increasingly complex levels of functioning. From a traditional viewpoint, the process of development proceeds in an irreversible sequence. Theoretically, one cannot return to an earlier form of development. The sequence of development is universal in nature. Development proceeds toward predictable end states. These end states may be influenced by maturational factors or environmental factors.

FREUD

Psychoanalytic theory was based on the contention that personality develops from a series of

qualitatively different stages of development from infancy through adolescence. The mental structures consist of the id, ego, and the super ego. The id is the force that seeks pleasure and self satisfaction at any cost, and is the primary force of energy during the infancy stage. The ego functions as a mediator between the urgent needs of the id and the constraints of the real world. The superego is the psychic mechanism by which the individual begins to internalize standards for right and wrong. The psychic stages of personality development include the oral stage (0–1), the anal stage (ages 2–3), infantile genital (ages 3–4), latency (age 4 to puberty), and the mature genital stage (mid teens to adulthood). The oral stage is the time at which energy is derived from oral satisfaction (as in the hunger–feeding–satisfaction behavioral sequence). The anal period focuses psychic energy on the child's emergent abilities to retain bowel control, or to feel satisfaction with the ability to retain a valued part of the self. The latency period finds the child emphasizing same sex relationships in an attempt to quell the disturbing thoughts and feelings of sexuality that emerged during the previous stage. The final stage emphasizes the mature emotional resolution of sexuality.

The contributions of the theory focus on the developmental approach, an emphasis on maturational processes, and an illustration that personality is sequential and cumulative. The theory is limited in that the concepts were never verified in empirical research, that the stages of personality development were narrowly conceptualized (to the exclusion of other domains of development), and that the role of culture and society was not emphasized sufficiently.

ERIKSON

Erikson developed a theory that emphasized a predetermined plan for healthy personality development. Erikson believed that several limitations needed to be addressed in Freud's theory. First, Freud emphasized that the steps in personality development were predetermined but failed to acknowledge any influence of the cultural environment on the individual. Second, Freud believed that little development occurred following puberty. Third, Freud

overemphasized sexuality to the exclusion of other domains of development that may influence personality development.

Erikson developed a theory of psychosocial development that emphasized the simultaneous process of psychological change (inward) and social change (outward) that occurs during the process of personality development. He also suggested that developmental change occurs throughout the lifespan. Erikson posited developmental turning points at designated times of enhanced vulnerability and the potential for positive development at eight times during the lifespan. Each developmental stage highlights a specific crisis, which will strengthen personality when mastered but will leave a weakness if the crisis is not mastered successfully. For example, stage one underscores the conflict of trust versus mistrust in which the primary objective is to provide a sense of predictability for the infant from birth through age 1. The toddler stage from age 1 through 3 highlights the crisis of autonomy (or the development of will) versus a sense of doubt or shame about one's abilities. During the preschool years of 3 to 5, children begin to take on increasing responsibility and initiative versus internalizing a sense of guilt. During the early elementary school years, children master skills and knowledge based on their personal sense of industry versus feeling inferior to peers.

The building block of the theory is the period of adolescence, when the young person develops a sense of identity based on how they see themselves and how society views them as individuals. Early adulthood highlights a developmental turning point that focuses on a sense of intimacy with another, but not at the expense of personal isolation. Adulthood, with responsibilities toward children, work roles, and society, focuses on generativity versus stagnation. The older years of adulthood are years when adults turn inward and internalize a sense of integrity or despair depending on the level of personal reward or satisfaction with past decisions and lives.

Erikson was the first to elaborate in detail the psychological change that extends into adulthood and old age. He also sharpened the use of techniques such as psychohistory as well as the use of sociological and anthropological techniques to enhance the importance of the

social environment in shaping personality development. Critiques suggest that elements of each crisis may exist at other age levels, not exclusively at the time of ascendance, as Erikson implies.

KOHLBERG

Kohlberg conceptualized moral development as a series of six qualitatively different stages of development. Each stage represents a specific mode of moral reasoning, ending with the highest and most complex level of moral development. The endpoint is a preservation of justice for the rights of individuals. The content of the values is not relevant to the type of reasoning within each stage. The progress of an individual is indicated by a gradual shift from an externally controlled sense of morality to an internally controlled sense of morality through the process of internalization.

Kohlberg suggests that there are three levels of moral reasoning: the preconventional level, the conventional level, and the postconventional level. Each level consists of two sublevels of reasoning. For example, at the preconventional stage, decision making is controlled by external rules (usually from parents). In stage one, the child's definition of good and bad is based totally on obedience to authority. In stage two, moral behavior is based on doing what is best because others will reward the behavior.

At the conventional level of reasoning, the individual defines moral behavior as conforming to the rules of the external society and maintaining order based on a set of external laws. In stage three, the person is motivated to gain the approval of others who are significant, and the motivation is now internal. In stage four, the individual typically believes that the social order should be maintained in order to support the legitimate rights and expectations of others.

The postconventional stage is the time at which moral decisions are governed by internal, shared principles. At this point, moral behavior is completely internalized. At stage five, moral behavior is defined in terms of contract, as opposed to the needs of the individual. Stage six is the morality of the principles of conscience, although individuals at this stage

are respectful of the authority of mutual respect and trust. The highest level of internalized authority, or the greatest good for the largest number, dictates behavior. Judgments of moral behavior at this stage may or may not be consistent with the laws of the country or the state.

Several critiques have been leveled at Kohlberg's theory as a result of more recent research. For example, although much research does support the notion of invariant sequence, recent evidence indicates that many adults (especially those who do not receive higher education) show no advancement in moral reasoning over time. Moreover, there is no clear evidence that stage six always follows stage five. Another criticism suggests that there is no evidence to suggest that moral reasoning will necessarily be transferred to behavior. Finally, many researchers suggest that Kohlberg's theory is based primarily on moral reasoning, or cognitive processing, with little attention to the influence of other variables such as gender or context. In fact, while Kohlberg's theory is based on the justice perspective, or a perspective that focuses on the rights of the individual, other theorists such as Carol Gilligan suggest an alternative care perspective. Gilligan suggests that the care perspective is a moral perspective that views individuals in light of connectedness with others. Moral decisions are based on the balance of justice and concern for others. Many females, as well as some males, make moral decisions based on the impact of their decision on the relationship rather than on the precise rights of the individual. In other words, males and females may utilize different strategies for moral decision making, as influenced by gender and culture.

FAMILY LIFE CYCLE

Carter and McGoldrick propose an alternative view of the stages in the life course. These researchers shift the unit of analysis from the individual to the family, tracing the developmental stages of the family from its inception to its dissolution. For example, the first stage involves leaving home and becoming a single adult, or launching from the family of origin. The launching period is complete when a young adult separates from the family of origin

and becomes fully independent. The mate selection and marriage stage is second, in which two individuals from separate families of origin join to form a new system. The third stage in the family life cycle is becoming a parent with children, and taking on the role of parent in addition to the roles of spouse and worker. The next stage is the family with adolescents, in which parents embark on the lengthy process (10–15 years) of supporting their children through the process of achieving independence. The fifth stage of the family life cycle involves completion of the process of launching children, caring for aging parents, and adapting to changes in mid life. The last stage of the family life cycle is the family in later life. The challenges in this stage involve taking on the role of grandparenting and either entering the retirement phase or making a change in career.

Although the family life cycle is recognized as a considerable contribution to sociology as a research paradigm, it is important to recognize that the framework is limited to cultures in which marriage precedes childbearing, and one in which marriages continue until the death of one partner. Demographic data indicate that there are many diverse family units other than married couples. Moreover, a large proportion of marriages will end by divorce before the last child is successfully launched into the world. With the addition of remarriage following divorce, new family life cycles must be recognized.

developmental state

Brad Williams

The developmental state is one that strongly influences the direction and pace of economic development by directly intervening in the development process, rather than simply relying on market forces to allocate economic resources (Beeson 2003). American scholar Chalmers Johnson is widely credited with coining the term in his seminal work *MITI and the Japanese Miracle: The Growth of Industrial Policy, 1925–1975* (1982), although the notion of state intervention in the market to ensure growth was not necessarily new. Johnson's book subsequently triggered a boom in studies of the state's role in the economy.

Like many observers in the 1960s and 1970s, Johnson was puzzled by Japan's post war economic miracle. His response was to highlight the important role of a plan rational capitalist developmental state, which combined private ownership and state guidance, as the key to Japan's remarkable industrial transformation and growth. By doing so, Johnson created a third category of state classification that transcended the traditional liberal (free market)–Stalinist (command economy) dichotomy. In Asia, this pattern of state intervention in the market was initially and successfully emulated by Japan's former colonies South Korea and Taiwan, and then later with mixed success by the countries of Southeast Asia, as well as China. The economic success of the East Asian states, rightly or wrongly, led many observers to perceive the developmental state "as a causal argument linking interventionism with rapid economic growth" (Woo Cumings 1999) throughout the world. The East Asian development experience challenged the arguments of dependency and world systems theorists – influential at the time – who were skeptical about the ability of the peripheral regions of an interconnected global economy to escape exploitation by the advanced industrialized states of Western Europe and North America. The developmental state thesis emerged during a period in which Japan, in particular, achieved rising trade surpluses with the US. In a manifestation of Orientalist thinking, scholars from

the so called “revisionist” school saw this as the result of the mysterious Other’s unfair adoption of a deviant form of capitalism that threatened not only established western economic thinking, but also its way of life.

The developmental state can also be located within the contexts of late developments and the influences of social mobilization and economic nationalism (Woo Cumings 1999). Modern Japanese history has been characterized by the determined attempt to catch up with the West – first, following the stagnation of the isolationist Tokugawa period, and then after the destruction resulting from its disastrous wartime defeat. The Japanese state devised a system of political economy that would enable it to achieve this task and survive in a western dominated world. Nationalism emerged from the war and imperialism and was an important component of the East Asian development experience, serving as an ideological mobilizing force behind the sacrifices the populace were forced to endure in pursuit of reconstruction and growth objectives.

There is a divergence of views regarding the factors contributing to the developmental state’s success, which can be broadly linked to the agency–structure debate within the social sciences. Some observers are critical of the inward orientation of Johnson’s model, believing it overlooks important structural factors such as the superpower conflict. Johnson downplays (but does not dismiss) the influence of the Cold War, arguing that Japan would have grown anyway. However, it is difficult to deny that Japan benefited enormously from the US security guarantee, which allowed it to concentrate on economic growth without being burdened by excessive defense outlays, and unfettered access to the vast consumer market of its superpower patron facilitated by its status as a bulwark against communist expansion in East Asia.

At the heart of the developmental state and the key institution of social mobilization was the economic bureaucracy. In Japan this was the Ministry of International Trade and Industry, or MITI (now METI) – the analytical focus of Johnson’s study – and its institutional equivalents in South Korea and Taiwan, the Economic Planning Board and Council for Economic Planning, respectively. In true Weberian fashion, the

economic bureaucracy that administered the developmental state was extremely professional, meritocratic, and rational. In the case of Japan, elite state bureaucrats were recruited from the top ranks of the best law schools in the country and entry into this world of prestige and power was limited to those who passed legally binding and highly competitive national examinations (Johnson 1995). For Johnson, the locus of state power in Japan was found in elite economic bureaucrats who formulated industrial policy, identified the means for implementing it, and ensured highly regulated competition in designated strategic sectors.

This is not to say that the state completely dominated society. The developmental state’s relationship to society has been described variously as “embedded” (Evans), “governed interdependence” (Weiss), and “dependent development” (Gold). State and society, in the form of big business (in Japan the *zaibatsu* and its post war successor the *keiretsu*, and in Korea the *chaebol*), are in a mutually beneficial relationship, with the state providing, inter alia, access to low cost finance, as well as markets and business helping to achieve the state’s development goals. According to Woo Cumings (1999), the developmental state is diachronic: the cooperative relationship between the bureaucracy and business had been learned and perfected over time through a process of institutional adaptation that meets the demands of the time.

While instrumental in achieving rapid growth, the close relationship between the bureaucracy and big business in South Korea and Japan, in particular, also has a negative aspect manifested as severe structural corruption. Here, the money made available by the state for business often found its way into the pockets of politicians from the ruling government parties. The bureaucracies’ role in these illicit flows, used to protect vested interests, suggested a significant deviance from Weberian ideals.

In addition to protecting vested interests, the East Asian developmental state was often undemocratic and authoritarian. While there was no inevitable causal link between authoritarianism and developmentalism, Johnson did acknowledge that authoritarian states could be successful in mobilizing people to work and

sacrifice for developmental goals. There existed what Woo Cumings referred to as an “elective affinity” between these two components. Many western observers sought culturalist explanations for the developmental state’s ability to mobilize the populace, or its legitimacy, highlighting the importance of Asian political acquiescence and the notion of “Asian values” with their accordant emphasis on community before the individual. The truth is its legitimacy rested on both violent and non violent foundations.

The 1997 Asian financial crisis represented a watershed for the developmental state. The collapse of several of Asia’s economies and the international community’s intervention to help the ailing region led to claims that the developmental state was inefficient, obsolete, and unable to cope with the forces of globalization. Laudatory labels such as “Asian miracle” were replaced by more pejorative expressions such as “booty capitalism” and “crony capitalism” in western analyses of East Asian political economy.

While many observers were quick to point out the obsolescence of the developmental state in East Asia, others surveying events a few years beyond the economic malaise of the late 1990s instead saw resilience, which derived from its adaptive qualities. Articles by Pekkanen, Peng, and Wong featuring in a special issue of the *Journal of East Asian Studies* devoted to the developmental state highlight the various ways in which the Japanese and South Korean variants have adapted in order to cope with emerging demands in public policymaking, social welfare reform, post industrial structuring, and state–society–global relations. Wong (2004) notes that the East Asian developmental state is currently under going an empirical and theoretical transformation, having moved beyond its initial narrow objective of rapid economic growth. The future of the developmental state model to a large extent depends on this continued ability to adapt, and especially whether government and business are prepared to eschew the corrupt and collusive practices of the past, provide greater accountability and transparency, and address new social demands in the face of a declining capacity to exercise power and authority.

deviance

Erich Goode

To the majority of sociologists, deviance is defined as the violation of a social norm which is likely to result in censure or punishment for the violator. Behind this seemingly simple and

clear cut definition, however, lurks a swarming host of controversies. A perusal of course curricula verifies that most sociologists who teach a course on deviance divide the field into two distinctly different perspectives: constructionist approaches and explanatory theories. The constructionist approach sees deviance as “subjectively problematic,” that is, “in the eye of the beholder,” and takes as its primary task an understanding of how judgments of deviance are put together, and with what consequences. Explanatory theories regard deviance as “objectively given,” that is, a syndrome like entity with more or less clear cut, identifiable properties whose causal etiology can be explicated by the social scientist. Each perspective has its own mission, agenda, enterprise, and methodology. And though these two approaches define deviance in superficially similar ways, their definitions point to sharply divergent universes of meaning. The enterprises in which these perspectives are engaged are in fact linked only by the objectively similar nature of their subject matter; conceptually and theoretically, they are worlds apart.

CONSTRUCTIONISM

The majority of sociologists of deviance are constructionists; that is, they argue that their mission is to understand how deviance is created or defined subjectivistically and culturally. They argue that what is important about deviance is the dynamics and consequences of its social construction rather than its objectivistic or essentialistic reality or its causal origin. Sometimes referred to as the western or the Chicago/California School (Ben Yehuda 1985: 3–4; Petrunik 1980), the proponents of constructionism tend to adopt symbolic interactionism as their theoretical inspiration, use participant observation as their principal methodology, and typically focus on “soft” or low consensus deviance – that is, acts that may or may not be crimes, but if they are, stand a low likelihood of arrest and incarceration, behavior that tends to be punished predominantly through the mechanism of informal social control. Constructionism seeks to shift the focus of deviance researchers away from the objective nature and causes of deviant behavior per se

to the processes by which phenomena and persons “come to be defined as deviant by others” (Kitsuse 1964).

The term deviance is used principally by sociologists rather than the lay public; to the extent that laypeople use the term, its meaning differs markedly from that used by the sociologists. To the constructionist, the concept is defined or *constituted* by particular reactions from observers or “audiences,” real or potential, *inferred* as a result of what persons *do* or *say* when they discuss or discover something they regard as reprehensible. In other words, it is a “definition in use.” According to this definition, deviance is implicit in all social interaction; one does not have to name it to see it in action. And the reactions that constitute deviance are universal, transhistorical, and transcultural; they are found everywhere humans congregate. The phenomena – the behavior, beliefs, or conditions – that have generated this reaction differ from one time and place to another, but identification and condemnation of the norm violator is a fixture in all societies and social groupings throughout history. Hence, the fact that laypeople do not use the term deviance says nothing about its sociological purchase. The fact is deviance is a fundamental sociological process, as essential to human existence as identity, social structure, status, and culture. All human collectivities establish and enforce norms; in all collectivities these norms are violated; as a consequence, the enforcement of norms (“social control”) constitutes the life blood of all social life.

The constructionist approach defines deviance (or “social deviance”) as a normative violation that is regarded among specified collectivities as reprehensible and, if made public, is likely to elicit negative reactions against the violator (such as censure, condemnation, punishment, scorn, stigma, and social isolation) from members of such collectivities. These collectivities are referred to as “audiences.” The issue of audiences addresses the question, “Deviance to whom?” The “to whom?” question indicates that definitions of what constitutes a normative violation vary from one collectivity to another. Audiences need not literally witness the violation in question; they may be told about it or they may be potential audiences whose reactions may be inferred

from their ongoing talk, that is, stated beliefs and attitudes. An even more radically constructionist definition of deviance is the *strict* constructionist or ethnomethodological definition, which argues that deviance *does not exist* in the absence of literal, concrete labeling or condemnation (Pollner 1974). No condemnation, no deviance. By the lights of this definition, “secret deviance” is an oxymoron, a contradiction in terms. Many sociologists believe that such a definition would paralyze the study of deviance, since the overwhelming majority of behavior, beliefs, and conditions that *would* generate disapproval in most collectivities are never detected or sanctioned. Moreover, it excludes behavior, beliefs, and conditions that the person enacting, holding, or possessing them *knows* would discredit him or her in the eyes of others, but are kept secret from them (Goffman 1963: 41). Very few sociologists adopt the “strict” constructionist or “hard” reactivist definition of deviance, hence it is not discussed here.

As indicated above, to the constructionist, persons violate norms not only by engaging in certain acts but also by holding unacceptable attitudes or beliefs and possessing undesirable characteristics; attitudes, behavior, and characteristics constitute the “ABCs” of deviance (Adler & Adler 2003: 8). In addition, in certain collectivities, the presence of a “tribal” outsider, that is, one who possesses what is considered in those circles an “unacceptable” or “inappropriate” racial, national background, or religious membership, will elicit hostile or other negative reactions (Goffman 1963: 4). Constructionist sociologists also study false accusations of deviance, since that generates condemnation, a defining element in their definition of deviance (Becker 1963: 20). The fact that the person who elicits negative reactions is not “at fault” or “to blame” is irrelevant to a sociological definition of deviance. The fact is, people can be, and are, punished for entirely involuntary – or nonexistent – normative violations over which they had no control or choice.

To the constructionist, “deviance” refers to the negative reactions, actual or potential, that are likely to follow the discovery of an act, belief, or trait that is regarded as reprehensible *in* a particular collectivity or *to* a particular audience. (That collectivity can include, but is not

coterminous with, the entire society.) A given person becomes *a* deviant to the extent that he or she is stigmatized within or by the members of a given collectivity or audience. In Becker’s well known formulation: “*social groups create deviance by making the rules whose infraction constitutes deviance*, and by applying those rules to particular people and labeling them as outsiders.” According to this definition, then, the deviance of a person, that is, whether he or she can be regarded as *a* deviant “is *not* [solely] a quality of the act the person commits, but rather a consequence of the application by others of rules and sanctions to an ‘offender.’ The deviant is one to whom that label has successfully been applied” (Becker 1963: 9).

Constructionists emphasize that the two defining building blocks of deviance mentioned above – the violation of a norm and the negative reactions to the normative violation – do not necessarily occur together, as Becker (1963: 19–22) has pointed out. In fact, the punishment or condemnation of the norm violator is influenced by contingencies, one of which is *who* engages in the violation. The ancillary characteristics of the rule violator can influence whether and to what extent others react negatively to the infraction; these include, among others, age, race, sex, socioeconomic status, and – perhaps most important – degree of intimacy between the violator and the person evaluating the supposed infraction. In addition, if there is a victim, just *who* is victimized by the act may determine whether and to what extent the actor is punished or condemned. Moreover, to repeat, false accusations represent a case in which some one did not violate a norm but attracts censure anyway. To the constructionist, an accusation of deviance that is successfully lodged against an innocent party represents a case of sociological deviance, whether baseless or justified. Here we have an instance of a deviant *person* who did not engage in deviant *behavior*. Whether or not such accusations are successful, the literal facticity of the charge is only one of the many reasons why it succeeds or fails.

It is axiomatic to the constructionist that deviance is a social convention, “relative” to time and place, and that an act, belief, or trait that is non normative in one collectivity or setting may be normative in another. Even more fundamental, independent of the issue of

normative valuation, the constructionist position argues that the very *categories* that constitute what is defined as deviant are constructed variously in different societies, indeed even within different collectivities in the same society. The same partners who are regarded as incestuous in society A are acceptable, even mandatory, marital partners in society B (Ford & Beach 1951), hence the very definition or conceptualization of what constitutes "incest" is a social construct, not an objective reality. In ritual contexts, same sex intercourse among the Sambia is not regarded as "homosexuality" at all, although it would be so regarded nearly everywhere else (Herdt 1987). In most quarters in the western world, the use of one mind altering substance (alcohol) is not conceptualized as "drug use," but the use of another such substance (marijuana) is so regarded. Hence, to the constructionist, behavior and other phenomena that are outwardly and objectively "the same" are not sociologically the same; conceptually, they may belong to entirely different categories or universes of meaning. In short, social and cultural relativism, both in terms of conceptualizing categories of phenomena and in evaluating representatives of these categories, is the foundation stone of the constructionist approach to deviance.

Constructionists divide into more "radical" and more "moderate" camps. For the radical constructionists, the issue of the cause or "etiology" of deviance or its constituent components is entirely irrelevant, even illusory. Seeking the cause or causes of deviance and its constituent elements is a fool's errand, most in this camp would say. If deviance is socially created, there is no objective or essential common thread independent of the label that ties it all together – in effect, there is no "there there" – and hence, any attempt to explain its causality is by its very nature futile. In contrast, the moderate constructionists argue that seeking an explanation for deviance is secondary to and to some degree separate from their mission; phenomena labeled "deviant" may or may not share an objective common thread, but their etiology is not the deviance specialist's central mission. Interestingly, however, some sociologists who study the social construction of deviance also examine the etiological impact of one or more legal or social constructions on the

commission of deviant behavior. For instance, some conflict theorists (who are mainly interested in the role of power and social class in the construction of the law) are also interested in how power and class influence behavioral violations of the law (Messerschmidt 1993); some labeling theorists, who typically look at the social construction of deviance labeling, argue that labeling may influence further, and more serious, deviant behavior (Scheff 1966).

Constructionists distinguish between "societal" deviance, which is the violation of the norms of the society at large, and "situational" deviance, which is the violation of the norms that apply within a particular context (Plummer 1979: 97–9). Hence, widespread agreement on the legitimacy of the norms in the society is not necessary to define situational deviance – although it is to define *societal* deviance – since the concept is always relative to specific contexts. In other words, a particular *audience* defines deviance; something is deviant *to* a particular audience *in* a particular context. If tattooing is normative among Hell's Angels, it is not deviant *to them*; if it is non normative among fundamentalist Christians and Orthodox Jews, it *is* deviant to them. The fact that tattooing is or is not deviant in the society at large is irrelevant to the issue of its normativity *within specified social circles*. Hence, "deviance" does not exist as an abstraction; it takes on relevance only within specified collectivities and in specified social contexts. Of course, *one* of these collectivities may be the society at large, which is how "societal" deviance is defined.

To the advocates of the constructionist approach, *social control* is the core of any sociological understanding of deviance. Social control is defined as any and all efforts to ensure conformity to a norm. Humans are irrepressible; all of us have a tendency to violate some of the norms. To engage in normative violations is tempting both because they more surely than conformity secure for us what we value, and because many of the things we have been told we cannot have are intrinsically rewarding (Gottfredson & Hirschi 1990). Hence, efforts to ensure conformity to the norms may be found in all collectivities, both historically and trans societally. These include positive efforts such as rewards, and negative efforts such as punishment; formal efforts such as arrest, and

informal efforts such as an insult or a slap in the face; and internal efforts, through the process of socialization, as well as external ones, such as censuring someone for engaging in a non normative act. Hence, while the state plays a major role in social control, it is only one of a wide range of agents dedicated to ensuring conformity. The many faces of social control represent the flip side of deviance; social control is an effort to deal with and suppress normative violations, as well as encourage by rewarding normative conformity. And it is the many efforts of social control that *define* and *constitute* deviance.

Nearly all constructionist definitions of deviance and social control include the component of power. Collectivities that control more of society's resources tend to have relatively more power to influence deviance defining social institutions, including the law and its enforcement. Members of relatively low status collectivities are more likely to find their behavior, beliefs, and traits defined and reacted to as deviant than those who have higher status and more power. Collectivities that have more power tend to have more influence on, in addition to the law, the content of the media as well as the educational, religious, and political institutions, all of which, in turn, influence definitions of right and wrong and hence what is considered deviant. Power over subordinate collectivities does not, however, ensure their conformity or agreement among members of those collectivities that dominant definitions of right and wrong are just or righteous. As we saw, humans are rebellious and irrepressible; smaller, non mainstream collectivities everywhere construct their own rules of right and wrong, independent of those of the most powerful strata of society. In all societies, the dominant institutions, regardless of how hegemonic they may seem, are incapable of intruding into each and every aspect of the lives of all human collectivities and groups within their scope. Still, power is a factor in the social construction of norms – and hence, in defining what is deviant. This is especially the case for “societal” deviance. It is often the case that the powerless are subject to the norms of the powerful, whereas it is rarer that the powerful are subject to the norms of the powerless. This is more likely to be true, however, of formal

definitions of crime than of informal definitions of deviance.

EXPLANATORY THEORIES OF DEVIANCE

The second approach to deviance encompasses explanatory theories. Explanations of deviance attempt to account for *why* non normative behavior occurs. (Some explanatory formulations turn the equation around and ask why *normative* – but for them, the logic is the same.) Their driving question is: “Why do they do it?” (or, alternatively, “Why *don't* they do it?”). Explanatory theories always take crime or deviance as the dependent variable and the explanatory factor they focus on as the independent or causal variable. Not all explanatory theories seek explanations of deviance in general; in fact, most attempt to explain one or more of its constituent components, such as mental disorder, drug abuse or addiction, crime, juvenile delinquency, white collar crime, embezzlement, burglary, motor vehicle theft, and so on. For the most part, adopting an explanatory paradigm entails examining deviance through the natural science model, an approach that is commonly referred to as positivism or, sometimes, methodological (as opposed to substantive) positivism (Hirschi & Gottfredson 1994). Positivism is characterized by *empiricism*, that is, reliance on the data of the five senses; *abstraction*, that is, the tendency to generalize beyond specific cases; the tendency to seek *cause and effect explanations* of phenomena in the material world; and, most important for our purposes, *essentialism* or *objectivism*. The last of these is the tendency to regard phenomena as pre-given entities, those that are internally consistent, containing one or more “common threads” that may be found more or less everywhere, or at the very least within a given society. For instance, the explanatory approach is comfortable referring to and studying the “epidemiology” of deviance (Crews 2001) – that is, the distribution of “deviance” in the population – whereas constructionists are likely to reject the very basis of such an enterprise. Explanation *presupposes* objectivism, since explanations are predicated on the existence of one or more common threads shared by the phenomena being explained. In other words, to the approach that

seeks explanations, deviance and its constituent components are a specific *type of action* – in medical terms, a “syndrome” – and not *merely* a convention or a social construction. And *because* it is a type of action, possessing internal coherence, it is the mission of the sociologist to account for it – that is, render a causal explanation of its origin. (Gottfredson and Hirschi (1990: 49) discuss the contradiction between substantive positivism’s acceptance of the legalistic definition of crime and their adoption of the natural science model, which presupposes objectivism.) Sociologists who seek explanations for deviance usually study behavior (or psychic conditions that presumably cause behavior), only very rarely beliefs, and practically never physical traits. They take for granted, assume, or hold in abeyance the social construction of definitions of deviance. For them, social control is interesting only insofar as it influences or causes deviant and criminal behavior, which is what they aim to explain in the first place (Hirschi 1969; Gottfredson & Hirschi 1990).

Although most do not articulate it in this fashion, many explanatory theorists would argue that societies tend to criminalize or penalize actions that are most harmful and disruptive both on a micro and a macro level, that is, both interpersonally and with respect to the viability of the society as a whole. For example, Gottfredson and Hirschi (1990: 15) define crime as “force or fraud in pursuit of self interest.” Rejecting the central tenet of constructionism, sociologists who seek explanations argue that it is incorrect to argue that “deviance” is relative to time and place. Though explanatory theorists would admit that while many customs and conventions do indeed vary the world over and throughout history, certain behavioral syndromes have identifiable, universal properties. For instance, even though mental disorder and illness, crime and delinquency, and alcoholism may be *thought of*, and persons characterized by them *dealt with*, differently in different societies, nonetheless, each has a common thread and hence a common etiology (Nettler 1974). Clearly – as with the constructionists – explanatory theorists may be divided into more “radical” and more “moderate” camps. The radical explanatory theorist argues that deviant categories are universal everywhere and for all times, and hence a universal explanation of deviance can

be devised (Gottfredson and Hirschi 1990). The moderate explanatory theorist says that deviance is shaped by the societies in which it occurs, and hence explanations of deviance and its components may apply only within each society. But both camps look for cause and effect explanations of behavioral syndromes that share one or more common, internally consistent components or elements.

For instance, practitioners of one explanatory theory, “self control” theory, adopt a “non relativistic position on the causes of crime.” This is the case, they say, because their theory does not regard deviance, crime, and delinquency as the products of unique cultures, peoples, settings, historical periods, or even variable legal definitions. Instead, self control theory assumes that the causes of crime are the same everywhere and at all times. In short, they argue, the mission of the sociologist of deviance, crime, and delinquency is to explain these phenomena, and in order to accomplish this mission it is necessary to conceptualize them essentialistically and objectivistically, that is, as possessing common, universal elements or components. Gottfredson and Hirschi (1990), two major advocates of this theory, use the term deviance throughout their theoretical discussion of crime. Crime, they argue, “is only part of a much larger set of deviant acts” (p. xvi). And they insist that a common explanation can be found for the constituent elements of crime and deviance, such as violence, white collar crime, reckless behavior, illicit, impulsive sex, and drug abuse.

To repeat, all explanatory theorists are aware that definitions of right and wrong are relative from one society to another; all criminologists that seek explanations for crime are aware that laws criminalizing certain acts vary the world over. But accounting for that variation, they would say, is not the sociologist’s mission. Moreover, they would argue, in spite of this variation, there are common threads running through the most fundamental of society’s norms and laws. Societies outlaw certain actions for a reason, and that is because the acts societies outlaw tear at the social fabric. Even if sociologists were to confine their analysis to a single society, the same logic applies: certain behaviors demand an explanation because of their internal consistency, and one *aspect* of that consistency,

many argue, is the harm and disruption these behaviors cause to the social order. Explaining phenomena bearing an internal consistency, a common thread, underlies *all* efforts to explain or account for crime, delinquency, violence, mental disorder, drug abuse, alcoholism, suicide, and prostitution. Such behaviors (or psychic conditions) demand an explanation because they are “different” from law abiding or “normal” behaviors and conditions. And the *way* they are different, many explanatory theorists argue, is that these behaviors are disordered, pathological, harmful, and/or exploitative. This approach is even less concerned about the fact that the lay public may not use such terms, or, when they do, mean different things by them from what the social scientist intends. To the scientifically inclined theorist, it is what the scientist says that counts, not the lay public.

In the most radical of explanatory arguments, the term deviant refers to a person with one or more specific, essentialistic or indwelling conditions that *manifest themselves* in specific actions. Certain people enact seriously deviant and criminal behavior, behavior that harms and exploits others and tears at the fabric of the society, because they are “different” from the rest of us. For instance, in one formulation, the overlap between the social deviant and persons characterized by the psychiatric terms “psychopath,” “sociopath,” and “antisocial personality disorder” is considerable (DeLisi 2003). Even in less radical formulations, criminals and deviants are persons primed to act in a certain fashion because they are certain *kinds of persons*. Other factors *in addition to* their characteristics may influence their deviant behavior, but with this approach individual characteristics are crucial.

Most *sociological* theories that attempt to account for the enactment of deviant behavior argue that the essentialistic, indwelling factors that cause (or inhibit) crime are to be found in actors’ environments, not in their individual traits or preconditions. These factors include the degree of social disorganization in the neighborhood in which people live; anomie, or society’s cultural and social malintegration; bonding with conventional others; and differential association with others who espouse positive definitions of normative violations. Here, the explanatory factor producing a particular

and “different” kind of behavior is shifted from specific *kinds of persons* to specific *kinds of social arrangements* and the actor’s place in them.

Opportunity theories, including routine activity theory, dispense altogether with explaining the propensity or tendency of individuals to engage in deviant or criminal acts, as well as the sociocultural environments that may influence actors to commit deviant and criminal acts, and focus entirely on the *situation* or *context* within which certain types of acts are likely to take place. Crime is committed to the extent that a motivated offender is in juxtaposition with a suitable target in the absence of a capable guardian (Cohen & Felson 1979). In this sense, then, the factor determining the criminal act is the context or situation – the opportunity to commit the crime. What accounts for the untoward behavior – in this perspective, nearly always crime, and usually economic crime – is neither a particular kind of person nor a particular kind of social arrangement, but particular kinds of opportunities, those that maximize potential rewards and minimize cost, of which punishment is a major component.

Most forms of crime that explanatory theorists study may be referred to as “hard,” serious, or *high consensus* deviance. Positivistic sociologists who see their mission as explaining or accounting for the origins of crime tend to be criminologists. All sociologists of deviance discuss and refer to the work of criminologists, but very few criminologists identify any longer with the field of the sociology of deviance. (This is less true of the UK than the US. For instance, in *Understanding Deviance*, 2003, Downes and Rock make little distinction between “deviance” and “crime.”) Criminologists typically study deviance only by implication, that is, conceptually and theoretically, but not as members of an intellectual community. As an identifiable field, the explanatory study of crime is separate and distinct from the field that is referred to as the sociology of deviance – and has been for more than a generation. Much the same can be said of sociologists who attempt to explain the etiology of the behavioral components of deviance, such as mental disorder, drug abuse, and alcoholism: they are sociologists of behavior that is regarded as deviant, but most do not adopt a “deviance” perspective, and few belong to the intellectual community of

the sociology of deviance. This intellectual split between these two camps – the constructionist and the explanatory theorists – as well as the departure of criminologists from the field of the sociology of deviance, have resulted in a smaller, less influential, and possibly less theoretically innovative school of deviance studies. The long term impact of this split has yet to be determined.

deviance, absolutist definitions of

Craig B. Little

Absolutist definitions of deviance distinguish conformity from nonconformity by reference to an invariant moral standard. Some external agent such as a religious, philosophical, scientific, or international authority may establish the moral standard. From an absolutist perspective, a given activity, like homosexual behavior, might be considered deviant because the majority in a society claim it violates a religious dictate or even because it appears to affront a declared conception of the natural order.

The sociologically relevant aspect of an absolutist position is that it places the basis for moral judgment on a behavior or practice beyond the social and cultural context of the society or social situation in which the behavior or practice takes place. Therefore, the definitional standard for proclaiming an activity deviant has nothing to do with the norms of the particular society or culture in which the activity occurs. Absolutist definitions of deviance assume that a given activity, according to the particular higher authority, is deviant for all time in all places.

In general, deviant behavior theorists and researchers do not subscribe to absolutist definitions of deviance. Rather, they more typically hold to definitional approaches that are normative or reactivist. The normative approach defines deviance according to the expressed or implied standards of the particular group in which the activity takes place. Thus, a behavior will be considered deviant if it violates the social group's formal rules (often articulated as laws) or typical norms and practices (customs, mores, rules of etiquette, and the like). According to the reactivist perspective, deviance need not even entail norm violation; it states that an activity or a condition, such as being physically handicapped, can be defined as deviant merely if the audience viewing it reacts negatively to it.

The divine expression of absolutist definitions of deviance is often associated with religious fundamentalism, where scripture is taken as the relevant external authority. From a philosophical perspective, Plato and Hegel both erected moral systems that defined deviance in relation to absolute standards. Many eighteenth and nineteenth century Europeans believed the world's cultures could be arrayed along an evolutionary continuum, with the cultural norms and practices of the West representing the highest stage of development. Thus, when Europeans made contact with non western cultures, the invaders frequently attempted to discourage or eradicate what they interpreted as these peoples' "backward," deviant activities, such as wearing immodest clothing or engaging in promiscuous sexual activity. Conquest itself was often justified in the name of imposing the absolute standards of Christianity on native peoples. By the nineteenth century, the social Darwinism of Herbert Spencer provided a

"scientific" rationale for the alleged absolute superiority of European cultural and behavior norms.

Sociological opposition to absolutist definitions of deviance finds its roots in early twentieth century cultural anthropology. Attacking nineteenth century absolutist and ethnocentric judgments concerning non western cultural practices, Franz Boas and his students, including Ruth Benedict, Melville Herskovits, and Margaret Mead, formulated the anthropological perspective of cultural relativism, stating that any society's customs and practices can only be understood and assessed in reference to the particular culture itself. For the strong relativist, there are no absolute standards for defining deviance, only culturally specific ones.

During most of the twentieth century, relativism was the dominant perspective of cultural anthropologists and sociological students of deviant behavior. In both disciplines, relativism entails an empathetic methodological approach in which the observer attempts to understand any given behavior or practice relative to the normative standards of the culture, or even subculture, in which it takes place. In recent years, however, relativism has been challenged by those who insist on the need for universalist standards of human conduct. The most commonly cited referent for the assertion of such standards is the 1948 United Nations Universal Declaration of Human Rights. Those opposed to a relativist standpoint argue that a practice like female genital mutilation, though culturally prescribed in a number of African societies, must be declared deviant and condemned because it violates one or more articles of the UN Declaration, taken to be the absolute definitional standard.

Any definition of deviance must confront the question: deviant according to what or whose standard? In a world rife with international contact and conflict, sociologists (and other social scientists) are likely to be debating the merits of alternative definitions of deviance – especially absolutist versus relativist approaches – well into the future.

deviance, academic

John W. Heeren

If we consider deviance as a breach of expectations, then any organization or occupation is likely to provide distinct opportunities for legal and/or ethical violations. College and university faculty members are professionals employed within the occupational context of higher education. Thus, the opportunities for deviance available to them derive from their roles in professional disciplines and in the occupational setting of the university. While some professors are more involved in teaching or governance at their home campus, others are more focused on research or other activities of nationwide professional associations. Both these "local" and "cosmopolitan" roles can produce deviant behavior.

Two dimensions of activities are helpful in delineating the nature of academic deviance (Heeren & Shichor 1993). First, one can distinguish between professional and occupational forms of deviance. The first of these refers to breaches of the ethics associated with professions, while the second points to the kind of normal crimes that people may commit in their usual line of work. This second dimension also has to do with deviance vis à vis property or persons. Though there is some overlap in these

categories, they do permit the differentiation of four basic classes of academic deviance (see Fig. 1).

Occupational deviance among academics shares many features in common with deviance in other occupations. Just as white collar workers or laborers pilfer property belonging to the organization which employs them, so also may professors. It seems that the more universities become entrepreneurial in obtaining outside funding, the more these kinds of opportunities will be available and exploited by faculty members. An academic example of misappropriation of resources occurred in 1995 when doctors working at a fertility clinic affiliated with the University of California at Irvine gave the eggs of some women/patients to others without the donors' knowledge or permission (Dodge & Geis 2003). Occupational deviance with interpersonal implications would include such behavior as sexual harassment of students, staff, or colleagues and exploitation of human participants in research.

Professional deviance reflects the distinctive features of university and disciplinary organizations, especially their reward and opportunity structures, constitutive roles, and systems of social control. Because academics are rarely strongly motivated to pursue a professional career for reasons of money or power, the attractions of occupational deviance found in material gain and personal domination seem less central to their efforts. However, professional deviance, centering on issues of intellectual capital, is inherently closer to the career goals of faculty. Hence, when such misbehavior is likened to property offenses, it takes the form of misappropriating intellectual property. Two well known and serious forms of this type of deviance are plagiarism and the fabrication or misrepresentation of research findings. These offenses are essentially acts of theft and fraud.

Where professional deviance is interpersonal, it entails evaluations of the work of others in the academic roles of scholar, teacher, and colleague. Such evaluations are evident in refereeing journal articles and grant proposals, grading student work, and evaluating faculty colleagues who are candidates for promotion or tenure. Deviance in these contexts involves breaches of the expected impartiality. For example, a reviewer may recognize the author of a

Norms Violated			
Focus of Deviation	<i>Property</i>	<i>Occupational</i>	<i>Professional</i>
		Theft or misuse of resources	Plagiarism or falsification of data
	<i>Interpersonal</i>	Sexual harassment or exploitation	Biased evaluation as referee for grants, jobs, articles, etc.

Figure 1 Dimensions and examples of academic deviance.

manuscript and slant the review positively or negatively accordingly. Because of the ambiguity of evaluation criteria and the meager accountability of the review process, the biased offender is not likely to be caught. Peer reviews for tenure and promotion and letters of recommendation provide similar opportunities for partiality in evaluation.

The teaching situation also allows biased evaluation to occur, as in the overvaluing of student work in light of the student's physical attractiveness, litigious attitude, or importance to the university's athletic program. According to the norms of universalism, none of these particularistic criteria should enter into the assessment of student performance. A more general overvaluation of students is the widely reported practice of grade inflation (Arnold 2004). Among the reasons suggested for this trend are attracting or retaining students where budgets are enrollment driven or improving student evaluations of a faculty member coming up for promotion. Whatever its sources, this grade inflation is deviant in that standards are lowered for ulterior reasons.

Though academic social control is similar to other forms of professional social control, in key ways it is also very different. Much of the evaluation of peers and students is protected by layers of confidentiality, anonymity, collegiality, and claims of academic freedom. Consequently, professors are granted considerable trust in carrying out these responsibilities. At the same time, scholarly work has a collective side which can operate to ensure that, prior to publication, academic work is ethically and competently done. One aspect of this is the existence of Institutional and Human Subjects Review Boards, which aim to prevent exploitation before the launching of a research project. In addition, prior to publication, most articles

will be scrutinized through the peer review process. After publication, this skepticism is continued through the critical response of peers to weaknesses and gaps in the finished work. Contrary to other work settings where open criticism of peers is regarded as a breach of personal loyalty, academics are more likely to prize and reward that kind of "whistle blowing." Finally, in most cases, the immediate professional rewards of academic success and recognition are relatively minor. Instead, the most important rewards are associated with more lengthy and distinguished contributions to scholarship. A single instance of plagiarism or falsifying results is not likely to provide significant reward. If a discovery is so spectacular as to provide immediate recognition, it would be the subject of careful scholarly scrutiny and would increase the chances of having the offense discovered.

Some occupational offenses, such as sexual harassment, have been thoroughly researched (e.g., Elgart & Schanfield 1991). However, the extensive professional trust granted professors, along with the confidentiality and anonymity of much of their work, has made it difficult to do much systematic research on most forms of academic deviance. What is known is often anecdotal and, even when thoroughly studied, findings are simply qualitative case studies of "scandals." Whereas journalists have uncovered violations such as the extensive "ghost writing" of medical journal articles (Barnett 2003), our understanding of academic deviance would be significantly enhanced if disciplinary organizations would undertake more methodical investigations.

deviance, constructionist perspectives

Stuart Henry

Constructionist perspectives are ways of viewing reality as a human cognitive or social production. The extent to which reality is seen as having an independent existence outside the human mind or social processes distinguishes different versions of constructionist theory, as does whether the construction occurs individually or socially. Individual or personal constructionism refers to how humans make cognitive meaning of their experiences of their environment. Social constructionism is about how people interactively make sense of their world by defining it and categorizing it, by representing it through language, symbols, maps, etc., and by acting toward the representations as though they were real.

Constructionists see deviance as the consequence of humans attempting to create a moral order by defining and classifying some behaviors, appearance, or statuses as normal, ethical, and acceptable, and creating rules that ban, censure, and/or sanction violators of normality.

Deviance is taken to be a variation from social norms that is perceived as different, judged as significant, and negatively evaluated as threatening. Social action or reaction by authorities or control agencies toward those so designated can result in a labeling effect or "self fulfilling prophecy" that amplifies the original deviant behavior or appearance, entrenches the incumbent in a deviant role, produces additional deviance as a result of attempting to maintain secrecy, and ultimately results in an identity transformation which, if not reversed, may produce "career deviance" as the rule violator becomes engulfed in attempts to cope with the associated stigma that comes with his or her transformed social identity. Social constructionist perspectives toward deviance have tended to focus on the practices of authoritative agents in creating moral panics through claims about the perceived threat posed by the activities of various types of deviance, real or imagined, and less on those who engage in such behavior.

SOCIAL AND INTELLECTUAL ROOTS

It is significant that much of the groundwork for the constructionist perspective on deviance emerged during the mid 1960s, at a time when significant elements of western society were challenging past traditions of social order, and embracing a social, sexual, and personal freedom. The Vietnam era protests against imperial state militarism, combined with political developments in civil rights and women's movements, created a social climate that was resonant with intellectual analyses that showed how social processes could be oppressive, and how taken for granted institutional forces could be transformed. Social constructionism offered a theoretical basis for personal and social empowerment and promised liberation from the preordered world. As psychologist Henderikus Stam (2001: 294) notes, "the emergence of social constructionism also coincides with the coming of age of a generation of scholars whose academic tutelage was colored by a political activism and the rapid growth of the post war universities followed by their recent and equally dramatic restructuring as branch plants of the corporate world." In sociology,

social constructionism was part of a critique of positivism and structuralism, represented on the conservative side by Parsonian and Mertonian functionalism that dominated the discipline during the 1950s, and on the radical side by Marxist conflict theory. Constructionism, initially through interactionism using interpretive rather than positivist methods, represented a third way of theorizing about the social world and one that brought human agency, meaning, and social process into the analysis.

While constructionism in general is rooted in the philosophy of Kant and Nietzsche, and has been traced back to eleventh century realist nominalist debates between Abelard and Anselm through the fourteenth century nominalist ideas of William Ockham (Ockham's razor), constructionist theory in deviance is intellectually rooted in five strands of the twentieth century hermeneutic (interpretive) tradition. The first of these is phenomenological sociology, beginning with Alfred Schütz's *Phenomenology of the Social World* (1932, 1967) and manifest in the work of Peter Berger and Thomas Luckmann's *The Social Construction of Reality* (1966) and branching into Harold Garfinkel's *Ethnomethodology* (1967). Second is symbolic interactionist theory, particularly Charles Horton Cooley's *Human Nature and the Social Order* (1902) and George Herbert Mead's *Mind, Self, and Society* (1934), that came to fruition in Herbert Blumer's *Symbolic Interactionism* (1969) and was evident in Charles Lemert's ideas on primary and secondary deviance, Howard Becker's *Outsiders* (1963), and Erving Goffman's *Stigma* (1963). A third strand of twentieth century intellectual thought that underlies constructionism is social problems theory in the tradition of Spector and Kitsuse's *Constructing Social Problems* (1977, 1987), and reflected in Joel Best's *Images of Issues* and Norman Ben Yehuda's *Moral Panics* (1994). Fourth is the poststructuralism of Anthony Giddens's structuration theory in his *Constitution of Society* (1984) and its integration with late Foucauldian postmodernism and Schützian sociological phenomenology in Henry and Milovanovic's *Constitutive Criminology* (1996). Finally, the fifth twentieth century influence stems from psychology and psychotherapy, originating in George Kelly's *Personal Construct Theory* (1955), through Kenneth Gergen's

narratives of the relational self in *Saturated Self* (1991) and *Realities and Relationships* (1994), Rom Harré's realist social constructionism, to the more recent postmodernist influenced narrative therapies, and meaning making for psychotherapists in Hugh Rosen and Kevin Kuehlewain's *Constructing Realities* (1996).

More broadly, constructionism has become a transcendent social theory, appearing not only in sociology and psychology but also in feminism, queer theory, the history and philosophy of science, narrative philosophy, literary theory, and everything from housing studies to duck shooting. As Stam (2001) has noted, not only has social constructionism permeated many fields of study, it has also broken out into popular culture.

Since its inception, constructionist theory has itself been differentiated into different approaches. One distinction is that made by Gergen in *Realities and Relationships* between the psychological version rooted in Kelly's personal construct theory, which concerns itself with how individuals cognitively construct their world, making sense of their own experiences of their environment, and the other rooted in the sociological interactionist phenomenological tradition of the shared construction of meaning, shaped by situational and social context, culture, and history. It is this second social constructionist approach that has been adopted by those examining deviance.

Social Construction of Reality

Social theorist Alfred Schütz was concerned with how humans, in their everyday lives, create a social world that seems real to them, and how they act toward that world, taking for granted its reality. He explored the way humans, based on their past biographical experience, develop ideal typical constructions that serve as working models or representations of the world, which contain recipe knowledge designed to allow them to achieve projected goals and objectives. These constructions or "typifications" are shared intersubjectively and can result in multiple realities.

Building on the work of Schütz, Berger and Luckmann described a series of interconnected

social processes through which humans create institutionalized social phenomena that are seen as having an independent existence outside of the people who created them. In this process humans lose sight of their own authorship of the world, “reifying” it into an apparent objective reality that then acts back on its producers. Thus, like Schütz, Berger and Luckmann revealed the dialectical relationship between social phenomena, experienced as typifications (taken for granted patterns of behavior and social types) that appear to exist independently and objectively, while simultaneously being created from humans’ meaningful subjective experiences. Berger and Luckmann saw typifications stemming from three linked processes: externalization, objectification, and internalization.

Externalization occurs when humans interact and communicate their experiences with others. Through communication humans construct categories to define the events they experience. Over time these social groupings, categories, and shared concepts become objectified by becoming institutionalized, formalized, and codified. Through this process the experiences, now categories, are made to appear independent of the people who created them and who develop recipe knowledge about them and about how to routinely act in relation to them. Through related processes, humans provide justifications and explanations for the existence of such institutionalized typifications that serve to legitimate their independent existence. Finally, this knowledge is communicated back to other members of society who internalize it and take it for granted as part of their knowledge of social reality. The overall effect of these three ongoing processes is reification: humans lose sight of what they author or create and thereby lose sight of their ability to change the apparent objective reality that stands before them.

Core Elements of Social Constructionism

Scholars who have adopted social constructionist perspectives more or less subscribe to the following core elements. First, social constructionists argue that knowledge or truth about the social world should not be uncritically accepted as real or self evident; its taken for grantedness

as a reality should be questioned. Thus, social constructionism takes a relativist epistemology rather than a realist one. Second, while communities of people may seem to agree on their understanding of certain phenomena or events as “the same,” this should not be seen as evidence that there is an underlying reality, nor even that what they accept as the same is identical. Third, the use of terms to label and classify social phenomena need not reflect an underlying real object. Fourth, commonsensical assumptions and expert knowledge are historically and culturally bound to time and place. Fifth, neither commonsense nor expert knowledge has a privileged claim to reveal the truth. Sixth, all knowledge is a result of social processes based on interaction and shared (intersubjective) meaning that is subject to negotiation by the participants involved. Seventh, the social construction of meaning is an ongoing production, gaining significance from the specific occasions of its use or displayed through its performance. Eighth, scholars who study the social process of knowledge production are themselves subject to the same critique as all knowledge production, and as such their claims are no more privileged than others. Ninth, knowledge production is a political process, subject to being shaped by concentrations of interests with a view to producing social effects; in other words, knowledge is intertwined with power and social action. Tenth, knowledge and meaning are not fixed but multiple and variable, and therefore changeable through reconstructing the language and altering the discursive processes that generate it.

Varieties of Social Constructionist Theory

Differences in social constructionist theory (recognizing that making such distinctions is itself to engage in social construction) are based on epistemology – how far its advocates reject realism and how reflexive is the perspective in subjecting its own analysis to a constructionist critique. (This same distinction also applies in the individualist version of constructionism.) Two contrasting approaches in social constructionist theory serve to illustrate their differences. In the most extreme version, developed in relation to the study of the history of science, and referred to by Paul Gross and Norman

Levitt in *Higher Superstition* (1994) as “strong social constructionism,” everything is seen as socially constructed. “Reality” is the product of specialized interpretive communities and can only be interpreted and verified in relation to agreed assumptions made by the community that created the assumptions; in other words, it is self referential. Versions of strong constructionism, also called “strict,” “extreme,” or “radical,” take the view that there is no way to objectively verify the existence of reality, and that all we are doing is observing the world from different communities and making “truth claims” about constructions of that world. Instead of engaging in “claims making,” scholars such as Ibarra and Kitsuse (1993) argue that we should be studying the language of truth claims.

In contrast, those taking a “minimalist,” “moderate,” or “contextual” view of constructionism believe that some underlying reality exists, we can know what it is, and that by selecting from and classifying this basic reality, humans build social constructions having different appearances, depending upon the social and cultural context. The task of analysis, according to Best (1993), is to locate social constructions in real cultural structural contexts, avoid being exclusively reflexive, and to focus on the substance of issues, evaluating false claims, and even creating new claims. The view of the contextual constructionist is that we need to examine the generation and sustenance of social phenomena; describe how they are defined, defended, and reacted to, with a view to making changes for the better. Those taking this more moderate contextual position thus afford themselves the basis of making judgments about which approach is better able to discern the nature of the construction process, how far it distorts any underlying reality, the extent of the “discrepancies” between objective reality and subjective experience, how realities can appear to exist and be sustained, and how changes may be made in the process to produce less harmful constructions. Unlike the strict constructionist who claims that positivism (a belief in reality) and constructionism are contradictory, the moderate or contextual constructionists argue that positivism and constructionism are separate, independent, and complementary.

While this distinction is important for allowing contextualists to use empirical evidence to support their claims that others are making fallacious claims (thus privileging their method of claims making), some commentators have argued that there is neither one constructionism nor many but a cluster of core themes (as identified above) engaged in differently depending on the authors’ aims and intent. In other words, social constructionism is itself seen as a politically framed claims making process.

CONSTRUCTING DEVIANCE

From the constructionist perspective, deviant behavior is a joint human enterprise between actors and audiences. Deviance is created by human agents making distinctions, perceiving differences, engaging in behaviors, interpreting their effects, and passing judgments about the desirability or unacceptability of the behaviors or people identified as deviant, as though they possessed object like qualities. In considering deviant behavior, constructionists identify five aspects of the deviancy construction process: (1) why and how rules are made; (2) how people interpret rules and act in ways that others perceive as deviant; (3) how behavior taken as deviant comes to represent an actor’s identity; (4) how people reject, avoid, resist, manage, or accept the deviant labels conferred upon them by others; and (5) how human actors develop new lives, either incorporating or transcending that which others label them as being.

While some social constructionist approaches to deviance have considered each of these as part of the process of creating deviance (Pfuhl & Henry 1993; Adler & Adler 1997), most constructionist work focuses on the first – the use of authoritative positions in society to create what British criminologist Stanley Cohen defined as “moral panics” around the perceived fear of certain designated behaviors, whether or not these behaviors exist, and whether or not persons actually engage in them. Classic historical examples include the sixteenth century European witch hunts and the twentieth century anti-Semitism by the Nazis against those of Jewish religion or identity.

Moral Panics

According to Erich Goode and Norman Ben Yehuda (1994), moral panics are societal reactions to perceived threats that are characterized by several features. First is their volatility, seen in their sudden appearance and rapid spread among large sections of the population via mass media, followed by a rapid decline in further instances of the problem. Second is the growth of experts who are claimed authorities in discerning cases of the feared behavior. Third, there is an increased identification of cases of the behavior that build into a "wave." Fourth, hostility and persecution are directed toward the accused, seen now as enemies of society. Fifth, measurement is made of society's concern through attitude surveys. Sixth, consensus is established about the seriousness of the threat. Seventh, there is a disproportionate fear of the threat relative to evidence of actual harm. Eighth, a backlash occurs against the persecution. Finally, there is an exposure of the flaws in identifying the problem. An excellent illustration is found in Jeffrey Victor's study of satanic ritualistic child abuse in his book *Satanic Panic* (1993). This explores the moral panic over the claimed existence of secret international organizations and/or family clans who abuse their own children or kidnap runaway youth, exposing them to ritual torture and sexual abuse, in order to brainwash them into the ideology of Satan worship. The members of such satanic cults are said to be immune from the law because Satanists have infiltrated society's institutions and protect them. Victor explored the process of accusations and claims made by adult psychotherapy patients, therapists, social workers, police officers, and the clergy. Thus constructionist perspectives on deviance tend to examine the agencies involved in the claims making process that produces the panic, rather than those designated as deviant or their behavior.

Goode and Ben Yehuda (1994) explain the production of moral panics, and thereby the social construction of deviance, by one of three models – grassroots, elite domination, or interest group conflict – that are similar to those used by sociologists to explain law creation. The grassroots model suggests that displaced anxiety from societal stress among a population

results in a spontaneous moral panic that scapegoats new categories of deviants. Here control agencies reflect opinion rather than create it. The elite domination model holds those in positions of power, whether government, industry, or religious leaders, responsible for promoting moral panic as a diversion from problems whose solution would undermine their own positions of power. The interest group conflict model sees the creation of moral panics as the outcome of moral entrepreneurs seeking to gain greater influence over society by defining its moral domain, which in turn brings reaction from other interest groups vying for their own prominence.

Victor (1998) has pointed out that moral panics claiming crime or deviance need not be based in reality but in imaginary deviants whose existence gains credibility in the eyes of the public when authorities, and those who claim expert knowledge, particularly science or medicine, legitimize the accusations that may begin as contemporary or urban legends. In such panics, actual people need not even be identified, but a category of behavior may be created, vilified, and demonized, without any real people being accused. Indeed, the behavior that the supposed perpetrators practice need not even have taken place for a moral panic to ensue. Research shows that moral panics are particularly likely to occur when bureaucratic interest, such as competing agencies, are vying for jurisdiction of authority, when methods of detection result in errors, and as Victor says, when there is a symbolic resonance with a perceived threat identified in a prevailing demonology – which serves as a master cognitive frame that organizes problems, gives meaning to them, explains them, and offers solutions.

In addition to explaining how moral panics occur, social constructionists examine the process of claims making.

The Politics of Claims Making

Social constructionists of deviance and social problems share a concern to examine how interest groups, moral entrepreneurs, and social movements create claims rather than examine the behavior of those about whom claims are

made. Claims making not only occurs in particular historical moments but also involves a process of, first, assembling and diagnosing claims about behavior or conditions seen as morally problematic. Second, it involves presenting these claims as legitimate to significant audiences, not least the news media. Third, a key task in framing a moral problem involves the prognosis of how to address the problem to bring about a desired outcome by defining strategies, tactics, and policy. Fourth, claims making involves contesting counterclaims and mobilizing the support of key groups.

CRITICISMS AND EVALUATION

Perhaps not surprisingly, critics both from outside and from within constructionism have challenged one another's epistemological position by taking either a pro or anti realist position. Pro realists accuse constructionists of being nihilistic and unscientific; anti realists ridicule any attempt at science as just another truth claim using scientific ideology to claim legitimacy for its own political ends. For example, Woolgar and Pawluch (1985) accuse moderate or contextual social constructionists of "ontological gerrymandering." They argue that claiming to be able to observe and document the variability in claims about a condition assumes the objectivity (i.e., reality) of the condition, without reflexively subjecting their own analysis to the same questioning. This, they argue, is theoretically inconsistent, if not contradictory. Instead, Woolgar and Pawluch suggest the development of forms of discourse about the social world that transcend the objectivist/relativist debate. For their part, contextual constructionists reject Woolgar and Pawluch's critique, arguing that it, and the attempts by Ibarra and Kitsuse to return to a "strict" anti realist reading of the original statement, lead to dead end, "armchair" sociology (Best 1993: 138). Best says that it is an illusion to believe that focusing on language avoids the problem of assuming reality because language is embedded in society: "An analyst who ignores the social embeddedness of claims makers' rhetoric takes that embeddedness for granted; this is another form of ontological gerrymandering" (Best 1993: 141).

More broadly, pure or strict social constructionism has been criticized for implying that problems of crime and deviance are merely fabrications, which is protested by those suffering their consequences, even though constructionists argue that there are often real consequences of acting toward constructions as though they are real. The point of constructionism, and here there are parallels with post modernism, is that revealing how what is taken to be real can be deconstructed enables the possibility of its being reconstructed differently through replacement discourse. Social problems, deviance and crime, subject to a deconstructionist analysis, can be reframed in ways that enable their reproduction to be slowed and even reversed, such that they become differently and less harmfully constituted (Henry & Milovanovic 1996). The question, indeed, the challenge for constructionists is how to demonstrate the value of this kind of analysis in bringing about changes in objective conditions, while maintaining that these conditions are only as real as we allow them to be. The value of social constructionism is that it seeks not only to understand the way humans constitute their world and are constituted by it, but also to use that knowledge to help them transform it into a more comfortable place.

deviance, crime and

Erich Goode and Alex Thio

The study of deviance is sometimes confused with criminology, or the study of crime. Sociologists define deviance as the violation of a norm which is likely to generate a negative reaction, such as censure, condemnation, punishment, hostility, or stigma. Stigmatized persons are socially disvalued and discredited by those who accept conventional norms. Norms apply to behavior (the way one acts), physical characteristics (the way one looks), beliefs (what one believes) – indeed, to any dimension along which people can and do evaluate one another. And norms are relevant to specific contexts, whether to the society at large or to specific groups, social circles, or units within the

society. Hence, a particular action may be condemned in one society but not another, one community but not another, one group but not another. Indeed, what is deviant in one collectivity may be regarded as praiseworthy in another. Sociologists always ask the question, “Deviant to *whom?*” Without reference to a specific collectivity, or *audience*, the concept of deviance is meaningless. Hence, deviance is by its very nature *relativistic*, not only with respect to cross cultural comparisons, but also when comparing one collectivity in the same society with another.

All contemporary nation states have developed a set of formally spelled out statutes enacted by a legislature, court precedent, or decree; in earlier times, a monarch decreed formal rules, or laws, and even spelled out the punishments for their violation. A violation of one or more such statutes is referred to as a crime. Sociologists define crime as a violation of a *formal* norm, that is, as spelled out in the criminal law. The criminal law calls for a state mandated punishment, ranging from a fine, through imprisonment, to execution. In principle, *universality* is one condition of the criminal law: all citizens in the same society or nation state are subject to the same laws. A crime in one collectivity or region of the country is a crime in another. This is the central idea behind “common law,” the innovation instituted by King Henry II (r. 1154–89), who sought to unify the many disparate customs, traditions, norms, rules, and laws in the many English shires throughout the kingdom through a system of case law or “judge made” law, law rendered in court that acquired precedent everywhere. Common law thus came to be a legal norm that applied throughout the kingdom, a law that everyone had “in common.” Hence, the first and most fundamental difference between deviance and crime is that deviance is *micro* relativistic, that is, it is variable from one group to another in the same society, whereas crime is *macro* relativistic, that is, in principle, it is non relativistic within a given society and varies only from one society or nation state to another. Indeed, some observers argue that the criminal law is not even variable across societies (Newman 1976; Gottfredson & Hirschi 1990).

The difference between deviance and crime can be captured in a definition in use, that is, by comparing what sociologists of deviance and criminologists study. A comparison of the articles published in the flagship journal of the sociology of deviance, *Deviant Behavior*, with those that appear in criminology's most prominent journal, *Criminology*, verifies that, though the subject matter of these fields is similar, it overlaps very imperfectly. A perusal of the chapters in the introductory textbooks of these two fields, again, conveys how different is the subject matter of the sociology of deviance and criminology. Even more significantly, the two fields differ strikingly with respect to their conceptual and theoretical approaches.

One complicating factor is that the difference between the two fields is sharper in the United States, where the sociology of deviance and criminology are more clearly demarcated, than in the United Kingdom, where they overlap much more heavily. In addition, criminology is a huge field while the sociology of deviance is tiny. In 2002, the circulation of *Deviant Behavior* was 632; that of *Criminology* was 4,181. There are roughly 100 textbooks in criminology and criminal justice; there are at most 10 or 12 in print texts and "text readers" in deviance. Introductory criminology enrolls perhaps a quarter of a million students, not including criminal justice; deviance, fewer than 100,000. In criminology and criminal justice programs, typically, a range of courses is offered beyond the introductory level; in deviance, typically, there are none (Goode 2002). This means, willy nilly, that the field of deviance studies inevitably borrows heavily from criminology, while the reverse is rarely true. As a result, the two fields cannot always be neatly and cleanly distinguished. And lastly, to make matters even more complicated, a number of prominent sociologists of deviance are also criminologists (Cullen 1983; Tittle 1995; Akers 1998).

There are distinct differences between the two fields, however. First as to subject matter. As we saw, a crime is the violation of a specific type of formal norm – the criminal law – which calls for a state sanctioned punishment, typically imprisonment. Any act that is likely to result in arrest, conviction, and punishment of

the perpetrator is by definition a crime. In contrast, deviance is not *necessarily* criminal. Many actions are deviant without being criminal, that is, they are condemned or punished entirely informally, interpersonally: nude dancing, binge drinking, joining a religious cult, and becoming emotionally disturbed at work. Hence, a great deal of behavior is deviant but not a crime.

However, the question of whether all criminal acts are by definition deviant is controversial. Many sociologists define deviance as the violation of *any and all* norms; hence, they consider crime as a *subtype* of deviance, since such violations encompass both formal and informal norms (Clinard & Meier 2004: 130–3). According to this definition, all crime is deviance but not all deviance is crime. In contrast, other sociologists refer to the violation of a *formal* norm as a crime and the violation of an *informal* norm as deviance (Quinney 1965; Robertson & Taylor 1973). According to this definition, no deviance is crime and no crime is deviance.

One problem with the definition that sees crime as the violation of a formal norm and deviance as the violation of an informal norm is that many criminal acts violate informal norms as well, that is, in addition to generating arrest, they are *also* interpersonally stigmatizing and discrediting. Being known in the community as a criminal, especially as an ex convict, is regarded by most audiences as deviant. Illicit drug use and sale are clearly criminal, but they are also regarded as a form of deviance.

Hence, the subject matter of deviance and crime, although distinct, overlaps heavily. But the topics of study of the two fields differ substantially. Most criminologists consider the study of the Federal Bureau of Investigation's Index crimes – that is, murder, rape, robbery, aggravated assault, burglary, motor vehicle theft, and larceny theft – as the foundational core of criminology. Indeed, chapters on these criminal acts constitute most of the chapters on types of crimes in criminology textbooks. These are "high consensus" crimes, that is, acts for which there is widespread public agreement that they *should be* illegal. In addition, some criminologists study white collar crime, for which consensus is lower, but are nonetheless very rarely studied by sociologists of

deviance. And lastly, criminologists investigate the criminal justice system – the police, the courts, and jails and prisons.

In contrast, again, with respect to subject matter, sociologists of deviance *tend to* study what are referred to, in criminology, as “public order” or “vice” crimes (prostitution, homo sexuality, drug use, and gambling), which are lower consensus crimes and have a lower likelihood of resulting in arrest; and they study acts which are not criminal at all. But the Index crimes are much less likely to attract the attention of deviance specialists. In addition, while criminologists study *only* behavior, sociologists of deviance study anything and everything that generates condemnation, punishment, and stigma – including physical characteristics and beliefs, both of which can be regarded as deviant. Both physical characteristics (“abominations of the body”) and beliefs (“treacherous and rigid beliefs”) are included in Goffman’s types of stigma (1963: 4), as are “tribal stigma of race, nation, and religion,” which are extremely rarely studied as a form of deviance but, in principle and by definition, could be.

In addition to their subject matter, conceptually and theoretically, the sociology of deviance and criminology differ as well. Insofar as sociologists of deviance do examine high consensus crimes such as rape, white collar crime, or any of criminology’s classic topics, they look at them through a very different lens. Most criminologists are positivists; they regard crime as a phenomenon whose epidemiology, or distribution in the population, and etiology, or causes, can be studied quantitatively. They tend to study crime by means of survey methods or the use of official police records, such as the FBI’s *Uniform Crime Reports*. In contrast, most sociologists of deviance are symbolic interactionists and constructionists, and take as their primary subject matter the social organization of the condemnation of particular beliefs, physical characteristics, or forms of behavior, as well as the impact of said condemnation on the identity, social interaction, and career of persons subject to said condemnation. For instance, a popular topic among sociologists of deviance is the “stigma neutralization” of criminal behaviors, such as rape (Scully & Marolla 1984), child molestation (McCaghy 1967, 1968), stealing drugs (Dabney 1995),

and shoplifting (Cromwell & Thurman 2003). Clearly, the concept of stigma neutralization is also applicable to deviant but not criminal acts, such as student cheating (McCabe 1995) and topless dancing (Thompson et al. 2003), as well as (with varying degrees of success) to physical characteristics such as obesity (Gimlin 2002: 110–40). This distinction between criminologists and deviance specialists is far from clear cut, however; some deviance specialists, a minority, still test etiological models, while some criminologists conduct research on deviant identities and the social construction of crime and criminals.

Since the 1960s, criminology has evolved into a profession as well as a field of study. Dozens, perhaps hundreds, of academic programs in criminology and criminal justice have been established during the past two decades; they are regarded as a stepping stone to a career outside of academia. Many criminology and criminal justice departments were formed after breaking away from sociology departments; today, non sociologists form a substantial minority of criminologists, and a majority of criminal justice specialists. Unlike the sociology of deviance, criminology is a distinctly policy oriented discipline. Perhaps the most important distinction between the study of deviance and the study of crime is that the majority of criminologists – and even more emphatically, criminal justice specialists – adopt a “correctional” view, conceiving of their research as a means of combating the problem of crime, whereas very few deviance specialists view their work in this fashion. In fact, a substantial proportion of sociologists of deviance harbor a certain *appreciation* for their subject matter and the people they study (Matza 1969: 24ff.), a fact likely to generate stigma and condemnation for the field as well as its practitioners (Hendershott 2002).

deviance, criminalization of

Daniel Hillyard

Imputations of deviance occur whenever there is stigmatization, condemnation, segregation, retribution, or rehabilitation. Criminalization refers to the process of applying the criminal law to certain behaviors. Criminalization reinforces the dominant standards in a society through threatened criminal penalties, criminal prosecution, and punishment. Not all deviant behaviors are criminal. Many scholars study the processes through which, and conditions under which, the criminal sanction is applied to particular deviance categories.

To change the status of a deviant category to a crime requires collective action. Thus studies of the criminalization of deviance reveal the links between deviance, political action, and social change. The dominant approaches to studying criminalization are the deviance and social control viewpoint, which asks whether criminalization is a neutral process or if it serves the interests of the powerful, and the social problems viewpoint, which looks at the social meanings, or collective definitions of crime.

In his highly regarded book *The Politics of Deviance*, Edwin M. Schur offers a definitive statement about the social processes of characterizing behaviors and conditions as deviant: "When people engage in organized political activity on deviance issues they are, in fact,

intentionally trying to ensure that a particular balance of power will tip in their favor." On this account, the criminalization of deviance involves not only groups who wield the power to impose or extend deviance definitions and see to it that others who deviate from favored moral stances are subjected to state administered punishment, but also a process of stigmatization that implies social standing or acceptability for these groups. Three propositions can be derived from these observations. First, what is officially designated as deviant is often a political decision. Second, official rules are tied to interest groups and power. Third, the criminalization of deviance is a form of social control.

Jenness (2004) presents an authoritative review and evaluation of criminalization scholarship. Organizing this massive literature both chronologically and thematically, she examines three lines of inquiry. The first is classic work examining criminal laws that emerge in response to demographic changes that upset the balance between powerful interest groups and those they control. Classic work demonstrates the roles of both instrumental and symbolic politics in deviance defining and the emergence of criminal law. The second, contemporary line of inquiry "unpacks" the relative influences of organizational, social movement, and state related factors involved in efforts to criminalize deviance. The focus is less on changes in structural conditions than on the specific strategies for producing criminal law. The third, more recent line of inquiry looks to connect local criminal law formation politics with broader processes of institutionalization, globalization, and modernization. This line of inquiry asks whether deviantization and criminalization at the local level (i.e., county, region, state, country, etc.) intersect with some larger social, political, or cultural system. For each of these three lines of inquiry, Jenness (2004) details the factors which influence the criminalization of deviance.

FACTORS INFLUENCING THE CRIMINALIZATION OF DEVIANCE

Generally, there are two approaches to examining the content of a specific criminal law. The

first approach entails merely deciphering what specific acts are criminal. The second approach, by contrast, ensues from conceptualizing law as a field of critical inquiry. To demonstrate the distinction, consider the Texas sodomy statute struck down by the US Supreme Court in the summer of 2003: "A person commits an offense if he engages in deviate sexual intercourse with another individual of the same sex." Employing the first approach, lawyers, judges, and law students examine the definition of "deviate sexual intercourse" and find that it includes "any contact between any part of the genitals of one person and the mouth or anus of another person." Typically, that ends the analysis. But to those who follow the second approach, the content of the anti sodomy law is not simply the definition of homosexual conduct, but the social processes by which criminal status has been assigned to sex acts between individuals of the same sex, and the reasons for it. The second approach thus expands the examination of law to the social context of the issue in question, and hence its political dimension. This is the approach taken by criminologists, sociolegal scholars, and others who concern themselves with the criminalization of deviance.

Demographic Changes, Social Control, and Criminalization

The criminalization literature is packed with empirically grounded case studies which indicate that the construction of deviant categories and outlawing of ensuing behaviors can be linked to changes in the size, density, or distribution of human populations. There are two accounts of this relationship. The first focuses on changes in economic relations between status groups. The second focuses on the struggle between these groups to secure deference through the control of symbols, including the law.

The classic example of the materialist account (pertaining to the economic institutions of society) is William Chambliss's 1964 study of the English creation of vagrancy laws. When the bubonic plague spread into northern Europe in the fourteenth century, it decimated the labor force, causing wages to rise beyond what landowners were willing to pay. As landowners

sought to keep wages low, laborers sought to migrate, in search of better pay. In response, landowners invented vagrancy laws to force workers to remain and work cheaply. Chambliss interpreted these events as evidence that the criminalization of deviance is often a reaction to demographic changes which upset the balance of power that inheres in economic relationships. Supporting this claim, Chambliss observed that later in history, vagrancy laws were expanded to cover loitering, associating with reputed criminals, prostitution, and drunkenness, during periods when demographic changes made cheap labor more readily available. Following in this vein, even homelessness, Jenness (2004) observes, has been criminalized in the United States – in response to gentrification and redevelopment in principal cities.

The second approach to studying demographic changes and the criminalization of deviance focuses less on the material basis for social control than on the role of symbolic politics. Here the classic study is Joseph Gusfield's 1963 analysis of the 18th Amendment, which made it a crime in the United States to manufacture, sell, transport, import, or export intoxicating liquors. Here again the analysis begins with a population shift, namely the mass influx of Europeans to major US cities in the 1800s. The swelling numbers of Catholic immigrants challenged the traditional dominance and prestige of Protestantism in American life, the response to which was defining the distribution and sale of alcoholic beverages as criminal. In Gusfield's view, although law enforcement played a role in Prohibition, the criminalization of liquor was more symbolic, for it "established the victory of Protestant over Catholic, rural over urban, tradition over modernity, [and] the middle class over both the lower and upper strata" (Gusfield 1963: 7).

While Chambliss and Gusfield each highlight the role of changing populations in the criminalization of deviance, they emphasize different means of social control. The example of vagrancy laws focuses on instrumental legislation, which attempts to control the actual behavior of those classified as deviant. The example of the 18th Amendment, on the other hand, focuses on the symbolic nature of criminalization, which for Gusfield does not depend on law enforcement for its effect (Jenness 2004).

Hundreds of case studies in the criminalization literature demonstrate the emergence of both instrumental and symbolic criminal law. Typical to these studies are populations perceived as threatening and "in need of control" by those in a position to bring about legal change.

Of course, not all demands to criminalize deviant behaviors and conditions are successful – many are ignored; others are overshadowed by new demands. Contemporary research seeks to discover and model how legal change is stimulated, defined, and institutionalized.

Organizational, Social Movement, and State Related Factors Involved in Criminalization

In 1971, Herbert Blumer called for reconceptualizing social problems as "products of a process of collective definition" rather than "objective conditions and social arrangements" (Blumer 1971: 298). Although undertaken more than 20 years earlier, Edwin Sutherland's groundbreaking and now classic study of the origins and diffusion of sexual psychopath laws illustrates Blumer's point.

Sexual psychopath laws called for taking criminals who were diagnosed as sexual psychopaths and confining them indefinitely. Sutherland depicted these laws as "futile" – noting first that they were rarely enforced, and second that there was no discernible difference between trends in rates of sex crimes among states with them and neighboring states without them. He argued that state legislatures hastened to adopt sexual psychopath laws not because they were effective, but in response to public hysteria, media hype, the institutionalization of erroneous claims about the nature and threat of sex crimes, and the influence of experts on the legal process.

Specifically, Sutherland observed, once a few serious sex crimes had been committed in quick succession, the stories were picked up by press associations and spread by news outlets across the country. Two to four spectacular sex crimes in a few weeks were enough to evoke the phrase "sex crime wave." The public hysteria which ensued led to the creation of committees to study the problem. Psychiatrists played an important part on many of these committees, and they made up the primary interest group

backing sexual psychopath laws. Most psychiatrists favored the view that criminals should be treated as patients, and frequently their opinions went unquestioned by state lawmakers. These views included what Sutherland believed to be erroneous claims about the prevalence of serious sex crimes, as well as their etiology, diagnosis, and curability. These events corresponded with a social movement to treat criminals rather than punish them. The result was a diffusion of laws that Sutherland feared "may injure the society more than do the sex crimes which [they are] designed to correct" (Sutherland 1950: 142).

Sutherland's study, and many others since, demonstrate Blumer's observation that more significant than the objective conditions of a putative (i.e., reputed) social problem are the definitional activities of social actors who perceive and judge them as offensive and undesirable. Sutherland's study also demonstrated the significance of the tactics, power, and motivations of those who seek to influence the law.

Jenness (2004) summarizes a second line of contemporary research that builds upon efforts to identify the political conditions and processes necessary for social actors to effect criminalization. An example is her research with Kendal Broad detailing the activities of grassroots activists to criminalize violence against gays and lesbians. These activities included documenting and publicizing anti gay and anti lesbian violence, providing victim assistance and crisis intervention programs, and launching educational campaigns. By these means, a sector of the larger gay and lesbian movement succeeded in getting people to notice violence against gays and lesbians, and to recognize it as a social problem in need of a political response. These and other actions gained the attention of the media and further facilitated the institutionalization of calls for legal reform. And as the movement gained legitimacy, activists succeeded in framing the response to bias motivated violence, and in drafting actual legislation.

Research in this vein also demonstrates how efforts to criminalize deviance are affected by timing and the presence or absence of organizational support. Lowney and Best (1995), for example, characterize the early failure and later success of efforts to criminalize what became known as "stalking." They report that although

there had been past attempts, no state legislature passed a law making stalking a crime until "star stalking" became an issue of concern for the Screen Actors Guild and that caught the interest of the general public. Similarly, not until the issue became part of the larger response to domestic violence did anti stalking laws become widespread. Thus, success and failure were related to whether claims were supported by significant organizational resources and whether they resonated with larger cultural concerns (Jenness 2004).

Significant factors in criminalizing deviance also include professional groups and networks, as well as the state (Jenness 2004). For example, Wolfson's (2001) study of the increasing social and legal control of tobacco use demonstrates how activists have been able to build upon the preexisting work of public health organizations, such as the American Lung Association and the American Cancer Society, and how the fight against big tobacco has spread on account of activities of people working within state, local, and federal agencies such as the Office of the Surgeon General and the National Cancer Institute.

METHODOLOGICAL ISSUES, CURRENT EMPHASES, FUTURE DIRECTIONS

The study of when and how deviant behaviors and statuses become defined as criminal has expanded in many directions since Sutherland wrote in 1950. The literature now reflects the work of criminologists, sociologists, political scientists, and sociolegal scholars. Areas of inquiry include demographic, organizational, political, structural, and institutional conditions. Theoretical accounts of criminalization have moved away from traditional consensus and conflict models and toward integrative models which point to multiple factors, including individual activists, interest groups, the media, and organized social movements; the tactics, power, and motivations of these social forces, entities, and actors; and the political opportunities and structural conditions that make the criminalization of deviance possible. Contemporary work includes more sophisticated analyses of combinations of these factors, as well as

how they operate across time. And very recent work is beginning to examine criminalization as a social process operating across geopolitical units. Thus empirical and theoretical accounts of the criminalization of deviance have progressed from the now classic studies of the relationship between demographic changes, social control, and criminalization to contemporary scholarship identifying and detailing the organizational, social movement, and state related factors which structure and mediate this relationship, and most recently to the larger processes of institutionalization, globalization, and modernization from which criminalization may arguably derive (Jenness 2004).

Methods for studying criminalization have progressed as well. Assessments of the field (e.g., Hagan 1980; McGarrell & Castellano 1993) argued that research on the emergence of criminal law suffered from a tendency to unconsciously vacillate between description and explanation, to focus on historically grounded case studies rather than general processes of criminalization, to substitute moral prejudgments for empirical inquiry, and to bog down in the stale debate between consensus and conflict theories. In response to these critiques, scholars began to inject other areas of sociological inquiry, to examine multiple case studies, and to create general models of the criminal law formation process. In a recent evaluation of this work, Jenness (2004) stresses that only recently have researchers begun seeking to understand processes of criminalization across diverse geopolitical units. One example is empirical research on innovation and diffusion in state hate crime laws (Grattet et al. 1998), which the authors argue is "affected by a state's internal political culture and traditions as well as by its location within the larger interstate system" (Grattet et al. 1998: 286).

Most recently, scholars have begun to address the impact of globalization on the origins of criminal law. Two hypotheses dominate this research. The first postulates that when local factors are paramount, there will be significant variation and tailoring of national laws. Support for this hypothesis is contained in the finding that distinctions between sexual harassment policies in France and the United States are due to particularities in the opportunities and constraints that activists and lawmakers

faced in their respective contexts. By sharp contrast, research on prohibitions against female genital cutting (Boyle 2002) shows that despite local opposition and widespread practice, international pressure has succeeded in getting countries to pass such laws. This finding supports the hypothesis that when factors external to nation state politics are paramount, there will be little variation between national laws. More subtly, however, Boyle's second finding that local context plays a role in the content, timing, and implementation of newly adopted anti female genital cutting laws and policies suggests that there is support for a third hypothesis: that both local context and particularities and global norms and system pressures matter (Jenness 2004).

Jenness (2004) suggests a variety of future directions for research, theory, and methodology. These include comparing the origins and making of criminal law to other forms of social control, elucidating the distinctions, if any exist, between instrumental and symbolic law, and examining how processes of decriminalization compare to processes of criminalization. Analyses of these processes may be expanded to include the influences of organizational fields and institutional logics, preexisting policy domains, and the workings of culture. These goals may be accomplished by linking research on the criminalization of deviance to the policy studies literature – particularly studies of the development of policy domains, the social processes involved in the generation of policy, and the influences of these processes on implementation.

deviance, explanatory theories of

Erich Goode

Sociologists define deviance as the violation of a norm that, if discovered, would typically result in punishment, scorn, or stigmatization of the offender. The normative violation can include acts, beliefs, and traits or characteristics, and it

can be a violation of both formal norms (laws) and informal norms (folkways and mores). This definition opens two radically different though complementary missions or lines of inquiry: those that attempt to explain the causes of normative violations, and those that explore the dynamics underlying the social construction, accompaniments, and consequences of the norms, including laws, and their enforcement. Criminologists and sociologists who attempt to explain deviance and crime nearly always study non normative *behavior*, while constructionists look at the full gamut of normative violations – behavior, beliefs, and physical characteristics.

Not all deviance is criminal, that is, is a violation of society's laws. Many actions that are likely to be punished informally are not against the law and entail no risk of arrest. Nonetheless, all the explanatory sociological theories that are discussed in deviance textbooks were originally formulated to account for both deviance and crime, and they play a prominent role in the field of criminology. During the past two decades or so, practitioners in the fields of criminology and the sociology of deviance have gone their separate ways. Today, criminology is mainly an empirical and explanatory field, while the sociology of deviance has become a field concerned mainly with detailed studies of deviant scenes, the social construction of deviance and conventionality, and the interaction between respectables and persons with discredited or deviant identities, as well as among deviant persons themselves. Hence, increasingly, theories that were originally devised to explain deviant behavior generally now apply more specifically to the field of criminology than to the field of the sociology of deviance.

EXPLANATORY THEORIES OF DEVIANCE AND CRIME

A theory is an explanation or cause and effect account of a general phenomenon. The epistemological foundation of the explanatory mission is usually referred to as *positivism* (or “methodological positivism”) and is made up of the following assumptions: *objectivism* (that is,

phenomena take on a reality independent of their social construction); *empiricism* (we can know the world through our five senses); and *determinism* (the phenomena of the material world, including the social world, are linked together in a cause and effect fashion). The goal of all explanatory theories is to explain or account for as wide a range of phenomena as possible. Hence, an explanation accounting for embezzlement in general is superior to an explanation only accounting for the illegal appropriation of money by bank tellers living in small cities; and an explanation for crime in general is superior to one accounting only for embezzlement specifically (Hirschi & Gottfredson 1994: 263).

Objectivism refers to the fact that any attempt to account for the occurrence of deviance and crime is predicated on the view that the violation of social and legal norms constitutes an objectively real, pregiven entity that contains a common thread that demands an explanation. If deviance, including crime, and its constituent elements did not contain a common thread – that is, if it were a social construction and nothing else – then no explanation attempting to account for it would be possible. *Empiricism* typically refers to the fact that the violations of social norms can be investigated by means of highly sophisticated, quantitative social research methodologies, such as surveys, which stress reliability and validity. And *determinism* refers to the fact that the central question in explanatory research is: “Why do they do it?” (Or, contrarily, “Why *don’t* they do it?”) In the field of the sociology of deviance and crime, theorists assume that they can discover law like generalizations that account for normative violations. All explanatory theories of deviance and crime – whether they focus on the individual, the individual in a particular context or social structure, or the social structure itself – address their research to the same basic question. In all of them, the *dependent* variable is the normative violation, and the *independent* variable is the factor their theory posits as the causal factor.

The Positive School. The earliest attempt to explain criminal behavior objectively, empirically, and in a materialistic cause and effect fashion was undertaken by a school of criminologists who are referred to as positivists, of

whom Adolphe Quetelet (1796–1874) was perhaps the first. Positivism broke with a much earlier, more legalistic tradition that ignored the characteristics of the offender. The most well known of the early positivists were the proponents of what came to be referred to as “the Positive School,” associated with the work of Italian physician Cesare Lombroso (1835–1909), author of *L’Uomo Delinquente* (1876, and subsequent editions). The Positive School was characterized by the following postulates. First, that legalistic investigations into the nature of crime be set aside for a scientific study of the characteristics of the criminal. This postulate led to accepting the criminal law as a given, and its violation as a crime. Second, that the criminal engaged in violations of the law as a result of forces that were beyond his awareness and understanding. This postulate was based on the assumption that the criminal lacked a free will. And third, the early criminological positivists attributed the cause of criminal behavior principally to a biological factor: one or more physical defects (or “atavisms”) in the human organism. Atavisms were thought to be ape like “throwbacks,” primitive characteristics that appear in some modern humans. They included a small brain, a sloping forehead, a large jaw, and a stooped posture. These defects, the theory argued, induce some people to commit crime.

Lombroso’s theory was a “kinds of people” explanation that looked no further than the individual, specifically, the biological characteristics of offenders. Over time, however, Lombroso modified his explanation; with each new edition of his book, he attributed a decreasing impact of biological factors and an increasing role to social and structural factors. Lombroso’s influence on the study of crime is immense. His focus on biological factors fell out of favor during the 1920s, when psychological behaviorism came into vogue, but made a comeback during the 1960s, and remains an emphasis among a few criminological circles to this day. However, his insistence that criminal behavior be studied objectively and scientifically is the foundational assumption of explanatory criminology. In spite of his emphasis on biological factors as a cause of criminal behavior, Lombroso is regarded as the “father” of scientific criminology.

CONTEMPORARY EXPLANATORY THEORIES OF DEVIANCE AND CRIME: AN INTRODUCTION

For the most part, explanatory theorists of deviance and crime take the social construction of the norms and the laws for granted; they do not regard an explanation of the content of norms and laws or their enforcement as their mission. Indeed, how laws and norms come into being and what their consequences are for the violators is not an issue for the explanatory theorist. And, while agreeing that all behavior, including deviance, is caused, contemporary sociological explanatory theories of deviance and crime do not universally share the Positive School's assumption about the norm violator's lack of free will. All agree that potential norm violators make choices, but they do so within constrained circumstances.

The most influential contemporary sociological explanatory theories (or theories devised by sociologists) of deviant behavior include: social disorganization theory; anomie theory; learning theory and the theory of differential association; social control theory; self control theory; and routine activity theory. In addition, several of the most prominent constructionist theories – labeling theory, conflict theory, including Marxism and feminism – harbor a “minor” explanatory mode.

Social disorganization theory. During the 1920s, the sociology faculty and graduate students at the University of Chicago developed a perspective toward deviance, crime, and delinquency that has come to be called the “Chicago School,” or social disorganization theory. Using the city of Chicago as their laboratory, these researchers took as their explanatory or independent variable the instability of entire neighborhoods and communities. Regardless of their individual characteristics, people who live in such communities are more likely to engage in illegal and non normative behaviors than persons residing in more stable communities. What makes for unstable or disorganized communities is that they are characterized by low rents, which means that residents who live in them invest little financially or emotionally in their community of residence, and tend to be socially and geographically mobile. Hence, the residents of unstable communities tend not to

monitor or sanction the behavior of wrong doing in their midst. As a result, residents can commit infractions of the law and the social norms without consequence, and tend to do so with greater frequency than in communities in which co residents monitor and sanction one another's behavior. In socially disorganized communities, street crime, drug abuse, alcoholism, prostitution, juvenile delinquency, and mental disorder are common; a high proportion of law abiding residents tend to move out as soon as they can, contributing to further crime, deviance, delinquency, and social disorganization. By the 1940s, the Chicago School had become regarded as obsolete (in the 1960s, a school of deviance research came to be dubbed the “neo Chicagoans,” but they had a very different orientation). However, by the late 1980s, social disorganization theory experienced a rebirth of interest, and is now a major perspective in the study of crime, delinquency, and social problems (Stark 1987; Skogan 1990; Bursik & Grasmick 1993).

Anomie theory. Émile Durkheim's book *Suicide* was the inspiration for anomie theory. Durkheim regarded anomie as a disturbance in the traditional social order which caused one form of deviant behavior in particular – suicide. In 1938, Robert K. Merton refashioned the concept of anomie as a disjunction or “mal integration” between a society's culture, that is, what members learn to value, what they are motivated to want and seek – material success – and its social and economic structure, which places limits on some of its members' ability to succeed. This disjunction places strain on members of the society who fail to achieve what they have been taught to want and strive for, which, in turn, results in deviant “modes of adaptation,” or behavioral consequences of this failure to achieve.

In the mode of adaptation Merton referred to as “innovation,” people retain the cultural goal of success but seek to achieve it in an unconventional, illegitimate, or deviant manner. Examples include pimping, drug dealing, and engaging in white collar crime. “Ritualism,” another deviant mode of adaptation, results from abandoning or scaling down success goals but compulsively following to the letter the norms and routines of proper behavior. A petty bureaucrat who insists that all

regulations be adhered to in every detail but has forgotten what the rules are for exemplifies this mode of adaptation. "Retreatism" represents the failure to achieve society's success goals in the conventional manner and giving up on those goals as well as giving up on any and all manner of achieving them. The ritualist is a "double failure" who has adapted by withdrawing from society's rat race in every way; examples include alcoholics, drug addicts, psychotics, and the homeless. And the last of Merton's modes of adaptation is "rebellion," the attempt to deal with the malintegration of society's culture and social and economic structure by overthrowing its culturally defined goals (material success) and any and all legitimate means to achieve those goals and replacing them with an alternative social, political, and economic structure. Clearly, the revolutionary fits here.

Merton's anomie theory argued something quite different from all prior theories of deviance and crime: that the conventional norms and the institutionalized social structure exerted pressures on actors in a social structure to violate the norms and the laws. Ironically, it was conventionality that produced deviance. While Durkheim argued that deviance resulted from a *too weak* hold of society's norms, Merton asserted the opposite – that anomie was a consequence of a *too strong* hold of the norms, that is, resulted from actors *following* society's norms. Merton's theory presupposes that it is deviance (not conformity) that is intellectually problematic, that is, that demands an explanation, that actors need to be motivated to commit infractions of the norms and the laws. It is also based on a high degree of consensus regarding the legitimacy of the norms and the laws. The theory is not concerned with how the laws or norms come to be devised nor how they come to be enforced. Indeed, the laws and norms are taken for granted. In addition, the theory does not explain how, once a person feels strain, he or she comes to devise one or another deviant adaptation. Anomie theory was a, perhaps the, dominant explanation of deviance and crime in the 1950s and the early to mid 1960s – indeed, the article that spawned the theory, "Social Structure and Anomie" (Merton 1938), is the most often cited article written by a sociologist ever written – but by the late 1960s

it fell out of favor and in some quarters was considered "disconfirmed." Like social disorganization, however, anomie theory made a comeback and is currently one of the more influential theories in the field (Messner & Rosenfeld 1997).

Differential association theory. In the third edition of his criminology textbook, Edwin Sutherland (1939) spelled out the theory of differential association. It has become one of a small number of important perspectives in the field. The first and most fundamental proposition of Sutherland's theory is that criminal behavior – and, by extension, deviant behavior as well – is learned. Hardly anyone stumbles upon or dreams up ways of violating the law. This must be passed on from one person to another in a genuine, more or less straightforward, learning process. The norms or values – or, in Sutherland's terminology, the *definitions* – favorable to committing crime must be learned in face to face interaction between and among people who are close or intimate with one another. Criminal knowledge, skills, sentiments, values, traditions, and motives are all passed down as a result of interpersonal – not impersonal – means. And the earlier in one's life this process takes place, as well as the more intense the relationship one has with one's interacting parties, the more influential it is. Sutherland's theory argued that people who eventually embark on engaging in criminal acts *differentially associate* with persons who endorse violations of the law. A person becomes criminal or delinquent because of an excess of definitions favorable to the violation of the law over definitions unfavorable to the violation of the law. The key to this process is the *ratio* of definitions favorable to the violation of the law to those that are unfavorable. When favorable definitions exceed unfavorable ones, an individual will turn to crime. Notice that Sutherland insisted that persons must *learn* and *be motivated* to commit crime; it is not simply something that someone would do naturally, spontaneously, or in the absence of social conditioning. Both crime and conformity to the legal code need explaining, Sutherland argued. There is no such thing as an asocial or culturally bereft social actor: we do what we have learned is good to do, and that includes both crime and law abiding behavior. Learning to

violate the law is no different from learning to speak English or eat with a fork or brush one's teeth. What is different for the criminal is that he or she has associated, and continues to associate, with persons who have promulgated the positive value of committing crime. Sutherland's theory has remained popular in criminology and the study of juvenile delinquency and deviant behavior; it has spawned a host of theoretical offspring, including the theory of "culture transmission" (Miller 1958), or the view that lower class culture is criminogenic, and the social learning school of crime and deviance (Akers 1998), which incorporates principles of operant conditioning into the theory of differential association.

Social control theory. Control theorists turn the traditional question – "Why do they do it?" – around and ask, "Why *don't* they do it?" Deviance, they argue, is not intellectually problematic. If left to our own devices, most of us would deviate from the rules of society and cheat, lie, steal, get drunk or high, and engage in all manner of sexually gratifying behavior. This approach takes the allure of deviance, crime, and delinquency for granted. What needs to be explained, they say, is conventional, law abiding behavior. Why don't we all violate the law and society's norms? What causes deviant behavior, control theorists argue, is the *absence* of the social control that ensures conformity to the rules. Conformists do not engage in deviant, criminal, or delinquent acts because of their strong bonds with or ties to conventional others, conventional institutions, their adherence to conventional beliefs, and involvement in conventional activities (Hirschi 1969). To the extent that persons have a stake in conformity – jobs, an education, a house, a relationship, a family – they will tend to conform to the norms of the society and not risk losing that stake. To the extent that persons lack that stake in conformity, they are more willing to violate the law, since they have "nothing to lose."

Self control theory. In 1990, a book was published that proclaimed itself "a general theory of crime" (Gottfredson & Hirschi 1990). The authors define crime as "force or fraud in pursuit of self interest" and argue that their explanation applies to any and all forms of crime, including white collar and corporate crime,

drug use, street crime, or the forms of crime traditionally studied by criminologists, as well as acts that may not be technically illegal, such as illicit or risky sex, the abuse of alcohol, and smoking. Like social control theory, self control theory argues that what needs to be explained is not violations of the law but conformity to the law. Crime does not need to be learned or motivated, Gottfredson and Hirschi argue. It is what anyone would do in the absence of controls. What causes violations of the law? True to its name, self control theory argues that a lack of self control is the cause of crime, and what causes a lack of self control is inadequate, inconsistent, and ineffective parenting or caregiving. Parents who fail to monitor or control the wrongdoing of their children produce offspring who lack self control and engage in criminal, deviant, delinquent, and high risk behavior. All of these behaviors have one thing in common: they are impulsive, intended to seize short term gratification without concern for long run risk to the actor or harm to the victim. Criminal and other high risk behavior is especially attractive to people who lack self control because these people "tend to lack diligence, tenacity, or persistence in a course of action," and such acts provide immediate and easy or simple gratification of desires, are "exciting, risky, or thrilling," provide "few or meager long term benefits," require "little skill or planning," and often result in "pain or discomfort for the victim" (p. 89).

Their "general theory of crime," Gottfredson and Hirschi argue, both is consistent with the facts of criminal behavior and contradicts nearly all competing theories of crime. The authors are not modest about the reach of their theory; they say they intend to explain "all crime, at all times" (p. 117). Indeed, they say, their theory also explains many other forms of deviant behavior that are not criminal, including alcohol abuse, risky sex, and being accident prone. Nor are they modest about their theory's devastating implications for the other explanations of crime, specifically, anomie and learning theory, as well as the explanatory component of labeling, conflict, and feminist theories. The only other explanations of deviance and crime that are compatible with self control theory, Gottfredson and Hirschi argue, are

social disorganization theory (since, in failing to exercise social control, the community, like the criminal's parents, fails to monitor or control wrongdoing) and routine activity theory (since that perspective focuses on criminal opportunity, not the criminal offender). Self control theory is based on the idea that the appeal of crime does not have to be learned or motivated. Deviants do not learn the value of engaging in deviance or crime. One does not learn to engage in crime because no learning is required. Criminal acts are simple, commonsensical, concrete, and result in immediate gratification. What causes criminal behavior is not the presence of something but the absence of something, that is, self control. Crime is in fact *asocial* rather than social in nature. In this sense, then, self control theory is a non sociological theory of crime. Though criminal opportunities may be sociologically structured, criminality, or the propensity to commit criminal acts, is a sociological factor only by virtue of its absence of social influence.

Routine activity theory. Routine activity theory is a contemporary version of the perspective put forth by the late eighteenth century utilitarians such as Jeremy Bentham (1748–1832) and Cesare Beccaria (1738–94), who argued for the importance of free will and the individual's rational calculation of pleasure and pain. Routine activity theory has purchase only among criminologists; typically, it is not discussed by sociologists of deviance. It focuses on crime rather than deviance, and most often monetary crimes rather than crimes of violence. A type of opportunity and rational choice theory, routine activity theory argues that crime takes place when there is a conjunction of a *motivated offender*, a *suitable target*, and the *lack of a capable guardian* (Cohen & Felson 1979). Since the theory is not an explanation of *criminality*, that is, the *tendency* or propensity to commit crime, but a theory of *crime*, or the likelihood of the commission of criminal acts, the "motivated offender" is assumed rather than explained. Routine activity theory argues that it is the opportunity to commit crime that is the key explanatory variable rather than the presence or absence of criminally inclined individuals. There will always be enough motivated offenders eager to capitalize on a criminal opportunity; what varies systematically is

social structural opportunities that increase the likelihood of offending. Hence, nighttime minimizes the presence of capable guardians and, hence, maximizes the likelihood of criminal behavior. An increase in the number of women working after 1945 removed persons (capable guardians) from domiciles and, hence, increased the likelihood of household burglaries. The rise in affluence increased the existence of movable goods in post World War II America, increasing the number of suitable targets, and thus increased rates of theft. The increase in ATMs led to increases in ATM related crime. In each case, the relevant variables are the suitable targets and the absence (or presence) of capable guardians – not the number of motivated offenders. The theory also focuses on the issue of victimization: the likelihood of being victimized by a predatory crime is directly proportional to the likelihood of being physically in juxtaposition with routine offenders, for instance, often being present, at night, outside the home, interacting with members of categories of the population more likely than the average to engage in criminal behavior – young, unmarried, relatively poor, especially minority, males. Routine activity theory is based on the assumption that people are more or less rational and act out of a free will, minimizing cost (or risk, that is, the likelihood of apprehension) and maximizing reward. It argues that crime is not a unique form of behavior, distinctly different from law abiding behavior, but follows the principles of all behavior, criminal or law abiding. The costs of crime are somewhat different from those of obeying the law, but the same principles apply: people are motivated to minimize cost and maximize reward. In this sense, then, routine activity theory challenges the basic assumption of the Positive School, which argued that criminals lacked a free will and acted without understanding what they are doing.

Constructionist theory's explanatory mode. The perspective in the sociology of deviance that is referred to as "labeling theory" arose in the 1960s as a reaction against the dominant positivistic study of normative violations. Labeling theory's principal focus was mainly on how conceptions of wrongdoing are developed, how rules are enforced, and what the consequences of being labeled as a deviant are. In

other words, its approach was mainly in the constructionist vein. However, a “minor” mode of labeling theory argued that being stigmatized as a wrongdoer – being labeled as a “deviant” – often has the ironic consequence of solidifying a deviant identity and entrenching patterns of deviant behavior. In other words, one aspect of this approach is causal or positivistic in its orientation: *labeling causes deviance*.

In a like vein, conflict theory is focused mainly on inequality in power as the primary determinant of the social construction of the criminal law and its enforcement – an entirely constructionist endeavor. Nonetheless, conflict theorists also examine inequality as a major *cause* of criminal behavior. Members of the lower class are more likely to commit common street crimes, this perspective argues, because in a society based on social class their options for success and social mobility are extremely limited. In contrast, corporate crime – the ability of executives to commit and, usually, get away with crimes that are vastly more lucrative than street crimes – is a manifestation of the immense power wielded by the corporate elite. “What is the cause of crime?” conflict theorists ask. Their answer: inequality. Similarly, Marxists argue that capitalism is the primary cause of crime in capitalist society.

And feminists, who usually focus on how norms and laws tend to reinforce patriarchal institutions, also argue that the cause of crimes against women is patriarchy. In tracing abusive, criminal behavior such as rape, sexual harassment, wife battering, and the molestation of children to male privilege, feminists adopt an explanatory approach to the study of criminal behavior. “What causes crimes against women?” they ask. Their answer: patriarchy.

CONCLUSION

The coin of the sociological study of deviance has two halves – the explanatory and the constructionist. The explanatory half accounts for the causes of deviant behavior as one or more pregiven entities, behavioral syndromes with a coherent common thread whose etiology demands to be studied, located, and explicated. Even the constructionist half harbors a “minor” positivist mode. The explanatory

approach is the dominant perspective in criminology, while, today, most researchers who identify themselves as sociologists of deviance tend to adopt a more constructionist orientation. These missions are radically different. Although an explanation of deviant behavior and the social construction of deviance are not contradictory, to a major extent their respective practitioners are separate. These two camps no longer form a single coherent intellectual community whose members refer to and make extensive use of one another’s work.

deviance, the media and

David L. Altheide

The mass media feature deviance as entertainment. It is as though deviance has become part of our popular culture and everyday lives. There are many reports about prostitution, pornography, gay rights – including marriage and having families – legalizing drugs such as marijuana, gang member initiation rites, and polygamy. Mass media reports about deviance and crime comprise a large portion of television and popular culture entertainment (Winick 1978). Most media messages rely on audience stereotypes about “weird behavior” and simply play back many of the moral messages in order to attract even larger audiences. Audiences learn to play with deviance by, on the one hand, sharing in stereotypes, being repulsed by certain conduct, and cheering on authorities who seek to eliminate deviance, while, on the other hand, celebrating deviance for its innovations and resistance to convention, and in many instances emulating deviant lifestyles. However, the mass media coverage of deviance, especially crime, has changed over the last 40 years.

Deviance and the mass media are closely joined as audiences and social control agencies (e.g., police departments) rely on, as well as promote, social meanings via the mass media. Deviance does not refer to some objective behavior, but is rather a concept that reflects socially constructed moral meanings attached to certain behavior (e.g., crime, suicide, mental illness, prostitution) that may run counter to the moral meanings of some groups (Pfuhl & Henry 1993: 33). Crime, a special segment of deviance, refers to behavior that violates the law and is therefore illegal. The mass media do not simply inform audiences about deviant behavior; rather, the mass media increasingly help shape definitions and perceptions about

deviance and social order. The relationship between what is deviant and what is illegal is somewhat complex since most of what certain audiences regard as deviant is not illegal; by the same token, however, some illegal behavior is not deviant, e.g., parental spanking and physical punishment of their own children. Moreover, widespread drug use, particularly of marijuana, is quite common even though it is illegal.

The mass media refer to information technologies that permit broadcasting and communication to a large audience. Traditionally, these media have included print (e.g., books, newspapers, magazines, billboards) and electronic media (e.g., cinema, radio, television) and, more recently, various computer communication formats, particularly the Internet. They also include personal communication devices (e.g., CD players, game players, music players – iPods), as well as pagers and cell telephones, especially when the latter are used for broadcasting messages to subscribers of paging and telephone services. The mass media are significant for our lives because they are both form and content of cultural categories and experience. As form, the mass media provide the criteria, shape, rhythm, and style of an expanding array of activities, many of which are outside of the communication process. As content, the new ideas, fashions, vocabularies, and a myriad of types of information (e.g., politics) are acquired through the mass media. Moreover, the advent of new media technologies also opens up new possibilities for deviance and crime (e.g., Internet fraud, identity theft, the use of digital camera phones for taking pictures surreptitiously of people in locker rooms).

The mass media and deviance illustrate a perspective about how perceptions of social reality are socially constructed. The key aspect is the way in which symbols become meaningful and familiar to people, who define situations as one thing rather than something else (Spector & Kitsuse 1977). From this perspective, social power is the ability to define situations. The mass media are important for defining situations and making them familiar to audiences. Numerous studies of deviance have documented the life cycle or career of public definitions of certain acts as deviant, e.g., illegal drugs (Becker 1973), alcohol (Gusfield 1986), child

abuse (Johnson 1978, 1995), and missing children (Fritz & Altheide 1987).

Contemporary life cannot be understood without acknowledging the role of various communication media in the temporal and spatial organization and coordination of everyday life. The important work of Harold Innis (Innis & Innis 1972) and Marshall McLuhan (McLuhan & Fiore 1967) not only directed attention to the contribution of the technology of media for any message, but further argued that it is the technology that is most important in altering information and social relationships. However, it has remained for others to examine their thesis and incorporate the surviving corpus within an awareness of culture and especially popular culture, commonly associated with mass production, including mass media programming and other information (Couch 1984; Couch et al. 1996). These media are important in understanding deviance for two reasons. First, the mass media have altered public perceptions about deviance, social problems, and especially crime by stressing the most violent attacks as typical of criminal behavior. Presentations about law enforcement and police behavior have influenced public views about the nature and effectiveness of criminal justice. Second, the deviance process is also affected by the mass media. This process involves how some behavior comes to be regarded as deviant, on the one hand, and how behavior that was once regarded as deviant becomes more acceptable, on the other hand.

A key aspect of mass media influence on deviance is due to the entertainment orientation of popular culture. As suggested by Snow's (1983) analysis of media culture, the entertainment format emphasizes: (1) an absence of the ordinary; (2) the openness of an adventure, outside the boundaries of routine behavior; (3) audience members' willingness to suspend disbelief. In addition, while the exact outcome may be in doubt, there is a clear and unambiguous point at which a scenario will be resolved. Packaging such emphases within formats that are visual, brief, action oriented, and dramatic produces an exciting and familiar tempo to audiences. Moreover, as audiences spend more time with these formats, the logic of advertising, entertainment, and popular culture becomes taken for granted as a normal form

of communication. For example, research suggests that corporate media seek to harvest audiences by promoting fear as entertainment throughout popular culture and news (Furedi 1997; Glassner 1999; Altheide 2002). Moreover, such emphasis cultivates audiences to support political campaigns and domestic policies on crime and control as well as foreign interventions.

Crime, as one aspect of deviance, illustrates some of these points. Crime news is so pervasive that most people believe that crime is constantly increasing and that our lives are increasingly in danger from wild, drug crazed criminals who, seemingly, choose victims at random; in other words, criminal assaults can happen to anybody, at anytime.

Criminals and victims are not the only parties featured in crime news. The police and SWAT teams also star in nightly news reports that typically feature a reporter talking with a police spokesperson about a crime that has occurred, against a backdrop of flashing red lights illuminating yellow police tape. The scenario is repeatedly played out in other television reality shows, interview programs, and numerous action movies featuring super sleuths, who solve crimes by acting as maverick investigators, often outside the boundaries of law enforcement organizations. The reality programs present scenarios and language that most viewers have heard, seen, or read about, so the tough dramatic action that is being presented seems quite plausible, especially when no nonsense crime fighters get physically abusive with "perps," browbeat reluctant witnesses who do not want to get involved, and demean judges, defense attorneys, and the criminal justice bureaucracy for "technical details" (e.g., procedures) and the rights of the accused (Fishman & Cavender 1998).

The development of television was largely built on celebrating the protectors of "normal, decent" life and people. Ranging from the western marshals, who wore white hats and enforced the law against nineteenth century desperadoes, to twenty first century superheroes and sleuths battling crime and deviance, there has been a structural role relationship between the appearance, style, and behavior of law enforcement and the relentless battle against deviance and disorder. Surette (1998)

suggests that the metaphor of sheep and wolves is appropriate, with the sheep (citizens) being protected from predatory wolves (criminals – and deviants) by sheepdogs (police and law enforcement). Perhaps the prime example of the development of this entertaining genre of television was the show *Dragnet*, produced by and starring Jack Webb. *Dragnet's* depiction of the Los Angeles Police Department illustrates the relationship between entertainment and reality, and had tremendous influence on the planning, financing, recruitment, and perception of the LAPD, as well as deviance and social problems (Shaw 1992).

Television and other popular culture materials about crime do not cover all aspects of the criminal justice system (Surette 1998). Little attention is paid to corrections and prisons, on the one hand, while court and adjudication procedures receive scant attention, on the other. Indeed, except for the occasional nasty remark about the “leniency” of the courts, American audiences receive little information about how the courts actually operate. It is not surprising that opinion polls reveal that the majority of the American public agrees with President Reagan’s attorney general, Edwin Meese III: “You don’t have many suspects who are innocent of a crime. That’s contradictory. If a person is innocent of a crime, then he is not a suspect” (*US News and World Report*, October 14, 1985).

It is apparent that the mass media contribute to definitions and images about deviance and deviant actors. When there were fewer media outlets, such as in the 1950s, during the early days of television, social problems such as alcoholism, illegal drug use, prostitution, and some criminal behavior, but usually not white collar crime, were presented very simplistically as social pathology due to moral failings of weak and evil individuals. For example, the movie *Reefer Madness* presented stereotypical images of drug users and the consequences of drug use, and is now a cult film that audiences, including law enforcement officers, now regard as absurd. However, police officials were very important news sources or claims makers about illegal drugs and their personal and social consequences. While police remain important spokespersons for news reporters, the spread of the mass media has opened up greater channels

of communication, and therefore greater opportunities for minority group members as well as individuals and organizations involved in activities that are regarded as deviant and undesirable. Numerous organizations that focus on the promotion or the control of deviant activities are claims makers that rely on mass communication to promote their issues.

The entertainment oriented mass media, especially local television newscasts, tend to be interested in presenting enticing reports about deviance. However, this interest also provides an opportunity for organized spokespersons associated with deviant behavior to express themselves and offer counterclaims about their activities, their meanings, and, quite often, their humanity. For example, stereotypical images of drug users were challenged by persons supporting ballot propositions to legalize medical marijuana; elderly women pleading for public approval to use this drug to alleviate their dying husbands’ pain appear to have been quite successful in shifting public opinion to support the passage of medical marijuana legislation in several states.

One of the major contributions of the mass media to the study of deviance and crime is familiarizing audiences with very rare behavior and scenarios. For example, sex change operations are quite rare, but individuals who have had them are featured on numerous cable channels, and increasingly the Internet as well (e.g., Jerry Springer, Oprah). As audience members, we become more familiar with the stories, scenarios, problems, and rationale for undergoing these rare treatments and surgeries. We can converse about them with friends and co workers, we can develop opinions, and even speculate on what we would do if we wanted to change, or if a son or daughter was faced with certain urges.

In sum, the mass media and deviant behavior are closely linked. Deviance, after all, is not a characteristic of the behavior per se, but rather is a result of human beings interpreting some act as deviant and undesirable. The mass media can contribute to this definition either by presenting very limiting stereotypical propaganda, or by providing more information to audiences. This entails turning to numerous claims makers, who can present accounts and experiences that may strike a responsive chord. In the

final analysis, then, the future of varieties of behavior defined as deviant will continue to be linked to the mass media.

deviance, medicalization of

PJ McGann and Peter Conrad

Medicalization is the process whereby previously non medical aspects of life come to be seen in medical terms, usually as disorders or illnesses. A wide range of phenomena has been *medicalized*, including normal life events (birth, death), biological processes (aging, menstruation), common human problems (learning and sexual difficulties), and forms of deviance. The medicalization of deviance thus refers to the process whereby non normative or morally condemned appearance (obesity, unattractiveness, shortness), belief (mental disorder, racism), and conduct (drinking, gambling, sexual practices) come under medical jurisdiction. The tendency to see badness – whether immoral, sinful, or criminal – as illness is part of a broader historical trend from overtly punitive to ostensibly more humanitarian responses to deviance. Within this trend most scholars agree that medicalization has been on the increase. They disagree, though, as to why, to what degree, and with what consequences this is the case. It is clear, however, that medicalization processes are caught up in and complicate struggles to define and respond to deviance. Constructing deviance as illness confers a moral status different from crime or sin. As such, medicalization has implications for social control, power, knowledge, authority, and personal liberty.

Deviance has been medicalized when it is defined in medical terms, described using

medical language, or a medical framework has been adopted to understand deviance. Due to the centrality of definition in medicalization, most studies are presented in a social constructionist genre. Work on medicalization has been conducted in sociology, history, psychology, psychiatry, medicine, education, anthropology, social work, and sexology. Across these disciplines, most scholars bypass the question of whether a form of deviance is “really” a medical disorder or disease in favor of analyses of how things become medicalized.

Medicalization is a collective and political achievement that requires moral entrepreneurs who champion a medical framing of a problem. Individuals, groups, and institutions have various stakes in questions over the applicability, desirability, extent, and consequences of the medical frame. Advocacy and self help groups, social movements, clinicians, lay people, even deviants themselves have been players in medicalization dramas. Sometimes physicians support medicalization, as in premenstrual syndrome (PMS) and transsexualism. In others they actively resist it, as when medical identification of domestic violence was first introduced. Early scholarship noted the possibility of medical imperialism or colonization in cases of medicalization, typically because it serves physicians’ material, strategic, or symbolic interests. The “discovery” of child abuse, for example, has been analyzed as enhancing the prestige and legitimacy of pediatric radiologists.

Constituencies outside medicine have also been advocates for medicalization. With autoimmune deficiency syndrome (AIDS) and post traumatic stress disorder (PTSD), social movement and advocacy group pressure increased medicalization through patient–physician collaboration. Hyperactivity disorder illustrates how the prior existence of a medical treatment (Ritalin) helped consolidate a nascent medical understanding of deviant childhood behavior as illness. Recent use of human growth hormone to treat “shortness” in children with normally functioning pituitary glands illustrates how difficult it is to disentangle therapeutic, cultural, and economic interests. The Human Growth Foundation (HGF), the primary supporter for the use of synthetic human growth hormone in children, grounded its advocacy in the

difficulties that shorter than average children and adults face. However, pharmaceutical companies, e.g., Genentech, provided most of HGF’s funding.

New evidence suggests that the engines driving medicalization are changing. The role of physicians in the expansion and contraction of medicalization has been declining. The Food and Drug Administration Modernization Act of 1997 allows pharmaceutical companies to advertise directly to US patients/consumers, perhaps facilitating an increased demand for medical intervention. Newly aware of disorders and treatments alike, potential patients now increasingly self diagnose then approach doctors, oftentimes asking for drugs by name. Thus men concerned about meeting rising standards of heterosexual potency “ask [their] physicians if Viagra is right for” them; shy people may request Paxil; those burdened with sadness seek relief with Wellbutrin. The shift to managed care is another factor in changing medicalization dynamics. Managed care organizations are now central to deciding what kinds of problems will be covered by health insurance. Whether this development inhibits rather than increases medicalization is a question for more politically and economically attuned constructionist analyses.

Because medicalization is a process, different phenomena reveal different *levels* of medicalization. At the *conceptual* level, medical vocabulary or a medical model organizes the problem; neither actual medical treatment nor doctors need be involved. The construction of deviant drinking as alcoholism is the exemplar here. Alcoholics Anonymous uses a medical model of understanding but eschews medical intervention. At the *institutional* level, organizations adopt a medical response and the medical model predominates, although medical professionals may or may not be directly involved. With gambling addictions and eating disorders, for example, physicians legitimate the treatment organization’s approach but are not necessarily involved in direct care. In contrast, at the *interactional* level, physicians tend to be directly involved either through diagnosis or through the provision of treatment as part of the doctor–patient relationship. For example, patients may come to their physicians with

vague life problems, and be prescribed psychoactive drugs without any particular medical diagnosis.

The degree a problem is medicalized can vary from minimal (sexual addiction), to partial (obesity), through nearly complete (mental illness). Such differences in the degree of medicalization mean that competing definitions of a form of deviance may exist. Remnants of previous understandings further complicate the definitional struggle; is compulsive shopping an illness or immature failure to inhibit desire? In addition, a medical definition may be salient in one context but not another. PMS, for example, is widely understood to be a medical disorder. But whether an individual woman experiences her menstruation as illness is another matter. Similarly, behavior that many people think of as run of the mill sissiness or tomboyism is medicalized in *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition* (DSM IV) as gender identity disorder. This dormant medical frame can be mobilized if the child's behavior or appearance comes to the attention of persons familiar with the diagnostic category; in such an instance, the "normal" tomboy or sissy is reframed as pathological.

With levels and degrees we see that medicalization is not an either/or phenomenon. Nor is medicalization a one way process. Just as deviance may become medical, the medical framing of deviance may be undone (in part or in full). As medical meaning is diluted or replaced, medical terminology and intervention are deemed inappropriate. Masturbation is the classic example of near total *demedicalization*; in the nineteenth century, masturbation was medicalized as "onanism," a disease in itself, as well as a gateway perversion that rendered those of weak constitutions more susceptible to other forms of sexual deviation. Another example is the removal of homosexuality from the third edition of the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* (DSM III). But whereas earlier medical framing of masturbation now seems absurd to many, the reclassification of homosexuality illustrates *contested* demedicalization. Despite the 1973 decision by the American Psychiatric Association to remove homosexuality from the roster of mental disorders, a small

but vocal psychiatric minority provides reparative or conversion therapy, and a portion of the public still views homosexuality as deviance (but not necessarily as illness). Homosexuality thus also illustrates that demedicalization does not automatically mean a form of deviance has or will become conventional, only that the official medical framing has ended. Medicalization may also be contested between institutions with different jurisdictions. Deviant drinking and illicit drug use, for example, may be seen as medical, criminal, or both, setting the stage not only for "turf" battles, but also for vastly different deviant careers depending on how and by whom an individual's drinking or drugging is interpreted and responded to.

The consequences of medicalization may be positive or negative – oftentimes both. As noted, the therapeutic ethos of medicine changes the moral status of both deviance and deviant. Extension of the sick role to the deviant diminishes stigma and culpability, both of which may increase the likelihood that a pedophile, batterer, or addict for example might seek treatment. Medical explanations for inchoate or diffuse difficulties can provide coherence to symptoms, validate and legitimate troubles, and support their self management. In addition, medical recognition may facilitate insurance coverage of medical treatment, thereby transforming potential deviants into disease victims seen worthy of care and compassion. Chronic fatigue syndrome, PMS, post partum depression, and PTSD illustrate these positive effects. Moreover, as with child abuse, medicalization may increase the visibility of a form of deviance, which in turn may help transform a seemingly isolated individual trouble into a socially recognized public issue.

Despite these benefits, many analysts are wary of medicalization and its potential negative consequences. The sick role, for example, may provide a "medical excuse" for deviance; certainly, it diminishes individual responsibility. As the medical model becomes more attuned to physiological and genetic "causes" of behavior, blame shifts from the person to the body, further displacing responsibility. Medicalization allows for the use of powerful forms of social control, such as psychoactive drugs or surgical procedures. But the guise of medical scientific neutrality and/or a therapeutic

modality means medicalization may be an insidious expansion of social control. Tendencies to individualize and depoliticize social problems are also linked to medicalization. Both obscure insight that deviance may be a reflection of or adaptation to the social organization of a situation; focus on the individual symptoms of gender identity disorder or battery, for example, deflects attention from the hetero normative gender order, gender inequality, and patriarchal values. Medicalization also enlarges medical jurisdiction. Medical expertise may then be privileged at the expense of lay or competing views. Some transsexuals, for example, decline – or cannot afford – surgical intervention for “gender dysphoria.” Others exhibit less than stereotypically conventional expressions of gender and/or refuse to pass as non transsexuals. Because such people do not fit the prevailing medical framing of transsexualism, they may be subject to ridicule, censure, or denial of service by medical gatekeepers.

Medicalization appears to be on the increase, but how much depends in part on what is measured. One approach looks at the growing number of people diagnosed. Another considers the increasing number of diagnostic categories. In addition to the proliferation of categories, medicalization increases through expansion of extant categories. That is, diagnostic categories themselves may be stretched, encompassing more behavior within their bounds over time. Psychiatric categories, especially the functional disorders, seem especially prone to such expansion. The emergence of adult attention deficit hyperactivity disorder (ADHD), the extension of the uses of PTSD, and the widespread use of psychoactive medications like Prozac for unspecified psychological discomfort are examples of this.

The movement to medicalization has also normalized medical intervention in some forms of deviance, such as plastic surgery for unattractiveness, aging, and obesity. This proliferation of medical fixes may create an imperative to submit to medicalization such that failure to use medical enhancements or treatments itself becomes a form of deviance. Thus refusal to take antidepressants for unhappiness, or failure to surgically reconstruct racialized facial features, may be seen as deviant in some circles.

The turn toward genetic understandings of personality and social behavior also has implications for medicalization processes. But geneticization is not the same as medicalization, although interpretation is the key to both. Discovery of a genetic component of homosexuality, for example, may fuel medicalization if medical technology (genetic screening, abortion, genetic therapy) is used to decrease the homosexual “defect.” In this case, a genetic link may catalyze a *remedicalization* of homosexuality. Alternatively, a genetic cause may be viewed as evidence of the naturalness of homosexuality, perhaps facilitating further demedicalization.

Finally, genetics suggests that a further shift in medicalization processes may be under way, from external control of deviant bodies and behaviors toward manipulation of internal processes. Whether such *biomedicalization* is a change in medicalization strategy or a new beast altogether is an open question. Some argue that medicalization is a modernist phenomenon concerned with imposing and maintaining bodily homogeneity. In contrast, biomedicalization’s transformation of bodily processes produces customized bodies and identities, a dynamic characterized as postmodern. Either way, medicalization and biomedicalization processes coexist. Both are implicated in and are facilitating new patterns of physician–patient/consumer collaboration. And both are part of the trend toward increased levels of self surveillance in the pursuit of new norms of health and bodily perfection.

deviance, moral boundaries and

Pat Lauderdale

Through a variety of social mechanisms, most human diversity is categorized as normal variation and a varying fraction as deviance. This area of research asks how the moral boundaries of these categories are drawn, i.e., normal versus deviant, and what determines the placement of specific actors and acts within the categories (Lauderdale 1976; Ben Yehuda 1985). The sociologist, therefore, can examine how certain actions are defined as deviant from specific social reactions and the creation of moral boundaries that separate the varying definitions of normal from deviant ones. The creation of the boundaries and the placement of individuals as either normal or deviant are viewed as basic processes of social definition that often are found to be outcomes of political variables.

Extending the seminal work of Émile Durkheim, this line of research is contrary to the conventional view of deviance as social pathology that must be normalized or eradicated. Durkheim suggested the relevance of the relationship between political power and deviance in his analysis of sanctioning, in which he posited that increases in the consolidation of

power in society will lead to proportional increases in the repressive sanctioning of people who are defined as the most deviant (i.e., criminal). Deviance is studied as a normal phenomenon, which under certain conditions can play a part in facilitating social change. Socrates in his time, for example, was seen as a serious deviant under the law of Athens. His offense, however, was his independent thought and his call to his students to think as independently as possible. Now, Socrates is viewed as having acted for a higher moral good, not only for his country but also for all people. Under the Fugitive Slave Laws of the 1850s, aiding and abetting escaped slaves was a crime. With the passage of the 14th Amendment less than a decade later, however, slavery itself was the crime. In 1800, the organization of a labor union was defined as a crime (conspiracy in restraint of trade), yet by 1940 labor unions were legal, and many employers were even required by law to engage in collective bargaining (Lauderdale 2003). Definitions of deviance not only presage actions that come to be accepted later but also reveal that some actions continue to be unacceptable.

A basic question, thus, concerns how the boundary between normal and deviant, or good and bad, is constructed, maintained, or changed. In his watershed book entitled *Wayward Puritans* (1966), Kai Erikson attempted to answer part of this question. His book focuses on a variety of central issues in politics and power, and who and what might account for the shift in the boundary between normal and deviant. His analysis of specific cases of deviance amplification or creation by the Puritans is critical because the Puritans encountered diversity and reacted to it as deviance. The people who were designated as deviants, i.e., the religious dissenters, the Quakers, and the witches, were caught in a set of larger crises. For example, the designation of Anne Hutchinson, a religious dissenter, as a deviant resulted more from the power struggle among the male religious leaders than any of her actions. Erikson (1966: 68) presents the conditions under which the boundary might shift, for example, by "a realignment of power within the group," or threats from outside the group. Moreover, the redefinition of many Japanese Americans from normal to deviant (often including imprisonment in "relocation" camps)

following the invasion of Pearl Harbor suggests similar conditions and processes. During times of crises such as “terrorist” attacks or war, external threats and realignments of power continue to be key concepts in this area of study.

Such changing social conditions also are particularly useful when we extend the ideas by also focusing upon an emerging group or larger forces in society, and the emergence of “modern” society. Mies notes in her research on the terrorizing of midwives as witches that the terror was directly related to changes in society and the state, including medical professionalization, the increasing view of medicine as a “natural science,” and the legitimization of science. Witch hunters used torture chambers as the “laboratories where the texture, the anatomy, the resistance of the human body – mainly the female body – was studied.” Mies suggests that modern medicine and hegemony in this area were established on the base of “millions of crushed, maimed, torn, disfigured and finally burnt, female bodies” (1986: 83).

At more specific levels of analysis, researchers have examined how the moral boundaries have changed via the actions of moral entrepreneurs, social movements, organizations, the state, and global institutions (Goode & Ben Yehuda 1994; Oliverio 1998; Lauderdale 2003). Moral entrepreneurs, for example, initiate public discourses on particular issues trying to persuade the public and the state of their view of the truth. Joseph McCarthy, a classic example, who was a senator from Wisconsin, called for the purge of suspected communists in the 1950s. Initially, he was lauded as a great leader as he helped shift the moral boundaries, but evidence later revealed that many of the suspects were simply exercising their freedom of speech or were misidentified. The sociological literature on the changes in status, i.e., from normal to deviant or vice versa, of moral entrepreneurs such as McCarthy can be extended to examine other entrepreneurs working on various crusades or projects. Such entrepreneurs include people such as Ralph Nader (his early work on consumer protection), Leonard Peltier (his concerns with American Indian issues), Bobby Seals (his actions on racialization and freedom), and Mother Teresa (her projects on charity and love).

Social movement research has included people protesting in numerous arenas, such as the diverse movements against the North American Free Trade Agreement and the World Trade Organization, where protestors demand free access to water, air, and public space. Other movements are those such as MADD (Mothers Against Drunk Driving), the anti abortion a.k.a. pro life movement, the pro gun or anti gun movement, anti pornography groups, and the anti smoking movement. Researchers also are exploring the factors that lead to the transformation of a social movement into a social organization, which is important because most social movements do not reach institutional levels.

Research on the role of social organizations in creating, maintaining, or transforming moral boundaries recently has concentrated narrowly on the media. This research agenda can be extended by examining organizational forces that influence the media. In addition, the historical overview of scholars such as Annamarie Oliverio (1998) suggests the importance of unraveling the deep connections between expanding organizations, law, trials, the state, and globalization.

deviance, normative definitions of

Robert F. Meier

Sociologists tend to define deviance in one of two ways: by the negative reactions an act, the expression of a belief, or a physical characteristic generates, or by the violation of the norms or the rules that prevail in a given society or group. Reactivist definitions come in two varieties: the "hard" or strict reactivist definition, which defines deviance as acts, beliefs, or conditions that have already attracted a negative reaction from one or more audiences, and the "soft" or moderate definition, which defines deviance as behavior, beliefs, or conditions that are likely to generate negative reactions from audiences. In contrast, the normative definition identifies deviance as a violation of a norm held in certain social circles or by a majority of the members of the society at large. A norm is a standard about "what human beings should or

should not think, say, or do under given circumstances" (Blake & Kingsley 1964). Put another way, a norm is a social expectation concerning thought or behavior in particular situations. Violations of norms tend to draw reactions or sanctions from their social audiences. These sanctions generate the pressure that most people feel to conform to social norms. However, even if the actor, the believer, or the possessor is not detected or chastised for a normative violation, the non normative act, belief, or trait is deviant nonetheless. To the normative definition, what defines something as deviance is a formal violation of the rules.

Norms evaluate conduct; recognizing that some acts (including beliefs and the expression of beliefs) ought or ought not to occur, either in specific situations (e.g., no smoking in public elevators) or at any time or place (e.g., no armed robbery, ever). The use of proper etiquette reflects deliberate decisions to adhere to norms of respect and consideration for others (Post 2003). The norms that comprise etiquette are also situational, but are more likely to be codified than norms in many social situations.

The conception of norms as expectations highlights regularities of behavior based on habit or traditional customs. People expect a child, for example, to act a certain way in church, another way on the playground. This raises another dimension of norms: they are situationally bound. Running and yelling of children is appropriate for the playground, but not in church. Laughing is expected behavior in a comedy club, but not at a funeral.

Norms are not necessarily clear cut rules; instead, they are social properties. They are shared group evaluations or guidelines, and many of them are learned implicitly in the more general process of socialization. Rules come from one or more authorities which formulate them individually and impose them on members of a particular society. This authority could be the state, which reserves the right to exercise coercive force over the citizenry, or a monarch or a despot. Norms are an absolutely essential component of the social order.

No one has attempted to count norms because the number is quite large, depending on the group. There is an enormous number of possible situations in which norms regulate behavior. There is, for example, a norm that

guides people's behavior in elevators: one is expected to face the door. Sometimes the rationale for norms is vague. In this example, every one facing the same direction avoids invading someone else's "personal space," the distance between two strangers that feels most comfortable. This distance varies from culture to culture. Italians are comfortable with less distance between them than are Americans.

People risk being labeled as a deviant by audiences when they express unacceptable beliefs (such as worshiping devils), violate behavioral norms (such as engaging in proscribed sexual acts), or possessing certain physical traits widely regarded as undesirable, which include physical handicaps (being confined to a wheelchair) and violations of appearance norms (e.g., obesity) (Clinard & Meier 2004). However, even if audiences do not witness or learn about the normative violation, it is deviant nonetheless. In other words, to the normative definition, "secret" deviance is not a contradiction in terms; it exists, and is an important variety of deviance. In fact, it is possible that most normative violations remain a secret and never generate negative reactions of any kind from disapproving audiences. The normative definition is based on a certain measure of predictability that normative violations are likely to attract negative reactions, even if they are never observed. The fact that in a particular context or instance, a given observed act, expressed belief, or physical characteristic did not generate negative sanctions for the actor, believer, or possessor is beside the point. The normative sociologist does not have to wait until condemnation takes place to know that something is deviant. It is the violation of what the norms of a society or group say about proper and improper behavior, beliefs, and characteristics that defines them as deviant. For instance, we know in advance that it is a violation of society's norms to walk down the street, nude (Gibbs 1972), and hence, that that act is deviant. In contrast, the "strict" reactivist definition denies the predictability that negative sanctions follow normative violations, and denies the existence of "secret" deviance, arguing that the concept is an oxymoron (Pollner 1974). Most sociologists of deviance adopt some version of a normative definition of the concept, arguing that the strict normative definition makes it

impossible to study most normative violations as deviance, hence, fatally restricting the sociologist's domain of investigation.

deviance, positivist theories of

Robert F. Meier

Sociologists define deviance as the violation of a norm that, if discovered, typically results in punishment, scorn, or stigmatization of the offender. The normative violation can include acts, beliefs, and traits or characteristics. This definition opens two radically different though complementary missions or lines of inquiry: those that attempt to explain the causes and consequences of normative violations, and those that explore the dynamics underlying the social construction, accompaniments, and consequences of the norms, including laws and their enforcement. Sociologists of deviance – including criminologists – who adopt the first

of these missions are usually referred to as “positivists”; those who adopt the second are called “constructionists.” Positivist sociologists of deviance and crime nearly always study non normative behavior, while constructionists look at the full gamut of normative violations – behavior, beliefs, and physical characteristics.

In the social sciences, positivism is usually defined as the natural science approach to social life. This means that the methods by which scientists study the world of biology, chemistry, and physics can be applied – taking their different subject matter into account, of course – to the social, anthropological, economic, psychological, political, and even religious worlds. The positivist approach is made up of the following assumptions: objectivism (i.e., phenomena take on a reality independent of their social construction); empiricism (we can know the world through our five senses); and determinism (the phenomena of the material world, including the social world, are linked together in a cause and effect fashion).

Objectivism refers to the fact that the positivist approach to deviance would argue that the violation of social and legal norms constitutes an objectively real, pre given entity that contains a common thread that demands an explanation. If deviance, including crime, and its constituent elements did not contain a common thread – that is, if it were a social label and nothing else – then no explanation attempting to account for it would be possible. *Empiricism* typically refers to the fact that the violations of social norms can be investigated by means of highly sophisticated, quantitative social research methodologies, such as surveys, which stress reliability and validity. *Determinism* refers to the fact that the central question in positivist research is: “Why do they do it?” In the field of the sociology of deviance and crime, positivists assume that they can discover law like generalizations that account for normative violations. Positivist approaches are not confined to sociology, of course; the factor attempting to explain crime has included biological, psychological, and sociological variables. All positivist theories of deviance – whether they focus on the individual, the individual in a particular context or social structure, or the social structure itself – address their research to the same basic question. In all of them, the *dependent*

variable is the normative violation, and the *independent* variable is the factor their theory addresses.

THE EARLY POSITIVISTS

The first positivists of deviance and crime belonged to a group of social statisticians who studied the social, physical, and environmental conditions associated with normative and legal violations, the most well known of whom was Adolphe Quetelet (1796–1874). Quetelet identified the existence of law like regularities in officially recorded criminal behavior, suggesting to him that crime was subject to causal laws that could be revealed through an approach and a research methodology similar to those of the natural sciences. By implying that crime is a product of society, Quetelet opened the possibility of a sociological analysis of crime.

The early years of the positivist approach to deviance and crime are most closely associated with the Positive School founded by Italian physician Cesare Lombroso (1835–1909). The Positive School was an attempt to apply the methods of studying the physical world to the world of crime. Advocates of the Positive School believed that violations of the law could be accounted for by natural causes rather than by free will. In this sense, the Positive School was a rejection of the free will hedonism of the Classical School, associated with the writings of Cesare Beccaria (1738–94), Jeremy Bentham (1748–1832), and Adam Smith (1723–90). The approach of the Positive School was far more radically positivistic than that adopted by Quetelet, in that it identified the cause of criminal behavior principally as a biological factor: one or more physical defects (or “atavisms”) in the human organism. Atavisms are ape like “throw backs,” primitive characteristics that appear in some modern humans. They included a small brain, a sloping forehead, a large jaw, and a stooped posture. These defects, the theory argued, induce some people to commit crime. Lombroso’s early focus on biological factors has led some observers to dub his approach as the “born criminals” theory. Unlike Quetelet’s theory, which was structural and sociological, Lombroso’s was a “kinds of people” explanation that looked no further than the individual

characteristics of offenders. Over time, however, Lombroso modified his explanation; with each new edition of his book, *The Criminal Man*, he attributed a decreasing impact of biological factors and an increasing role for social factors. Lombroso's influence on the study of crime is immense, both in his insistence that criminal behavior be studied objectively and scientifically and in his focus on biological factors, an emphasis that remains in certain quarters of the field of criminology to this day. Lombroso argued that engaging in criminal behavior was the result of forces that diminish the role of free will or rational choice – again, a hallmark of contemporary positivistic approach to deviance and crime.

All positivists *assume but do not investigate* the social construction of the norms and the laws. Indeed, how laws and norms come into being and what their consequences are for the violators is not an issue for the positivist, who assumes that answers to the “Why do they do it?” question would be the same regardless of how they emerged and operate. In other words, the relativity of the social norms and the law is irrelevant; the same cause and effect mechanisms would produce more or less the same pattern of normative and legal violations, regardless of what society or historical time period we are discussing. Positivists are interested in the cause or causes of deviant and criminal behavior under any and all normative and legal circumstances.

POSITIVIST THEORIES OF CRIME AND DEVIANCE

Positivist theories of crime and deviance run the gamut from genetic and biochemical through psychological to sociological. The *sociological* theories that attempt to explain or account for normative or legal violations include: social disorganization theory; anomie theory; learning theory; social control theory; and self control theory. In addition, several of the most prominent constructionist theories harbor a “minor” or positivistic mode: labeling theory; control theory, including Marxism; and feminism.

Social disorganization theory. During the 1920s, the sociology faculty and graduate

students at the University of Chicago developed a perspective toward deviance, crime, and delinquency that has come to be called the Chicago School, or social disorganization theory. Using the city of Chicago as their laboratory, these researchers took as their explanatory variable the instability of entire neighborhoods and communities. Regardless of their individual characteristics, people who live in such communities are more likely to engage in illegal and non normative behaviors than persons residing in more stable communities. What makes for unstable or disorganized communities is that rents are inexpensive, the populations who live in them invest little financially or emotionally in living there, and they tend to be socially and geographically mobile. Hence, they tend not to monitor or sanction the behavior of wrongdoing in their midst. As a result, residents can commit infractions of the law and the social norms without consequence, and tend to do so with greater frequency than in communities in which their co residents monitor and sanction their behavior. In such communities, street crime, drug abuse, alcoholism, prostitution, juvenile delinquency, and mental disorder are common; law abiding residents tend to move as soon as they can, contributing to further crime, deviance, delinquency, and social disorganization. By the 1940s, the Chicago School had become regarded as obsolete (in the 1960s, a school of deviance research came to be dubbed the “neo Chicagoans,” but they had a very different orientation). But by the late 1980s, social disorganization theory experienced a rebirth of interest, and is now a major perspective in the study of crime, delinquency, and social problems.

Anomie theory. Closely associated with the early work of Robert Merton (1968), the anomie perspective was a structural theory of crime and delinquency. Modern societies, Merton reasoned, especially the United States, offered their residents substantial opportunities. But while status goals, like materialism and wealth, are stressed, access to these goals is limited. Important status goals remain inaccessible to many groups, including the poor, the lower class, and certain racial and ethnic groups who suffer discrimination, such as blacks and Chicanos. Anomie develops as a result of an acute disjuncture between culturally valued

goals and the legitimate means through which society allows certain groups to achieve those goals. So, while everyone learns to aspire to the "American Dream" of financial success, in reality the social structure can provide legitimate opportunities to only a few, leaving others frustrated in their search for success. As a result, some will turn to alternative means by which to reach their success goals. These will be mainly lower class minority males in urban areas whom the system fails to benefit. Anomie theory continues to be popular, as do variations of anomie theory that provide more detail about both societal pressure to succeed and adapting to those pressures.

Learning theory. There are a number of learning theories of deviance, but one of the most respected is criminologist Edwin Sutherland's (1947) theory of differential association. Crime and other forms of deviance are the result not of biological or psychological defect but of learning criminal norms. Sutherland, like other learning theorists, believed that the most powerful learning takes place in small, intimate groups among people who know one another well, such as close friends. These groups are very important because the members have high credibility with one another. During social interaction, people can teach other people many things, including techniques and rationale for committing crimes. Sutherland called the content of most of this learning "definitions favorable to violation of law." In other words, the content of the learning was a justification or motivation to commit a crime. Such definitions can, of course, be reinforced over time. There are other kinds of learning theories which identify the psychological processes involved in the learning, but all learning theories are consistent on a central point: crime is neither inherited nor inevitable. Rather, it is acquired from others in a process of communication and interaction.

Social control theory. Social control theory, or more conventionally just control theory, asserts that deviance is not so much learned or the result of societal pressure as it is simply not controlled (Hirschi 1969). Popularized in the late 1960s, control theory stresses not things that push people to crime (like criminal motivation) but things that keep a person restrained and in

conformity. Control theorists believe that crime results when a person is not restrained or controlled by society. The control of particular interest in control theory is the individual's bond with society. The closer the bond, the less likely that person will commit a deviant act. There are several elements of the bond, including attachment, commitment, involvement, and belief. The more a person is attached to his or her group, the more that person is committed to the group and its goals, the more time the person spends in the group, and the more the person believes in the norms of the group, the less likely will that person deviate from the group's norms. Control theory generated a good deal of research and was a leading positivist theory in the 1970s and 1980s.

Self control theory. Self control theory, developed by Michael Gottfredson and Travis Hirschi (1990), is a theory with both learning and control elements. Self control theory posits that through the general socialization process, some people fail to develop self control over their behavior. They are therefore more likely to engage in risky acts, including crime, drugs, alcohol, and other behavior that overlooks or neglects the long term consequences of continuing to engage in that behavior.

Constructionist theory's positivistic mode. The perspective in the sociology of deviance that is referred to as "labeling theory" arose in the 1960s as a reaction against the dominant positivistic study of normative violations (Lemert 1951; Becker 1973). Labeling theory's principal focus was on how conceptions of wrongdoing are developed, how rules are enforced, and what the consequences of being labeled as a deviant are. In other words, its approach was mainly in the constructionist vein. However, a "minor" mode of labeling theory argued that being stigmatized as a wrongdoer – a "deviant" – often has the ironic consequence of solidifying a deviant identity and entrenching patterns of deviant behavior. In other words, one aspect of this approach is causal or positivistic in its orientation: *labeling causes deviance*.

In a like vein, conflict theory is focused mainly on inequality in power as the primary determinant of the criminal law and its enforcement – an entirely constructionist endeavor. Nonetheless, conflict theorists also examine

inequality as a major *cause* of criminal behavior. Members of the lower class are more likely to commit common street crimes, this perspective argues, because in a society based on social class, their options for success and social mobility are extremely limited. In contrast, corporate crime – the ability of executives to commit and, usually, get away with crimes that are vastly more lucrative than street crimes – is a manifestation of the immense power wielded by the corporate elite. “What is the cause of crime?” conflict theorists ask. Their answer: inequality. Similarly, Marxists argue that capitalism is the primary cause of crime in capitalist society.

Feminists, who usually focus on how norms and laws tend to reinforce patriarchal institutions, also argue that the cause of crimes against women is patriarchy. In tracing abusive, criminal behavior such as rape, sexual harassment, wife battering, and the molestation of children to male privilege, some feminists adopt a positivist approach to the study of criminal behavior.

The coin of the sociological study of deviance has two halves – the positivist and the constructionist. The positivist half examines the causes of deviant behavior as one or more pre given entities, behavioral syndromes with a coherent common thread whose etiology demands to be studied, located, and explained. Even the constructionist half harbors a “minor” positivist mode. Positivism is the dominant approach in criminology, while today most researchers who identify themselves as sociologists of deviance tend to adopt a more constructionist orientation. Although positivism and constructionism are not contradictory, to a major extent, their respective practitioners are to some degree separate; they no longer form an intellectual community who refer to one another’s work.

deviance processing agencies

George S. Rigakos

Deviance processing agencies refers to a wide gamut of institutions and agencies both public and private involved in the identification, vetting, and dispensation of populations considered at risk, dangerous, or that presumably require monitoring and surveillance to mitigate potential harms. Deviance processing agencies have been considered in a more comprehensive manner since the 1960s and 1970s and constitute a central focus of inquiry for social theorists interested in governmentality risk and social control. During anti war student protests and the radicalization of academia in the 1960s and 1970s, sociologists and criminologists employed critical approaches often born out of a Marxian orientation (e.g., Spitzer 1975) to critically analyze developments in police practices, punitive legal measures, and inhumane prison conditions. They offered explanations of repressive state practices (Cooper et al. 1975) against dissidents and socially constructed deviants within the context of managing crises of

capitalist legitimacy, the symbolic importance of the labeling process, and the inherently biased function of legal norms (Quinney 1974). By the 1980s, a rather substantial body of scholarly work tied to an evolving critical criminology movement analyzed and deconstructed the practices of criminal justice agencies, particularly in the context of rising crime rates, mass imprisonment, and punitive neoconservative crime control policies (Lowman et al. 1987).

While interest in a critical analysis of state agencies was piqued by the unrest of the 1960s and 1970s, perhaps the best known deconstruction of the internal classification practices of a deviance processing agency is Goffman's (1961) ethnographic analysis of the asylum. His approach exposed how both initial classification and subsequent personal bias and discretion on the part of institutional workers reinforced the interpretation of seemingly innocuous behaviors as constitutive of a pre diagnosed mental malady. Thus, central to an understanding of how deviance processing agencies operate is to come to terms with the logics by which such organizations identify deviancy in the first place and how this vetting process accomplishes institutional objectives. Another focal concern, of course, is how these targeted populations are managed (or treated).

Reflecting general political and meta theoretical changes in academic climate, contemporary analyses of deviance processing agencies have moved away from Marxian interpretations. The most influential work in this area is now by Foucault (1977), whom some later analysts have read as both a rejection of Marxist functionalist interpretations and as an impetus for the decentering of the state in sociological explanations. The utility of Foucauldian notions such as panoptics, governmentality, and surveillance has significantly altered the lexicon of analysis in this area (Garland 1997). This shift in thinking is comprised of two main attributes. First, a realization that a significant proportion of deviance processing is accomplished by state, quasi state, and private institutions or organizations outside the context of the criminal justice system. Contemporary analysts have, for example, turned their attention towards state welfare agencies, private policing, and the profound disciplinary powers of insurance companies. Second, that

in the historical development of the science of "knowing" populations an important qualitative shift has occurred with the mass availability and distribution of computers after World War II. Sociologists have offered both substantive empirical examinations and general theoretical explanations for this profound transformation. A central element of this conversion is the institutional reliance on statistical *deviation* from a prescribed norm as actually constituting *deviance*. Thus, increasingly, private agencies such as insurance companies rely on actuarial grids to assess risky populations that in the eyes of such institutional needs constitutes deviance – a potential harm to the corporation.

Of course, such techniques are also wide spread in the criminal justice system, including important decision making on likelihood to reoffend, the classification of prisoners within levels of custodial security, and even the designation of dangerous offenders based on indicators such as the psychopathy checklist. In other words, deviance processing has become multifarious and ubiquitous as we consistently come into contact with institutional requirements that we provide identification and that our credentials (ranging from criminal history to credit standing) become known. This routine provision of personal data is alternately considered part of a system of dataveillance, the move to a superpanopticon (Poster 1990), and even the ushering in of a new risk society. Indeed, risk and probability thus become unavoidable components of the deviance processing system acting as not only methodological solutions but also the problems (i.e., a bottomless barrel of risks) (Beck 1992).

Some of the critiques of these schools of thought have to do with the perceived "newness" of such surveillance practices for deviance processing and to what extent the purpose and function of such processing is qualitatively different from the targeted populations previously identified under Marxian formulations; the extent to which these processes are largely an expansion of Weberian identified tendencies toward rationalization and bureaucratization; and a conceptual slippage between deviance, social control, risk, and regulation. Each of these three issues has significant theoretical implications for our understanding of not only deviance processing but also, by

implication, political and social theory and his toriography (Rigakos & Hadden 2001).

deviance, reactivist definitions of

Henry N. Pontell

The sociology of deviance entails two major perspectives, both of which emphasize the relative nature of the phenomenon. The normative

perspective, which most sociologists adhere to, views deviance as being located in customs and rules; deviance is the formal violation of one or more norms. The reactivist perspective, which has been associated with the labeling theory of deviance, takes a more radical approach to the relative nature of deviance, and views the existence and characteristics of deviance in how real behaviors, beliefs, or conditions are actually judged by relevant audiences (Goode 2001). Labeling theory has been marked by controversy since it arrived on the sociological scene in the 1960s. Two of its major proponents (Kitsuse 1972; Becker 1973) do not consider it a theory at all, and reject the term labeling, in characterizing what they view as the interactionist perspective. This term derives from the sociological perspective of symbolic interactionism, which sees all acts emanating from meanings that persons attach to social phenomena, with these meanings growing and changing through a continual interpretive process involving interactions with others (Blumer 1969). In a major review of labeling theory, Goode (1975) concludes that it "isn't a theory at all," and further relates that it might not even be a "general perspective," but rather a way of considering specific aspects of deviance through the application of symbolic interactionism.

The reactivist perspective is commonly traced to the writings of historian Frank Tanenbaum (1938), who highlighted the nature of community reactions to juvenile delinquency as the "dramatization of evil," whereby the social definition of the behavior was attached instead to the people who behaved that way, making them more prone to take on a deviant (evil) role. A little over a decade later, sociologist Edwin M. Lemert (1951) greatly expanded upon this general idea, including broader conceptualizations that related symbolic interactionism to the study of deviance. His classic distinction between primary deviance (related to the original causes of deviant behavior, which he termed "polygenetic," or due to a wide range of causes) and secondary deviance (related to the effective causes, after labeling took place, and a person formed a deviant identity), and his insistence that reactions form the essential quality of the social reality of deviance, formed the basis for the reactivist definition of deviance.

"Strict" reactivists (Kitsuse 1962) claim that in order for deviance to exist, the act, condition, or belief must first be heard about or witnessed, and second, must be met with concrete social disapproval, condemnation, or punishment. If these conditions are not satisfied, according to strict reactivists, deviance does not socially exist. If acts, beliefs, or conditions are known about and not reacted to as deviant, or if they remain hidden, makes no difference to strict reactivists. Real responses by audiences to concrete phenomena are what matter, and not the act, belief, or condition. Strict reactivists deny that audiences react to phenomena "in the abstract," that is, as *classes* of acts, beliefs, or conditions (Gibbs 1972). It is the real life expression of some disapproval or condemnation to a specific act that defines deviance, according to strict reactivists.

Although Lemert's work was among the most influential in what became known as the labeling perspective, it is quite clear that he was not a "strict" reactivist. In his landmark work *Social Pathology* (1951), he acknowledges deviant acts that are "clandestine," have "low visibility," and "escape the public eye." That is, deviant forms can exist without actual reactions of audiences. What he does draw major intellectual attention to, however, is that socially visible deviations can attract a wide range of expressions and attitudes from a conforming majority. This entails an important dynamic process between *doing* deviance (for whatever reasons) and *becoming* a deviant (forming a deviant identity) that comprises the heart of the reactivist definition of deviance and the labeling perspective. He wrote that "older sociology . . . tended to rest heavily upon the idea that deviance leads to social control. I have come to believe that the reverse idea, i.e., social control leads to deviance, is equally tenable and the potentially richer premise for studying deviance in modern society" (Lemert 1967: v).

While both Lemert and Tannenbaum highlighted the ironic consequences of condemning deviance, in that this could produce further rule breaking behavior, Lemert (1951) noted that sometimes a reduction or elimination of the behavior in question resulted as well; an idea that fell by the wayside as later labeling proponents, in an effort to distinguish their new perspective from older ones, emphasized

the notion that negative reactions lead to further deviance.

Goode (2001: 27–8) notes three major criticisms of strict reactivism. "First, it ignores secret behavior or conditions that would be reacted to as deviance, were they known to the community." Gibbs (1972) and Polsky (1969), among others, claim that strict reactivism is self defeating, as it poses a theoretical dilemma that concerns the notion of "secret deviance," or phenomena that would be condemned if they were viewed by the community or other relevant audience. Secret deviance does not exist according to the strict reactivist; it is a contradiction in terms. This dilemma makes it impossible to research behavior and conditions that have not been reacted to or punished as deviance. A professional thief, white collar criminal, terrorist, or drug dealer who had not been reacted to would not be a legitimate subject for the study of deviance according to a strict reactivist perspective. "Second, the strict reactivist definition ignores secret behavior and conditions that would be reacted to as deviant, even where the actor or possessor knows that it would be condemned by the community at large" (Goode 2001). Strict reactivism ignores the views of persons who would be considered deviant by others. Such persons know they are different, usually disagree that they are worthy of condemnation, and have beliefs about how they would be treated upon discovery by others. These "secret deviants" are different than conformists, even though they exist among them. Denying this through strict reactivism denies a good part of the social reality of deviance. "Third, the strict reactivist definition denies the possibility that there is predictability in the reactive process" (Goode 2001). Strict reactivism assumes that researchers cannot predict in advance what real acts or conditions will be responded to negatively. A more reasonable assumption would be that there is a general association between types of acts and types of reactions (Gibbs 1972), a position that is taken by "moderate" reactivists, who acknowledge and incorporate the normative aspects of deviance into their analyses.

The utility of a moderate reactivist definition of deviance is demonstrated in the seminal work of symbolic interactionist Erving Goffman

(1963) on the concept of stigma. Goffman distinguishes between discredited and discreditable individuals. The former have already been negatively labeled. The latter are in danger of being discredited if information about them becomes known. These "potential" deviants would stand a high probability of being condemned and stigmatized if their true status were revealed. By relating the fact that a person who holds such discrediting information is sociologically different from one who does not, Goffman shows that actual labeling by audiences is but one aspect of defining deviance, and not the sole criterion for making such a determination (Goode 2001).

Others theorists, most notably Howard Becker (1963, 1973) and Kai Erikson (1962, 1966) – the latter of whose work can also be placed within the functionalist school of thought – can be considered moderate reactivists. Unlike strict reactivists, they do not view deviance as simply residing in a concrete negative reaction to an actual behavior. Rather, moderate reactivists believe that the labeling process is crucial to understanding deviance as a social phenomenon and cannot be ignored scientifically. Their approach centers on the problems inherent in the origins and consequences of labeling, which behaviors are condemned at different times and in different places, selectivity issues, the role and consequences of stigmatization, and the differences between known and secret deviants. In other words, the "soft" or moderate reactivist argues that *categories* of deviance exist, even if *specific* actors, believers, and possessors of non normative characteristics have not been *concretely* punished or labeled.

A critical defining variable used by both strict and moderate reactivists is the audience involved in the labeling process. Audiences vary from single individuals (even the perpetrators themselves), to small groups, intimates, communities, official agents of social control, societies, or all humanity (Schur 1971). The question that separates strict and moderate reactivists is whether or not audiences always have to directly respond to deviant acts in order for these acts to be considered deviant. Moderate reactivists (which include most labeling proponents) would assert that audiences do not always have to witness an act for it to be deviant. In many common instances the

reaction can be predicted. This also means that acts are not deviant in some absolute sense, but only as so judged by real or potential audiences.

Labeling proponents, whether they are strict or moderate reactivists, have been referred to as "neo Chicagoans" (Matza 1969) in that – unlike the Chicago School, which focused on social disorganization as a cause of deviance – they do not consider the etiology of deviant behavior other than that which may further emanate from the labeling process. However, labeling researchers follow in the Chicago tradition of applying anthropological ethnography to the study of deviance, including an up close examination of the deviant's world, as well as the audiences who label them.

deviance, research methods

Scott Grills

It is in part through their methodologies that sociological studies of deviance are distinguished from other disciplinary interests (e.g., philosophical, legal) in troublesome or otherwise offensive aspects of human group life. Questions of method are fundamentally questions related to our theories of knowing: how we claim to know what we know, how we go about the work of supporting our knowledge claims, and how we construct the intersubjective realities we share. The process of doing research involves a critical assessment of our theories of the social world in light of the empirical world that we are claiming to represent.

Sociology is a discipline that is marked by internal controversies about the preferred ways to conceptualize the social world and to study it. Unlike many of the traditional disciplines within the natural sciences, sociology is not dominated by one theoretical tradition, but is best understood as a discipline that is home to multiple paradigms. Of the various understandings of deviance that are to be found in the extended literature, this author's commitments are best contextualized relative to interactionist

understandings of deviance. Deviance is understood therein as a negative quality that is attributed to any social act or social object by some audience. From these perspectives, deviance is not a quality of any thought, act, or object, but rather is a quality that is attributed by an audience. Understanding deviance as a social construction firmly distances these sociological interests from those of the moralists. By so doing the work and commitment of moral entrepreneurs (e.g., rule creators, promoters of definitions of social problems, those promoting particular campaigns and crusades) is distinguished from those whose interests are more fully grounded in the sociological traditions of empirical inquiry, conceptual development, and theoretically attentive analysis. The sociological life is of course also a form of commitment – a commitment to research practice, to theorizing, and to empirically grounded and referential research. This is not a value free enterprise, but is one that reflects a commitment to understanding the social world. As such, a sociological interest in deviance is meaningfully distinct from the agenda of the moral entrepreneur, whose position ultimately shares more with other promoters of definitions of good and evil than it does with the sociological method or the sociological imagination.

Additionally, an understanding of deviance that is attentive to the moral attributions of some audience thereby clearly distinguishes “deviance” from “difference.” While any aspect of social life may be attributed with negative definitions, simple statistical difference is never enough to establish some aspect of social life as deviant. Therefore, a sociological understanding of deviant behavior is necessarily attentive to the moral dramas that accompany the social production of deviance. As such, an air of disrespectability accompanies the work of deviance scholars.

As Prus and Grills (2003) have argued, the study of deviance is marked by the deviant mystique. That is, what people think of as deviant may be defined simultaneously as offensive, immoral or otherwise troubling, and intriguing, fascinating, and alluring. The interest that the inquirer and various audiences may bring to the study of deviance in no way absolves the researcher from the best practices that accompany good research. In fact, the

reverse is the case. In the context of studies that may see researchers experience stigma arising from their chosen areas of study, the requirement to sustain committed and articulated research practices for the problem at hand remains rather crucial. Students of deviance and deviant behavior face the professional imperative to resist the deviant mystique in order to bring the same rigorous commitment to this inquiry as is to be expected of the sociological tradition more generally. The methodological practice that sociologists bring to the studies of deviance are not, in their most fundamental forms, distinct. However, the real life obstacles to understanding deviance – research in settings that may be marked by disrespectability, participants who define themselves at risk, the problems of the distinction between the discredited and the discreditable, formal control and institutionalization, and subcultural dynamics – establish deviance research as particularly challenging professionally and personally.

The challenges that accompany the empirical study of deviant behavior are many and each strategy that researchers may employ brings with it a mixture of insight and blindness. Where some aspects of social life are highlighted, others are necessarily lost to the gaze of the researcher. While some have argued for multiple methods as a proposed solution to this problem (e.g., survey research and participant observation and experimental design as component parts of a single project), others are less than convinced that methodological eclecticism is a reasonable position for the theorist to adopt. The methods we employ reflect the interests of the researcher and are not in any way neutral, accompanied as they are with their own theories of knowing and assumptions about the fundamental qualities of human group life. For example, if one's intention is to collect data amenable to statistical analysis and one's analytical modeling is linear, then some very specific assumptions about population, sample, and the causation of human action are necessarily incorporated into one's analysis. Where the researcher is willing to argue for and defend these assumptions this is non-problematic relative to the diversity that is found within the discipline. However, should the same research simultaneously "triangulate"

by adopting methods which make divergent and contradictory assumptions about human group life and human action, one might reasonably ask upon which rock they are standing, for the contradictions in such a circumstance are irresolvable. Quite apart from the specific methodological practices that are utilized to engage the empirical world, it is essential that students of deviant behavior attend to the relative congruence of the methodological and the theoretical positions adopted in the study of deviant behavior.

At the risk of doing harm to the wonderful diversity which is to be found in the sociological study of deviant behavior, the distinction made by Rubington and Weinberg (1996) between those theorists of deviance who take deviance to be objectively given and those who understand deviance to be subjectively problematic remains a useful one. Prus and Grills (2003) argue that there is (or ought to be) a reciprocity between the methodological positions of theorists and where they place their work relative to this rather rough edged typology. Ultimately, it is the questions we ask that define our interests, reveal our theoretical commitments, and position us as inquirers. Given the various theoretical positions that scholars bring to the study of deviance, some methods are more appropriate for the questions that accompany their interests than others.

QUANTITATIVE RESEARCH METHODS: COUNTING DEVIANCE

For some researchers, questions pertaining to "offense" rates are particularly salient to their work. What proportion of the population is gay or lesbian? What is the age of first sexual intercourse and how has this changed over time? How do homicide rates vary between the cities of Seattle and Vancouver? Questions of this order are most appropriately addressed through quantitative measures. C. Wright Mills's grand question for the sociological imagination, "What are the major issues for publics and the key troubles of private individuals in our time?" requires an attentiveness to the characteristics of a given society and its historical social structures (Mills 1959: 11–22). The ability to frame deviance relative to unemployment, changing

religiosity, perceived quality of life, changing gender roles, and societal change rests, in part, on being able to secure reliable and valid data that appropriately pertain to the population under study.

Official data may be particularly helpful for those who are interested in learning more about the formal regulation of deviance – the quantity of targets who have come to the attention of control agents, the demographic characteristics of targets, treatments and punishments applied by control agents, official assessment of treatment program successes, and regional variations manifested in preceding indicators.

In the US the Uniform Crime Reports represent the most fully articulated source of official data of the Federal Bureau of Investigation index of crimes. As Grove et al. (1985) argue, these data reflect a valid measure of offenses that the public and the police jointly consider to be crimes that are a threat to order and community. Since 1961 Canada has also established a uniform crime reporting system. Official statistics pertaining to deviant behavior are collected and publicly disseminated by Statistics Canada and the Canadian Centre for Justice Statistics.

These data include relatively complete and thorough accountings of those who are incarcerated, as well as related recidivism rates. Of course, this aspect of the criminal justice system is but a small part of the production of deviance. A limited range of behavior considered deviant is represented in data collected by the state or state related agencies. As researchers move further from the corrections system, official data become less and less convincing. For example, at the risk of stating the obvious, data on convicted bank robbers is limited to those whose level of relative effectiveness as a bank robber or abilities to engage the justice system were inadequate to avoid conviction. Likewise, the system of plea bargaining produces a context where researchers would be naïve at best to assume the crime for which a conviction is registered is, in fact, the offense which brought the deviant actor to the attention of the criminal justice system.

Official quantitative data is necessarily socially constructed, as targets determine the appropriateness of informing agents of control, as policing and like agencies manage caseloads,

as pleas are bargained and judicial systems make determinations. The officially derived quantitative data that are employed to test theories, evaluate the efficacy of programs, and establish funding priorities reflect this constructive process.

Respondent Derived Quantitative Data

For students of deviant behavior, official data may be useful, but they are also inherently limited. The range of behavior considered deviant by some audience is more wide ranging and encompassing than behavior that is defined by the official crime reports. Additionally, those who are publicly and officially identified as having engaged in this or that deviant behavior are a subset of those who participate in such deviant activities. For example, those identified by control agents will include those who are wrongly accused and exclude those who participate in the deviant activity yet have not or will not come to the attention of control agents (Becker 1963). Official statistics are not measures of deviant behavior as much as measures of the formal control of deviance.

Researchers who are interested in describing and theorizing about deviance more generally have made a concerted effort to move beyond official data sources to self report surveys. Self report surveys allow researchers to resist the systemic bias in official data and to study aspects of deviance that are excluded from official data.

Short and Nye's (1958) seminal work has established the relative analytical value of asking those involved in deviant behavior to report on their own activities. Self report studies tend to suggest the following: that the rate of offense is higher than that attended to by official agencies, that offenses committed by those of lower classes are more likely to come to police attention than those committed by those with greater financial resources, and, importantly, that much informal (and some would argue less serious) deviance is excluded from the public gaze.

While respondents' ability/willingness to self disclose will vary relative to perceived risk levels and the extent to which respondents attend to and recall deviant involvements, self report surveys also continue to be challenged

by the extent to which respondents are willing and able to accurately portray or disclose their involvements. For example, a 2004 Canadian Community Health Survey conducted by Statistics Canada ($n = 83,729$; 2003 data) found that 1.7 percent of Canadians self identified as gay, lesbian, and bisexual. This rate of participation in homosexual and bisexual activities tends to be lower than the 5–10 percent participation rate suggested by advocacy groups or by those extrapolating from behaviorally based studies.

At the risk of being trite, self report surveys only tell researchers what respondents are willing to reveal to them. As the above example illustrates, there may be a rather important disjunction between what people say they do and what they do. While self report surveys may be shown to be internally consistent (e.g., Hindelang et al. 1981) they are far removed from the accomplishment of everyday life. As Couch (1995) has argued, for a discipline that claims to attend to the social, sociology has historically been exceptionally reliant on the individual as the primary unit of analysis. Survey research perpetuates this concern, as it is inherently individualizing. As it is often derived from one person's responses to a series of prescribed questions, it thereby establishes the individual as the primary unit of analysis.

ETHNOGRAPHIC RESEARCH TRADITION: PARTICIPANT OBSERVATION AND CASE STUDIES

Ethnographic research refers to the various research practices that scholars may use to study and represent the way of life of a group of people. The extended ethnographic tradition is grounded in the research practices of observation, participant observation, and in depth interviewing. While ethnographers may draw on a variety of other research strategies to support their work (e.g., unobtrusive measures, visual records, diaries, auto ethnography, textual analysis, content analysis), field based research is as central to this tradition as is the survey to more quantitatively oriented research. Given the nature of fieldwork, researchers are less likely to present their data quantitatively or to use the language of the natural sciences in

their analysis. Readers are cautioned against assuming, however, that this work is any less empirically grounded or any less appropriate for developing meaningful theories of deviant behavior. In fact, field research may be the only means by which empirically grounded knowledge of aspects of deviance can be achieved.

Given that deviant subcultures may be marked by illegal activity, secrecy, purposive misdirection, and skepticism, and may sustain an amplified suspicion awareness context, investigative field research (Douglas 1976) may be the only way to develop a scientific understanding of deviant subcultures. This argument is eloquently made by Adler (1985) in the context of her membership role with drug dealers and smugglers. She clearly demonstrates that the only way to get close enough to the activities of upper level drug dealers was to take up a membership role (in this specific case, a peripheral role) within the subculture. This general point is also most certainly true of the most complete study we have on outlaw motorcycle gangs (Wolf 1991). Wolf's participation in the Rebels offers a clarity of understanding of the social organization of the group, the marginality of its members, and accompanying gender roles that would simply be unavailable to the non member.

Membership status is not a prerequisite for the development of ethnographic understandings of deviant behavior. The case study is an example of a research posture that is not predicated on membership status. Case studies are a research strategy that may be employed to develop a rich understanding of a subculture, a person's life, an organization, or a community. The case study model is marked by the depth of data collected and is often derived from participant observation, in depth interviews, and the personal involvement of the researcher(s) in the field site for an extended period of time. While most certainly not exclusive to sociology (for example, field derived case studies have been employed by biologists to better understand primate behavior), foundational work employing the case study model marked the development of the Chicago School in the 1920s, 1930s, and 1940s. Early work such as Anderson's *The Hobo* (1923), Cressey's *The Taxi Dance Hall* (1932), Shaw's *The Jack Roller* (1930), and Thomas's *The Unadjusted*

Girl (1923) served to place deviance in a community context. It was framed in the context of the city and the tension between urban and rural life, of differing life chances, and life as it was lived.

The case study approach is particularly appropriate where researchers are interested in understanding the creation of local cultures and the social construction of multiple realities. An interest in the lives and perspectives of slum dwellers, the homeless, and juvenile delinquents is an important move away from the moral certainty that had accompanied the work of earlier social pathologists, who tended to view deviance as indicative of sick persons or sick societies or perhaps both. While case studies attempt to be "true" to the lived experiences of the people whose lives inform the research, the contributions to the sociological study of deviance extend well beyond the "thick description" (Geertz 1973). The import to sociological theory of the case study is significant. For example, our collective understanding of the social construction of gender and the management of disrespectability owes much to Garfinkel's (1967) ability to move beyond the particular to the general, while grounding his account in the lived experiences of Agnes, an "intersexed" person.

IN SUM

Maines (2001: 225) suggests our theoretical commitments and our methodological inclinations are "not because any of them make a priori sense, but because we like these things and are reasonably good at them." There is wisdom in this deceptively simple claim. Research methodologies are in part skills based. The quantitative skills required for inferential modeling are not for everyone; neither is the commitment required to sustain a meaningful field presence in the context of a deviant subculture. Likewise, our theoretical commitments are an extension of the perspectives we bring to our work and our life. In many respects, a variety of sociological theories distil human group life into a conceptual heuristic that is unknown to experience. As Cooley (1922) taught many years ago, the distinction between individual and society may be analytically

useful, but pragmatically it is much less so. Likewise, we do a significant violence to our research on deviance if we adopt a simple structural determinism that views social interaction as a neutral medium through which social factors merely pass, or if we become so enamored with "lived experience" that participants become isolated from their histories, their institutions, and the circumstances of their lives that are not of their own choosing.

The study of deviant behavior is in part a pragmatic exercise. The sociological study of deviance requires that researchers attend to a phenomenon that is situationally defined by some audience, a population that is rarely known, participants who may be reluctant to more openly associate with discreditable identities, careers of involvement that vary rather markedly over time, and the reality that deviance occurs within a community context that extends well beyond practitioners and their confederates. As Grills (1998) has argued, the work of doing research is productively understood as problem solving activity. The more that one is interested in how people come to view the world as they do, how relationships are created and sustained, how activities are accomplished, how people come to be involved in various subcultural affiliations, and how identities are managed, embraced, or resisted, the more it is imperative that researchers focus on naturally occurring events rather than self reported data or laboratory experiments. Likewise, the more one is attentive to issues of measuring the incidence of deviant behavior, attempting to measure the effectiveness of control agents or self report data based upon random sampling techniques, the more one's research demands rigorous survey based quantitative analysis.

At the close of his essay entitled "The Methodological Position of Symbolic Interactionism," Herbert Blumer (1969: 60) writes: "Respect the nature of the empirical world and organize a methodological stance to reflect that respect." This is exceptionally fine advice for the student of deviant behavior, for to do so resists the deviant mystique and brings the same intellectual standards to the study of deviance as is to be demanded of other research endeavors. The study of deviance is marked by disrespectability – the disrespectability of topic,

of spoiled identities, of subculture, and the contagion that may be experienced by the scholar. Quite apart from the specific methodological positions that researchers may adopt, respecting the nature of deviance as a social phenomenon requires that we fully attend to deviance in a community context.

deviance, sport and

Timothy Jon Curry

Sports may be defined as physical contests that are competitive, fair, and guided by rules, organization, and/or tradition. The roots of sport are ancient, and probably stem from hunting. Although modern sports have more symbolic quests than the choice cuts of meat available to the successful prehistoric hunter, the thrill of the chase is much the same (Carroll 2000). The rules and traditions of sport may or may not be codified, but they ensure that the ritualistic aspects of sport are respected. And the ritualistic aspects of sport, the before and after ceremonies and events, the coin toss that ensures a fair beginning, the awarding of trophies and medals, and so on, are every bit as important as the game itself.

Deviance refers to behavior that goes against widely accepted traditions, norms, values, ideology, rules, and laws of society, and that draws mild to severe sanctions. Deviance in sport has existed across time and space and throughout the world, and whether or not someone commits a deviant act depends upon the time and place and who does the judging. Determining what deviance is, in other words,

is a social process. The behavior itself is not enough; there must also be a reaction to it. For instance, when Art Modell moved his Cleveland Browns football team from Cleveland to Baltimore in 1995, he broke no criminal law. But his actions precipitated violent outbursts on the part of Cleveland fans, who believed he went against accepted norms that bind professional sports teams to the cities that support them.

Deviance in sport includes a wide assortment of behavior. Many types of people are involved, and the perpetrators of deviance in sport cut across gender, race, and class lines. An abbreviated list of transgressors includes owners of professional teams, athletes, coaches, sport agents, fans, professional gamblers, pharmacists, educational institutions, corporations that promote sport, cities, states, and international organizations that govern sport. In contemporary society, deviance in sport is seen as news worthy, and newspapers and television news channels routinely feature stories of deviant sports figures. Misdeeds that occur at educational institutions affiliated with religious organizations have special fascination. When a basketball player at Baylor University was shot and killed apparently by a teammate in 2003, newspapers were anxious to report every detail of the incident partly because it took place at the world's largest Baptist University.

Previous generations of reporters and writers thought of sport as a character building exercise, and they were reluctant to report on the misdeeds of sport heroes (Dinan 1998). As a result of the attention given to deviance in sport by media today, it seems that it is more prevalent than a generation ago, but this is more than likely due to the coverage given to the topic rather than the actual rate of deviant acts committed. Even so, empirical research has failed to support the idea that sport participation builds character. If anything, the longer one participates in sport, the more likely it is that moral constraints such as fair play and honesty give way to the desire to win (see Miracle & Rees 1994).

CLASSIC TOPICS

Some of the classic topics studied by those interested in deviance and sport are cheating,

drug abuse, gambling, and violence (particularly among athletes or between athletes and fans). These are classic or standard topics because they concern the fundamental social conditions defining sport. Any activity that destroys or vastly alters the physical challenges of sport or the fair competition between opponents poses a threat to the basic premises of sport, and a serious threat to its continuation. For instance, consider the following examples.

Cheating – the intentional violation of rules and norms for one's advantage – has long been associated with sport. The National Collegiate Athletic Association (NCAA) estimated that 14 percent of member schools engaged in serious cheating in the 1970s, an estimate that seemed too low at the time according to Curry and Jobu (1984). Today, without good data, it is impossible to tell whether the figure is the same or much higher or lower, but cheating is still an important concern for the NCAA and its member institutions. Cheating can take many forms, and is especially serious when it involves coaches and others responsible for the integrity of the sports program. When Georgia Tech coach George O'Leary successfully applied for the head coach position at Notre Dame, he falsified information on his résumé by claiming to have acquired a master's degree (which he never earned) and to have lettered at a college where he never played. When this was discovered, he was immediately fired from Notre Dame. As sociologist Stan Eitzen (2003) notes, coaches who cheat on their résumés can hardly qualify as role models for their athletes.

Drug abuse – particularly *additive* drugs that are meant to stimulate the body beyond normal capabilities – are not a recent discovery. Anabolic steroids were first marketed in 1958 under the name of Dianabol and they proved to be effective when combined with exercise to produce gains in muscle mass. Sport historian Allen Guttman (1988: 165) notes that this effectiveness has been a "curse" because steroids can cause serious negative side effects to the body. Even so, athletes continue to use them, and the records they set through the help of additive drugs only encourage others to violate rules. Even the most talented professional athletes, who seemingly could get along without using banned substances, use them. In 2004, the names of some of the most respected

and highest paid professional baseball players were linked to the use of steroids during testimony to a US federal grand jury investigating possible steroid distribution by the Bay Area Laboratory Cooperative in California.

Gambling – particularly gambling that involves athletes or others in a position to alter the outcome of a contest – has long been associated with sport. Perhaps the most famous incident of sports gambling is the Black Sox Scandal (Curry & Jiobu 1984). In 1919 the Cincinnati Reds upset the Chicago White Sox – soon to be called “Black Sox” – to win the World Series. Rumors of a fix circulated, and a year later eight players who were on the White Sox World Series team were indicted and charged with complicity in a conspiracy with gamblers to throw the game. Two of the players confessed. The Commissioner of Baseball at the time was Judge Kenesaw Mountain Landis; he strove to make an example of the players by banning them for life, even though the accused players were later found innocent in a court of law. In spite of the harsh penalties, gambling continues to be a problem in baseball, most recently with controversy over Pete Rose, an accomplished player whose admittance to the Baseball Hall of Fame seemed assured until it was discovered he bet on baseball games in 1985, 1986, and 1987 while manager of the Cincinnati Reds. Other sports, including collegiate and professional football and basketball, have had serious problems with gambling; so have boxing and horseracing. The problem stems from the great popularity of gambling in society. Billions of dollars are wagered on sports events by millions of respectable people. The Internet has increased opportunities for gambling on all types of sports. Athletes are tempted to gamble, partly because they enjoy competition and winning and see gambling as another challenge. According to some sociologists, the sheer volume of dollars involved in betting on sport attracts people who will look for ways to fix a sporting event despite the harsh penalties invoked if they are caught.

Violence – defined as the use of excessive physical force intended to cause mental or physical pain to another person – has long been associated with sport. Particularly alarming is when excessive violence is used as part of the strategy of competition. In 1905 President

Theodore Roosevelt became so concerned about violence in college football he spearheaded a move to clean up the excessive violence through rule changes and modifications to equipment. Such formations as the “flying wedge” were eliminated, and players were required to wear more protective gear. Even so, football remains a violent game, and some players take advantage of the rules to injure or maim their opponents. Coaches frequently overlook borderline violence, and applaud brutal body contact. Sport sociologist Jay Coakley (2004) believes that acceptance of excessive physical force can be looked at as deviant *over conformity* to the norms of sport. Both male and female athletes are so focused on maintaining their identities as athletes and so caught up in the emotions and physicality of sport that they fail to consider the consequences of unquestioned normative conformity. Serious injury and shortened careers can result.

THEORY

There is no single theoretical approach that dominates research in deviance, and sport sociologists employ a number of theories drawn from mainstream sociology and criminology. Two of the most popular are differential association and strain theory. Differential association is based on the work of Edwin Sutherland, who emphasized that people learn conformity or deviance from the people with whom they associate. In the case of young athletes, teammates might prove to be especially important, since peers typically have strong influences on young people. Sutherland noted that like behavior in general, deviant behavior is learned through interaction with others, especially in small, intimate groups. Such learning of deviant behavior consists of acquiring techniques, motives, drives, and attitudes. An individual learns “definitions” (mindsets or attitudes) that are favorable or unfavorable to prevailing norms, and becomes deviant when he or she learns to accept more unfavorable definitions than favorable definitions. The frequency, length, and intensity of a person’s associations determine the impact of associations on the person. Infrequent contacts of limited duration will have less impact than frequent, intense

contact (Sutherland & Cressey 1978: 80–3). To illustrate, Curry (2000) studied the interactions of a group of athletes in an elite sport program who engaged in bar fights and inappropriate sexual behavior. He found that the athletes knew that this behavior would be considered deviant by others, but that the prevailing norms among their teammates encouraged an occasional visit to what they called the “dark side.”

Strain or anomie theory is less concerned with the interaction among team members, and more concerned with the structure of opportunity in society. According to Robert Merton, who first constructed the theory, structural strain develops when the culturally prescribed goals of the social system cannot be achieved through socially approved means. The strain may produce deviance, and Merton outlined five typical social responses or adaptations to such a situation.

Conformity, the only non deviant response, is the first adaptation. A *conformist* accepts the conventional goals of society and the conventional means to obtain them. For example, an athlete who desires to win an Olympic gold medal will spend many years practicing and improving his or her skills until able to perform and succeed at the highest levels. In contrast, an *innovator* accepts the goals, but rejects the socially approved means and thus opts for deviance to attain the goals. In the case of Olympic athletes who use banned substances such as steroids, they are still trying to win medals, but are doing so through innovative practices with performance enhancing drugs (Lüschen 2001).

Other athletes may decide to continue to go through the motions of competing for an Olympic medal, yet abandon the goal of actually winning one. They realize that the competition is too difficult and so become *ritualists*. Merton also recognized *retreatism* and *rebellion* as reactions to strain. The retreatist rejects both the means and the goals of society. In the case of sports, the competitive athlete who gives up the sport entirely has retreated from the scene rather than try to compete to win. The rebel, on the other hand, rejects the goals and means of society but replaces them with new goals and means. Athletes who rebel against the Olympic Games might substitute other games that allow for a greater chance of success. For instance,

Tom Waddell began the Gay Games competition in 1988, to provide a more accepting environment for homosexuals. The Gay Games have been held periodically ever since, and in 2002 included over 11,000 athletes competing in over 30 events.

The major strength of Merton’s approach is that it places the origins of deviance in the broader social setting. To the extent that those who control sport, particularly elite sport, narrowly define what constitutes success, they encourage deviance. In other words, many gifted athletes feel they must cheat in order to win because the opportunities for success are so limited (see Leonard 1998: 139–72).

While these classic topics and theoretical approaches have long dominated research on deviance in sport, several new topics and theories are emerging. For instance, persons closely associated with sport may become involved in sexual harassment and sexual assault cases, homophobia and attacks on gay men, hazing in high school and collegiate sport, celebratory violence, eating disorders, excessive drinking, and many other deviant activities. Sport sociologists researching these topics face the difficult methodological problem of tracing the influence sport participation may have had in creating social conditions that encourage such deviance, while at the same time recognizing that these deviant activities are engaged in by others outside of sport.

Masculinity issues in the study of crime and deviance have come to the forefront, and sport sociologists are becoming aware of how boys and men strive through risky behavior, including deviance, to establish masculinity (Messner & Sabo 1994). Off the field violence toward women is increasingly understood through the dynamics of gender (Benedict 1997, 1998). Pressures on young men and women athletes to perform at the highest levels may result in psychological disorders that lead to numerous problem behaviors.

In addition, corporate or organizational deviance in sport is now recognized as a serious problem (Coakley 2004). Since corporations control vast resources, they are able to influence the media and create symbolic representation of sport that makes it difficult for the public to recognize their actions as deviant. For instance, sport sociologist Helen Lenskyj

(2000) notes that those in charge of the International Olympic Committee have been very eager to control the image of the Olympic Games. The Olympic "industry," as she calls it, has until recently been able to disguise much of its deviance as the occasional misbehavior of certain individuals rather than part of its corporate culture. She argues that inside the Olympic industry, bribery and scandals involving high ranking political figures are common.

As sport sociologists research more of the corporate and organizational cultures that govern professional and big time amateur sport, the more the topic of deviance and sport moves away from the individual athlete and coach. This is all to the good, because many of the forces perpetuating deviance in sport lie outside the individual. In the future, a better understanding of deviance and sport may be generated through analysis of the close ties between corporations, the media, and consumer culture (Blackshaw & Crabbe 2004). Researchers have come to understand that the image of the athlete as a superior being is only an image; elite sport is not conducive to the development of moral behavior. But such images can be used to sell vast amounts of consumer goods. This does not mean that the idea of physical tests or challenges and fair competition is itself flawed. Humans have long enjoyed physical challenges, and the idea of fair competition, while more recent, has broad appeal. As in other spheres of human endeavor, the devil is in the details.

deviance, theories of

Paul Rock and David Downes

"Deviance" and its companion words, deviant and deviation, have their roots in Latin and point to a straying from the *via*, road or path. Some of its variants have a long history: the thirteenth century *Romance of the Rose*, for example, talks of "deviant" in the sense of

being out of the way; "deviation" appeared in publications in the sixteenth century; and Durkheim powerfully foreshadowed its sociological usage in *Les Règles de la méthode sociologique* (1895), where he took deviance (which he did not name as such but rather awkwardly referred to as crimes against religion, ceremony, etiquette, tradition, "and so on") to be the pivotal concept for what turned out to be his founding theory of functional analysis. (Durkheim contrasted his own approach with a more limited notion of crime he somewhat misleadingly attributed to Garofalo's *La Criminologie*, 1890.) But "deviance" itself is a neologism with multiple meanings. The *Oxford English Dictionary* traces its first appearance in English to a piece written in 1944 by the psychologist Gregory Bateson, who presented it as a corollary of "standardization" (and see Bateson 1972). The English sociologist Walter Spcott employed it ten years later to refer to departures from culturally expected rules of conduct (Spcott 1954). And the most celebrated, if not the most elusive, description was offered nine years later still in 1963 by Howard Becker. In a passage that avoided exact definition, but which would have the greatest impact, he insisted on the social character of deviance: deviance, he said, "is *not* a quality of the act the person commits, but rather a consequence of the application by others of rules and sanctions to an 'offender.' The deviant is one to whom that label has been successfully applied; deviant behavior is behavior that people so label" (Becker 1963: 9).

That etymology is important because "deviance" is a latecomer which does not appear to be part of the currency of everyday speech. It was imported into the sociology of the English speaking world in the early 1960s by a number of its sponsors precisely because it did not seem to be freighted with the unwelcome or extraneous meanings that its predecessors, such as social disorganization (Faris 1955), social pathology (Wootton 1959), sociopathic behavior, and social problems, were thought to have acquired. Neither was it marred by what many of its proponents saw as the abstracted empiricism, "correctionalism" (Matza 1969), excessive positivism, and atheoretical leanings of the criminology of the time. One may see the transition marked in the titles of academic works of the period. Edwin Lemert, for

instance, published *Social Pathology* in 1951 but, in 1967, he titled a collection of essays *Human Deviance, Social Problems, and Social Control*. On the very cusp of change in 1961, and listing three variations simultaneously, was Robert Merton and Robert Nisbet's *Contemporary Social Problems: An Introduction to the Sociology of Deviant Behaviour and Social Disorganization*.

"Deviance" had for a while the semblance of a moderately neutral term which implied no adverse or unnecessary social, political, or moral judgment. (That confidence was probably short lived. If the 1953 edition of *Rogers's Thesaurus* did not contain the term, the 2002 *Collins Thesaurus* gives among its synonyms "perverted," "sick," "twisted," "bent," "abnormal," "queer," "warped," "perverse," "wayward," "kinky," "devious," "freaky," and "aberrant.") But, because it was in effect thought to be a new term of art, a term that was employed principally to distinguish it from its discredited antecedents rather than being an accepted definition in its own right, it rendered itself open to multiple interpretations that encapsulated the larger systems of theorizing that framed it. It was used by the self taught social statistician and criminologist Leslie Wilkins (1964) to mean a statistically uncommon event with peculiar social consequences. Wilkins made much of the alleged correspondence between the outlying location on a normal statistical distribution curve of certain forms of conduct and the social position of the person or group exhibiting them. Almost all people lie, Wilkins said, but there are a few, furthest from the mean, who are pathological in the high or low frequency of their lying and they are deviants. Those who were the furthest were somehow held structurally to be the most remote from the commonality of people in a society. The idea was misconceived (after all, much deviance, like traffic infractions or sexual misconduct, is commonplace), but it did engender some interesting ideas about how feedback loops could distort information as it traveled over large social distances, affected people's reactions to populations at the extremes, and so amplified deviant conduct (see Young 1971) and led to what were called moral panics (Cohen 1972). It also raised the prospect of studying the saintly as deviants, although it

was an invitation accepted almost alone by Cohen (1966) inside criminology, but with greater alacrity by the sociologists of new religious movements outside (Barker 1984).

Deviance could be represented by the functionalist Talcott Parsons (1951) as the temporary or longer lasting failure of individual or group adjustment in social systems undergoing change. It could be said by other functionalists to play the unintended role of acting as an illicit support to conventional institutions – prostitution supporting monogamy by providing an emotionally sanitized outlet for otherwise dangerous sexual liaisons, or the taint of an illegitimate birth preserving primogeniture. It could, by extension, present the dialectical contrasts by which the respectable, normal, and conventional would be recognized and strengthened. And there were those who argued in their turn that deviance is manufactured precisely to support the moral order (Erikson 1966), deviance and morality being symbolically interdependent twins. In structuralist anthropology and sociology it could be a property of classification systems where the deviant was a worrying anomalous phenomenon that did not fit neatly into existing categories, and so posed a threat to the project of collective sense making and social order (Scott 1972). Deviance was there both symbolic matter out of place and, potentially, new matter coming into being, an experiment with the new and a foretaste of future existential styles (Scott and Lyman 1970). It could mirror the symbolic workings of systems of social stratification, where some symmetry may be expected between authority, wealth, and moral esteem, and where deviants are typically to be found among the lowest and least valued strata (Duster 1970) or, indeed, outcast altogether (see Heymowski 1969). It could thereby refract the capacity of some effectively to assign others to a devalued social status, although such assignments could be, and were, frequently challenged (Haug & Sussman 1969). And it was that link with signifying processes that was perhaps most strongly to promote its elective affinity with the ideas of symbolic interactionism, phenomenology, and ethno methodology. The ensuing bundle of ideas was probably the most distinctive theory of deviance of all. What came to be called labeling theory (to the distaste of Edwin Lemert and

Howard Becker, its progenitors), methodically explored the symbolic work undertaken when attempts are made to affix the deviant “label” to some person or group of persons, event, process, or phenomenon, encouraging power, “signification” (Matza 1969), and moral passages to become central topics.

Deviance was held in those theories to be an attribute bestowed on behavior and people by a defining audience. John Kitsuse (1968: 19), for instance, declared that he proposed “to shift the focus of theory and research from the forms of deviant behavior to processes by which persons come to be defined as deviant by others.” And Kai Erikson (1964: 11) proposed that analysis should turn away from the actor and towards the audience of behavior because it is the audience that will ultimately determine significance. Vital to that conception was the distinction mapped by Edwin Lemert (1951) between “primary” and “secondary” deviation, the first a possibly uneventful instance of the abounding violation of rules which escape public notice, the second, consequent upon public response, which required the rule breaker not only to react to his or her own behavior, but also to others’ reactions to that behavior. Secondary deviation was a social phenomenon shaped by social processes. The idea invited consideration of the symbolic adjustments that might have to be made to others’ responses, and of the reorganization of identity that could well have less to do with the “innate” character of the violator or violation and more to do with the assumptions, stereotypes, and stigmas that were incorporated in public judgment and imposed in practical action.

In that formulation, deviance was held to be the object of defining procedures that are themselves contingent on audience, time, place, power, and occasion. What is deviant in one setting will not be so in another, what is deviant for one may not be so for another, and it is not always easy to cast in absolute or categorical terms the rules by which it may be identified. To the contrary: it was a precept of many of those who studied deviance that the phenomenon resisted neat or absolute definition. Bittner (1963), for example, argued that there is such an infinite regression of rules for judging when and where rules should be applied that it becomes quite impossible to establish

absolute categories. It followed that deviance was thought often to be marked by experiential confusion, contradiction, and absurdity, prompting David Matza (1969) to suggest that deviance ineluctably coexists with ambiguity and "shifting standards."

Subjectively problematic, multiform, contested, and uncertain, deviance had major attractions for the phenomenological sociologist. Often involving extended exchanges between definers and defined, it invited an examination of existential processes that unfolded not only in interaction between a putative deviant and those who ascribed his or her identity, but also reflexively within the deviant himself or herself as the moral meanings of acts and selves were tested and explored (Becker 1963). Deviance was characteristically presented not as a stable or fixed state but as an emergent *process* of becoming, a moral career (Goffman 1959), that might at times be more or less orderly but which also lacked certain or necessary outcomes.

As a site of contestation, where meanings were problematic and people were marginal, deviance was also especially appealing to those who sought to use the methods of participant observation to achieve an anthropological distance from the world of the taken for granted and commonplace. By looking at and through deviance, they argued, by adopting perspective through incongruity, they might see the familiar as new and strange and so discover what might otherwise have escaped attention (Hughes 1958). Many of the deviant worlds which have thus been analyzed were amenable to ethnographic inquiry, and they tended to overlap or adjoin the sociologist's own.

It must be emphasized that the term deviance is at once theoretically denotative and connotative. It points, on the one hand, to thinking about an ill assorted range of behavior with fuzzy boundaries and indeterminate definition, including homosexuals, the blind, the mad, stutterers, alcoholics, strippers, nudists, drug users, thieves, convicts, robbers, prostitutes, delinquents, and those whom Gouldner (1962) rather disparagingly dismissed as the inhabitants of "the world of hip ... drug addicts, jazz musicians ... drifters, grifters and skidders." It attends to the way in which the meaning of deviance is contingent on a

politics of power and authority. Where control becomes a variable, it has been argued, crime is but one of a number of possible outcomes. Control might just as readily lead to conduct being informally regulated, mitigated or condoned, or treated as a matter for medical, psychiatric, religious, or political intervention (Gusfield 1968).

Theories of deviance were thus potentially wider by far in their reach than criminology and they made the criminal law, criminalization, and the facts of crime newly and interestingly problematic. Indeed, Lemert (1967) and Ditton (1979) came to propose that attention should shift away from deviant acts and people towards the phenomena of control. And where control was the variable, rule making, policing (Reiss 1971), and regulation (Hawkins 1984) came newly into view, no longer to be taken for granted as the backdrop of criminology, but occupying center stage.

It was but a step to study what came to be known as crimes of the powerful. Presaged by Sutherland (1949) (himself rooted in symbolic interactionism), it looked at how crime and control were bound up in a politics of naming, shaming, accounting, and enforcement (Geis & Jesilow 1993). Those matters, involving the trading of critical definitions of the situation, were also to be at the heart of labeling theory. Much was to be made of how people portrayed their motives and actions to themselves and others, how their deviance and conformity were eased by the narratives that could be so told, and how those narratives might be challenged, corroborated, and negotiated as deviant careers unfolded (Mills 1940; Sykes & Matza 1957; Maruna 2001).

But theories of deviance were also importantly connotative. Institutionally anchored in the British National Deviancy Symposium and in the American Society for the Study of Social Problems and its journal *Social Problems*, they advertised for many that there had been a conceptual, indeed, for some, political, break with past work whose errors and omissions were sometimes caricatured for dramatic effect. They stood for the treatment of deviance as a social process to be described, not as a thing apart, but in the stock language of sociological analysis, and of interactionist sociology in particular.

By and large the new theories succeeded in their object. Criminology is more fully sociological than before. It is now more responsive to the argument that deviant phenomena are emergent, political, negotiated, contingent, and meaningful. And it has moved on. Theories of deviance are still being advanced, and the ethnographic mapping of deviance is still vigorous (Duneier 1992, 2001), but they no longer hold sway as in the past. They had their period of flowering – perhaps something of a false dawn – in which crime, mental illness, sexual deviance, political deviance, and the like were to be analyzed afresh and in a way that transcended the limitations of criminology. Theirs was the era indicated by the dates of the publications cited in this entry and by three generations of encyclopedias: *The Encyclopedia of the Social Sciences*, published in 1931 (Seligman), made no mention of deviance or deviation; *The International Encyclopedia of the Social Sciences*, published in 1968 (Sills), had an extensive treatment of deviant behavior and deviance; and the *The International Encyclopedia of the Social and Behavioral Sciences*, published in 2001 (Smelser & Baltes), had none. It is now criminology that people again practice, but it is a criminology that has absorbed the theories of deviance (and many other, more recent theories) in its passage (Lea & Young 1984).

deviant beliefs/cognitive deviance

Robin D. Perrin

Sociological discussions of deviance typically focus on non normative *behaviors*. Cognitive deviance, on the other hand, refers to deviant *beliefs*. The study of cognitive deviance “reveals

that social rules apply not only to how one behaves but also to how and what one thinks” (Douglas & Waksler 1982: 366). Beliefs are deviant if they fall outside the norms of acceptability and are deemed wrong, irrational, eccentric, or dangerous in a given society or by the members of a particular collectivity within a given society. Deviant beliefs are important to study because they reveal basic social processes and affirm the belief structure on which the culture of a society is built. In addition, the study of deviant beliefs is important because deviance is often the first step toward social change. Today’s deviant idea may well be tomorrow’s norm.

History is filled with fascinating examples of attempts to control or eliminate beliefs that threaten those in power. During the Inquisition, for example, real and imagined beliefs were severely sanctioned. In the United States in the 1950s, people who supposedly held communist beliefs were ostracized, fired from jobs, and sometimes imprisoned. An examination of most of the world’s major religions reveals that early followers were despised and sometimes killed for their beliefs.

Goode (2000) maintains that deviant beliefs are not always, or necessarily, minority beliefs. In fact, many widespread beliefs are rejected by society’s dominant social institutions. He suggests that paranormal beliefs – those that science regards as contrary to the laws of nature – are deviant despite the fact that many are widely endorsed. Belief in the validity of such phenomena as extrasensory perception, astrology, lucky numbers, ghosts, and UFOs is deviant, he maintains, because it is derided in the educational system, the dominant media, and the medical profession. That is to say, the most powerful representatives of society’s dominant institutions regard these beliefs as deviant. Yet, the deviant status of a given belief is only secured when the person who holds that belief is ostracized and stigmatized. The person who has a lucky number is not stigmatized, despite the fact that his view is seen as empirically indefensible by the scientific mainstream. Ultimately, therefore, it is the powerful and stigmatizing reaction of others – mainstream culture, people in power, interest groups – that determines the deviate status of a belief.

To define a belief as deviant is not necessarily to suggest that it is wrong or misguided. Its empirical, objective, or scientific erroneousness is a separate issue. Nearly all scientists regard paranormal beliefs as scientifically wrong, but what makes these beliefs deviant is the negative reaction they evoke from the scientific community, not the presumed wrongness of the beliefs themselves. The non judgmental approach of the sociologist is especially evident in matters of religious faith. Beliefs that challenge religious norms will likely be ridiculed by the religious mainstream, which may label the competing religion a "cult." The sociologist, however, uses the term "cult" without prejudice. "Cult" merely distinguishes "new" religion from more established churches and sects. A cult is a deviant religion not because it is evil, but because it violates the norms of conventional religion, and because others react negatively to it. It is worth noting that all religions, including culturally acceptable religions like Christianity, began as deviant/cult movements (Stark & Bainbridge 1985).

One of the most fascinating areas within cognitive deviance is studies which focus on the process by which presumably erroneous beliefs come to be accepted by many people. This area of research fits into the larger sociological literature on collective behavior (e.g., panics, rumors, moral crusades, social movements) and the social construction of social problems (see Spector & Kitsuse 1977). For example, during the 1980s and 1990s many people, including prominent clergy and mental health professionals, came to believe that a large and active satanic cult had infiltrated the highest level of government and business. The satanists allegedly committed many heinous crimes, including the sexual exploitation of women and children, and human sacrifices. The beliefs persisted despite the fact that law enforcement personnel charged with the task of investigating the crimes routinely dismissed the claims. The "satanism scare" is a fascinating example of how widespread belief in a threat can persist even in the absence of evidence that the threat is real (Victor 1993).

Sociologists maintain that beliefs are formed in interaction with others – they are *socially constructed* (Berger & Luckmann 1966). Even

commonly accepted "facts" are socially produced. Most people accept that the earth is round, but they did not reach this conclusion all by themselves. The social constructionist perspective is especially relevant in the production of cognitive deviance, which often focuses on supernatural or otherworldly beliefs that must be accepted as a matter of faith. People can be convinced to believe in something they cannot see if those around them are convinced that the claims are true. The commitment of others provides for us, in the words of Peter Berger, a "plausibility structure." Others will help convince us that the unbelievable is believable. We will be drawn to the convictions, commitment, sacrifice, and enthusiasm of others.

The study of deviant beliefs reveals to the sociologist the socially constructed nature of reality. What members of the society, or of specific social collectivities, take to be real and true has momentous consequences for the nature of the society. Beliefs that challenge these collective understandings may be reacted to negatively, and the punishment of alternate beliefs constitutes a major segment of the apparatus of social control. Since the costs can be significant, deviant beliefs are difficult to maintain. Occasionally, the fringe may become the mainstream, blasphemy the inspiration, or the nutcase the prophet. Yet more commonly they remain fringe and lunatic. Most deviant beliefs, in fact, come and go with hardly a notice.

deviant careers

Axel Groenemeyer

The concept of career has its origin in the sociology of professions, where it has been used since the 1950s with different meanings. Corresponding to everyday meaning, career refers to certain occupations and professions of high status and stable upward mobility. In this context career means a highly institutionalized social and cultural pattern of social positions in an orderly sequence or a system of sequences of positions with growing prestige and earnings within a bureaucratic organization. This definition was first applied in functionalist perspectives and was linked to the question of the social function of this patterned organization of professions for the integration of modern societies (Wilensky 1960).

Besides this narrow meaning, career refers also to a structure of an occupational biography in general, as the sequence of occupations in the life of an individual or a group of individuals. In this meaning career is not linked to professions or to vertical mobility within an organization, but indicates any pattern of occupational change or – even more generally – individual movement through a sequence of roles and status, which does not necessarily have to be institutionalized or prescribed by a system of rules. This definition refers to questions on the social conditions and processes for changes of occupations, roles, and positions within the life course. Whether and how these patterns of mobility are in fact institutionalized are empirical questions. The research on life course development has shown that the idea of a standardized career pattern with institutionalized upward mobility always only concerned a minority of individuals. In high modern

societies life courses and career mobility are increasingly destandardized and individualized. As a consequence, in life course research the concept of career has lost meaning (Marshall et al. 2001) and very often is replaced by the concepts of trajectory or status passage (Heinz 1991).

In a third meaning career refers to processes of individual adaptations and socialization within roles and positions of an occupational biography. In this context career is defined as a series of adjustments made to institutions, for formal organizations, and informal social relationships involved in the occupation. This definition partly is used also in research on social conditions of positional changes, but normally is linked to analyses of individual developments of social and personal identities that take place in the context of occupational mobility as individual adaptation to the organization and culture of an occupation (Strauss 1971). In this perspective career development has to be analyzed within an action frame of reference, and changes of positions are the result or the consequence of individual developments and decisions.

The metaphor of career thus in general stands for the link between social structures, biographical development, and individual action within the life course: “development as action in context” (Silbereisen et al. 1986). Career refers to the social structure of the individual’s movement through defined social positions, to the individual’s movement through these positions; it can also focus on the intersection of individual biography and social structures.

The common frame of the career concept is the construction of a related sequence of stages and positions that have to be passed through one after the other. Preceding stages and positions constitute specific preconditions for succeeding stages or positions. In this sense the sequences of a career form an inherent causal connection, but changes of positions as turning points or transitions between stages have to be explained by specific social conditions and processes. The career concept also allows analysis of individual changes of positions and roles as a process of active individual adaptations of orientations, competencies, and perspectives that take place before “turning points” in the

life course, as well as processes of socialization that are the consequence of taking a new position or status.

At the same time, careers also constitute a pattern of providing meaning; they are constructed in prospect and accounted for in retrospect. The construction of a structured and coherent career provides meaning and sense, not only for institutions that guide and control individual biographies, but also for the individuals themselves (Collin & Young 2000).

Individual developments in deviant behavior normally do not follow institutionalized or organized sequences. Nevertheless, in a retrospective view there can be constructed typical patterns and sequences of development, organized around the deviant behavior itself, by patterns of problematic social conditions seen as causes of the deviant behavior, or by a sequence of consecutive institutions that have reacted to the deviant behavior (Cicourel 1969). Also in this context the assumption of a continuity and coherence of the individual biography constitutes the guiding idea of constructing a career pattern.

Another meaning of the career concept is emphasized when specific forms of deviant behavior are interpreted as a profession to earn one's living. In fact, some types of deviant behavior could be described as occupation, like some forms of organized larceny, fraud, or economic crime, but also prostitution and drug dealing, where different social positions or a status hierarchy and processes of learning and role adaptations could be analyzed in analogy with positions in respectable occupations (Letkemann 1973).

The sociology of deviance first adopted a perspective of career implicitly within analyses of deviant biographies in the context of the Chicago School of sociology (Shaw 1931; Sutherland 1937) and in the perspective of the theory of differential association (Sutherland and Cressey 1939). Also, the multifactor approach of Eleanor and Sheldon Gluck used the concept of career, but only to order variables in a temporal sequence. Synonymous with the career concept, very often the term natural history has been employed.

It was the development of the labeling approach that promoted the concept of deviant career in the 1960s. As a critique of etiological

theories of deviant behavior with emphasis on personality defects, the labeling approach demands explicit analyses of the dynamic processes by which the labels of deviant behavior are constructed, applied to specific persons, and adopted by them. Classical works from this perspective include Becker's analyses of the learning processes of "Becoming a Marijuana Smoker" (1953), Erving Goffman's (1961) description of individual adaptations and processes of identity development in the context of the total institution, Scheff's (1966) theory of psychic disorders, Suchman's (1965) work on patient careers, and the analyses of drug careers by Rubington (1967). Since then the notion of deviant career has spread into everyday meaning in different connections, such as drug career, criminal careers, illness career, and poverty career.

The biographies of drug addicts very often have a typical sequence of drug use that can be reconstructed as a sequence from soft to hard drug or patterns of increasing usage. The typical sequences are constructed as a drug career and laid the groundwork for ideological versions of the stepping stone hypothesis: the assumption of a quasi naturally progressing involvement into drug addiction that ends in the total misery of addiction. Empirical research has shown that this hypothesis cannot find justification without taking into consideration the social and institutionalized reaction, as well as the social context of drug use, marked by stigmatization and criminalization. In a sociological career perspective the use of drugs could increase the statistical probability of using other drugs, which also means that most of the persons involved in the use do not go on to other drugs. The transition between different stages of drug use is marked by specific biographical and social conditions, so that the causes for starting smoking or drinking alcohol are quite different from those of smoking marijuana, which are different from taking hard drugs (Kandel 1980).

But in fact the use of the career concept in this context always is only a very rough simplification. Biographical research on drug use has shown that drug careers only very seldom follow a linear sequence. They are always marked by interruptions, by processes of reintegration into respectable social contexts, and subcultural integration. This also holds for processes for

giving up drug addiction, for processes of reintegration and maturing out of the drug using context (Biernacki 1986), and also for the effectiveness of intervention and treatment (Groenemeyer 1990). In this approach, the career perspective has to be integrated into a larger analysis of deviant life courses and biographies, marked by status passages, turning points, and transitions.

The idea of criminal careers refers either to crime as work or occupation (Letkemann 1973), to the consequences of interventions of social control (Cicourel 1969), or to the causes and consequences of crime and criminal offenses in the life course (Sampson & Laub 1993; Farrington 1994).

One starting point for the rediscovery of the careers metaphor in criminology has been the development of self report studies in the 1960s and 1970s, which showed that criminal offenses are quite common behaviors for certain age groups, but for most offenders this behavior must be interpreted as transitory and occurs only once or very seldom. In this perspective a concept of criminal careers does not make much sense when it is defined analogously to that of the drug career as a sequence of different offenses. In the Philadelphia birth cohort study, Wolfgang et al. (1972) came to the conclusion that about 70 percent of all serious offenses are committed by about 6 percent of offenders. With this result they identified a small group of "career criminals," variously characterized as dangerous, habitual, or chronic offenders, who commit serious offenses with high frequency over extended periods of time (Blumstein et al. 1986). In this context criminal careers are defined as the longitudinal sequence of offenses committed by an individual offender (Farrington 1994). This construction of the career criminal gave way to extended research activities on patterns of individual offending and constituted the scientific base for the development of "three strikes and you're out" policies in the US.

Whereas in this perspective the differentiation between offenders is the starting point, other perspectives using the career metaphor start from the multifactor approach of Glueck and Glueck (1943) in searching for specific conditions in the development of crime. The

results of this branch of empirical research are extremely varied (Farrington et al. 1986; Loeber & LeBlanc 1990). In this context the career concept is only used to give the choice of factors and variables a temporal order from birth (and even before) to adulthood, without much claim to developing theoretical generalizations.

Dewey, John (1859–1952)

Mark D. Jacobs

John Dewey, perhaps the most prominent US public philosopher in the first half of the twentieth century, has cast a large shadow over many fields of sociology: social psychology, urban sociology, the sociology of education, the sociology of culture, political sociology, and public sphere theory, among others. Above all, he helped infuse much of American sociology

with a spirit of pragmatism. In addition to his seminal contributions to the study of method and of ethics, his sociological works focus on the active nature of education, democracy as community, and art and experience – and their interrelations. His students and colleagues – George Herbert Mead, W. I. Thomas, Robert Park, and Jane Addams – helped spread his influence almost immediately over sociological research and practice; it is not accidental that the three universities to which he devoted the bulk of his faculty career – Michigan, Chicago, and Columbia – all nurtured elite departments of sociology, and that the New School for Social Research, which he helped found, has continually sharpened the critical normative edge of sociology.

Dewey led a team at Chicago in elaborating and systematizing the insights of William James, among other pragmatists, to produce what James himself recognized as the first “school” of American philosophy. Pragmatism is an approach to philosophy that dispenses with metaphysical assumptions and hierarchies, relying instead on practical experimentation – seeing what works – to arrive at provisional assessments of truth. The focus is on ameliorating problems that arise in experience. Reality is seen as uncertain – probabilistic and contingent. Meanings are relational and emergent, conditioned by particular contexts; moral judgments rest on evaluations of consequences. The method is reflexive, involving the exercise of cooperative and deliberative intelligence to choose among projected alternative paths of social action, while making value and other assumptions as explicit as possible, and continually adjusting plans to incorporate the lessons of experience. Reflexivity extends to the method itself: there is continual inquiry into the very process of inquiry, as well as into the very meanings of the core ideas.

Pragmatism dissolves metaphysical dualisms between subjects and objects, nature and culture, facts and values, the knower and the known, means and ends, self and society. Dewey himself preferred the label “instrumentalism” to “pragmatism,” although by instrumentalism he meant the very opposite of adherence to instrumental reason, since he considered ends and values themselves to require constant reevaluation.

It is impossible even to summarize the range of Dewey's scholarly interests, which encompassed all branches of philosophy, including psychological philosophy. But perhaps his overarching *sociological* research problem involves the simultaneous strengthening of individualism and community. The interrelations of his core sociological concepts describe an arc from micro analysis to macrostructure. *Habits* are not personal properties, but rather interpersonal adaptations to *institutional* arrangements, which are therefore amenable to improvement through the exercise of *deliberative intelligence* exercised by *communities*. The most important such institution is the school, which is therefore optimally organized as a community of active doers (students and teachers alike), integrated as fully as possible into the larger community. *Democracy* (an ideal far from realized in the US) is the process of participation in communities of deliberation. In addressing social problems, the *public* must rely on communities of social scientists for alternative policy formulations, continually evaluated (as the public is perfectly capable of doing) according to their consequences. A public exists as a community of shared interest, containing all those whose lives are touched by the consequences of conjoint action. Reconstructing communities and institutions is necessary to endow practical activity with the expressive quality of aesthetic experience, making normal life processes into living works of art.

Dewey's pragmatic methods and conceptions shaped in fundamental ways not only the Chicago School of Sociology, but the Second, postwar, Chicago School as well. Dewey's influence is explicit, for example, in Becker's (1992) classic argument that the very meaning of art is the cooperative product of art worlds. It is equally evident in the "logic of systemic analysis" and the core concept of "social control" that guides Morris Janowitz's magisterial survey of *The Last Half Century* (1978), as well as Janowitz's prescription for *Institution Building in Urban Education* (1969). But Dewey's influence reaches far beyond Chicago; for example, to Philip Selznick's masterly analysis of the naturalistic ethics, moral persons, moral institutions, and moral communities that make up *The Moral Commonwealth* (1992), and to Jürgen Habermas's *Theory of Communicative Action* (1984).

dialectic

Kevin B. Anderson and Peter Hudis

While its roots go back to the Socratic dialogues, dialectics as social theory begins with G. W. F. Hegel, and extends through Karl Marx to today. With Hegel, the dialectic takes the form of a double negation. Ideas or social forms face negativity from within. If the process deepens, the old idea or form is overthrown. However, such a first or bare negation remains a "formless abstraction" unless it develops some determinateness or specificity (Hegel 1969: 113). This requires going beyond "the first negation as negation in general," to "the second negation, the negation of the negation," which is "concrete, absolute negativity" (p. 116). This

absolute negativity creates a new idea or social form in place of the old. Then the process may resume, with negation growing again within what has been newly created. Some have erroneously described this process as one of thesis antithesis synthesis, an expression Hegel himself never used (Pinkard 2000).

As against such formulaic notions, Hegel's dialectic is deeply rooted in historical and social development, especially the period of the Enlightenment and the French Revolution. These form the backdrop to all of his major works. As against the earlier Socratic dialectic, conflict and dialogue take place between real social forces, as well as between ideas. In the *Phenomenology of Mind* (1807), Hegel traces the development of consciousness and knowledge, from the ancient world to his own time. Successive forms of consciousness are negations of previous ones. For example, in the much discussed dialectic of the master and the slave (literally, lordship and bondage), slaves in the Greco Roman world acquire a more developed form of self consciousness than their masters. This is because they have experienced "absolute negativity," as their personal world has been shattered through the wrenching experience of slavery. This form of consciousness, he writes, has had "that experience melted into its every fiber," leading to a negation of the self (Hegel 1967: 237). But the fact that the slave performs physical labor, while the master enjoys a life of leisure, points in the direction of a second or absolute negation: "Thus precisely in labor where there seemed to be merely some outsider's mind and ideas involved, the bondsman becomes aware, through this rediscovery of himself by himself, of having and being 'a mind of his own'" (p. 239). This leads in turn to a new form of consciousness, Stoicism, which Hegel portrays as an advance. Alluding to the fact that several prominent Stoics were manumitted slaves, however, Hegel also stresses the limitations placed upon human consciousness by a historical period he characterizes as "a time of universal fear and bondage" (p. 245).

Hegel develops a number of other dialectical categories, including identity, difference, and contradiction. He writes that although identity between two forms also includes of necessity some sort of difference, difference also has to

involve some identity, a common set of terms or a framework through which they can express that difference. This could include a common language, for example. The impasse is overcome in a third stage, that of contradiction. Expanding the notion of contradiction from the sphere of ideas to that of social life, Hegel concludes that "everything is inherently contradictory" and that "contradiction is the root of all movement and all vitality" (Hegel 1969: 439).

Hegel's negations and contradictions create ground for a radical form of subjectivity, and he enjoins us to grasp reality "not as substance but as subject as well" (Hegel 1967: 80). He sees a drive for freedom as the overarching theme of human history, although this involves contradiction, even sometimes retrogression. As humanity strives for the universal, for an absolute liberation, internal barriers to its realization repeatedly manifest themselves. Prominent among these are abstract universals, which lack particularity or concreteness. The French Revolution, especially its Jacobin phase, was marked by universals of "pure abstraction," which "lacked a filling and a content," thus lapsing into the "sheer horror of the negative that has nothing positive in it" (p. 608). However, Hegel's system ends not here, but with a series of absolutes in which freedom is concretized, ultimately as the idea "engenders and enjoys itself as absolute mind" (Hegel 1971: 315).

Marx attacks the conservative side of Hegel's social and political philosophy, for example in his 1843 critique of the anti democratic *Philosophy of Right*. At the same time, Marx takes over the dialectic. In his "Critique of the Hegelian Dialectic" in the unpublished 1844 *Manuscripts*, he characterizes Hegel's "outstanding achievement" as "the dialectic of negativity as the moving and creative principle" (Marx, in Fromm 1961: 176). At the same time, Marx distances himself from some aspects of Hegel's idealism: "For Hegel, human life ... is equivalent to self consciousness" (p. 179). Nonetheless, many core principles of Hegel's dialectic – negation of the negation, contradiction, the concrete universal, etc. – are retained in the Marxian dialectic. Nor is idealism rejected *in toto*. A year later, in the "Theses on Feuerbach," Marx writes that many forms

of materialism lack the subjective element, are too contemplative: "Hence, in contradistinction to materialism, the active side was set forth abstractly by idealism" (MECW 5: 3).

With Marx, the notion of contradiction migrates to the sphere of political economy, where social change is driven by class struggle, as he and Engels maintain in *The Communist Manifesto* (1848). Change also occurs when, due to social development, "the material productive forces of society come into contradiction with the existing production relationships," as he wrote in the preface to the *Critique of Political Economy* in 1859 (Marx, in Fromm 1961: 218). Eight years later, in volume 1 of *Capital*, Marx confirms his debt to Hegel by writing of "the Hegelian 'contradiction,' which is the source of all dialectics" (Marx 1976: 744).

In the closing pages of *Capital* Marx uses the Hegelian negation of the negation to frame a discussion of the possible demise of capitalism. In the section on "primitive accumulation" he describes the expropriation of the English peasantry during the agricultural revolution as "the first negation of private property," as the peasants lose their land. Driven into the cities, they become the working class. Capitalism eventually "begets its own negation," however, the revolt of the working class, a class that it has called into existence. "This," Marx concludes, "is the negation of the negation" (pp. 929–30). Elsewhere, for example in the 1873 preface to a new edition of *Capital*, he criticizes "the mystificatory side of the Hegelian dialectic," and writes: "It must be inverted, in order to discover the rational kernel within the mystificatory shell." Nonetheless, he avows himself "a pupil of that mighty thinker" (pp. 102–3). In a letter to Engels of January 16, 1858, Marx expresses the intention to publish an essay on what was "rational" in Hegel's dialectic, this after he reviewed Hegel's *Logic* while in the process of writing the *Grundrisse* (MECW 40: 249). He never did so.

In his *Ludwig Feuerbach and the End of Classical German Philosophy* (1886), Engels develops two schema, which are embraced to this day by more orthodox currents within Marxism. First, Engels writes that Hegel's "system" is conservative, while his "dialectical method" was revolutionary. Second, he divides all of philosophy into "two great camps," idealism and

materialism, with the latter the progressive and revolutionary one (MECW 26: 363, 366). It was in this spirit that Georgi Plekhanov coined the term "dialectical materialism" five years later. Engels also enunciated three "laws" of dialectics: (1) transformation of quantity into quality, (2) interpenetration of opposites, and (3) negation of the negation.

Until the publication of the *1844 Manuscripts* in German in 1932 (a Russian edition appeared in 1927), Marx's concept of dialectic and its relation to that of Hegel was obscured. Some Marxists delved directly into Hegel, however. In his 1914–15 *Notebooks* on Hegel's *Logic*, Lenin returns directly to Hegel's writings, modifying some aspects of the dominant form of dialectical materialism. Concerning the Hegelian notion of consciousness, he writes: "cognition not only reflects the objective world, but creates it" (LCW 38: 212). Lenin also expresses reservations about Engels and Plekhanov, attempting to go beyond the rigid divide between idealism and materialism by attacking not only abstract idealism, but also "vulgar materialism" (LCW 38: 114). He kept these reflections on the dialectic mostly private, however, allowing the very "vulgar materialism" he had critiqued to reign relatively unchallenged in the Soviet Union.

In his *History and Class Consciousness* (1923), Georg Lukács independently recovers the Hegelian dialectic for Marxism. He accuses Engels of confusing "the scientific experiment" with "praxis in the dialectical, philosophical sense" (Lukács 1971: 132). Moreover, he attacks Engels for neglecting the element of subjectivity in his three laws of dialectic: "But he does not even mention the most vital interaction, namely the dialectical relation between subject and object in the historical process." The mere recourse to "fluid" concepts does not solve this problem, Lukács holds (p. 3). He also develops a concept of concrete totality, which allows a move from the factory – "in concentrated form the whole of capitalist society" (p. 90) – to the concept of fetishism or reification. The first to point to commodity fetishism as the core of Marx's critique of capital, Lukács also extended reification from the factory to the entire human condition under capitalism – to the white collar worker, or the scientist, for example. In doing so, he incorporated Weber's

theory of rationalization. Later, Lucien Goldmann (1969) discussed Lukács in relation to sociological methodology.

Frankfurt School member Herbert Marcuse's *Reason and Revolution* (1941) was the first major study of dialectics that appeared after the publication of Marx's *1844 Manuscripts*. Marcuse again places negativity at the center of dialectical thought: "Hegel's philosophy is indeed what the subsequent reaction termed it, a negative philosophy. It is originally motivated by the conviction that the given facts that appear to common sense as the positive index of truth are in reality the negation of truth, so that truth can only be established by their destruction" (Marcuse 1941: 27). Commonsense reason also traps consciousness in the particular and the empirical, blocking it from grasping the universal, and therefore the possibilities for radical change. With dialectical reason, in contrast, "possibility belongs to the very character of reality" (p. 150). In this sense, universals such as human emancipation are actually part of social reality, whereas oppressive social forms are in an ultimate sense unreal and false. Theodor Adorno, also of the Frankfurt School, parts company with Hegel on absolute negativity, taking issue with the concept of totality as well. Adorno, who seeks to expunge the affirmative character from dialectics, goes so far as to link absolute negativity to the Holocaust, this in his *Negative Dialectics* (1966).

Dialectic also marks some of the major treatments of race and colonialism, whether in W. E. B. Du Bois's notion of "double consciousness" in *Souls of Black Folk* (1903), or in Frantz Fanon's dialectic of colonialism and resistance in *Wretched of the Earth* (1961). C. L. R. James in his *Notes on Dialectics* (1948) and especially Raya Dunayevskaya developed a concept of dialectic that eschews abstract universals, elaborating a multiple concept of subjectivity that includes not only the traditional working class, but also blacks, women, and youth. Writing later on as a Marxist humanist, Dunayevskaya makes absolute negativity her point of departure, arguing in *Philosophy and Revolution* (1973) that Hegel's absolutes are not closures, but imbued with absolute negativity. She holds that dialectical thought, if concretized, can impact radical social movements,

helping to give them form and direction: "Philosophy and revolution will then liberate the innate talents of men and women who will become whole" (p. 292). Hegel's dialectic also allows oppositional movements to navigate periods of retrogression as well as progressive ones: "Far from expressing a sequence of never ending progression, the Hegelian dialectic lets retrogression appear as translucent as progression" (Dunayevskaya 2002: 332).

Strong challenges to dialectics have come from scientific positivism, and more recently from poststructuralism. Among others, poststructuralists attack the dialectic as too affirmative, counterposing a Nietzschean notion of absolute difference. These critics have also argued that Hegel's universals swallow up particularity and difference in grand totalities or narratives. Nonetheless, dialectical thought persists, especially through the traditions of Marxism and critical theory.

dialectical materialism

Rob Beamish

The term “dialectical materialism” first appeared in Joseph Dietzgen’s 1887 essay “Excursions of a Socialist into the Domain of Epistemology,” but only became a central concept within Marxism following George Plekhanov’s 1891 essay commemorating the sixtieth anniversary of Hegel’s death and his ensuing efforts to establish a monist view of history. Dialectical materialism became the dominant philosophy of Marxism during the Second International (1889–1917) and the official, formulaic philosophy of communist parties controlled by the USSR during Joseph Stalin’s dictatorship (1929–53).

As the official philosophy of Soviet communism, dialectical materialism brought together a simplistic notion of Hegel’s dialectical method – one that presented change as the result of the internal struggle of opposites in which a thesis gives way to its antithesis and is then followed by a higher synthesis of the original opposites – with Marx and Engels’s materialism to constitute a single, allegedly coherent science that applied to all material, biological, historical, social, and political phenomena. Its supporters claimed that it represented the extension and culmination of “historical materialism” – a term Engels used to designate a formalized philosophy of history based on Marx’s 1859 sketch of his “materialist conception of history.” All change, according to dialectical materialists, resulted from the thesis–antithesis–synthesis dialectic inherent in historical, social, even natural phenomena.

Marx himself never used the terms historical or dialectical materialism and, despite a few expressions of interest, never wrote a

comprehensive philosophical or methodological statement. On the contrary, Marx resisted attempts to convert his materialist conception into a substantive theory of history or totalizing philosophy, although in reading *Anti Duhring* and not rejecting the extension of dialectics to nature he gave Engels’s ideas tacit support. Marx’s own materialism was limited to the labor process and the material conditions of production. As the social relations of production developed, Marx argued, they became, at a certain stage, fetters to the material forces of production, creating the conditions for revolutionary change. In grasping such events, Marx noted, one had to distinguish between the transformation of the material conditions of production and the ideological forms through which people became aware of the conflict and engaged in struggles for change. This guideline focused on the key factors involved in historical change but it was not a rigid or comprehensive theory of history. Marx’s own historical writings demonstrate his appreciation for nuance and detail rather than slavish conformity to a restrictive rubric.

From 1875 until his death, Engels sought to bring greater coherence to his and Marx’s work by developing a philosophy which incorporated Hegel’s dialectics into an eighteenth century inspired materialism. This thrust, contrary to Engels’s and Marx’s original conception that conscious human action, directed against particular social relations, created social change, began to reduce history to one aspect of a general, material, natural evolution, in which social history and nature were subject to the same laws. Engels sought to extend his dialectical conception of nature – itself a questionable theory – to the study of historical development in all branches of science.

Socialism Utopian and Scientific popularized Engels’s claim that one could unify socialist history, idealist philosophy, and mechanistic materialism into a “scientific socialism.” Plekhanov and Lenin gave added intellectual and political credence to the Engelsian inspired materialist philosophy and by 1938 Stalin, the General Secretary of the Communist Party of the Soviet Union (CPSU), affirmed that dialectical materialism was the sole and correct philosophy of Marxism Leninism. Maintaining

that all material phenomena constitute an interconnected whole, the explanations for all historical change were based on “diamat’s” three laws: the transformation of quantity into quality (small quantitative changes lead to abrupt “leaps” of qualitative transformation), the unity of opposites (all phenomena are comprised of opposites which internally “struggle” with each other), and the negation of the negation (in the “struggle of opposites,” one negates the other but it is later negated, leading to a higher, more developed unity). The crude triad of thesis–antithesis–synthesis was diamat’s dialectical conception. As the philosophy of Marxism, dialectical materialism encompassed all aspects of thought, events, and the material world.

Diamat’s major significance was political rather than philosophical or scientific. By maintaining that nature and the material world were primary and thought was derivative, the Marxism of the CPSU rejected human reason and consciousness as key factors in social change and focused exclusively on the dialectics of material reality. Because one could only provide after the fact reconstructions of events through diamat’s three laws, the powerful CPSU became the official interpreter of social events and the guide to further social change.

The critique of dialectical materialism began with Karl Korsch’s *Marxism and Philosophy* and Georg Lukács’s *History and Class Consciousness*. Written independently, both rejected the reduction of history to a materialist dialectic, emphasized the importance of consciousness in history, and stimulated ensuing western Marxists to focus on questions of epistemology, method, and a renewed understanding of Marx’s critique of Hegel. Korsch and Lukács’s focus on the active, mediated engagement of humankind with the natural world through labor was buttressed by the 1932 publication of Marx’s 1844 manuscripts, which, along with the *Grundrisse*, undermined diamat as a credible legacy to Marx’s materialist conception of history.

diaspora

Larissa Remennick

The term “diaspora” originates from the Greek “dia” (over) and “speiro” (to sow). The Greeks understood diaspora as migration and colonization of new lands. In modern parlance the term diaspora usually refers to ethnic groups whose sizable parts have lived outside their country of origin for at least several generations, while maintaining some ties (even if purely symbolic or sentimental) to the historic homeland. The “classic” diasporas in terms of the ancient history of dispersion are Jewish, Armenian, and Greek; the more modern (and also more numerous) diasporas include the African (“Black American”) diaspora resulting from the forced migration of slaves to the Americas, and Irish, Italian, Polish, Chinese, and Indian diasporas resulting from voluntary migrations.

Today the word diaspora is applied to a broad range of migrant populations whose current or historic uprooting was politically or

economically motivated, including political refugees, voluntary migrants, guest workers, expatriates, stable ethnic minorities, and other dispersed groups. Modern political and social thinkers (Sheffer 1986; Safran 1991; Cohen 1997) put forward several criteria for defining ethnic communities as diasporas: a history of dispersal (often forced or motivated by harsh living conditions), myths and memories of a homeland, alienation in the host country, a desire for eventual return (which can be ambivalent, eschatological, or utopian), ongoing support of the homeland, and a collective identity (often including common linguistic and cultural practices). Thus, the German diaspora embraces many generations of *Aussiedler* in Eastern Europe and the former Soviet Union (now making a mass return to a reunified Germany); the Turkish/Kurdish diasporas include at least two generations of guest workers in Germany; and the Filipino diaspora embraces two generations of women and men working in medical and personal services across the western world. New diasporas may appear on the global map as a result of seminal geopolitical events, such as the founding of the State of Israel in 1948, with the following War of Independence and the dispersion of thousands of Palestinian Arabs across the Middle East and western countries. Another recent example of diasporization of a seemingly monolith ethnic entity is an estimated 25 million Russians and other Slavs remaining in the former Soviet successor states as a result of the collapse of the unitary USSR. Another result of the post communist transition is the emigration of about 1.7 million former Soviet Jews who resettled in Israel and in the West (mainly the US, Canada, and Germany), enlarging and invigorating the existing multi ethnic global diaspora of Russian speakers (Remennick 2002).

Some communities that used to have strong diasporic consciousness during the initial two or three generations upon resettlement later assimilated in the receiving societies and lost active ties with their homelands – the examples include Irish and Italian immigrants in North America and Australia. Other diasporas continued to exist for centuries without actual homelands (e.g., 1,500 years of living in *galut* – dispersion – in the case of the Jews), or even without a tangible concept of a homeland, like

Gypsies, also known as Roma people, scattered across Europe and Asia. Indeed, the term diaspora has acquired metaphoric implications and is used as a generic description of displaced people who feel, maintain, invent, or revive a connection with a prior home, real or imagined (Safran 1991). Robin Cohen (1997) has proposed another typology of diasporas in relation to the circumstances of their formation, social contexts, mythologies, and grounds for solidarity. These include: victim diasporas (e.g., refugees from war stricken regions), labor and imperial diasporas (Russians and other Slavs in the former Soviet Union), trade diasporas, cultural diasporas (e.g., today's secular Jews living outside Israel), and global deterritorialized diasporas such as the Roma.

In the late twentieth and early twenty first centuries, the closely entwined processes of mass migration, globalization, and ethnic revival led to a fortification and thriving of transnational diasporas, i.e., global communities with common ethnic origins whose economic, political, and social networks cross the borders of nation states. Diaspora discourse reflects a sense of being part of an ongoing transnational network and includes dispersed people who retain a sense of their uniqueness and an interest in their ancestral homeland. From a sociological standpoint, a diaspora is a social construct founded on group identity, common history, cultural practices, narratives, and dreams, i.e., it includes many virtual elements that nevertheless play a central role in its sustainability. The diasporic mindset is characterized by a sense of living in one place while simultaneously belonging to another, or even to many others, as many contemporary diasporas have multiple centers (e.g., the Russian Jewish diaspora stretching between Israel, North America, and Europe). As a result of the cross fertilization of different traditions, diasporic minorities often develop cultural hybrids between home and host styles of clothing, eating, socializing, and so on that often entail the invention and use of hybrid languages and new vocabularies (e.g., Turkish German, Israeli Russian).

The maintenance of close ties between diasporic centers has been strongly reinforced by new communication and transportation technologies that compress time and space (Castells 1996). Electronic media including television

channels transmitted via cable and satellite across diasporic communities, Internet, and email make the contemporary world increasingly interconnected. Relatively cheap phone calls and air travel make homeland and other branches of the ethnic diaspora easily accessible. Altogether, these vehicles of globalization have dramatically increased the amount and intensity of contacts between co ethnics scattered across the globe. Many members of diasporic communities (expatriates) hold dual citizenship, vote in elections (and sometimes sponsor political parties or activist groups) in both the home and host countries, and participate in their economic life via entrepreneurial activities, sending remittances to families, and so on (Portes et al. 1999).

It can be argued that the majority of today's immigrants display some elements of diasporic consciousness and lifestyle. These are often seen as a challenge to the dominance of the existing nation states, especially if immigrants show a reluctance to assimilate into the main stream and exhibit signs of cultural separatism. Nationalism and nativist sentiments of the hegemonic majority can lead to social and political exclusion of minority groups that are often seen as a threat to national unity and security. The issue of dual or multiple loyalties of diasporic immigrants is often heralded by the conservative and right wing political forces in order to limit their access to citizenship and political participation, and thus to reaffirm their marginal status (e.g., Turkish and Kurdish guest workers in Germany). Anti immigrant tendencies have been further stimulated by the recent upsurge in international terrorism and the ensuing fears of the western nations that feel under attack and in an enhanced need for self defense. Despite this backlash, contemporary global diasporas continue to question the binary mode of identity and loyalty to one nation state and make hyphenated or multitiered identities more common and gradually more acceptable.

difference

Hasmita Ramji

The concept of difference seeks to recognize social diversity. Its growing profile is underpinned by a refiguration of the discourses of "multi," "commonality," and "universalism" in a variety of arenas and forms. Spurred by the postmodern turn, difference has been a key way to problematize universal categories such as "women" and "men." An analysis of gender, race, and other categories of difference points to the multilayered and fractured construction of collective and individual identities. The current interest in difference has in part been because of a belief that as a concept it can illuminate social diversity, but also in part because of its importance in recent recognition claims. Debates here have highlighted the relational underpinnings of diversity. What has attracted attention is "what are significant markers of difference in society" and "how are they made so"? The creation of difference on the basis of race, gender, or class at social, economic, and political levels is crucial, not

as individual characteristics but insofar as they are primary organizing principles of a society which locates and positions groups within opportunity structures. They can unlock how social inequality is created.

The key importance of difference in social existence was highlighted by the deconstructionism of Derrida. Derrida's starting point was his rejection of a common model of knowledge and language, according to which understanding something requires acquaintance with its meaning – ideally a kind of acquaintance in which this meaning is directly present to consciousness. For him, this model involved the “myth of presence,” the supposition that we gain our best understanding of something when it – and it alone – is present to consciousness. He argued that understanding something requires a grasp of the ways in which it relates to other things, and a capacity to recognize it on other occasions and in different contexts – which can never be exhaustively predicted. He coined the term “différance” (*différance* in French, combining the meanings of difference and deferral) in 1968 in response to structuralist theories of language (such as Saussure's structuralist linguistics) to characterize these aspects of understanding, and proposed that *différance* is the phenomenon lying at the heart of language and thought, at work in all meaningful activities in a necessarily elusive and provisional way.

The deconstructionist account of difference argues that opposites are already united; they depend on each other integrally; thus, there is no black without white, etc. Reality is fragmented and saturated with difference, and language is a key way of understanding this fragmentation. Derrida quotes Saussure, who wrote: “in language there are only differences. Even more important: a difference generally implies positive terms between which the difference is set up; but in language there are only differences without positive terms.” Derrida reemphasizes the point that meaning is not in the signifier itself, but that it only exists in a network, in relation to other things. *Différance* comes before being. This throws the idea of “origin,” of true original meaning, into radical question. With the idea of origin in question, Derrida pushes further than Saussure did to claim that there is no absolute identity, nothing that “is itself” by virtue of its being. This can be related to the

current debate in multicultural societies about difference.

The key issue, for many, is not about “difference” per se, but about the question of who defines difference, how different categories of previously conceived universal categories (e.g., women) are represented within the discourses of “difference,” and whether “difference” differentiates laterally or hierarchically. How does difference designate the “other”? Who defines difference? What are the presumed norms from which a group is marked as being different? What is the nature of attributions that are claimed as characterizing a group as different? How are boundaries of difference constituted, maintained, or dissipated? How is difference interiorized in the landscapes of the psyche? How are various groups represented in different discourses of difference? Questions such as these raise a more general problematic about difference as an analytical category. Brah (1996) suggests four ways in which difference may be conceptualized: difference as experience, difference as social relations, difference as subjectivity, and difference as identity.

The concept of difference, then, refers to the variety of ways in which specific discourses of difference are constituted, contested, reproduced, or resignified. Some constructions of difference, such as racism, posit fixed and immutable boundaries between groups signified as inherently different. Other constructions may present difference as relational, contingent, and variable. In other words, difference is not always a marker of hierarchy and oppression. Therefore, it is a contextually contingent question whether difference pans out as inequity, exploitation, and oppression or as egalitarianism, diversity, and democratic forms of political agency. Sandra Harding expresses the shift best in her claim that “there are no gender relations per se, but only gender relations that are constructed by and between classes, races, and cultures” (in Zinn & Dill 1999: 104).

Charles Taylor's (1994) seminal essay discusses difference as a need for (individual) recognition. Increasing cultural diversity and the emergence of multiculturalism leads to potentially contradictory discourses on two levels. On the one hand, the politics of universalism means emphasizing the equal dignity of individuals through the equalization of rights and

entitlements. On the other hand, the modern notion of identity has given rise to a politics of difference, based on recognition of the unique identity of individuals or groups, and their distinctness from everyone else. The politics of universalism require norms of non discrimination which are blind to difference, while the politics of difference require special rights and treatment for certain groups.

The contradictory implications of the recognition of difference that Taylor's work highlights are apparent in recent feminist debates. Many feminists now contend that difference occupies a central stage as the project of women's studies today. If difference has helped revitalize academic feminisms, it has also "upset the apple cart" and introduced new conflicts into feminist studies. For example, in a widely discussed essay, Jane Rowland Martin argues that the current preoccupation with difference is leading feminism into dangerous traps. She fears that it is giving privileged status to a predetermined set of analytical categories (race, ethnicity, and class): "we affirm the existence of nothing but difference" (in Zinn & Dill 1999: 104). Despite the much heralded diversity trend within feminist studies, difference is often reduced to mere pluralism: a "live and let live" approach where principles of relativism generate a long list of diversities which begin with gender, class, and race and continue through a range of social structural as well as personal characteristics.

However, despite seeing the pitfalls in some strands of the difference project, it is still the case that it has prised open discursive closures which asserted the primacy of, say, class or gender over all other axes of differentiation, and it has interrogated the constructions of such privileged signifiers as unified autonomous cores. The political subject of black feminism, for example, decenters the unitary, masculinist subject of Eurocentric discourse, as well as masculinist rendering of "black" as a political color, while seriously disrupting any notion of "woman" as a unitary category.

Conceptualizing the postmodern category of difference, then, remains paramount. Breaking down the barriers of artificial (socially constructed) difference enables the cultural politics of genuine difference based on achieving the principles of justice, freedom, and equality for students occupying varying historical locations

to commence. Giroux organized his understanding of the concept of difference into the categories of conservative, liberal, and radical (Miron 1999). There is a clear relevance to contemporary multicultural politics in western societies. As Giroux observes, conservative ideological forces such as the New Right have invoked the notion of difference to justify social relations of racism, male dominance, and classism. Invoking the supposed natural laws of science and culture, New Right groups have justified these unequal power relations by equating the category of difference with the idea of deviance.

differential treatment of children by sex

Erin Trapp and Jane Menken

In nearly all populations, in the absence of special circumstances, the numbers of males and females are approximately equal; female

advantage in life expectancy balances the slightly higher birth rate of boys. Cultural practices such as infanticide, differential feeding, and provision of health care by sex have, in some populations in the past, led to an unequal ratio of boys to girls and higher mortality and morbidity for girls compared to boys. The last two decades of the twentieth century have, however, seen a rapid convergence in the treatment of children by sex, particularly in the developed world. Despite improvements in the treatment of girls and women, inequalities still exist, most notably in developing countries in Asia and Africa.

FUNDAMENTAL CAUSES AND SOCIAL CONTEXT

In the developed world, waning parental preference for sons has led to a corresponding decline in differential treatment of children by sex. In the past, sex preferences were thought to be the result of the differing value of children of each sex in many cultures, gender roles enforced by traditionally patriarchal societies, and the desire of both parents to have a child whose sex matches their own. The decline in sex preference is thought to be the result of increased gender equality and broad attitudinal shifts across economic and socioeconomic lines. Further, in industrialized countries, children are seen less as an economic asset, but rather an economic burden due to educational and maintenance costs associated with extended adolescence. Therefore, sex preference is a value only the very well off can afford.

Evidence of a decline in differential treatment of children by sex also is abundant in many parts of the developing world, but disparities remain. In parts of Asia, previously observed advantages in male life expectancy have disappeared, and more girls now have access to education. Sex preferences in traditionally patrilocal societies were thought to be immutably embedded in cultural, religious, and behavioral norms. Change has occurred, but only in the context of some combination of fertility decline, female empowerment, and/or economic development, which are necessary, if not sufficient, conditions for improvement in the status of women and girls. Additionally,

since high rates of fertility permit sex preferences to be satisfied easily, fertility transition also corresponds with declining sex preference.

In populations in which male life expectancy exceeds that of females, the differential usually is attributed to cultural practices that lead to discrimination against girls and women and to the low social standing of mothers and their lack of power within the household. Maternal education and well being generally are found to lead to more equal treatment of children, affecting their mortality and morbidity as well as life chances. The higher standing of these mothers in the household is believed to be responsible for these changes. However, some research finds that maternal education has a negligible effect on standing in the household. Further, while mortality rates have equalized in many countries, girls still may experience higher rates of morbidity, including malnutrition, wasting, and/or stunting.

These changes illustrate a shift in our understanding of differential treatment of children, and point to resource dependent causes of differential treatment of family members, including household economics, the cost and efficacy of fertility control, education, and family planning.

MAJOR DIMENSIONS OF REMAINING DISPARITIES IN DEVELOPING COUNTRIES

The existence and effects of differential treatment of children by sex in developing countries can be illustrated in three major areas: mortality, health, and education. Although mortality (expressed in higher than expected ratios of boys to girls, higher mortality rates for girls, and/or a male life expectancy advantage) is the most obvious outcome of differential treatment, human capital effects such as poor health and less education provide evidence of disparities in treatment short of death.

Higher rates of mortality in girls than boys or higher than expected sex ratios favoring males, the clearest demonstration of the preference for sons, are found in some countries in Africa and Asia (most notably China, discussed below). Little documentation of excess female mortality exists outside of these regions.

Further, discerning female disadvantage from mortality data can be difficult because biological factors favor girls, so that female disadvantage may actually be more severe than is immediately apparent.

In the 1970s and 1980s, the median sex ratio of infant mortality in 82 countries in Latin America, Asia, and Africa averaged 118 male deaths to 100 female deaths; the median ratio was much lower in countries in Northern Africa (111), Western Asia (111), and South Central Asia (108), suggesting regional concentrations of female disadvantage. Significant female disadvantage, particularly in infant mortality, also is reported in the Middle Eastern Crescent. Factors such as low income, lack of maternal education, inadequate health care use, and large family size are associated with higher mortality risks in South Asia and affect all children. However, girls' excess mortality risks transcend socioeconomic status, and more recent studies continue to find selective neglect of girls based on certain sex and birth order combinations. For example, those with an older surviving sister may fare less well than those without a sister. Research evaluating programs aimed at reducing child mortality has found that improved maternal education serves to decrease child mortality as well as to equalize child mortality by sex, but sex differentials still exist.

These differentials in mortality are troubling, but fail to capture the human capital consequences of female disadvantage adequately. According to the United Nations (1998), child health disparities, like mortality disparities, by sex are most evident in South Central Asia, and girls in Northern and Western Africa also experience poorer health than boys due to disparate treatment. Girls in three countries in South Central Asia (Bangladesh, northern India, and Pakistan) also are far less likely to receive necessary immunizations than boys, although differential rates of immunization are small in other parts of the world and do not favor either sex. Studies of morbidity typically use malnutrition, wasting, and/or stunting to pinpoint the existence and mechanisms of differential treatment. In Bangladesh, nutritional and educational differences that were previously reported have narrowed after two decades of fertility decline. In India family

composition rather than sex leads to poorer health; both boys and girls with two or more surviving siblings of the same sex are worse off in terms of severe stunting and incomplete immunization. By contrast, evidence exists of better nourishment among girls than boys in six African countries. Although trends are not the same everywhere, the status and treatment of girls is improving in Asia and Africa, but significant room for improvement still exists.

The well known benefits of education in developing countries include declining fertility, improved child mortality and morbidity rates, improved health and status of women, and more educational attainment for subsequent generations. Yet educational opportunities remain limited, and female enrollment in primary school is significantly lower than male enrollment in 39 out of 40 developing countries in one study, which leads to higher mortality risks for girls than boys in these countries. Education differences persist at nearly all levels of socioeconomic status. Adherence to traditional gender roles in many countries contributes to unequal rates of education, with girls benefiting less from educational opportunities in Ghana, for example, and at higher risk of dropping out of school. In Thailand, the belief prevails that schooling is more important for boys than for girls. Thus, while family planning and economic development programs have improved girls' educational prospects in the developing world and their education has increased, traditional attitudes and resource limitations continue to limit opportunities for formal schooling.

AN IN BETWEEN CASE: CHINA

China often is thought of as an "in between" case, straddling the developed and developing worlds. As such, the treatment of children in China provides a stark example of the changes in the treatment of children by sex over time. Cultural preferences for sons led to high rates of female infanticide as late as the 1950s, a practice that waned with the establishment of the People's Republic of China, and a strong government that enacted policies aimed at modifying this and other cultural norms. However, the interruption in excess female mortality during

this period was brief due to famines experienced during the Great Leap Forward, and high rates of “missing” girls have persisted since the establishment of the one child policy in 1979. In this later period, sex selective abortion and adopting out of females are thought to be the means used to create the unequal ratio of boys and girls. The Chinese government modified the one child policy in rural areas in the late 1990s, allowing families with a first born daughter to pay “social compensation fees” in order to have an additional child, partially in response to this demographic imbalance. Yet China still is experiencing a deficit of marriageable girls, which could in turn affect the norms favoring boys and actually increase the value of daughters, lead to practices such as infant betrothal and bride buying, and create a large glut of unmarried men (already underway).

CURRENT EMPHASES, METHODOLOGICAL ISSUES, PROBLEMS, AND FUTURE DIRECTIONS

It is important to note that a high ratio of boys to girls exists in Korea, illustrating the potential for cultural practices to persist even absent government policies like those in China. Therefore, the need to study the differential treatment of children by sex – a complex and expensive process – persists. In particular, data concerning household allocation of resources that illustrate intra household access to nutrition, education, health care, and other resources are time consuming and labor intensive to collect. Proxy measures such as weight and height for age and weight for height (body mass index) are useful for measuring child treatment, absent direct observation, but have their own limitations. Low weight for age is considered an indicator of recent morbidity or poor nutrition, while low height for age is used as a marker of long term or chronic malnutrition. Yet the lack of an international, developing world based set of standards by which to judge the health of children is particularly troubling. Although the World Health Organization has endorsed a nutritional standard for developing countries that classifies a child as malnourished if weight for age is more than two

standard deviations below the median in the standard population from the US, researchers recognize that a standard based on US children may be inappropriate in developing world contexts, particularly given the growing problem of obesity in American children. Further, the biologically different rates at which children of both sexes develop confounds our understanding of their treatment in the home.

Increasingly, we recognize the interdependence of resource and cultural theories of child preference and treatment. Resource dependent explanations in the past suggested that parents would only value daughters for the economic benefit they bring to the household. Yet if this were the case, the dividends accruing from increased budgets or smaller family sizes would merely be used to more aggressively discriminate against daughters. Conversely, declining sex preferences can be expected to occur only if the status of women and their relative importance to their parents increases. Improvements in female nutrition, education, and status provide potentially powerful insight into this hypothesis. They suggest that family planning, microcredit, and other programs aimed at women’s empowerment have a direct effect on incentives to invest in daughters. It is also possible, however, that declining gender inequality in child outcomes reflects not just the role of programs in subsidizing and encouraging investment in daughters, but an increasing awareness of an emerging equalization of sons’ and daughters’ roles in providing support in old age.

Given the success in changing cultural practices that favor boys, development programs that aim to improve the status of girls have taken many shapes. In South Asia, girls’ education has increased, in part through government scholarship programs aimed at girls. Microcredit programs such as those run by Grameen Bank and BRAC in Bangladesh focus specifically on empowering women to participate in market and monetary activities. Employment of women outside the home has become acceptable and opportunities for their employment now exist, especially in the cities.

Unequal treatment of children by sex continues, with particularly egregious examples of female disadvantage found in developing countries in Africa and South Asia. There is room

for optimism, however, as differential valuation and treatment of children by sex is largely disappearing in developed countries. Further, traditional cultural practices in developing countries that favor sons appear to be subject to economic forces and resource development, and programs aimed at family planning, educating women, and providing health care to families appear to reduce differentials by sex in mortality, morbidity, and education.

digital

Luke Goode

To understand the significance of the term “digital,” we must place it alongside its “other” – the term “analogue.” The technical

distinction between these terms is relatively straightforward. Each signifies a different method by which data are captured, transported, processed, distributed, and represented, that is, the means by which they are *mediated*. Whilst analogue media “encode” data using “traces” – such as light burnt on to chemical film stock, or grooves cut into vinyl records – whose patterns have a physical connection to the source data, digital media translate source data into strings of binary computer code lacking that physical connection. Like the written word, digital code is an “arbitrary” signifier. Unlike the written word, however, it is a system comprising just two “symbols” (the “on” and “off” states of an electrical current), making it unreadable by human beings (it first has to be translated back into analogue forms such as light or sound waves) and robust enough to encode many different types of data simultaneously, including words, images, and sounds.

A commonly held assumption is that whilst we may still be in a transition phase, the future will be wholly digital. This is problematic on both technological and cultural grounds. Technologically, mediation is never *purely* digital: when “Cypher” in *The Matrix* (1999) performs the unthinkable feat of reading raw digital code – green cascades of zeros and ones – even he is separated from the data by two layers of representation: light waves represent a numeric system which, in turn, constitutes a cultural representation of the underlying molecular activity occurring within the machine. Culturally, moreover, the digitization of the media scape constitutes a process that contributes to a range of complex tensions and conflicts, rather than a gestalt switch pitting “old” against “new.” Digitization reconfigures some very old social and cultural issues. These include: access and democracy; authorship and intellectual property; and the social status of competing cultural forms. Other controversies linked with digitization may be more recent but also have pre digital genealogies. These include: the globalization of media; the significance of “interactivity”; and the ascendancy of “network” and “decentered” models of social agency within sociological discourse. Digitization, then, is best understood as a tension charged process which spans and provides a stage for various social controversies. As such,

we can avoid the twin pitfalls of *technological determinism*, which treats technological change as an independent cause of broader social changes, and *technological voluntarism*, which overlooks the role technology plays in shaping various choices faced by human societies by assuming that the significance of technology lies only in the uses to which human actors choose to put it.

CHARACTERISTICS OF DIGITAL MEDIA

It can be argued that computers have always functioned as communications media. From their inception, they have both enabled *and* shaped (i.e., mediated) various forms of communication between *humans* (as in computer generated data used in scientific discourse), and between *machines* (as in early military “cybernetics” research on computer guided missiles), as well as between humans *and* machines (as in early artificial intelligence experiments or chess playing computers). But the term “digital media” is usually associated with a cluster of more recent developments: the rise of the PC, multimedia applications, video games, and the popularization of the Internet, to name a few. These developments collectively brought the computer into the purview of everyday popular culture. And, as computers became conduits for images and sounds (and for “entertainment”), and not merely alphanumeric data, they became “media machines.” As digital technology was becoming more “mediatized,” extant media were becoming more digitized. Media industries began to explore new outreach opportunities, including the Internet and proprietary digital broadcasting and telecommunications networks.

Discussions of digital media have revolved especially around two keywords: “interactivity” and “convergence.” In the analogue era, interactivity was limited by various factors. Production and transmission facilities were costly. In the case of broadcast technologies, spectrum was scarce and had to be carefully managed. (Concerns about the power of radio and television as a propaganda tool were also drivers for political regulation of access to the airwaves.) In the digital age, the situation is radically

changed. Streams of digital code can be transmitted in close proximity without causing the interference that would occur with analogue data. They can also be compressed to eliminate redundant data. As such, digitization dramatically increases data flow capacity through channels such as copper telephone wires, radio waves, and fiber optic cables. In principle, the traditional “mass media” imbalance between “transmitters” and “receivers” could be radically reduced (a hope that predates the digital era as in the Brechtian vision of democratic radio and, later, public access television experiments). In reality, most digital broadcasting and broadband Internet networks are structured asymmetrically with greater “download” than “upload” capacity, countering this potential “democratizing” effect.

The singular term “interactivity” is problematic because it conflates diverse possibilities (Manovich 2000), including: forms of conversation, e.g., in chat rooms, via mobile phones or email; distributed or “networked” cultural production, e.g., collaborative “net art”; menu based interactivity and “bespoke” media, e.g., selecting the camera angle for an action replay during televised sport; multilinear navigation that has users determining a sequence of events or data, e.g., video games or hypertext literature; and experiments in reality TV and game shows where audiences can influence the narrative through remote controls or cell phones.

It is important to note that various forms of “interactivity” predate digitization. These include talk radio, TV channel “zapping,” and letters to the editor. Digitization has greatly expanded the scope for interactive practices *and* stimulated an unprecedented level of cultural fascination with “two way” media. John Durham Peters (1999) suggests that contemporary fascination with the interactive potentials of digital media reflects a largely unquestioned tendency in western culture (with ancient, Socratic roots), to treat one way communication as intrinsically inferior to conversation and dialogue.

Convergence is another digital keyword. The fact that all digital technology speaks the universal language of binary code has stimulated debate about the opportunities and dangers of media convergence. Digital data are, in principle, able to traverse and integrate different

sites and devices (such as PCs, handheld computers, mobile phones, digital cameras), whereas different media remained largely discrete in the analogue era. Certainly, there is an unprecedented degree of connectivity between media and communications devices (interacting with TV shows via mobile phones, for example). This is a source of concern for some analysts, conjuring up images of a seamless, seductive, and commercialized web of information and entertainment that leaves little room for independent thought or engagement with the "real world." For others, it is a cause for optimism, promising not only convenience but also better communication flows: being able to switch between a television news report and a "primary source" it cites (such as a government document) may make us better informed, critical, and discerning citizens.

In reality, the "universal language" of digital code has been, and looks set to remain, beset by technological, cultural, and economic obstacles. Technologically, devices are actually programmed using various "higher level" languages rather than binary code. Unless protocols are developed carefully and cooperatively, large scale convergence remains a pipe dream. Corporations often prefer proprietary rather than common standards, in the hope of exerting greater control over markets and future innovations. Culturally, there are still question marks over the value of convergence. Despite unprecedented cross media connectivity, the genres, conventions, locations, and discourses of various media are still characterized by a remarkable degree of separation: common technical standards will not necessarily lead to a melting pot of the diverse media forms that have emerged in the modern era.

A significant tension within digital discourse exists between visions dominated by "high fidelity," on the one hand, and "multiplication," on the other. In the first vision, the radical increase in data capacity afforded by the digitization of media networks is understood primarily as the basis for technically improved "signals": typically, these visions are populated by high definition and wide screen television sets, home theater systems with pristine 3D audio, stunning cinematic realism in video games, virtual reality environments, CGI (computer generated imagery) animations, and

digital special effects. The second vision emphasizes instead the enlarged scope for multiplication and differentiation of media texts: here, the focus tends to be on the dense communication flows of the Internet, digital compression formats such as MP3 audio, the multiplication of channels, interactive services, and customization facilities in digital television, and the proliferation of mobile and increasingly miniaturized media devices including Internet capable mobile phones and wireless handheld computers.

DIGITAL POLITICAL ECONOMY

A significant amount of sociological research and discourse has emerged as a reaction against the optimistic prognoses for the digital age offered by libertarian commentators in the early to mid 1990s. Influential analysts such as Nicholas Negroponte of the MIT Media Lab and his colleagues at *Wired* magazine, alongside various politicians from both the right and center left, argued that digital technology heralded a new economy in which entrepreneurial individuals would triumph over large corporations. The Internet would become an arena of vigorous economic competition, where overheads would be slashed and great advantages would accrue to small electronic "cottage industries" that were sufficiently flexible to adapt quickly to changing market conditions. "Middlemen" such as advertisers and retailers would be swept aside as companies would interact directly with customers through "smart" systems able to automate and personalize transactions. In this account, the "cyberspace" economy would also make geography irrelevant, meaning that developing countries would be able to compete on a level playing field.

Since these optimistic forecasts, we have witnessed the infamous "dot.com" crash of the late 1990s. Financial markets finally lost confidence in the new economy as e-commerce enterprises, propped up by "venture capital," struggled to turn a profit. From the beginning, however, a strong vein of skeptical discourse challenged the claims of the optimistic libertarians. For example, research has highlighted the large vested interests that control the gateways to digital networks such as the Internet, and the

rise of “electronic sweatshops” in the developing world whereby corporations outsource database management, technical support, and other aspects of digital industry to low wage economies. Dan Schiller’s (1999) neo Marxist analysis of “digital capitalism” argues that networks such as the World Wide Web, digital broadcasting, and mobile telecommunications lend themselves to hyperlinked webs of mass consumption, advertising, and marketing, favoring corporate synergies and vested interests rather than independent or small scale producers. Much attention has also been directed toward the global “digital divide,” where unequal access to digital technology is patterned by class and gender, but also by factors such as age, language, culture, and geography. In order to participate in digital networks, both specific and transferable skills have to be acquired by older generations, whilst they are increasingly “second nature” for younger people socialized within technology rich environments. In terms of language and culture, American English is a virtual lingua franca in globalized digital environments; and in terms of geography, even affluent rural populations often have poorer access to digital networks than their urban counterparts.

With the libertarian discourse losing much of its potency, sociological discourses on digital political economy have begun to shift in emphasis, supplementing macro analysis of ownership, control, and the corporatization of digital networks with closer attention to particular sites of tension and contestation. In particular, issues of intellectual property and “digital rights management” have a major currency. The “open source” movement promotes the development and distribution of non copyright software “source code.” Although the movement is characterized by some internal tensions, for the most part it is motivated by something other than simple antipathy toward large corporations such as Microsoft. The movement is also imbued with ideals that can be traced back to the 1960s and 1970s “hacker” counterculture. Here, digital networks are considered to be a matter of public, and not merely private, interest. Society as a whole stands to benefit from new technology, in this account, and technologies develop most efficiently when anybody with the requisite expertise can

contribute to their development. Interestingly, echoes of the early hacker counterculture also resonate in the libertarian discourse mentioned above. *Wired* magazine, for example, has frequently promoted the values of “netizenship” and digital democracy, celebrating the potential role of digital networks as spaces for political debate, polling, and voting. Libertarian groups campaigning against government regulation and censorship of the Internet have drawn heavily on hacker idealism which argues that information must be “set free.”

By comparison with the open source movement, the development of file sharing networks in which copyrighted music, movies, and other media are freely circulated does not readily lend itself to analysis as a “movement.” Instrumental motives, guilty pleasures, and anti corporate values can all play their part in these complex, anonymous, and contradictory spaces. Another fertile area for analysis is the emergence of flexible digital copyright arrangements, such as the “Creative Commons” license, which, unlike the “all rights reserved” arrangements favored by large corporations, allows for compromise between authorial rights and the impulse, prevalent within digital culture, to treat borrowing, sampling, and remixing as an integral aspect of creativity.

Opportunities and constraints in digital creative industries constitute another important aspect of political economy. On the one hand, digitization has made many areas of cultural production more capital intensive, to the detriment of small scale and independent producers. Special effects budgets have tended to spiral upwards, for example, as sophisticated illusions and visual spectacles become increasingly de rigueur for popular films, television shows, and music videos. Some smaller scale digital ventures and creative industries in smaller countries have, though, benefited from the outsourcing of digital graphics and special effects by Hollywood studios and other large media corporations. On the other hand, “second tier” desktop technologies have tended to advance rapidly in terms of sophistication and to decline rapidly in cost. Technical capabilities in music, film, animation, and publishing that were only recently the sole preserve of the few are becoming much more widely accessible. To generalize, the paradox of digitization is that it has

opened the way for burgeoning sites of diverse, creative, and increasingly sophisticated independent cultural production, but opportunities for making a living by it or getting mainstream distribution are fewer and further between.

DIGITAL CREATIVITY

Although “digital culture” is generally associated with novel and rapidly changing practices, we are already witnessing the emergence and consolidation of various digital “disciplines,” each demanding specific skills and approaches, and each giving rise to particular styles, conventions, and genres. Some of the key disciplines include: digital imaging; digital video; animation; 3D graphic design; digital music and sound design; web and interface design. But despite the emergence of these distinct disciplines, many “digital creatives” (and employers) attach great importance to flexible and cross disciplinary skills.

Digital creative and aesthetic tactics are too diverse to summarize here. But we can at least point to some recurring themes that are best understood as a series of tensions rather than a coherent set of principles. The first of these is the tension between immersion and self referentialism. Whilst digital special effects and 3D animation are often geared toward the creation of believable, “hyperreal” fantasy worlds, into which audiences, players, and users can become immersed, temporarily suspending their awareness of their artificiality, many digital cultural forms (such as dance and hip hop music, and various styles of graphic design) actively emphasize their technological provenance through the appearance of phenomena such as dissonant juxtapositions, “noise” (e.g., deliberately “pixelated” images or warped sounds), or computer related tropes (computer related noises or icons, for example). Some digital forms, such as computer games, that switch between sequences of “cinematic realism” and complex “interface” shots featuring level indicators, maps, and so forth combine both perspectives. The importance of the “interface” is, itself, a strong theme in digital culture. The way we interact with digital texts (with a mouse and cursor, for example) can become so culturally familiar as to recede from view. But alongside the desire to

create self effacing and naturalistic interfaces, digital culture is also characterized by frequent experiments with novel types of interface designed to be interesting and stimulating in their own right, rather than simply a conduit for “content.” Examples include the still young discipline of DVD interface design, which often brings elements of gaming into the experience of filmic consumption, many computer games themselves, and experimental website interfaces.

A related tension within visual digital culture revolves around the status of two different elements of creativity: the “pixel” and the “vector.” A digital imaging tradition has emerged that places great store by compositing (merging multiple images in technically proficient, though frequently surrealistic, fashion), texture (shading, shadows, and grain), depth (building images out of multiple “layers”), blending (seamless as opposed to harsh juxtaposition), and visual “noise” (blurs, graininess, and washed out colors, for example). In other words, there is a strong “painterly” tradition in digital imaging. This tradition is caught between the desire to showcase the visual feats of digital technology and the desire to erase its cold, machinic characteristics in favor of something more organic (something mirrored in hip hop and other pop music forms, where scratches, hisses, and so forth are used to add depth or “authenticity”). But a very different tradition has also emerged, based on mathematical “vectors” rather than pixels. “Vector” images are comprised of lines and flat color fills, whereas “bitmap” images, such as digital photographs and complex textures, represent matrices of discrete pixels that each have their own hue, saturation, and brightness values. Because vector images contain fewer data and are scalable (they can be enlarged indefinitely without deteriorating in quality), they lend themselves to more efficient distribution over digital networks such as the Internet and to “repurposing,” that is, they can easily be transferred between different sites, from large billboards to miniature handheld devices. The vector tradition is populated by many different styles including a minimalist and geometric modernism, and brash, cartoonish styles evoking a range of aesthetic influences including pop art, trash culture South Park style, “Jap animation,” and Nintendo. Experiments in

combining the vector and bitmap traditions continue to grow.

Linearity is another important site of tension within digital aesthetics. Early fascination with hypertext literature where readers construct their own pathways through texts, with cyclical loops in digital video and dance music, and with split screen or "windowed" video and computer screens, contributed to a sense that digitization heralded the ascendancy of a non-linear and spatial (as opposed to temporal) media culture. The emergence of devices such as MP3 players or hard disk digital video recorders, which allow for previously linear forms to break down in favor of more archival, random access structures, gives even more credence to this view. This is complicated, however, by the growing popularity of time based digital forms, including filmic sequences in computer games, "Flash" animation on the World Wide Web, and the online phenomenon of "blogging." At most, we can say that digital culture is increasingly "multilinear," rather than "non-linear."

As well as calling into question the concept of beginnings, middles, and ends, digital texts often call into question the idea of the center, traditionally premised on the figure of the "author," "auteur," or "artist" as "originator." Whilst hypertexts have been heralded as exemplars of the poststructuralist "death of the author" thesis, many digital texts appear to take this theme even further in two senses: firstly, the prevalence of "sampling," modifying and remixing, within audiovisual culture, where very basic digital tools allow for the multiplication of pristine and malleable copies of "original" texts, has aroused debates not only around ethics and copyright, but also around the value of originality in the digital age; secondly, digital texts that are designed to be reworked over and over by multiple "authors," such as collaborative "net art" projects, call into question the stability of the text and the notion of origins, authors, and centers. But despite these postmodern characteristics, digital media such as desktop video production suites, "virtual" music studios, and blogging tools multiply the opportunities and sites for individuals to become "authors," "artists," and "auteurs" and, if anything, modern dreams of

authorship and publicity are being nourished rather than diminished in the digital age.

direct action

Kelly Moore

Direct action is a method and a theory of stopping objectionable practices or creating more favorable conditions using immediately available means to obstruct another agent or organization from performing some objectionable practice. It is direct in the sense that users seek an immediate remedy for perceived ills, as opposed to indirect tactics such as electing representatives who promise to provide remedy at some later date. Direct action is usually undertaken by individuals and groups for three reasons: the group believes that the urgency of the problem requires immediate intervention; they believe that any other form of action is

unlikely to solve the problem; they do not have rights to affect targets in any other way. Examples of direct action include vigils, blockades, wildcat strikes, demonstrations, the occupation of buildings and other spaces, the destruction of property, street parties and theater, encampments, and symbolic illegal activities, such as cutting one piece of wire from a fence surrounding a military base to protest war.

The use of strategies to invoke an immediate response to an injustice is not new. For thousands of years people have drawn attention to problems using immediate means, such as "rough music," refusal to work, and attacks on property. The use of the term direct action did not emerge until the late nineteenth century during labor struggles and revolutionary activity in Western Europe, Russia, and the US.

There are two main political theories that have advocated and justified the use of direct action. The first is anarchism. Anarchism is a political philosophy that first emerged during the Enlightenment. It rejects the moral legitimacy and utility of the state, and advocates instead the organization of individuals into self governing groups and federations. It was not until the nineteenth century that writers such as Proudhon, Bakunin, Kropotkin, and Goodwin began fully to develop anarchism as a viable means of governing. In the 1870s Bakunin, a Russian born writer and active participant in the labor movement, first articulated the link between direct action and the achievement of an anarchist political system (Crowder 1991).

The second political theory of direct action is based on the ideas and practices of the Indian political leader, Mohandas K. Gandhi. In the early twentieth century he began to develop a new form of direct action. His method, called Satyagraha or "the way of truth," greatly influenced many other users of direct action in the twentieth and twenty first centuries. Satyagraha was inspired by the writings of Tolstoy and Ruskin, and by Gandhi's Hindu religious beliefs. The core principle of Satyagraha was the appeal to the moral goodness of opponents through the acceptance of the consequences of refusing to participate in unjust systems (Diwakar 1949). Users of Satyagraha were required to make sacrifices, such as fasting, and be prepared and willing to accept the

consequences of their actions, including incarceration or violence. Between 1906 and 1913 Gandhi worked for equal rights for Indians in South Africa using Satyagraha. Thousands of people went to jail for refusing to pay an annual tax levied on former indentured servants, among whom were Indians, and for refusing to carry identification papers that the government required of Indians. He later used this method to help unite Indians and help them gain independence from Great Britain in 1947.

Gandhi's methods inspired religiously based peace and civil rights activists in the US during the 1940s, 1950s, and 1960s. Men who refused to fight in World War II for religious or other moral reasons were given conscientious objector status and assigned to work camps. Some of the members of the camps refused to engage in menial or degrading labor because they believed that they should be able to contribute to ending the war in more significant ways. Many were jailed as a result of their refusal to cooperate with camp authorities. At the end of the war some of those who were jailed and other religiously based peace activists used Satyagraha methods. Among them were the Moscow-San Francisco Peace March in 1961, sailing a boat into nuclear testing zones in the South Pacific, and refusal to cooperate with government mandated civil defense drills. Martin Luther King, Jr., the leader of the civil rights group Southern Christian Leadership Conference, used methods based on Satyagraha in a series of campaigns to end segregation in the Southern United States between 1954 and 1965. These methods included the use of sit ins, Freedom Rides, and mass arrest. In the 1960s and 1970s people involved in ending the war in Vietnam also used Gandhi's methods, but evolved them into more confrontational forms such as destroying draft cards and the occupation of buildings.

The use of direct action took a more carnival like and celebratory form when it was used by anti Vietnam War activists and members of the counterculture in the late 1960s. Taking inspiration from the Bohemian art community in San Francisco, groups such as the Diggers, Yippies, and the San Francisco Mime Troupe used direct action that embodied principles of freedom, playfulness, and joy. Distributing free

food, engaging in street theater, and mocking traditional culture through new styles of dress and living, as well as parodying conventional life, were hallmarks of these groups.

In the late 1960s and early 1970s the use of violent direct action reemerged as the mass based political movements of the previous decade dissolved. Small, armed, underground, clandestine groups such as the Weather Underground and the German Red Army Faction used robbery and murder to try to start a revolution. During this same time a practice known as "monkeywrenching" was used by ecological activists in the Southwestern United States. Rejecting the legal strategy of environmentalists that had developed in the 1960s, ecological activists destroyed equipment used for logging and other activities that they believed were used to harm the environment.

In the contemporary period, anarchist inspired direct action, Satyagraha based passive resistance and moral witnessing, and celebratory direct action can be found in some of the more distinctive forms of earlier periods, and also in more blended forms. Among the most important recent developments is the use of celebratory activities with other kinds of more confrontational direct action. Global justice groups such as the Direct Action Network and People's Global Action, for example, use festivity as well as more serious demonstrations to draw attention to their claims and to build solidarity among themselves. Two other developments that have attracted attention are the growing use of property destruction and violence, especially among radical environmental and animal rights groups, and the role of the police in suppressing direct action.

The earliest sociological study of the use of direct action tactics is Gamson's (1975) study of the relationship between tactics and organizational characteristics and the likelihood that a group wins concessions from targets. Gamson showed that groups that used violence were likely to win new concessions. Gamson's study treated tactics as a set of rationally chosen practices designed to elicit maximum results from opponents. McAdam (1982) and Morris (1986) are now classic studies of the use of direct action in the Civil Rights Movement that further developed Gamson's perspective. Both writers argued that Southern blacks use

marches, demonstrations, sit ins, and Freedom Rides to end segregation because blacks had no other means of affecting the political system. In their view, direct action was primarily a rational tactic chosen for its ability to pressure opponents. Piven and Cloward's *Poor People's Movements* (1979) shared with earlier studies a focus on when direct action works. They argued that the poor were more likely to win new benefits when they used disruptive tactics such as mass demonstrations and the illegal occupation of their targets' offices. Unlike Gamson, McAdam, and Morris, Piven and Cloward saw direct action as a result of high levels of frustration rather than rationally chosen strategies.

In the 1980s and 1990s the effectiveness of direct action continued to be a central focus of most sociological studies of the subject. In the 1990s writers began to examine several new questions, including how and why groups choose to use direct action techniques. Earlier research had focused on the strategic uses of direct action. New research began to examine the role of moral motivations and social identities in shaping choices to use direct action. One important area of research has been in religiously based direct action. In a study of direct action in the US between World War II and 1968, James Tracy (1996) shows that some peace activists were motivated to use civil disobedience because their religious beliefs compelled them to do so. The act of civil disobedience itself, not only its formal political practices, was considered a politically important act because it revealed the power of users' beliefs. Other research has found a similar pattern in studies of secular groups' choices about direct action, such as AIDS activists (Epstein 1991), women (Naples & Desai 2002), and anti nuclear activists (Gamson 1989).

A second important direction of new research on direct action is to explain how the use of specific tactics spreads from one group or place to another. Since the middle of the twentieth century and in the present, activists have used workshops, conferences, and other meetings to teach others how to use specific direct action techniques. They also spread when people who used a tactic in one setting or geographical area make use of it in other settings and areas. There is less evidence that reading about or seeing new tactics, in the absence of face to face interaction

between users and potential adopters, is a major method of diffusion.

The role of repression, in its direct and indirect forms, on the use of direct action is an important new area of research for students of social movements in general and of direct action in particular (Earl 2003). Repression can drive groups to become involved in clandestine and sometimes violent direct action, but it can also force groups to use more routinized or less dramatic direct action.

Direct action has been studied using a variety of research methods. Earlier studies often used survey techniques. Data on many instances in which direct action was used was collected to examine the factors that contributed to its success or failure. Gamson's study is exemplary of this tradition. This method is currently used to study diffusion processes. In this case, researchers count the number of times an action is used in one place or setting at one point in time, and then measure its presence at later times and other places. Another common method for studying direct action is the use of historical records, such as newspapers, personal correspondence, oral history, police reports, and organizational records, to recreate how and why groups chose to use direct action. Tracy's (1996) study is a good example of this method. More recently, researchers have begun to use field observation to gather information about how new tactics are created, and why and how they are used. In these cases, researchers spend time with social movement groups by participating in their meetings and sometimes engaging in direct action with them. This method has the advantage of providing researchers with richer understanding of what direct action means to users and how they decide to use it, but it is less useful for examining effectiveness.

One of the major new initiatives in the study of direct action is the analysis of terrorism. Terrorism is the collective use of violence, especially against people, to intimidate a group or government into granting political demands. Terrorism is not new. It has been used by political actors for many reasons, and usually targeted heads of states or other leaders. More recently, terrorists have used violence against civilians and bystanders and have killed large groups of people at a time. Terrorists are

often conventionally understood to be mentally unbalanced or religious fanatics. Current research on armed, underground, clandestine groups and other users of terror, by contrast, has focused on the conditions under which people become involved in terrorist networks (Zwerman et al. 2000), the role of ideology (including religious ideology), and the failure of governments to respond to the demands of citizens.

disability as a social problem

Anne Waldschmidt

Common sense takes disability as a simple natural fact, but the sociology of disability emphasizes that disability has to be differentiated from impairment. Not every chronic health condition is acknowledged as disability. There are cultures in which the social fact of disability does not exist (Ingstad & Whyte 1995). Disability as a social problem has evolved as a product of the modern welfare state. With the beginning of modernity and, above all, during the period of industrialization, a line was drawn between "the disabled" and other poor and unemployed people. In the course of the twentieth century disability became a horizontal category of social stratification. Even today the ascription process is ambivalent: it includes rights and benefits as well as discrimination and segregation.

Despite many efforts, an internationally accepted definition of disability does not exist (Albrecht et al. 2001). Nonetheless, on the national level classifications that constitute disability as social fact are in operation. Pedagogical diagnostics defining special educational needs are of great significance for establishing individual positions not only in the school system but also in later life. Medical experts serve as gatekeepers to the rehabilitation system and have great influence on disability categories, while legislation and courts serve as agencies to control disability as social problem.

The World Health Organization (WHO) made special efforts to find a universal disability concept on an international level. In 1980 it published the Classification of Impairments, Disabilities, and Handicaps (ICIDH). It was based on a threefold model: "impairment" denoted a defect or disorder in the medical sense, "disability" meant functional limitations, and "handicap" indicated the individual inability to fulfill normal social roles. More than 20 years later, the WHO (2001) revised this classification scheme. The topical Classification of Functioning, Disability, and Health (ICF) uses a multidimensional approach. Its first part,

"functioning and disability," differentiates between "body functions and structures" and "activities and participation." The second part consists of "contextual factors" and contains "environmental" and "personal" factors. The use of the participation concept as well as the reference to environmental factors are important novelties in contrast to the ICIDH. Additionally, terminology was changed. The term disability now comprises medically defined impairments as well as activity limitations and participation restrictions. The term handicap was completely given up. Despite these innovations disability studies scholars criticize the ICF because the social model of disability was only half heartedly implemented.

The epidemiology of disability aims at answering these three basic questions: (1) How many people have a disability? (2) How is disability distributed within the population? (3) What are the major causes? However, these questions are not easily answered. The complexity, relativity, and multidimensionality of bodily, mental, and psychological phenomena make it difficult to establish a clear cut disability definition as a starting point and to agree on operational categories that meet the basic requirements of valid statistics, such as one dimensionality, exclusiveness, and completeness. With regard to methods, there are different possibilities when counting people with disabilities. First, studies focusing on regions, certain groups, subsystems, institutions or programs can be used as sources for estimating the overall number of a disability population. Second, population studies are undertaken, either as a complete recording of the entire population or as representative random surveys. A third means is to officially register all persons who have been certified as having a disability by an official authority. In disability statistics – the history of which can be traced to the early twentieth century – all three ways have been used. Owing to the great methodological problems of counting disabled people, international statistical findings vary to a great extent. The population quotas range from an estimated disability population of 0.2 percent in Qatar (1986) to 8.1 percent officially registered severely disabled people in Germany (2001) and 19.3 percent of the civilian non institutionalized North American population counted in the 2000

census. The main disability causes have changed over time. War injury and accidents at the workplace used to be prevalent, but in industrialized countries chronic diseases amount to over 80 percent of all causes nowadays. Congenital anomalies and perinatal conditions add up to only 4–6 percent. In all countries chronic health problems correlate with lower class, manual work, low level of education, low income, female sex, and old age, as well as ethnic background and migration status.

As with all social categories, disability has its own history which is closely linked to the development of the modern welfare state (Albrecht et al. 2001; Waldschmidt 2006). Until the early modern age the treatment of bodily differences and health conditions was characterized by religion and magic as well as exclusion and charity. The seventeenth century became the epoch of confinement (Foucault 1961). After the Thirty Years War, in the age of absolutism and mercantilism, legitimized by Protestant ethics, a system of workhouses was installed all over Europe. Even the great majority of war invalids did not get any pensions. During the sixteenth and seventeenth centuries, in connection with the beginning of modern science, attempts were made to treat people with impairments. In eighteenth century Paris the first public institutions were founded to educate deaf and blind children. Psychiatry and orthopaedics were new medical disciplines that originated in the age of the Enlightenment.

As a consequence of the working and living conditions in early capitalist society, chronic diseases, impairments, and injuries were widespread in the nineteenth century. Poor health was one of the main causes of deprivation and pauperization. At the end of the century, social insurance systems were established with the consequence that victims of work accidents and invalidity pensioners were entitled to individual social security benefits. A distinction was installed between them and the mass of the poor still relying on private or communal welfare. The nineteenth century was also the period of institutionalization, in which asylums for people with impairments were built at great speed around Europe as well as the US. At the end of the century, against a setting of economic crisis and political restoration, Social Darwinism and degeneration theory gained

influence in public and scientific discourse and former educational institutions gradually changed into nursing and custody homes.

World War I served as a turning point in disability history as impairment suddenly became a mass experience and could no longer be ignored by society and the state. The years after the Great War witnessed the birth of modern rehabilitation policy. The old repressive policy of forcing people into work was now given up in favor of medical therapy, training programs, and legislation that aimed at offering paid employment as a means of social integration. The self help organizations not only of war invalids but also of the civilian disabled that sprang up at that time were important factors in the beginning of recognition of disability as a social problem. On the other hand, radical Social Darwinist attitudes met with more and more public acceptance, due to the financial crisis of the welfare state. The internationally successful eugenic movement led to sterilization policies in many countries. It is estimated that in Germany up to 400,000 people fell victim to compulsory sterilization during National Socialism. In the second phase of the racial hygiene program of Nazi Germany, roughly 275,000 inmates of psychiatric and nursing institutions were systematically murdered (Schmuhl 1992).

After World War II social policy again focused on the problem of war invalidity. Rehabilitation programs were installed during the 1950s and 1960s, which originally aimed at integrating disabled adults into the labor force. Later, they were extended to other groups of people with disabilities and to additional areas of life, such as early childhood, the family, and leisure time. Since the 1970s, the segregation approach has been substituted with the concepts of deinstitutionalization, normalization, and inclusion as a result of efforts by international social movements of disabled people that put ideas like independent living, participation, and civil rights on the disability agenda. Nowadays it is internationally accepted that disabled people form one of the largest minority groups and are entitled to social support.

Since the 1960s, Goffman's (1963) stigma theory has been dominant in the sociology of disability. This microsociological approach views disability as constituted in social interaction. If

a person has a highly visible bodily feature or behaves in a peculiar way and is therefore negatively valued by interaction partners, he or she becomes stigmatized. The stigma will result in social distance, but at the same time interaction rules demand "quasi normalcy" to be maintained. For this reason, "mixed" social situations are typically characterized by feelings of ambivalence and insecurity about how to act. Stigma theory makes it possible to analyze disability not as an inner personal characteristic, but as a product of social relations (Scott 1969).

The labeling approach plays a role in disability discourse as well. In contrast to stigma theory, it emphasizes social power relations and the influence of social control agencies that define norms and sanction individuals who commit violations of these norms. Accordingly, disability can be examined as deviant behavior in a society based on the norms of bodily fitness, functioning at the workplace, individual capacity to self care, and beautiful outer appearance. As secondary deviance, disability is the effect of diagnostics and special treatment. As a result, people marked as disabled find themselves permanently marginalized. The labeling approach is useful for understanding the interactions between the life course of the individual and the rehabilitation system.

From the view of structural functionalism founded by Talcott Parsons, the question is posed whether or not a "disability role" exists (Haber & Smith 1971). Disability is distinguished from both deviant behavior as conscious norm violation and illness as temporary, legitimate exemption from normal role obligations. In contrast, disability is regarded as a form of socially accepted adaptive behavior that allows persons not able to permanently fulfill normal roles to obtain legitimate role exemption. They also obtain opportunities to fulfill restricted social obligations. The "disability role" enables social control agencies to register and acknowledge health problems and to regulate them by offering caring and rehabilitative programs to those concerned. Structural functionalism perceives disability as a socially functional role pattern that makes it possible to integrate people into society who would otherwise have been excluded.

Besides these three main theories, poststructuralist discourse theory inspired by Foucault

(1961) understands disability as an effect of "power/knowledge." Additionally, one can find neo Marxist perspectives (Oliver 1996) focusing on socioeconomic conditions. The social theory of Pierre Bourdieu is used to analyze disability as a combination of structure and agency.

disability sport

Howard L. Nixon II

Disability sport refers to any form of organized physical competition intended specifically for people with disabilities and contrasts with able bodied or mainstream sport, which is organized for people without disabilities. The historical lack of mainstream sports opportunities for people with disabilities is one of the important rationales for the development of disability sport. People are considered disabled, e.g., regarding physical mobility, sight, hearing, or mental functioning, when they have biomedical conditions or impairments that limit their ability to use certain skills, carry out certain tasks, or participate in certain activities or roles. Although their overall sports participation rates remain relatively low, people with disabilities have become increasingly involved in the pursuit of sport at various levels over the past few decades.

Disability sport has arisen and grown in popularity in recent decades, as people with disabilities have enhanced their rights, status, and perceptions of opportunity in society. Disabled people were relatively invisible in the United States until the 1970s, when federal law mandated the public education of American children and youths with disabilities in appropriate settings. What was known about people with disabilities was typically based on myth and stigma, but increasing public education, advocacy, and research in recent decades has resulted in a more accurate understanding of people with disabilities.

The scholarly study of social and cultural aspects of disability sport is relatively new. The first comprehensive collection of scholarly work in this area, *Sport and Disabled Athletes*, was edited by Sherrill in 1986, and the first comprehensive text on disability sport, *Disability and Sport*, by DePauw and Gavron, was published

in 1995. Two major scholarly journals publishing studies of disability sport have been the *Adapted Physical Activity Quarterly* and *Sociology of Sport Journal*. The Disability in Sport Program of the Center for the Study of Sport in Society at Northeastern University is an important source of education, advocacy, and research concerning disability sport and athletes with disabilities.

Disability and mainstream sport opportunities for people with disabilities may vary along a number of structural dimensions, including inclusiveness of eligibility, the amount of segregation or integration of disabled athletes and able bodied athletes or of athletes with different types or degrees of disability within a sport, disability adaptation, disability classifications, level of competitive intensity, and whether or not there is direct competition between disabled and able bodied athletes. Disability sports are divided into different classifications, according to the functional ability or medical or vision status of the participants with disabilities. There are also cases of disability sport divisions within mainstream sports, such as the Boston Marathon, but they are relatively few.

Two prominent examples of disability sport are the Special Olympics and the Paralympics. The controlled competition philosophy of the Special Olympics is to treat everyone as a winner, and the Special Olympics is open to everyone with an intellectual disability who is 8 years old or older. The Special Olympics training and competition program involves over 1 million children and adult athletes from around the world, and it has provided international competitive experiences through its World Games since 1968. The International Paralympic Committee organizes elite sports events for athletes with a number of different types of impairments, including spinal cord injury, amputee, intellectual and visual impairment, cerebral palsy, and other motor impairments. The Paralympics developed from a modest start in 1948 in England, was first staged as an Olympic style competition in Rome in 1960, and has developed into one of the largest sports competitions in the world, drawing nearly 4,000 athletes with physical, visual, or mental disabilities from 140 countries in 19 events to the 2004 Games in Athens, Greece. The International Paralympic Committee (IPC) and International Olympic

Committee (IOC) signed an agreement in 2001 for their respective Games to appear alongside each other in the future. The 1996 Summer Paralympics were the first such Games to get mass media sponsorship. Paralympic sports range from archery to volleyball and winter sports such as Alpine and Nordic skiing.

Despite groundbreaking legislation, such as the Americans with Disabilities Act of 1990, people with disabilities in the US and other countries continue to face barriers to equal rights and full participation in society. These challenges help explain at least part of the appeal of disability sport to people with disabilities and the value of disability sport in reshaping public attitudes and treatment of people with disabilities. Thus, a major focus of some recent studies of disability sport is the empowerment potential of sport to enable people with disabilities to overcome stereotypes, stigma, prejudice, and discrimination based on conceptions of disability as *inability*. That is, disability sport is seen as a means of enhancing a sense of social identity, status, and power as well as personal competence or self efficacy. A shift from a rehabilitative philosophy in physical activity to an emphasis on empowerment in disability sport over the past few decades reflects the increasing seriousness of disabled athletes. Although there have been problems operationalizing the empowerment idea, it has been listed as a priority research topic of the International Paralympic Sport Science Committee.

For many disability sport scholars, sport classification is a central issue. Its main purpose is to classify sports and assign participants in ways that make competition fair, so that the outcome of events depends on factors such as ability, skill, training, and motivation rather than the nature or extent of disability. It is intended to avoid, for example, pitting athletes with amputations against those with cerebral palsy or who are blind in the same event. Official classifiers, who have the responsibility of assessing the functional ability or medical status of athletes and assigning them to particular sports classes or events, are important agents of social control in disability sport, and a study of disability swimming showed that classifiers generally maintained the social order of the sport and kept competition fair.

The dominant theoretical perspective in the sociological study of disability sport, especially regarding sport socialization, has been structural functionalism, although its dominance has been challenged in recent years by various forms of critical and feminist theory and sociocultural discourses on the body. We get a sense of the variety of disability and sport topics addressed by sport sociologists from a 2001 special issue of the *Sociology of Sport Journal* on "the sociology of ability and disability in physical activity." It focused on topics such as women's management of their physical disabilities through sport and physical activity; media representations of disabled sport and athletes; the politics of inclusion in sport of university students with mobility impairments; disability, sport, and the body in China; and stereotypes of gender and disability in elite disability sport.

A number of recent critical media analyses have focused on social marginality, inequality, and bias in print and electronic media coverage of disability sport. Some studies have critically pointed to the common "supercrip" image portraying disabled athletes as heroic within the boundaries of the world of disability, which some disabled athletes have strenuously resisted in an effort to portray themselves as a part of the larger society. Critics of this media image also argue that it implies that people with disabilities are only worthy of respect in society if they have overcome seemingly insurmountable odds to "conquer" their disability. In addition, some have observed a "hierarchy of acceptability" in the mass media that has resulted in more attention for athletes with disabilities who looked more like able bodied or "normal" athletes or for athletes with disabilities that were acquired rather than congenital or seemed more "correctable." A common finding in this type of research has been less attention to female than male disabled athletes.

With the rapid development of elite disability sport, topics concerning integration and inclusion have been among the most debated about disability sport. Major questions have focused on who should be eligible to compete, against whom, and in what sports. More specifically, some have argued in favor of having able bodied people participate in certain disability sports, as a means of increasing their sensitivity to the needs

of people with disabilities, but others have strenuously opposed such "reverse integration" because they believed it reflected an outdated view of disability sport as rehabilitation rather than competitive sport, would reduce competitive opportunities for people with disabilities, and was at odds with the preferences of disabled athletes, who opposed the inclusion of able bodied athletes in their sports. A potentially useful concept in this context is appropriate integration, which involves matching the abilities and motivation of participants with the structural parameters of a sport. Today, many disability sport advocates and scholars are focusing attention on the recognition and support from mainstream sport organizers needed to be able to include more disability sport divisions in mainstream sports events, from the interscholastic level to the Olympics. Scholars need to learn more about the kinds of sports opportunities pursued by people with disabilities, how they are socialized into, in, and through sport, and how the nature of their integration or segregation in sport influences how they and others with disabilities are integrated into society.

Various methodological approaches have been used in sociological research on disability sport and athletes with disabilities. Relatively little systematic empirical research has been done on the sociology of disability sport. Most of the published studies have relied on qualitative or interpretive approaches, such as participant observation, semi structured or unstructured interviews, and content analysis. The number of participants in these studies have been small, with few having over 30 participants. Thus, a number of these studies could be viewed as exploratory.

With the sociological study of disability sport still in its relative infancy, it is not surprising to find a limited amount of empirical research on disability sport, small sample sizes, and few attempts to replicate studies of specific research topics in this area. Future studies of disability sport are likely to rely heavily on critical perspectives and qualitative methods to pursue new ways of looking at disability, the disabled body, and sport, but large scale surveys, guided by more structural perspectives, are also needed. There is much to learn about the culture, organization, governance, commercialization, and

stratification of disability sport; power relations in and affecting disability sport; disability sport socialization and the social identity, status, and experiences of disabled athletes; the impact of the mass media on disability sport, sports experiences of athletes with disabilities, and perceptions of people with disabilities in general; the integrating influence of sport for people with disabilities; and the relationship of disability sport to mainstream sport and the mainstream of society.

disasters

Hilary Silver

Disasters are sudden, unexpected, localized, rare, and acute events that disrupt the environment and social structure, and inflict substantial harm on individuals, groups, and property. They differ from accidents in the greater scale of their individual and collective impacts. Roughly speaking, such catastrophes entail over a hundred deaths in a short period of time.

The sociological study of disasters dates to the late 1940s, when governments sought to comprehend the damage of World War II and started planning for potential nuclear holocaust. First at the National Opinion Research Center (NORC) and later at the Disaster Research Center at Ohio State, sociologists drew upon experience from natural disasters. Over time, disaster scholars borrowed from other subfields in the discipline.

The number of disasters has increased, especially since 1990. Ulrich Beck argues that, unlike modern industrial society based upon the distribution of goods, contemporary risk society is founded upon the distribution of dangers. Science and industry are creating more and deadlier risks with impacts less limited in time and space. These physical risks are situated in social systems that aim to control them. However, many technically risky activities require society to depend upon and trust inaccessible, unaccountable, and unintelligible organizations and institutions. Scientific realism should be tempered with the viewpoints of ordinary citizens who may be affected by oversights in rational systems. This means modernization must become “reflexive.” These observations hold for most disasters, regardless of cause. For some purposes, however, sociologists classify disasters by type, often distinguishing between natural and technological disasters. Increasingly,

political disasters have become a third category of study.

Natural disasters are often viewed as “acts of God.” Yet numerous studies of the social impacts of floods, earthquakes, tornadoes, hurricanes, wildfires, eruptions, famines, plagues, and pandemics demonstrate the importance of social structure and cultural context in determining the incidence and outcomes of these events. For example, Mike Davis’s *Ecology of Fear* (1998) argues that profit driven, sprawling urban development in Southern California without regard to its fragile ecosystem causes any one natural disaster in the area to set off others. John Barry’s *Rising Tide* (1997) similarly finds that engineering ineptitude and greed of planters and bankers helped cause the great Mississippi flood of 1927. Similarly, Eric Klinenberg’s “social autopsy” of the 1995 Chicago *Heat Wave* (2003) demonstrates the contributions of selective government preparations, privatized service delivery, and biased coverage of the local media to the death of over 700 people.

Technological disasters are often attributed to human error or worse. Thus, some say, they produce more enduring and debilitating impacts – anger, fear, uncertainty, stress, and distrust – than natural ones. Sociologists have studied explosions, dam breaks, blackouts, oil and toxic spills, fires, genetic mishaps, mad cow disease, Y2K and computer viruses, and accidents at nuclear power plants, chemical plants, and NASA. Such studies refute the usual risk management response based upon “high reliability theory” which maintains that decentralized authority and built in redundancy enhance reliability and safety.

Vaughan’s study of organizational deviance in *The Challenger Launch Decision* (1996) identifies risk taking, ignored warnings, and deception trickling down from the top to the bottom of the space agency. In uncertain environments such as agency competition for scarce federal funds, formal organizations like NASA develop technical cultures and bureaucratic and political accountability systems that tolerate mistakes, misconduct, and risk taking for the sake of ultimate goals. Social constructions of reality unnecessarily produce disastrous accidents.

However, Charles Perrow, in *Normal Accidents* (1999), says social constructionist

explanations miss the power structure that devises such risky complex systems in the first place. "Normal accidents" are inevitable in complex (vs. linear) interaction systems with tightly coupled, interdependent components. In such systems, failures multiply and spread in unexpected ways, making rational planning impossible and high reliability approaches even more damaging. Yet such catastrophes, Perrow points out, are rare because they have no one cause. Disasters require a "negative synergy" of combined conditions, from lack of warning to concentrated population.

Webb (2002) notes that sociologists currently know far less about political disasters – riots, revolutions, and terrorism – than about natural and technological ones. Man made disasters are not accidental, but deliberate. Terrorist disasters are designed to inflict as much death and damage as possible on symbolic victims. The sheer arbitrariness of their targets diffuses fear among entire populations, thereby magnifying the disastrous effects. After the World Trade Center catastrophe, the study of urban disasters became a growth industry. Savitch (2001) identifies three factors – social breakdown; resource mobilization; and global target proneness (including international media centrality) – that are responsible for which cities around the world are more vulnerable to terrorist disasters. Nancy Foner's collection *Wounded City* (2005) shows there was also variation in the impact of 9/11 among New York City communities. Vale and Campanella (2005) analyze the recovery of a wide range of cities throughout the world. They identify a dozen "axioms of resilience," including narratives to interpret and remember the disaster and the importance of surviving property.

Whether natural or man made, disasters have many similar social consequences. The majority of property losses in urban disasters are due to housing damage. Disaster victims disproportionately consist of the aged, the isolated, and the destitute. African Americans and renters are also over represented.

Disasters tend to have a life cycle, says Drabek (1986), progressing through the stages of preparedness, response, recovery, and mitigation. Most scholarly attention has focused on the second. There are widespread myths that, in an emergency, the population will panic and loot, and first responders will abandon their

posts, requiring a paramilitary, command and control structure to impose order. In fact, during the immediate crisis, studies find that people become more cohesive and converge upon the disaster site, offering help. This "therapeutic community" reaction is more typical in the wake of disaster than conflict, or what Freudenberg (1997) calls "corrosive community." Established, expanding, and emergent organizations, Dynes (1970) argues, together provide flexible and diverse responses.

Once disasters recede into the past, the political incentives to prepare for future contingencies diminish. Mitigation usually entails tradeoffs between profit and safety, security and civil liberties. Private insurers may withdraw from communities hit by natural catastrophes, forcing the federal government to become the insurer of last resort. Policy continues to be disaster driven, offering short term compensation rather than long term prevention strategies.

During the recovery stage, there is an opportunity for social change, but it may not be seized. In some cases, community corrosion ensues, prolonged by endless litigation, uncertainty about long term health, organizational competition, and "recreancy" (perceived governmental failure). As Kai Erikson's *Everything in Its Path* (1978), a classic study of the Buffalo Creek flood, concludes, the survivors of disasters suffer from both individual and collective trauma. Disasters disrupt the social bonds, networks of relations, and common patterns of life that would otherwise support people. Thus, sociologists are now studying disaster memorials and the social construction of collective memory. Commemorations cement social bonds after a common tragedy.

disciplinary society

Susanne Krasmann

Talk about the disciplinary society is frequently linked to the idea of a society of total surveillance and adjustment. However, in his seemingly most popular and at the same time highly complex book *Discipline and Punish*, Foucault (1977) describes the disciplinary society not as a social reality but as a *program* of disciplining individuals. Thus it was the “dream” of the old authoritarian police to establish a society organized along military lines, functioning like the cogs of a machine. This aspiration did indeed have historical configurations: in the “social disciplining” (Gerhard Oestreich) of an administrative and regulatory organization of society, already being instituted in early modern times, aimed at producing obedient individuals; and in an unprecedented process of rationalization of power, provoking Weber to speak of the “iron cage” of bureaucratic rulership in modern societies. Foucault’s intention, however, is not to point out historical continuities and general principles shaping society, like “capitalism,” “modernity,” or “rationalization.” Rather, the disciplinary society is the effect of micro mechanisms of power and has itself to be distinguished from a type of power that donated the name: *discipline* does not refer to an institution, but designates a technology of power. It is unacquainted with a ruling center as it unfolds beyond the state. It is a mechanism of power localized amid society: the “productivity of the norm” (Macherey 1991), operating in occidental

societies since the seventeenth century. It thus differs from the juridical sovereign power of the *ancien régime* legitimized by the implementation and enforcement of law.

The topic of *Discipline and Punish* is the self-conception of modern societies, referring to ideals like humanity, civilization, and progress. Foucault exemplifies his critique of this self-conception, focusing on the transition to a new practice of confinement. The “birth of the prison” marks the new self-conception of the modern constitutional state dissociating itself from cruel practices such as the exhibition of sovereign power through the spectacle of public punishment. However, modern societies cannot count as better societies, as they are not free from power and repression. They operate with different mechanisms of power. This is the central argument in *Discipline and Punish*. The repeatedly evoked process of humanization turns out to be a shift to a new regime of power, a new economy of power, making the prison appear not only as a practice of confinement, punishment, and treatment, but particularly as a more effective and economically useful practice compared to corporeal punishment.

Two kinds of shift are significant for the transition to the disciplinary society, which Foucault exemplifies in his focus on the figure of the delinquent: the mechanisms of power shift from the body to the “soul” and from law to the norm. The practice of the prison is in no way unphysical, as confinement also is a physically noticeable restriction of freedom. Yet, while the offender in the *ancien régime* is punished conspicuously, in order to restore the king’s law, his power, disciplinary power is interested in the individual. Thus, rather than the body of the offender, the “soul” of the delinquent; rather than the real, the possible act; rather than the behavior, the character of the person takes center stage. With the emergence of the prison the delinquent has been born as an individual to know. Psychologists and psychiatrists, and later on social workers, are concerned with the motives and the biography of this person in order to reform his or her personality. The delinquent becomes a category describable in generalized terms, and that allows for subsuming the discrete offender like a species. The prison makes possible the establishment of criminology as a science – and as a practice of surveillance and control.

This is what designates discipline: a regime of knowledge and practices of power crystallizing in prison, but not reducible to this institution. Rather, prison is exemplary for the architectural model of the Panopticon that renders the inmates observable at any time from the tower in the middle of the building. Devised by the English lawyer Jeremy Bentham in the eighteenth century, it stands for the program of producing compliant individuals controlling themselves in a state of permanent visibility. In the disciplinary society this mechanism of normalization prevails in the most varied sectors of society and institutions producing their respective "useful" individuals: school, family, psychiatry, and the military impose similar mechanisms to fabricate pupils, soldiers, and workers, with body and soul suitable for the conditions of production. Thus, discipline is effective precisely in that it is a program, rather than social reality; in that it does not come upon individuals already disciplined. Rather, technologies of education, healing, confinement, and correction have to be employed again and again finally to generate discipline. As a result, social norms are constantly being produced and reproduced, regulating the action and the way of life of individuals, their work, their nutrition, their sexuality, their relationships. In this respect Foucault identifies the regime of the welfare state as a prototype of the disciplinary society. Expertise cultures develop the most varied social fields driven by the idea that society can intentionally be created and controlled.

In a double sense disciplinary power is productive. It appears to reproduce itself independently, and, differently from sovereign power, it does not simply prohibit, impede, force, and repress, but constitutes domains of reality and thereby individuals as objects of control and surveillance. At the same time, disciplinary power in no way abstains from law, but it no longer asserts itself primarily by law, as the sovereign power does. The norm now is a principle that predominates over law. It enables and designates the law in modern societies; it operates like a motor and serves as an indication for the production of laws that regulate the functioning of the social system. Norms do not emerge from a sovereign will, but from social processes. Thus, rather than resulting from contracts or from a legislator, they form part of social

systems that they are at the same time establishing. Norms are inherently relational. They establish social relations by being designated in relation to the demands of an environment and, due to their generality, by implementing an anonymous principle of comparability (Ewald 1990): an individual might mark itself only in difference to others. Subjectivation is impossible without objectification. The individual therefore is an inherently social product, certainly without being determined socially. However, subjectivity cannot be conceived of without social experience, and the notion of an autonomous individual self determined by free acts of will therefore is invalid. Norms imply forms of judgment and of communication and they display mechanisms of reproduction and differentiation. Serving as a normative measure, they demand comparison, while the empirical comparison creates new standards. Prescriptive normalization, the alignment of the individual according to model like norms, and descriptive, statistically generated normalization that takes the empirical reality itself as a norm, work together hand in hand.

Disciplinary techniques do not seek to operate through violence. They concentrate on the human body in two ways. External practices on the one hand shape, for example, the body of the soldier in military drill, while normalization power on the other hand operates implicitly. Both forms of power conjoin, with the result that a disciplined attitude is at the same time also a manifestation of moral conduct. Disciplinary power nevertheless does not only act on already existing bodies, but it also constitutes these: the body of the sick person holding certain symptoms; the body of sexual desire inhabited by drives and articulating longings; or the female and the male body familiar with their respective sensitivities. This fabrication of bodies is always due to the access of knowledge based technologies of power, involving specific notions of the human being (Foucault 1972; Butler 1993).

If Foucault's analysis has been accused of having a problematic normative reservation (for example, by Nancy Fraser, Jürgen Habermas, Axel Honneth, Charles Taylor, and Michael Walzer), it is precisely here that it can be seen how appropriately such critics judged, in the best sense: Foucault scrutinizes the norm itself

on how it accomplishes, asserts itself, and produces forms of knowledge, perceptions, and worldviews. The norm does not form the prerequisite but the vanishing point of his critique, focusing on the ways of subjectivation of people and the adjustment of the individual as a part of society. Elaborating a normative foundation would mean to close one's mind to understanding and appreciating that changing regimes might result in forms of domination that only recently have worked as forms of resistance. How power is being composed and how it is functioning have to be found out.

In the disciplinary society, man and his body become the objects of knowledge and of economic utility. In this respect, disciplinary power discovers life as a resource, an embodiment of energy, whose productivity might be increased. The "power over life" initially concentrates on "disciplining the individual body," subsequently also on "regulating the population." One precondition for this is an abstract knowledge of society rendered possible by procedures going back to the cameralistics of the seventeenth century, the establishing sciences of political administration, and the social statistics of the nineteenth century. In view of statistics and probability calculation, disease, crime, and accidents no longer appear as individual pathologies, fate, or chance, but as "social facts" (Durkheim). Understanding their social regularity allows for dealing with them as issues of demographic policy and social hygiene, in order to develop the mechanisms of security accordingly. The delinquent thus appears as a danger to society and fighting crime becomes an issue of *social defense* (Pasquino 1991; Foucault 2004).

Sovereign power only knows the right "to kill and to let live" (killing the offender while not being interested further in the individual), whereas "to make live and to let die" becomes the emblem of a "bio power" (Foucault 1979), designated as much by the aspiration of fostering life as by the dread of killing publicly. This dread appears nowadays, for example, in discussions about euthanasia and in the practice of capital punishment, technically perfected to make it unspectacular and to avoid pain to the delinquent and render invisible the responsibility of executioners. However, such practices reveal that bio power is based on discretion

and reaches decisions not only about valuable life to be enhanced, but also about degraded, hostile life to be annihilated. Killing forms a disaccord with a power devoted to the productivity of life. This power does not exclude killing. In the name of bio power racism not only is a matter of ideological attitude, but also to be rationalized as population policy, for the protection of society.

Foucault implicitly conceived of the disciplinary society as situated within the borders of the (nation)state. Therefore, the noticeable transformation of the modern state (the neoliberal retreat of the welfare state and the "responsibilization" of individuals for the risks of their existence; the inter- and transnationalization of politics; the armament of the state in the name of home security) cannot be problematized by the categories of *Discipline and Punish*. The disciplinary society, however, embodies precisely the type of power that has not lost its currency: discipline, as a positive technique of power, links domination with morality and freedom with subjection. It operates through the suggestion that it is more prudent to dominate oneself than to be dominated, more virtuous to work of one's own free will than to be forced to work, etc. The self control that modern societies demand from individuals implies this double sense already in the concept: the control of the self by the self *and* through determination by others (Valverde 1996). More freedom can thus be misleading and sometimes only indicates a *shift*: a policy of economic deregulation, for example, may be accompanied by bureaucratic modes of control; the performance of individuals released from regulated paternalism in order to conceive of themselves as entrepreneurs will still be subjected to permanent evaluation and thus control. The flexibilized individual is faced with a new regime.

The panoptic principle – paradigmatic for the disciplinary society – has diversified in the age of media, automatic techniques of control, and practices of optimization in working life. The disciplinary society, operating with prescriptive norms, dissolves with the contingency of norms oriented on average values and constantly creating variable possibilities; the techniques of (self-) disciplining, however, do not disappear.

discourse

Martin M. Jacobsen

The primary definition of discourse denotes a method of communication that conforms to particular structural and ethnographic norms and marks a particular social group by providing a means of solidarity for its members and a means of differentiating that group from other groups. It is, perhaps, more accurate and useful

to regard this concept in the plural, that is, as *discourses*, thus encompassing its capacity not only for marking boundaries for the group and against other groups (using linguistic borders philosopher Kenneth Burke called “terministic screens,” which are essentially the points at which one discourse becomes distinct from another), but also as a method in many disciplines.

Discourses come to be in different ways. One discourse may be chosen by the group to specifically designate its identity and membership (called a discourse community and often requiring a highly specialized lexicon and superstructure, perhaps professional training to gain membership, e.g., sociology). Another discourse also may be imposed or identified by others as a means of stratification or “othering” a group, such as a pidgin language or other “non standard language variety,” leading to the recent pejorative overtones in terms like dialect or vernacular. Yet other discourses develop more natively, determined by cultural, technological, or other factors (such as primary orality or computerese).

A second definition of discourse lies within the field of linguistics and underlies the metatheory discourse analysis, a term brought into use in 1952 through an article of the same name by linguist Zellig Harris. This definition, which to some degree defines and therefore precedes the others, holds that discourse describes extra grammatical linguistic units, variably described as speech acts, speech events, exchanges, utterances, conversations, adjacency pairs, or combinations of these and other language chunks. The basic distinction ascribed to this definition is its extra sentential status. Thus, to the linguist, discourse is often referred to as the study of language above the sentence. Each of the six methodological approaches to discourse analysis posits its own extra sentential point of departure; thus, determining a central minimal unit for discourse analysis as a discipline remains problematic.

Interestingly, discourse analysis as an academic discipline provides a well developed example of the concept of discourse. The major methodological stances of discourse analysis restate sociological, anthropological, linguistic, or other related disciplinary approaches and bring them under the aegis of discourse analysis,

which unifies the disparate specialties by reframing them within the terministic screen created by and for discourse analysis. An analysis of how this happens may serve to illustrate the ways in which discourse analysis is a discourse community.

An excellent example of how discourse analysis is a discourse in and of itself rests in the formulation of the discipline by Deborah Schifffrin in her influential 1994 textbook, *Approaches to Discourse*. The book defines and elaborates the terministic screen identifying discourse analysis as a discourse community. Schifffrin characterizes discourse analysis as a metatheory that creates a subdiscipline of linguistics (i.e., a discourse community) by unifying six methodological approaches toward the sociolinguistic uses of language. While these approaches do not always agree on what constitutes a minimal unit, with some of them regarding multiple configurations of linguistic data as valid, they do share a focus on the extra grammatical structures of language. That is, the vast majority of linguistic data in discourse analysis come in units larger than a sentence. Smaller elements are sometimes analyzed for their use in social behavior, but their grammatical status is usually regarded as secondary to their social function, which means that these units are being studied for extra grammatical reasons.

Schifffrin further characterizes discourse analysis as comprising two theoretical perspectives: formalist and functionalist. The formalist perspective views discourse in terms of its linguistic structures and sequences; the functionalist perspective views discourse in terms of the way language is used for social reasons. These two perspectives (elaborated in Table 1) extend

Noam Chomsky's concepts of grammatical (formalist) and communicative (functionalist) competence, thus placing discourse analysis in the discipline of linguistics. Of course, each paradigm contextualizes the other: functionalism needs structuralist data; formalism, for all its claims to be based on the code alone, ultimately serves extra formalist purposes. These two paradigms exhibit the foundational approach taken by discourse analysis: they are terms in the terministic screen.

The formalist and functionalist paradigms, then, provide a framework for the six methodological approaches to discourse analysis (see Table 2), defining them based on methodological principles and unifying them under the discipline of linguistics, which is not where most of the approaches originated. Table 2 abstracts the starting points, research questions, minimal units, and major theorist (in parentheses) for those six methodological approaches to discourse analysis.

The model of discourse analysis posited above illustrates the way in which discourse analysis constitutes a discourse. Each of the six methodologies under the metatheoretical banner of discourse analysis belongs to an already extant academic discipline such as philosophy or linguistics and is a discourse in its own right. However, all of the methodologies are brought together by the designation of functionalist or formalist approach, the assignment of a starting point for analysis, the identification of a central research question, and the suggestion of a minimal structural unit.

The description of discourse analysis as a methodology has been accomplished by using the concept as the subject of this illustration.

Table 1 Discourse: formalist/functionalist principles

<i>Formalist</i>	<i>Functionalist</i>
"Etic" analysis based on form	"Emic" analysis based on meaning
Code-centered	Use-centered
Analyze code first	Analyze use first
Referential function	Social function
Elements/structures are arbitrary and universal	Elements/structures are ethnographically appropriate
All languages equivalent	Languages and varieties not necessarily equivalent
One code	Code diversity
Fundamental concepts taken for granted	Fundamental concepts problematic and to be investigated

Source: Schifffrin (1994: 21).

Table 2 Approaches to discourse analysis

	<i>Starting point</i>	<i>Research question</i>	<i>Minimal unit</i>
<i>Formalist</i>			
Conversation analysis (H. Sacks)	Sequencing/ adjacency	Why that next?	Adjacency pair
Variation analysis (W. Labov)	Structural variable	Why that form?	Multiple possibilities
<i>Functionalist</i>			
Speech act theory (J. Austin; J. Searle)	Speaker intention	How to do things with words?	Speech act
Ethnography of communication (D. Hymes)	Speech events/ speech acts	How does discourse reflect culture?	Speech event
Interactional sociolinguistics (E. Goffman)	Interpersonal goals	What are they doing?	Interchange
Pragmatics (H. P. Grice)	Grice's maxims/ speech acts	What are the cultural norms for speech acts?	Multiple possibilities

Source: Schifffrin (1994).

More important, the description shows discourse analysis to be a method of communication that conforms to particular structural and ethnographic norms and marks a particular social group by providing a means of solidarity for its members and a means of differentiating that group from other groups. Further, while discourse analysis is a discourse, the six methodological perspectives within discourse analysis are themselves separate discourses with their own terministic screens maintaining parallel distinctions as fully realized varieties of discourse analysis, not unlike the distinction accorded to dialects of a language.

Therefore, discourse analysis exhibits characteristics of both definitions of discourse offered here, accounting for every element of those definitions. Clearly, the concept of discourse analysis conforms to the basic definition of discourse by both establishing and following the stylistic and disciplinary norms of the discipline it names. Those adopting the distinction of discourse analyst will situate themselves within the discourse community of discourse analysis, either rejecting or claiming simultaneous membership in a related discourse community. The member of the discourse community of discourse analysis will command the lexicon and training required of a discourse analyst and will recognize the boundaries coincident with the terministic screen that lexicon and training impose, thus adopting the identity of that group.

If the discourse analyst claims additional membership in discourse analysis and another discourse community, say, discursive psychology (which studies language use as social process) or critical discourse analysis (which merges literary, psychological, and other theoretical perspectives with the methods of discourse analysis to challenge political power by challenging the language used to advance it), the discursive psychologist or critical discourse analyst may question the discourse analyst's status as a member of that discourse community by identifying the claimant within the confines of the terministic screen of discourse analysis. In the same way, a discourse analyst may contend that the stances of the discursive psychologist or critical discourse analyst focus on purposes outside the form and function of language above the sentence, therefore excluding them from the discourse community of discourse analysis. Either way, discourse analysis, as defined here, is a discourse.

Current research trends show that discourse is a concept in the social science, natural science, business, engineering, and humanities fields. In addition to the applications of the term detailed here, the term discourse functions as a way of identifying an approach to a subject (as in the case of analyzing a discourse community or terministic screen), a way of identifying the methodology used to extract information (as in the case of therapeutic analysis), or a way of identifying a subject in itself (as in the case of specific

extra grammatical analyses of linguistic phenomena). Further, the number of graduate level discourse studies programs is growing in English speaking countries, promising an interest in the subject of discourse now and well into the future. The omnipresence of the term confirms its inherent interdisciplinary and cross disciplinary value. That said, the term may also be in danger of overuse. Appropriating the term to describe virtually any use of language diminishes its capacity to function as shown above. Interestingly, the very difficulty brought about by overuse of the term discourse is a discourse phenomenon. Thus, an important future project may entail either a firmer definition or redefinition of discourse itself.

discrimination

Ian Law

Discrimination refers to the differential, and often unequal, treatment of people who have been either formally or informally grouped into a particular class of persons. There are many forms of discrimination that are specified according to the ways in which particular groups are identified, including race, ethnicity, gender, marital status, class, age, disability, nationality, religion, or language. The United Nations Charter (1954) declared in article 55 that the UN will promote human rights and freedoms for all, “without distinction as to race, sex, language, and religion.” Later in 1958, the Universal Declaration of Human Rights added eight further grounds for possible discrimination, which were color, political or other opinion, national or social origin, property, birth, or other status.

Social scientists need to consider all kinds of differential treatment, as this is a general feature of social life. As Banton (1994) notes, for example, the family, the ethnic group, and the state are all based on acts of discrimination. In families, different individuals have differing roles and obligations that require particular types of behavior, for example husband and wife and parent and child. Members of ethnic groups may differentiate in their association with or exclusion of other people depending on the identification of their ethnic origins. States frequently discriminate between citizens and non citizens in conferring rights and responsibilities. Although discrimination is often an individual action, it is also a social pattern of aggregate behavior. So, structures of inequality may be reproduced over generations through repeated patterns of differential treatment. Here, individuals are denied opportunities and resources for reasons that are not related to their merits, capacities, or behavior but primarily because of their membership of an identifiable group.

Discrimination takes many forms. Marger (2000) identifies a "spectrum of discrimination," which includes wide variations in both its forms and severity. Broadly, three categories of discrimination are identified as comprising this spectrum. Firstly, the most severe acts of discrimination involve mass societal aggression such as the annihilation of native peoples in North America, South Africa, and Australia, the Nazi Holocaust, plantation slavery, or more recent massacres of ethnic groups in Rwanda and Bosnia. Violent racism and domestic violence are two further examples of widespread discriminatory aggression. Secondly, discrimination involves denial of access to societal opportunities and rewards, for example in employment, education, housing, health, and justice. Thirdly, use of derogatory, abusive verbal language that is felt to be offensive (e.g., "Paki," "nigger"), which, together with racist jokes, use of Nazi insignia, and unwitting stereotyping and pejorative phrases, may all constitute lesser forms of discrimination. Dualistic notions of degradation and desire, love and hate, purity and disease, and inferiority and superiority may be involved in discursive strategies through which forms of discrimination are expressed. Explanations for discrimination require complex accounts that are able to

embrace micropsychological processes, individual and group experiences, competition and socialization, together with structural power relations and aspects of globalization.

Feminist perspectives on anti discrimination law have challenged the fundamental assumptions underlying the treatment and analysis of comparators. This position involves a critique of liberal legalism and the invisible construction of white male norms, in law, public policy, and sociology, which provide the benchmarks for assessing the scale of discrimination (Hepple & Szyszczak 1992). Other than using the position of the white majority as a test of differential treatment of minorities, assessment of material position in comparison to indicators of human needs/rights provides an alternative method of sociological analysis (Law 1996).

Poststructuralist and postmodernist directions in contemporary sociological theory have nurtured an increasing focus on the complexity of interactions between different forms of discrimination. The critique of the conceptual inflation of racism, which warns against labeling institutional practices as racist as they may have exclusionary effects on other groups, further supports the building of sociological complexity into the study of how discrimination works. This shift is also apparent in the development of international and national protections and remedies. Here, development of human rights approaches that emphasize particularly freedom from discrimination and respect for the dignity of individuals and their ways of life and personal development seek to build a collective agenda that encompasses the needs and interests of all individuals and groups. The shift toward the creation of general equality commissions in the UK and in Europe and the dismantling of institutions concerned with separate forms of discrimination such as race or disability further exemplifies this process. In future research, focus on the interactions between different structures of discrimination is likely to be key.

The United Nations Third World Conference in Durban 2001 affirmed the paramount importance of implementing the International Convention on the Elimination of Racial Discrimination. It also concluded that the major obstacles to overcoming racial discrimination were lack of political will, weak legislation, and poor implementation of relevant strategies

by nation states. In moving forward, the key role played by non governmental organizations in campaigning for change and raising awareness of many forms of discrimination was acknowledged.

disease, social causation

Joseph T. Young

Social causation of disease is defined as the origin of illness that results from social conditions and social interactions. This definition assumes that human biological factors are not the sole cause of disease. The definition further assumes that social factors such as socioeconomic status (SES), religion, and social networks have an effect on the level and severity of illness and mortality. The idea that social interaction and culture play parts in the causation of disease has been present in social thought since John Gaunt's discussion of the interaction between politics and mortality in 1662.

Social causes of disease can be divided into fundamental causes (Link & Phelan 1995) and proximate (or lifestyle) causes. Proximate causes

of illness directly produce illness by affecting biological processes and are individually controlled. For example, diet, smoking, alcohol and drug use, seatbelt use, and exercise behaviors are lifestyle choices that directly affect disease prevalence.

Fundamental causes of disease can be defined as indirect causes of disease that act through specific proximate statuses and behaviors caused by variable access to resources (social capital) that may help people avoid disease, and the negative consequences of disease (Link & Phelan 1995: 81). Social capital is available to an individual through social networks, education, occupation, income and wealth, religious ties, and social power. The amount of social capital available to an individual, as well as other social factors, partially determines the severity and type of diseases the individual is afflicted with and may ultimately be more important as causes of disease than proximate causes (Link & Phelan 1995).

Why is the study of social causation of disease important? The obvious answer is that with adequate linkage between the causes of disease, society is able to achieve remedies for the disease states and reduce the negative effects of these causes of disease on the individual and society as a whole. Understanding causative factors for disease supports disease prevention, potentially improves health, longevity, and quality of life, informs health policy, improves access to care, and increases the level of health knowledge. Major social causes include occupation, income, gender, education, social networks, health care access availability, institutional causes (such as insurance), diet and nutrition, and stress (event related) and psychological factors.

Biological explanations of disease do not fully explain either the prevalence levels or the severity of disease. Disease is thus multicausal in origin and is manifest from multiple causal pathways. We have moved from attempting to eliminate the causal connection between lifestyle, proximate causes, and disease to looking at the reasons that people have such behaviors that negatively impact their health. Those reasons for negative behavior are uniformly social in nature.

Methods used to delineate social causes of disease must, of necessity, be complex because

of the complex nature of the topic and the many interactions between levels of inquiry and factors involved. The methods primarily used are quantitative in nature and involve multilevel regression models of various types. General linear models, hierarchical models, and structural equation models are becoming the norms of inquiry, because the data are layered from individual factors to neighborhood factors and social institutions. These interactions require sophisticated models for accurate description, which makes inquiry in the area of study quite intricate.

The difficulty in delineating social causes of disease (hereinafter fundamental causes, because we shall assume that fundamental causes are more important to disease causation) is thus equally methodologically and theoretically complex. The effects of fundamental causes on disease are often indirect, working through more proximate statuses and behaviors, and thus the magnitude of their effect may be difficult to delineate. Methodological problems are compounded by the bidirectional nature of disease causation and the difficulty in defining the social causes. In other words, a single disease may have multiple causes, acting in concert to produce the resultant disorder and its effects. Further, the causes of the disease may interact with the resultant disease to cause further disease. For example, persons who smoke may have sedentary lifestyles, lower educational status, poorer jobs, more stress, and poorer diets because of less income, which may affect the levels of heart, lung, and kidney disease. If one disease state is present, this may lead to other disease states that synergistically affect the overall health of the individual (such as hypertension leading to renal failure, leading to heart disease and stroke). Indirect and direct causes may combine in a complex of causative factors that may be difficult to untangle, both from a methodological and a theoretical standpoint. Further lost in this decidedly social discussion of disease is the obvious effect of genetics and biology that do play some part in disease causation.

The difficulty in measuring social factors (how do we define a social factor and how do we measure it? what is the direction of causation and its level of effect?) may affect the resultant influence of the social factor on disease causation. Factors such as social integration, stress, social support, social capital, and

life events must be defined uniformly and systematically in order for meaning to be ascribed to their effects. The measure used to show the effect of social factors on health and disease must be equally precise. For example, mortality as an outcome is relatively precise. We all die, and we all die of something, but that "something" may not be a single disease or have a single cause. If we use cure, or worse yet control, in chronic disease states as a measure of outcome, the standard of what is cure and what is control may vary with the research involved. Standards for outcomes are not present in the literature, in many cases, to guide research.

The old dichotomy of causation, direct and indirect causes, seems to be too imprecise to explain social causation of disease. Direct physical causes of disease occur in a social context. Smoking may have social causes. Direct physical harm from injury occurs in a social milieu (e.g., driving too fast without a seatbelt may be the result of low SES, cultural preference, and excess alcohol use because the stress of life is too much to directly confront). All of these factors comprise a complex interplay of causation grounded in the fundamental causes of disease, which are primarily social in nature. The work of McKeown and associates on public health and smoking, and of Dubos (1959) on environmental factors in health and disease, makes a strong case for multifactorial causation of disease. The effect of nutritional deficits due to poor economic status may affect lifelong immunity and susceptibility to disease. To complicate matters, Barker and associates hypothesized that diseases, thought to be chronic and afflicting the more aged of the population, are perhaps genetically programmed before birth through poor nutrition of the mother, to be later expressed by metabolic pathways (e.g., metabolic syndrome leading to heart, vascular, endocrine, and kidney disease) later in life. Fundamental and social causes of disease may therefore have direct and indirect effects as a result of large, and as yet not fully delineated, social contexts of wealth, power, social capital, and social control, which may partially determine the level and severity of disease in the individual.

The theoretical underpinnings of the social causation of illness are material, cultural, behavioral, psychosocial, sociopolitical, and longitudinal in nature. The common thread of all the

theories is that differences in social factors lead to differences in illness levels and the ability to maintain and regain healthy status (Bartley 2004).

The material or socioeconomic status theory (Kitigawa & Hauser 1973; Kawachi & Kennedy 1997) links levels of illness to income. Income determines behaviors, diet, and type of work done, and is linked to housing quality and environmental determinants of illness as well as stress levels and work related levels of self identity and worth.

The cultural/behavioral theory states that socialized values and norms determine behavior and social identity, which in turn control health behaviors and levels of disease. A subset of behavioral/cultural theory, psychosocial theory (Wilkinson 1996; Elstad 1998), suggests that social status levels, social networks, and biochemical processes in the body are linked to behavior and thus to levels of illness.

Political economy theory (Lynch 2000) suggests that health and illness differentials are caused by differentials in social power controlled by external political and institutional hierarchies. Finally, life course theory states that events before and after birth affect physical health, the ability to maintain and repair health, and the level of illness through biological and social/behavioral pathways that change with age and the evolution of social institutions. A unified theory of social causation of illness must contain material, socialization and network, longitudinal and biological, stress and psychological, and behavioral/cultural factors. As yet, all the theories ignore the global aspects of illness causation and the interactions between the various aspects of social causation (Young 2004).

The term "social causes of disease" has been supplanted, first by the term social determinants of disease, and now by a field of study termed "social epidemiology," which includes the social determinants of health and disease (Kawachi 2002). This subfield of public health, health sociology, and epidemiology has helped to define social policy related to neighborhood improvement, health services access, and socioeconomic improvements that have decreased disease prevalence and delineated the pathways of social causation of disease.

Future research will depend on the ability of researchers to meet the demands of large,

complex longitudinal databases and methodological issues required for adequate analysis of this topic. Certainly, topics extending the idea of the life course perspective will require longitudinal multilevel analysis (Hayward et al. 2000). Other areas of future research should include the relationship of direct causes of disease to social causes and social outcomes; the effects of social causation of disease on the developing world and development (Sen 1987); the development of biomarkers and their reliability in linking health to social variables; and GIS techniques for analysis of area effects. We have only scratched the surface of all the environmental effects on illness and health.

Social epidemiology provides an avenue for formal empirical and theoretical research into the multifactorial causes of disease so that social and medical scientists can work together to improve global health and well being.

Disneyization

Alan Bryman

Disneyization refers to “the process by which the principles of the Disney theme parks are coming to dominate more and more sectors of American society as well as the rest of the world” (Bryman 2004: 1). The term was devised by Bryman (2004) to parallel George Ritzer’s (2004) notion of McDonaldization and the definition is a deliberate adaptation of that concept. Disneyization does not refer to the spread of theme parks, though that is certainly happening, but to principles that the Disney theme parks exemplify. As such, Disneyization refers to the ways in which modern consumption opportunities in institutions as diverse as hotels, restaurants, shopping malls, and shops are increasingly infused with Disneyization.

In portraying the principles that the Disney theme parks exemplify, four dimensions of Disneyization are distinguished:

- 1 *Theming*. This refers to the application of a narrative to an institution that is external to that institution. An example is the

deployment of a narrative of the cinema or the natural world to a restaurant. Theming can add allure to otherwise commonplace consumption opportunities.

- 2 *Hybrid consumption*. This is the bringing together of different forms of consumption in a single location or site, such as shops attached to restaurants, amusement park attractions attached to hotels or shopping malls, and fusions of hotels with casinos, as in Las Vegas. The rationale for hybrid consumption is that it keeps consumers at a site for longer and turns it into a destination.
- 3 *Merchandising*. This term refers to the sale of goods bearing or in the form of company images or logos. It includes such things as tee shirts, mugs, pens, and other paraphernalia which are used to extract additional revenue from popular images, such as movie and television series tie ins or company symbols. The idea is to extend people’s enjoyment of the underlying image and in the process mining further value from it.
- 4 *Performative labor*. Workers in consumption environments in service industries are increasingly encouraged to view their labor in ways that suggest a performance, similar to that which occurs in the theater. One of the chief forms of this trend is that service organizations increasingly encourage workers to engage in *emotional labor* (Hochschild 1983). This means that workers are enjoined to display positive emotions through smiling and other external signs.

Bryman (2004) draws a distinction between structural and transferred Disneyization, suggesting that two separate processes may be at work in the spread of Disneyization. The former refers to the essential changes exemplified by the Disney theme parks. Transferred Disneyization refers to the relocation of the principles associated with the Disney theme parks into other spheres, such as shopping malls and restaurants.

The process of Disneyization should be viewed as a platform for rendering goods and particularly services desirable and consequently more likely to be purchased. As such, it is very much a strategy that is at the heart of modern consumerism.

distanciation and disembedding

Christoph Henning

Modern society is based on a functional differentiation of different social systems. Therefore, face to face interactions lose their significance in everyday life, as modern media such as money or more recently the Internet step in between. The consequence for individuals is the process of distanciation. It has both a spatial and an emotional side: people who feel a sense of belonging can live far away from each other, and people sharing the same neighborhood may not even talk to one another. Social interdependence is ever more mediated and behavioral patterns often adapt towards a mutual ignorance. The consequence for societal subsystems is that they are increasingly disembedded. They follow their own logic only, without reflecting upon social concerns or society as a whole.

Though these two related processes are but two sides of the same coin of modernization, they have been described in rather different theoretical schools. The term distanciation comes from Nietzsche. It was taken up by authors like Georg Simmel, Helmuth Plessner, and Norbert Elias. The term disembedding was first used by Karl

Polanyi, though the idea was already elaborated a hundred years earlier by Marx. It was taken up by anthropologists and later on by economic sociology (Granovetter & Swedberg 2001) and also by Giddens. Following Polanyi, it is the disembedding of the market in particular that is typical for modern capitalistic society. The economy has become the central process of modern society, yet an economy is more than just the market. It also includes consumption and (most importantly) production. In traditional societies the economy used to be embedded in larger cultural frames. Ethics, politics, and religion had a great influence on economic behavior. In modern society the economy can only process what is inputted into the economic system as *economic* information; that is, as monetary calculation. In Marxian terms, economic thinking was transformed from a logic of use value to a logic of exchange value. This logic is blind towards qualitative differences and only cares for quantitative dimensions of how much something costs or pays. The effect on individuals is distanciation: a weakening of social bonds and an increased individuality.

The Marxian interpretation of this process of disembedding and distanciation was mostly negative: now there are no more limits to growth, even if growth turns out to be ecologically destructive. In other words, the price for disembedding is a much greater social risk. Also, there are no more qualitative criteria for deciding at which point economic progress comes at the price of social instability. Classical sociology stressed the ambivalence of this process, pointing especially to the good sides of this very process. The argument was not capitalism's greater economic efficiency, as used by liberal economists like Hayek and Friedman. The sociological argument was a cultural one. The modern individual can no longer rely on "natural" bonds and ties with neighbors and fellow citizens. Some (e.g., communitarians) judged this as a loss. But at the same time this allows for more freedom. Now that individuals are independent of what neighbours think and do, they are free to do whatever they like. Modern culture is only possible because of this loss. If the economy were not disembedded and individuals could not distance themselves from one another, there would be no culture of individualism, no pluralism, no independent art or a free press.

Simmel and Elias were interested in how modern culture and the modern individual managed to deal with this distancing and disembedding. "Distance" here refers to the increased "social space" between different individuals, especially those from different classes, ethnicities, religions, ages, or genders. The concept of social space was further elaborated by Bourdieu. Giddens also followed Simmel's footsteps, claiming that it is especially money as a modern medium that allows for a growing disembedding of social interactions ("the 'lifting out' of forms of life, their recombination across time and space") (Giddens & Pierson 1998: 98). Money allows for economic interactions across distances, both in terms of time (via credit) and space (via the banking system).

Recent economic sociology and research on international management have shown that the modern economy is not as distanced and disembedded as Polanyi thought, not even on the market. Even in the heart of economic transactions – be it inside a firm, between firms, or between a firm and its customers – there are many social and cultural bonds that embed economic actions and bring partners closer. The debate on "glocalization" and the cultural turn in many disciplines have shown that this is a fundamental necessity. So, together with growing distancing and disembedding, one can most likely find counteracting tendencies of reembedding and trust (Giddens 1990).

distinction

Douglas B. Holt

Distinction references the social consequences of expressions of taste. When people consume – whether it be popular culture, leisure, fine arts, the home, vacations, or fashion – these actions, among other things, act to express tastes. And tastes are not innocuous. Rather, what and how people consume can act as a social reproduction mechanism. So expressions of taste are acts of distinction to the extent that they signal, and help to reproduce, differences in social class. Distinction can be distinguished from other important class reproduction mechanisms such as educational credentials, the accumulation of financial assets, and membership in clubs and associations.

The term distinction is often used as a synonym for related concepts concerning status display, especially Thorstein Veblen's popular idea of conspicuous consumption. But distinction, as developed by Pierre Bourdieu in his seminal *Distinction: A Social Critique of the Judgment of Taste* (1984), is a more precise term. To understand the nuances of Bourdieu's ideas, we need to compare *Distinction* to prior work. (Bourdieu was more interested in berating Parisian elites than in conversing with related social theory.) The most influential ideas prior to Bourdieu were Simmel's trickle down theory of fashion and Veblen's theory of the "honorific" consumption of the leisure class.

In Simmel's model, society's elites are in a continual race to distinguish their consumption from their social inferiors, who do their best to

imitate higher status tastes. The constant inflation due to copying creates a very dynamic fashion system. Simmel proposes what may be termed a consensus symbol model: what is consumed is irrelevant as long as elites decide collectively that it will be a class signal. The anthropologist Lloyd Warner worked with a similar model in his famous ethnographic studies of the American social class system.

Veblen, unlike Simmel, is concerned with claims to distinction that are not necessarily defined as such by their participants. Much like Bourdieu, he is a close observer of elite status signals that have become naturalized as simply "good taste." But Veblen's model differs from Bourdieu's in that he defines elites by their wealth and then looks at how they convert their wealth into acts of consumption that are not easily imitated: they spend excessively on "was teful" indulgences, they use their wives as stage props, they define beauty in terms of expense, and so on.

By comparison, Bourdieu's theory of distinction makes three major contributions. First, he carefully unpacks and details the independent contributions of economic capital and what he terms cultural capital. Economic capital allows one to express tastes for luxurious and scarce goods, much like Veblen describes. Cultural capital is different in that it consists of the socialized tastes that come from "good breeding": growing up among educated parents and peers. Cultural elites express tastes that are conceptual, distanced, ironic, and idiosyncratic. So rather than a unidimensional social class hierarchy, Bourdieu is able to specify carefully how class fractions are composed (and often clash) due to differences in their relative amounts of economic and cultural capital.

Second, he specifies a materialist theory that explains why different class fractions tend toward particular tastes. He traces the causal linkages between social conditions and tastes; for example, the economic deprivations of the working class lead to the "taste for necessity." Rather than a consensus model, with Bourdieu's theory, one is able to predict the kinds of cultural products different class fractions will like and the ways in which they will consume them.

Third, what is most notable about Bourdieu's book, and least commented upon, is his nuanced

eye for the subtle distinguishing practices that pervade everyday life. Much like Erving Goffman, Bourdieu is able to pick apart the micro details – how one dresses, how one vacations, the way in which one justifies aesthetic preferences – to reveal their broader sociological impact.

Bourdieu's research has stimulated a variety of empirical studies that have sought to test the relationship between tastes and social reproduction. The results of these studies have been inconclusive. One of the inherent problems in such studies is that cultural practices that communicate distinction are often quite subtle. Many of these practices are not easily captured by conventional social science constructs, nor by survey measures, the primary method for follow up studies to date.

For this reason, some of the most telling treatments of distinction have been written by cultural critics who are acute observers of the social world around them and are more sensitive to the historical shifts in taste. While less systematic, books such as Tom Wolfe's *Radical Chic and Mau Mauing the Flak Catchers* (1999), Paul Fussell's *Class: A Guide through the American Status System* (1992), and David Brooks's *Bobos in Paradise: The New Upper Class and How They Got There* (2001) capture better than any sociological study how American elites signaled distinction in the 1970s, 1980s, and 1990s, respectively. The challenge for future sociological research is to develop theories and methods that are sensitive to these nuances.

Bourdieu's theory has also drawn considerable criticism, particularly for its overly structural and economist approach. Certainly, a primary weakness of Bourdieu's theory is that he posits a nomothetic model that abstracts away from historical particulars in order to claim universal application. There is a fundamental tension between Bourdieu's universalizing model and his nuanced description of tastes, many of which are particular to France. So, rather than "test" Bourdieu's model in its nomothetic form, the most fruitful future work will be to treat Bourdieu's framework as a skeleton and then specify the particular characteristics of distinction across different societies and historical periods. Mapping these particular formations of distinction

is a massive and important project that has only just begun.

distributive justice

Guillermina Jasso

Every day, and in all walks of life, the sense of justice is at work. Humans form ideas about what is just; and they make judgments about the justice or injustice of the things they see around them. Both the ideas of justice and the assessments of injustice set in motion a train of individual and social processes, touching virtually every area of the human experience. Thus, in the quest to understand human behavior, understanding the operation of the sense of justice is basic. And justice is central across the subfields of sociology.

This entry summarizes the synthesis of the late twentieth century and the foundation for the coming synthesis of the twenty first century. The first synthesis looks inward, providing a parsimonious and coherent model for understanding and investigating every aspect of distributive justice. The coming second synthesis looks outward, forging the links between justice and the two other primordial sociobehavioral forces, status and power, and proposing a new unified theory.

JUSTICE ANALYSIS: THE SYNTHESIS OF THE LATE TWENTIETH CENTURY

Justice analysis begins with four central questions (Jasso & Wegener 1997):

- 1 What do individuals and societies think is just, and why?
- 2 How do ideas of justice shape determination of actual situations?
- 3 What is the magnitude of the perceived injustice associated with departures from perfect justice?
- 4 What are the behavioral and social consequences of perceived injustice?

Justice analysis addresses the four central questions by developing three elements – framework for justice analysis, theoretical justice analysis, and empirical justice analysis (Jasso 2004). Developing the framework entails analyzing each of the four questions, identifying the fundamental ingredients in justice phenomena, and formulating a set of fundamental building blocks – the fundamental actors, quantities, functions, distributions, matrices, and contexts. Theoretical justice analysis focuses on building theories, of both deductive and non deductive type, each theory addressing one of the central questions and using as a starting premise one of the building blocks provided by the framework. Empirical justice analysis spans testing the implications derived from deductive theories and the propositions suggested by non deductive theories, and also carrying out measurement of the justice quantities, estimation of the justice relations, and inductive exploration.

The aim is a purity of approach, in which there is a minimum of terms and all terms are related to each other in specified ways.

Framework for Justice Analysis

The first central question – the scientific version of the ancient question, “What is just?” – immediately highlights two fundamental actors, the observer and the rewarder, and one fundamental quantity, the observer’s idea of the just reward for the rewarder. Pioneering

contributions of the last quarter of the twentieth century include Hatfield's idea that "equity is in the eye of the beholder" (Walster et al. 1976: 4), Brickman's distinction between principles of microjustice and principles of macrojustice, and Berger et al.'s (1972) idea that the just reward is a function of rewardee characteristics. Together these led to (1) the just reward matrix, which collects all the ideas of the just reward for a set of rewardees among a set of observers; (2) the observer specific just reward function (JRF) and just reward distribution (JRD) and their tight links to the principles of microjustice (now seen to be parameters of the JRF) and the principles of macrojustice (now seen to be parameters of the JRD); and (3) a new approach for pinpointing the effects of observer and social characteristics on the principles of justice (Jasso & Wegener 1997).

The third central question – "What is the magnitude of the injustice associated with departures from perfect justice?" – highlights a new fundamental quantity, the justice evaluation, and a new fundamental function, the justice evaluation function. The justice evaluation is the observer's judgment that a rewardee is justly or unjustly rewarded, and if unjustly rewarded whether underrewarded or overrewarded, and to what degree; it is represented by the full realnumber line, with zero representing the point of perfect justice, negative numbers representing unjust underreward, and positive numbers representing unjust overreward. The justice evaluation function represents the process by which the observer compares the actual reward to the just reward, generating the justice evaluation. The justice evaluation variable has twin roots in Berger et al.'s (1972) theoretical three category variable and Jasso and Rossi's (1977) empirical nine category fairness rating, emerging as a fully continuous variable with Jasso's (1978) introduction of the justice evaluation function:

$$\text{justice evaluation} = \theta \ln \left(\frac{\text{actual reward}}{\text{just reward}} \right), \quad (1)$$

abbreviated:

$$\mathcal{J} = \theta \ln \left(\frac{A}{C} \right), \quad (2)$$

where \mathcal{J} denotes the justice evaluation, A denotes the actual reward, C denotes the just reward, and θ denotes the signature constant, which governs both framing and expressiveness. The log of the ratio of A to C is the experienced justice evaluation; θ transforms it into expressed \mathcal{J} .

The just reward and the justice evaluation may pertain to self (reflexive) or to others (non reflexive). Both are assembled in the just reward matrix and the justice evaluation matrix.

The justice evaluation function (JEF) has several appealing properties. The first three noticed were: (1) exact mapping from combinations of A and C to \mathcal{J} ; (2) integration of rival conceptions of \mathcal{J} as a ratio and as a difference (Berger et al. 1972); and (3) deficiency aversion, viz., deficiency is felt more keenly than comparable excess (and loss aversion, viz., losses are felt more keenly than gains). These properties were quickly discussed (e.g., Wagner & Berger 1985) and remain the most often cited (Turner 2005). But, as will be seen below, a new theory for which the justice evaluation function served as first postulate was yielding a large number of implications for a wide variety of behavioral domains, and a stronger foundation was needed. In the course of scrutinizing the JEF, two new properties emerged: (4) additivity, such that the effect of A on \mathcal{J} is independent of the level of C , and conversely; and (5) scale invariance. Six years later two other desirable properties were noticed: (6) symmetry, such that interchanging A and C changes only the sign of \mathcal{J} ; and (7) the fact that the log ratio form of the JEF is the limiting form of the difference between two power functions,

$$\lim_{k \rightarrow 0} \frac{A^k - C^k}{k} = \ln \left(\frac{A}{C} \right), \quad (3)$$

which both strengthens integration of the ratio and difference views and also integrates power function and logarithmic approaches. More recently, an eighth (almost magical) property has come to light, linking the JEF and the Golden Number, $(\sqrt{5} - 1)/2$ (Jasso 2005).

The logarithmic ratio form is the only functional form which satisfies both scale invariance and additivity.

The JEF connects the two great literatures in the study of justice, the literature on ideas of

justice and the literature on reactions to injustice. As well, it generates several useful links, via the justice index (the arithmetic mean of \mathcal{J}): (1) a link between justice and two measures of inequality, Atkinson's measure defined as one minus the ratio of the geometric mean to the arithmetic mean and Theil's MLD; (2) a link with ideology, via decomposition of the justice index into the amount of overall injustice due to reality and the amount due to ideology; and (3) a link with poverty and inequality, via another decomposition of the justice index into the amount of overall injustice due to poverty and the amount due to inequality (Jasso 1999).

The JEF is linked to emotions at several crucial junctures. Experienced \mathcal{J} releases emotion, variously imagined as an explosion when the logarithm of the A/C ratio is taken or when $\ln A$ confronts $\ln C$. Next, the signature constant shapes emotion display. Finally, change in \mathcal{J} releases a new round of emotion. Further, it is thought that distinct emotions emanate from particular constellations of reflexive and non reflexive justice evaluations (Turner 2005).

The framework for justice analysis provides a large set of tightly integrated tools for doing theoretical and empirical work. Beyond the foregoing, these include \mathcal{J} , for use when the specific type of injustice, underreward or over reward, does not matter, and five context subscripts, for studying the effects of the social milieu, the time period, etc.

Finally, the justice profile – the time series of \mathcal{J} – permits assessment of the relative importance in a person's life of goods, bads, groups, self, others, of justice itself, as well as enabling analysis of location, scale, extreme values, drop offs, etc.

Theoretical Justice Analysis

The JEF has proved fruitful in generating testable implications. The early question, "If we know the distribution of the actual reward, what does the distribution of \mathcal{J} look like?" was soon answered, and joined by new questions and new answers (Jasso 1980).

The problem of how to calculate \mathcal{J} when rewards are ordinal (for everyone understood that all quantitative characteristics can arouse

the sense of justice, not only cardinal things like money but also ordinal things like beauty and intelligence) led to a new rule, "Cardinal rewards are measured in their own units, ordinal things as relative ranks within a group," a rule which would have profound substantive consequences, including the prediction that the most beautiful person in a collectivity experiences less overreward than the wealthiest. The rule for ordinal things also now joined the case in which C arises from a parameter of a distribution (e.g., mean wealth) in securing within justice theory a place for qualitative characteristics, thereby providing yet another instance of the pervasive import of the distinction pioneered by Blau (1974).

The problem of how to represent C led to an identity – with roots in Merton and Rossi's (1950) work on reference groups – in which C is replaced by the product of average A and an idiosyncrasy parameter. Average A was in turn replaced by its constituent factors in the cardinal and ordinal cases, such as the total amount of a cardinal thing and the population size, again leading to profound substantive consequences.

Theoretical derivation is, of course, not automatic, especially if the goal is the "marvelous deductive unfolding" which not only yields a wealth of implications but also reaches novel predictions (Popper 1963: 221, see also pp. 117, 241–8). In this endeavor, mathematics is the power tool, enabling long deductive chains which take the theory "far afield from its original domain" (Danto 1967: 299–300). Purely verbal arguments tend to tether the deduced consequences to overt phenomena in the assumptions, constraining fruitfulness and destroying the possibility of novel predictions. Instantiation, for example, cannot produce novel predictions, for novel predictions are novel precisely because nothing superficially evident in the assumptions could lead to them.

Four main techniques of theoretical derivation have developed, called the micromodel, the macromodel, the mesomodel, and the matrix model. They have different starting points (e.g., \mathcal{J} , change in \mathcal{J} , distribution of \mathcal{J}) and use different mathematical approaches.

Examples of testable predictions derived include:

- 1 A thief's gain from theft is greater when stealing from a fellow group member than from an outsider, and this premium is greater in poor groups than in rich groups.
- 2 Parents of two or more non twin children will spend more of their toy budget at an annual gift giving occasion than at the children's birthday.
- 3 Blind persons are less at risk of eating disorders than are sighted persons.
- 4 In a materialistic society, social distance between subgroups always increases with inequality.
- 5 Veterans of wars fought away from home are more vulnerable to post traumatic stress disorder than veterans of wars fought on home soil.

As well, justice theory provides interpretation of rare events, such as the invention of mendicant institutions in the thirteenth century and of detective fiction in the nineteenth. And it also suggests the existence of fundamental constants, including a constant governing the switch between valuing cardinal and ordinal goods.

Empirical Justice Analysis

The justice framework and justice theory set in motion a vast array of empirical work – testing derived predictions, testing constructed propositions, and measurement and estimation of justice terms and relations. Testing predictions requires talents in the farflung domains to which the long hand of justice reaches (Turner 2005) and thus brings the synergies of distant ideas and subfields. Measurement and estimation sharpen understanding of the elements in the framework (Jasso & Wegener 1997; Whitmeyer 2004).

In general, measurement and estimation distinguish between justice for self, justice for others, and justice for all. Because, as noted above, A and C are arguments of the JEF, it is convenient to set up a three equation system, comprised of the JRF, the JEF, and the actual reward function (ARF):

$$\begin{aligned} \mathcal{J} &= \theta \ln\left(\frac{A}{C}\right), \\ A &= A(X, Y, \varepsilon) \\ C &= C(X, Q, \varepsilon). \end{aligned} \quad (4)$$

This basic system can be augmented by equations representing determination of the principles of justice (parameters of the JRF and JRD). Specification and estimation of this system yield new insights and new tools, three of which are briefly discussed.

The just reward in the JEF formulas (1), (2), and (4) generates the justice evaluation – it provides the crucial idea of justice against which the actual reward is compared – and hence has come to be called the “true just reward” (Jasso & Wegener 1997). It can be expressed:

$$C = A \exp(-\mathcal{J}/\theta). \quad (5)$$

A challenge is how to estimate it. Of course, respondents can be directly asked what they think is just, as in the International Social Science Project. The possibility remains, however, that the response – called the “disclosed just reward” – differs from the true just reward, incorporating such mechanisms as socialization, response sets, and the like (Jasso & Wegener 1997). Equation (4), together with Rossi's factorial survey method (Jasso & Rossi 1977; Rossi 1979), points the way to a new technique for estimating the true just reward: ask respondents to rate the justice or injustice of the actual rewards randomly attached to a large set of rewarddees, estimate the signature constant, and then use equation (5) to estimate C . This procedure yields the estimated true just reward, which substantively is free of disclosure mechanisms and statistically is biased but consistent. A second procedure, proposed by Evans (1989) for estimating the just reward for self and by Jasso and Webster for studying non reflexive just rewards, obtains ratings for several hypothetical actual rewards for each rewarddee. Developments in brain imaging techniques may suggest other approaches for estimating the true just reward.

The multiple rewards per rewarddee design has a further appealing property: enabling test

for whether the signature constant varies not only by observer but also by rewarder – i.e., enabling test for two new kinds of impartiality in the justice process, framing impartiality and expressiveness impartiality.

As a third example, consider the three equation system in (4). Because \mathcal{J} varies only with A and C , the old practice of assessing the “determinants” of \mathcal{J} can now be precisely understood and its results correctly interpreted. For example, if \mathcal{J} is regressed on schooling, the obtained coefficient equals the actual rate of return to schooling minus the just rate of return to schooling; however, the signs and magnitudes of each rate cannot be identified from the coefficient.

The accumulating empirical record indicates that the judgment that oneself is overrewarded is rare and that societies differ sharply in the proportions who see themselves as underrewarded. In the United States, the independence of mind proposed by Hatfield is dramatic, there being wide variation in the ideas of justice; and college and graduate students view the gender wage gap as unjust. Justice indexes for the formerly socialist countries of Eastern Europe, which in 1991 indicated that inequality was too low, by 1996 indicated that inequality was too high. Finally, initial estimates of impartiality, carried out with US undergraduates, indicate that 70 percent fail the impartiality test, their expressiveness varying across the workers whose earnings they judge.

JUSTICE IN THE UNIFIED THEORY OF SOCIOBEHAVIORAL PROCESSES: THE COMING SYNTHESIS OF THE TWENTY FIRST CENTURY

Still under the rule of parsimony, the proposed ideas for the new synthesis, to be analyzed and tested, add the spirit of Samuel Smiles: “A place for everything, and everything in its place.”

- 1 Fundamental forces. All observed phenomena are the product of the joint operation of several basic forces (Jasso 2003).
- 2 Middle range forces. The basic forces generate middle range forces, in the spirit of Merton’s theories of the middle range.

- 3 Primordial sociobehavioral outcomes, goods/bads, and groups/subgroups. The middle range forces produce primordial sociobehavioral outcomes (PSO) from personal quantitative characteristics. Qualitative characteristics provide the groups for calculating relative ranks and distributional parameters and generating subgroup structures.
- 4 Three rates of change and three PSOs. Because there are three possible rates of change, a useful starting point posits the existence of three middle range sociobehavioral forces.
- 5 Justice, status, and power. As Homans believed, justice, status, and power are the three prime candidates for middle range forces. Justice increases at a decreasing rate, status increases at an increasing rate (Goode 1978; Sørensen 1979). While the rate of change in power processes has not been directly addressed, the reasoning here suggests that power increases at a constant rate.
- 6 Identity. Each instantaneous combination of a PSO, a quantitative characteristic, and a qualitative characteristic is an identity, consistent with the tenets of identity theory (Stryker & Burke 2000; Tajfel & Turner 1986).
- 7 Persons. A person is a collection of identities. This classic idea in identity theory is also a generalization of the justice profile to all three PSOs.
- 8 Personality. Persons can be characterized by the configuration of quantitative characteristics, qualitative characteristics, and PSOs in their identities. Examples include status obsessed, race conscious, beauty fixated. The distinctive configuration constitutes the individual’s personality.
- 9 Groups. A group is a collection of persons. This is a classic idea in identity theory.
- 10 Culture. Groups can be characterized by the configuration of quantitative characteristics, qualitative characteristics, and PSOs in the identities of their members. Groups, too, may be dominated by one or another element. Examples include materialistic society, status society, jock culture, nerd group. The constellation constitutes the group’s culture.

- 11 Two types of subgroups, preexisting and emergent. Preexisting subgroups arise from the categories of personal qualitative characteristics (e.g., gender based or race based subgroups). Emergent subgroups arise from the operation of PSOs (e.g., the overrewarded, the fairly rewarded, and the underrewarded).
- 12 Theoretical derivation of predictions. The four techniques developed in justice theory – the micromodel, macromodel, mesomodel, and matrixmodel – are used to derive predictions for all three PSOs. Novel predictions include predictions concerning the competition among PSOs and the effects of the relative importance of PSOs in personality and culture. For example, an early prediction is that in a justice group, each person is closer to the neighbor above than to the neighbor below, while in a status group, each person is closer to the neighbor below than to the neighbor above, and in a power group, each person is equally close to the neighbors above and below – a consequence of the distinctive rates of change of the three PSOs.
- 13 Emotions. Emotion is released by the PSOs and by change in PSO. An early idea is that the valence of the emotion matches the valence of the PSO or the change in PSO. Justice always releases both positive and negative emotions. Status releases only positive emotions, though intensity may be very low. Change in PSO can, of course, be positive or negative.
- 14 Inequality – form and content. Inequality is distinguished along two dimensions, form and content.
 - 14.1 Inequality – two types of content. Inequalities of interest include both inequality in quantitative characteristics and inequality in PSOs. A new question immediately arises: is inequality greater in the good or in the PSO, for example, in wealth or in status?
 - 14.2 Inequality – two types of form. The forms of inequality are inequality between persons and inequality between subgroups. Inequality between persons is typically measured by the dispersion in the distribution of a quantitative characteristic; the Gini coefficient exemplifies this kind of inequality. Inequality between subgroups is typically measured by contrasting the location parameters in the subdistributions of a quantitative characteristic corresponding to two subgroups; examples include the gender gap in earnings and the race gap in wealth. A new question immediately arises: what is the exact relation between the two forms of inequality?
- 15 Happiness. Happiness is produced by the individual's PSO profile. New questions that can be posed and precisely answered include questions about the effects on happiness of changes in income inequality, changes in valued quantitative and qualitative characteristics, and changes in dominant PSO.

In the coming synthesis, justice will be more deeply understood, its operation contrasted with that of its sibling PSOs. Though only one of three PSOs, justice will be remembered as the first to yield its secrets to exact mathematical expression.

diversity

Gillian Stevens and Heather Downs

In ecology, where the concept is most highly developed, the simplest description of "diversity" is the number of species living in a specific environment: the greater the number of species, the higher the level of diversity. When describing social phenomena, "diversity" generally refers to the distribution of units of analysis (e.g., people, students, families) in a specific social environment (e.g., workplace, classroom, state) along a dimension (e.g., race, social status, political orientation). When measured empirically through one or more of a variety of indexes (such as the index of diversity), the highest levels of diversity occur when the units of analysis (e.g., people) are distributed evenly across the social dimension (e.g., racial categories). However, it is also common for a political ideal to serve as the benchmark for the assessment of levels of diversity. An American work setting may be considered to be appropriately diverse, for example, if the proportions of workers who are African American or Asian are comparable to the proportions of people in the general (or local) population who are African American or Asian. More loosely, some observers consider a setting to be diverse when the proportions of people with a selected characteristic (e.g., membership in a minority group) are relatively high.

Diversity is an important concept along numerous social dimensions, such as ethnicity, race, gender, socioeconomic status, sexuality, age, physical ability, and language repertoires.

Racial and ethnic diversity is a particularly important issue in many societies because race and ethnicity are strongly related to issues of power. Levels of racial and ethnic diversity within a nation as a whole are often used to establish the ideal levels of diversity within a nation's major social institutions, such as its labor force, educational system, and political system. Low levels of diversity within particular social institutions that occur because members of a minority group are underrepresented often lead to studies of gender or racial discrimination including processes of exclusion, and the policies designed to redress these inequalities. Investigating levels of diversity within geographical areas (rather than social institutions) leads to studies of residential segregation. Phenomena such as interreligious marriages or interracial adoption highlight the presumption that the more intimate social domains are expected to be homogeneous, i.e., not diverse, along important dimensions such as race and religion. Studies of the family are increasingly recognizing, however, that these presumptions are too restrictive.

Levels of diversity can change over time through social or demographic processes. For example, levels of ethnic and racial diversity at the national level can change because of migration streams dominated by selected racial or ethnic groups, or by group specific variation in levels of fertility. Social demographic processes such as racial and ethnic intermarriage or transracial adoption are responsible for introducing diversity within narrower, more intimate spheres such as the family and household.

In smaller settings such as the family, variation in levels of diversity along the lines of age and gender are an underappreciated facet of household and family life cycle stages. Individuals' experiences of age specific and gender specific diversity in their immediate households vacillate as they pass through the life cycle stages from childhood to the older ages. For example, people commonly live the first half of their lives in a gender diverse household but after middle adulthood are increasingly likely to live in households with a higher proportion of women.

Levels of diversity in a specific social setting help determine the number of opportunities for

social interaction and the consequent formation of relationships between people of differing characteristics; levels of diversity are also associated with group specific levels of inequality. For example, high levels of occupational segregation (i.e., low levels of diversity within occupations) help maintain sex specific and race specific differentials in income. High (or increases in) levels of racial and ethnic diversity can lead to cultural misunderstandings, or at worst, intergroup conflict. Groups in power may view high levels of diversity as threatening. National immigration policies, such as Australia's "Whites only" policy or the United States' national origins quota system, sought to restrict the entry of selected races to avoid increasing racial diversity in the nation.

In general, though, high levels of diversity along most social dimensions have positive social connotations. Highly diverse settings have numerous opportunities for intergroup interactions and therefore numerous opportunities for the breaking down of misunderstandings and the dissolving of cultural barriers. In racially or ethnically diverse schools, for example, children are more likely to form interracial friendships. Levels of interracial marriage are higher in geographical areas that are racially diverse. The rationale for affirmative action policies in the United States includes the presumptive positive effects of diversity on intergroup relations as well as the issue of equity of opportunity for minority group members. Highly diverse settings, by virtue of including people with a wide variety of characteristics, can also result in a more equitable representation of opinions and sharing of resources.

division of labor

Michael T. Ryan

The concept of the division of labor is used both by structural functionalists (the students of Durkheim) and conflict theorists (the students of Marx), but the meaning of the concept differs. For Durkheim and his followers, it means the occupational structure, and it also includes a new form of social solidarity, organic solidarity, that integrates the members of industrial societies in contrast to the mechanical solidarity of traditional societies. Durkheim saw this as a weaker, more precarious form of solidarity that was still in the process of development in the early twentieth century. For Marx and his followers, it means a double division of labor, the technical division of labor in the enterprise and in a particular industry that broke down the production process into a sequence of tasks and the social division of labor among enterprises, industries, and social classes that was mediated through commodity exchange in market relations. While the social labor of the enterprise was rationally organized, Marx saw contradictions and class exploitation and domination in the social division of labor.

Despite the chronic warfare of agrarian societies, the social structures of these societies remained relatively stable over hundreds, if not thousands, of years, with most of the changes taking place at the top – a change of regimes. The transition to industrial forms of society involved a lot of dislocations, conflicts, social movements, and chronic technological revolutions that have made this society far more

unstable, with the changes reaching down and disrupting the everyday lives of many members of this society. Durkheim and Marx have some common intellectual roots which have been obscured over time by their interpreters. Both were materialists influenced by German critical philosophy, especially Ludwig Feuerbach. Durkheim has been seen as a conservative theorist whose central focus was on the problem of social order. Marx has been seen as a radical theorist whose central focus was on the problem of social change. As Anthony Giddens points out, this is a simplistic and reductionist interpretation, especially of Durkheim, who was just as concerned as Marx about social change, and while Durkheim saw communists as hopeless utopians, he was a socialist himself, although he saw no possibility for the “withering away of the state.” He – like most of the early founders of the discipline of sociology – tried to explain how one form of society was transformed into another form. Durkheim and his school, under the influence of Darwin, were interested in the evolution of societies. So was Marx, who actually sent a letter to Darwin asking him if it was all right with him if he dedicated the first volume of *Capital* to him. Darwin passed on this honor. Yet the violent conflicts, the dislocations, and the social problems that accompanied the early development of industrial societies gave sociology problems to analyze and a reason for being.

Both Durkheim and Marx saw the social order of industrial societies as problematic. Durkheim saw the problems in terms of both the tendency to anomie, or normlessness, and the “forced division of labor.” In traditional societies there was a deep consensus over norms, values, and behavioral expectations. This was because members of these societies shared a common religion, performed similar work, and took care of most of their needs in their immediate communities, occasionally trading excess craft products and food with adjoining tribes. These commonalities formed the basis for what Durkheim called mechanical solidarity. However, industrialization created a new form of society where this normative consensus broke down. In the wake of the industrial revolution, urbanization and immigration brought together people with different values

and norms, different religions and subcultures. Further, industrial work forced workers to specialize and to take up new occupations and professions. Specialization meant that the members of this new society became dependent upon each other for all of their needs, and now their needs were no longer taken care of in their immediate communities. This division of labor created a new form of solidarity which Durkheim called organic solidarity. But this division of labor produced a form of solidarity that was weaker and more fragile than the mechanical solidarity of traditional societies, hence the structural tendency to anomie. He thought that a new corporate order constituted by professional and occupational organizations would create norms and ethics, a new moral order, which would address this problem. These guild like organizations would mediate between the level of the state and the level of employers and workers.

The problem with the forced division of labor is that inherited wealth gave a distinct advantage to the children of the capitalist class to take up the most remunerative positions in the division of labor, in many cases regardless of their natural talent. Wealth gave them the money and social capital, or social connections, to go to the best colleges and universities, as well as allowing them to follow their parents into the family business or to launch new enterprises. He thought the abolition of inherited wealth would address this problem and allow those with natural talent to get the education they deserved, so that they could assume appropriate positions in the division of labor regardless of the social locations in which they were born. This would reduce the resentment of talented individuals who would no longer encounter class barriers in their quest for occupational and professional careers; the opportunity structure would be open to those with demonstrable talent, a meritocracy, and it also would mean that the ranks of professionals, managers, and entrepreneurs would be revitalized with new talent and new ideas.

On the other hand, Marx saw most of the problems in this new industrial society as rooted in alienated labor and the exploitation of living labor by “dead labor” (i.e., capital and class relations). One aspect of the problem of alienated

labor is in Marx’s analysis of the contradiction between mental and manual labor. The craft laborer in pre industrial societies produced works that were based on the unity of mental and manual labor and on immediate relations between producers and consumers. The craft worker came up with the idea for a work in relation to the specific demand of a client, planned out the immediate process of production on his own, and managed the creation of this work on his own without taking orders or directions from an entrepreneur or manager. Guilds established fair market prices for the works produced and regulated the relations among apprentices, journeymen, and master craftsmen. Whereas in industrial capitalism when the working class sells its labor power – its only commodity, to the capitalist class – it alienates control of the labor process to the entrepreneur. The unity of mental and manual labor is broken up according to class relations. Mental labor is the prerogative of the capital, or management; they do the thinking and planning. The industrial wage laborer is reduced to manual labor under the direction of capital or management; they do what they are told to do. Work is reduced to indifferent money making. Industrial workers rarely have immediate relations with consumers, the price of the commodity is determined by competitive market relations, and relations between capital and labor were initially unregulated except through class conflict.

As Frederick Winslow Taylor’s scientific management theory claims, whenever a worker does any thinking it is bad for the productivity of the organization. Through careful time and motion studies Taylorism reduced work to a series of bit parts that required very little thinking on the part of the worker, although Taylor was simply following the logic of the technical division of labor to its end, deskilling the worker in the process. However, this organization of work creates the possibility for the automation of work, or the “end of work” as we know it, through robots and computers; further, automation requires the return of workers who need to think at work in programming the smart machines as well as getting the machinery back up after the system crashes, thus reestablishing in part the unity of mental and manual labor. Wage workers who know how to use computers

potentially have the abilities to work in any industry, breaking the tendency to one sided development and the deskilling of the worker. This aspect of alienated labor resembles Durkheim's concept of the forced division of labor. There were a number of other ways in which wage workers were alienated. Wage workers were separated from the products and wealth that they produced; while labor was now social and the process of production was socialized, the profits and wealth were privately appropriated by the capitalist class. Capital confronted the workforce as an alien force, and the relation between capital and labor was also a relation of domination and subordination. In competition for jobs, workers were also alienated from each other. Marx also saw in wage labor the alienation of humans from their "species being" as producers of their material world.

Class exploitation of wage labor by capital is a related problem. The capitalist class takes advantage of the fact that the working class is propertyless and needs to exchange its labor power for a wage that will allow it to reproduce its labor power (and its dependents) in everyday life. Further, the capitalist class takes advantage of the fact that during the labor process the working class creates more value than is returned to it in the form of the wage; the use value of labor power produces surplus value beyond the exchange value of labor power and the value of materials and machinery used up in the process. The transformation of value is opaque to the members of the working class in contrast to the transparent process of exploitation and domination in production and property relations based on slavery, caste, or serfdom. In this process the workers transform their labor power, their ability to work, into a commodity which they exchange for wages; they enter the labor process and transform raw materials into finished products and services; the enterprise sells the products, transforming them into money which should have more value than the production costs that went into them if the enterprise is to be successful. This is where profits, capital formation, and luxury consumption for the capitalist class originate.

Marx saw class conflict and a social revolution led by a class conscious working class, the

proletariat, as the agent of societal transformation. The interests of the proletariat were identical to the interests of society as a whole, just as at an earlier stage of social development and class struggle the interests of the capitalist class were identical to the interests of society as a whole in their struggle to overthrow the feudal order. In socialism the working class would regain control over the labor process and the distribution of wealth through some form of self management; in communism the working class would abolish itself as a class, creating a classless society and the end of the different forms of alienated labor. However, the technical division of labor, the occupational structure, modified by automated technologies, would remain a lasting contribution of the capitalist class to a post capitalist mode of production and society. But work would no longer define the "species being" of humans, and we might see a return to *Homo Ludens* in an urban society organized around leisure and play.

divisions of household labor

Michele Adams

Prior to the Industrial Revolution, economic production was organized around the home, and households were relatively self sufficient. Households were multifunctional, acting, among other things, as eating establishment, educational institution, factory, and infirmary. Everyone belonging to the household, including family members, servants, and apprentices, did their part in the household's productive labor. The word "housework," first used in 1841 in England and in 1871 in the US, would have made little sense prior to that time, since *all* work was focused in and around the home.

Over the course of the nineteenth century, however, the Industrial Revolution severed the workplace from the place of residence. Coinciding with this process, the ideology of separate spheres emerged, reflecting an increasing tendency for men to seek work in urban factories while women stayed home to look after the family. This ideology defined not only separate spheres, but different personality characteristics and divergent family roles for men and women, as well. In doing so, it naturalized the notion that men, strong and unemotional, should occupy the status of family breadwinner. Conversely, women, frail, pure, and living under the spell of the "cult of true womanhood," should aspire to nothing more profound than being good wives, mothers, and home makers.

Thus, as men and single women ventured forth to work in the impersonal factories and workplaces of urban centers, married women, particularly those of the middle classes, stayed home to cook, clean, and raise the children. Production and productive activities moved out of these households into the industrializing workplace. Concurrently, the value and status of men's labor went up, while that of women's household labor went down. Previously an integral part of the home centered production process, middle class women found themselves with less "productive" work to do. As a result, their energies became more focused on reproductive

work, which included making sure that their husbands and children were clean, well fed, clothed, and nurtured. Although economic necessity continued to force working class wives and women of color to seek employment outside of the home, the pattern of separate spheres reflected an ideal that most families desired to emulate. Toward the end of the nineteenth century, as households were increasingly motivated to purchase industrially produced necessities, women also became the family household consumption experts. As such, they orchestrated the family's purchase of food, clothing, soap, candles, and other material necessities that they had once helped produce in the home.

In the US, the home economics movement emerged around the turn of the century, at least partly in an attempt to elevate the status of housework. Home economists provided instruction on the "science" of household labor, schooling women in the provision of a scientifically sound and hygienically pure home. As early twentieth century housewives found themselves at the mercy of these household labor "experts," standards of cleanliness began to rise. Meanwhile, newly developed electricity and indoor plumbing facilities encouraged the invention of household labor saving devices. Electric refrigerators replaced ice boxes and washing machines replaced wash tubs, scrub boards, and elbow grease. As the public sphere industrialized, so, too, did the household, albeit with certain important differences: in the home, the labor remained unpaid, workplaces were isolated, and the workers were generalists, good at all types of housework. Even with the industrialization of the home, however, the time non employed women spent doing housework remained stable from the late 1920s through the 1960s, as standards for cleanliness increased, and tasks such as canning and sewing gave way to increased time doing chores like laundry and shopping for prepared food and ready made clothing.

Before the 1970s few studies examined the division of household labor, since most people accepted as "natural" the separate spheres ideology making women the housework and childrearing experts. As the women's movement gained momentum, however, feminists began pointing out the disproportionate amount of time women spent doing housework, even as they labored alongside men in the paid

workforce. Moreover, feminists suggested, the fact that women did the majority of housework disadvantaged them in the workplace. These challenges prompted research examining the household division of labor, its relative distribution, and the relationship of housework contribution to women's status in the paid labor market. In 1965, researchers from the Survey Research Center of the University of Maryland found that women did roughly 92 percent of routine housework, while men did approximately 49 percent of occasional tasks such as lawn care, household repairs, and bill paying.

Changing patterns in the division of housework began to appear in research from the 1970s and 1980s, as women started to reduce their contributions, and men, somewhat less dramatically, began to increase theirs. Reasons for these changes included women's increasing presence in the paid labor market, as well as general trends toward egalitarian attitudes in the home. Nevertheless, even as women assumed more significant roles as family breadwinners, men continued to resist doing housework. By the mid to late 1980s, researchers found that women were still doing approximately three times the amount of routine housework that men were doing. This general pattern continued throughout the 1990s, with men's proportional contribution to routine housework increasing, primarily as the result of the cutbacks made by women. Researchers note that, although the gender gap in family work is reduced when accounting for total hours of paid and unpaid labor, nevertheless, women essentially put in one extra full day of family work per week, a phenomenon that has been referred to as the "second shift" (Hochschild 1989).

Today, in the US and much of the industrialized world, household labor continues to be performed mostly by women, with chores themselves also segregated by gender. Women are still doing the majority of "routine" tasks, including cooking and meal preparation, meal clean up and dish washing, laundry, house cleaning, and grocery shopping. Men, on the other hand, do the occasional chores such as lawn mowing, household repairs, car maintenance, and, less often, bill paying. Characteristically, routine chores tend to be more repetitious, time consuming, time sensitive, and boring than occasional chores, which are less tedious and can usually be completed when convenient. While studies of

household labor tend to separately analyze routine and occasional housework, they often omit childcare or, alternatively, include it as a separate category of family work. Nevertheless, the presence of children also substantially increases the amount of routine housework that needs to be done, so the amount of household labor that women perform tends to go up when children are born. Men, on the other hand, spend more time in paid labor when children arrive, but often reduce their household labor participation. Some studies suggest that when men do more childcare, they may also increase their contributions to housework.

Some researchers see shifts in the division of household labor over the latter part of the twentieth century as dramatic, while others characterize them as relatively modest. For instance, in the US, men's proportionate sharing more than doubled between 1965 and 1985. Nevertheless, the narrowing of the gender gap in housework performance has been driven more by women cutting back their hours than by men augmenting theirs. Moreover, time diary studies have shown that while reductions in women's housework performance continued throughout the 1990s, men's actual housework time has increased little since about 1985, creating what one sociologist has called a "stalled revolution" (Hochschild 1989). Thus, studies continue to show that women do at least two thirds of the family's routine household labor.

Besides continuing to do the bulk of routine chores, women are still considered to be the household managers. Whether they actually do the chores, delegate the work to other family members, or hire outside help, women are largely responsible for ensuring that the work gets done, as well as establishing the standards by which the completed work is judged. Men, even as they do more, tend to be seen (and to see themselves) as "helpers."

Although the amount of housework performed by unemployed women remained relatively stable over much of the twentieth century, in the US and other industrialized countries, women's participation in the paid labor force increased considerably. In 1890 only 4 percent of married women in the US reported having paid employment outside of the home. By the 1950s that figure jumped to about 22 percent, and by 2002 the labor force

participation rate of married women reached 61 percent. Married mothers with children under age 18 made particularly large strides in paid employment, and by 2002, 68 percent worked outside of the home. Importantly, the employment rate of married women with young children under age 6 has more than doubled since 1970 in the US, from 30 percent to 61 percent in 2002. By 2003, women comprised nearly half (47 percent) of the total US labor force. Similarly, the latter part of the twentieth century witnessed a significant increase in female labor force participation in countries such as Canada, Japan, and those of the European Union. Nevertheless, and in spite of the fact that many women worldwide now continue paid employment through their reproductive years, employed mothers report persistent unequal treatment in the workplace.

Although women's earnings remain substantially lower than those of men, the gender gap in wages has decreased in the US to the point that women earn approximately 76 percent of what men earn, based on full time, year round work. Thus, with married women sharing more of the family breadwinner duties, it has generally been expected that their husbands would share more of the housework. The absence of men's sustained movement in that direction has been, therefore, a source of some disappointment to advocates of gender equality. Moreover, these paid and unpaid labor patterns appear to extend well beyond the borders of the US.

International trends largely appear to reflect those occurring in the US. Women in most developed countries do the majority of the routine housework, although their contributions are declining while those of their male partners are increasing slightly. Japanese wives, for instance, continue to report doing a large majority of housework. On the other hand, wives in many formerly Soviet countries more often report that their husbands share housework equally than do women in the US. Still, women in most countries devote well over half of their work time to unpaid labor while men devote one third of their work time or less. The presence of young children increases women's unpaid labor time substantially more than that of men, while, in many countries, women whose education level exceeds that of their husbands do relatively less housework. Moreover, women worldwide are

balancing their unpaid family work with increased time spent in the paid labor force, and while men's economic activity rates have decreased in many areas, women's rates have generally increased.

Within the last several decades, the number of family and household types has grown. Studies have begun to examine how housework is shared between cohabitators (both same and opposite sex) and in remarried families. Findings show that in each of these family types, sharing between partners tends to be somewhat more egalitarian than it does between spouses. Children's participation in household labor has also been studied, although much less extensively. Data from one large national survey (the National Survey of Families and Households) showed that, in the late 1980s, all children in the household were doing slightly less than 6 hours total of housework per week. Moreover, children's housework is allocated based on age and sex, with teens delegated more tasks than younger children, and girls allocated more tasks than boys. As teens, in particular, girls are given more of the routine household tasks, while boys are expected to contribute to outdoor chores. In this way, children are socialized into gendered patterns of family work that often replicate those of their parents.

Studies have also started to examine racial and ethnic patterns of household labor sharing. In the US, most research shows that African American men do more housework than either white or Hispanic men, although they still do much less than that done by African American women. Whether Hispanic men do more or less household labor than white men continues to be at issue, although a more consistent finding is that Hispanic women do more housework than either black or white women. Thus, more housework is performed in Hispanic households, although African Americans tend to be more egalitarian in their patterns of sharing. Moreover, when household labor is bought in the marketplace, it tends to be African American or Hispanic women, often undocumented, doing the labor for more well heeled white women. In this way, gendered ideals about "rightful" domestic workers intersect with race/ethnicity to reproduce patterns of economic disadvantage and privilege.

Studies indicate that the most consistent predictors of men's housework participation are

related to women's employment. The more hours wives work outside of the home and, often, the greater their proportional share of family income, the more husbands tend to share in the housework. Gender ideology also has an effect, with women's belief in equal sharing predicting their partner's increased contribution. In some instances, men's egalitarian attitudes predict their increased sharing, although men's attitudes are somewhat less predictive of their own participation. Generally speaking, more highly educated women do less housework and purchase outside domestic help more frequently. On the other hand, men with more education tend to do more housework. Marital status is a consistent predictor, with women doing more housework when they marry, and men doing less. When children arrive, the need for routine household labor increases, and most of the demand is assumed by women. Men tend to increase their hours of employment when children are born, which may have to do with women decreasing their paid employment to care for children.

In spite of the unbalanced division of household labor, most men and women consider their share of housework to be fair. Traditional norms suggesting that men are entitled to women's labor in the home, and correspondingly, that women are obligated to perform it, can lead to this conclusion. Research shows that both men and women perceive housework distribution as fair when women are doing approximately two thirds of it. Reallocation of household labor, moreover, to create a more balanced division of labor typically does not happen spontaneously, instead requiring focused attention on change. While some may consider household chores to be a way to show love to family members, for the most part neither men nor women consider housework to be fun. Thus, wives may need to confront their husbands in order to get them to do more, thus causing marital conflict to increase. Since traditional norms tend to make women responsible for relationship harmony, wives may avoid "rocking the boat" to increase sharing. Accepting their unbalanced contributions as fair may be preferable for some women to creating disharmony in their marriage.

A number of theoretical perspectives have been proposed to account for the allocation of family labor. Three of the most often cited

perspectives include time availability, relative resources, and gender ideology. Theories invoking time availability imply that the person spending the least time in paid employment will be expected to do the most housework. Because men have historically been more visible in the workforce, working longer hours, women would thus be expected to do the housework. Relative resource theories suggest that the partner with the most resources, including income and education, should be able to avoid large contributions to household labor. Again, drawing on relative resource theory, women's disadvantage in terms of wages and, until recently, educational resources, has created expectations that they would do most of the household labor. Finally, theories implicating traditional notions about separate spheres point to housework as "women's work" and paid labor as "men's work." When spouses subscribe to this conservative gender ideology, it is seen as natural for women and men to do "their jobs," and women are therefore assumed to be the household labor experts. Other theories, such as economic dependency theory and the "new home economics" approach, also attempt to explain the persistence of disproportionate allocation of family work.

Family work includes both paid labor and unpaid household labor. While we are typically aware of the time family members spend in the paid workforce, we are generally less aware of the fact that nearly as much time is spent doing unpaid housework as is spent doing paid labor. We are also less aware of the ties between the two "spheres" and the fact that responsibility for unpaid housework takes away from time (and energy) that could be spent in the paid labor force. Because power accrues with work force participation, the person responsible for the unpaid household labor is less likely to be empowered, either in the household or when they do participate in paid employment. Moreover, since traditional norms presuppose unpaid housework as women's work, women have been historically disadvantaged by the assumption of these cultural norms as natural and unchangeable.

Nevertheless, family work, both paid and unpaid, is changing. Women today are spending less time doing unpaid domestic labor, either because of constraints surrounding paid

labor or diminishing expectations about how much time should be spent doing housework. Nothing suggests that women will spend less time at paid employment in the future. Men, on the other hand, appear to be doing some what more housework, particularly when that work is considered as a proportion of total household labor. This may reflect increasingly egalitarian attitudes in the home or it may point to more persistent demands by working wives that their husbands participate more equally at home. Whatever the reason, shifts that have occurred in the division of household labor over the course of the twentieth century are likely to continue into the twenty first.

divorce

Stephen J. Bahr, Chao Chin Lu, and Jonathan H. Westover

Sociologists who study divorce have focused on three major questions. First, some have taken a macro perspective and examined how and why divorce rates have changed over time. In this research, scholars have looked at broad social trends and how they are related to divorce rates. Second, there have been many studies of why individual couples decide to get a divorce. In this research, sociologists have examined the characteristics of individual couples and how they are associated with the risk of divorce. The third major thrust of research has been to explore the consequences of divorce. Major focuses of this research have been on how divorce affects economic well being, psychological well being, and physical health.

DIVORCE RATES

A major social trend during the past century has been a global increase in the divorce rate. During the second half of the twentieth century divorce rates increased in most industrialized countries. Divorce rates have been highest in the US, but there have been increases in many other countries as well. In the US the divorce rate was relatively stable between 1950 and 1965, increased dramatically between 1965 and 1980, and decreased slightly between 1980 and 2000. In the US it has been projected that about a half of all marriages will be terminated by divorce, and a half of all children will have spent some time in a single parent home by the time they reach age 18.

During the past 20 years there has been a gradual decrease in the US divorce rate. Small but consistent yearly decreases in the divorce rate have resulted in a significant reduction in

the divorce rate. From 1980 to 2000 the divorce rate per 1,000 married women decreased from 22.6 to 19.0, a decrease of 16.3 percent (US Census Bureau 2004). Recent evidence indicates that this decrease is not due to increased cohabitation or the aging of the population.

Sociologists have observed that the divorce rate is affected by rapid social change and social upheavals such as war and depression. For example, in the US the divorce rate increased after both world wars and during and after the Vietnam War. It decreased during the Great Depression, was relatively stable from 1950 to 1965, and decreased modestly from 1980 to 2000. Some of the social characteristics that appear to have contributed to the increase in the divorce rate are increased individualism, increasing marital expectations, the economic independence of women, and no fault divorce laws. These are trends that have been occurring globally during the past 50 years.

During the 1960s and 1970s there was social upheaval and change with much emphasis on rights and the questioning of traditional roles, responsibilities, and authority. The civil rights and feminist movements helped stimulate an emphasis on individualism. As a result, in contemporary western culture and across the globe, there has been increased emphasis on individualism, freedom, autonomy, and the pursuit of personal happiness, including individual marital happiness.

As individual happiness has been emphasized, the primary purpose of marriage has become the achievement of individual happiness. If love wanes and one does not achieve the expected happiness in marriage, a logical solution is to dissolve the relationship. In short, one consequence of individualism is a trend toward less commitment to marriage and greater acceptance of divorce, cohabitation, and alternatives to marriage (Waite & Gallagher 2000; Wilson 2002). Recent research illustrates how divorce has become much more common and acceptable during the past 50 years. Compared to the past, young married mothers are much more likely to state that divorce is the best solution to persistent marital problems, and social sanctions against divorce have decreased (Thornton & Young DeMarco 2001).

Another major social change during the past 50 years has been the increasing economic

independence of women. For example, in the US the proportion of bachelor degrees earned by women increased from 35 percent in 1960 to 57 percent in 2002. The percentage of married women employed in the labor force increased from 32 percent in 1960 to 61 percent in 2003. Among married women with children under age six, 60 percent were in the labor force in 2003 compared with only 30 percent in 1970 (US Census Bureau 2004). A woman who is employed may be more likely to leave an unhappy marriage than a woman who is not employed. Similarly, an unhappy man may be more likely to leave if he knows his wife is financially independent (Schoen et al. 2002).

The norms of the broader culture are reflected in the law and as divorce became more common and accepted, no fault divorce laws were passed. Law is influenced by cultural norms, but it also may help shape cultural norms. The law may teach, reinforce values, and be a model for appropriate behavior. A number of researchers reported that no fault divorce laws had no effect on the divorce rate. On the other hand, several others found that divorce rates did increase as a result of the passage of no fault divorce laws. Debate continues over whether or not no fault divorce laws influenced the divorce rate. In recent research it was estimated that divorce rates would have been 6 percent lower if no fault laws had not been enacted (Friedberg 1998). Since the increase in divorce rates began before no fault laws were passed, the passage of no fault laws appears to have been a reflection of a cultural change already in existence. In addition, however, the findings suggest that no fault laws had an independent impact which helped shape the cultural acceptance of divorce and increase divorce rates.

DIVORCE RISK FACTORS

Divorce is a complex process influenced by many social and individual characteristics. Factors that have been found to be associated with the risk of divorce include age at marriage, premarital cohabitation, parental divorce, infidelity, alcohol and drug abuse, poor financial management, and domestic violence (Blumel 1992; Amato & Rogers 1997; Sanchez & Gager

2000). However, the nature and strength of risk factors differ across groups. To illustrate, in the US, premarital cohabitation is associated with subsequent marital dissolution among non Hispanic white women but not among African American or Mexican American women (Phillips & Sweeney 2005).

A major social change during the past century has been the increase in paid labor force participation of women. There has been debate about the influence of women's employment on the risk of marital dissolution. Schoen et al. (2002) found that women's employment was associated with an increased risk of marital dissolution among unhappily married women but not among happily married women.

There has been considerable study of couple interaction patterns and how they are associated with subsequent divorce. Contrary to expert opinion, Gottman et al. (1998) found that the extent of active listening by couples was not related to subsequent dissolution, nor was the amount of anger expressed. Rather, the risk of divorce was influenced by how couples handled disagreement and anger. Couples who could disagree without contempt or withdrawal were more likely to remain married. The ability to accept the influence of the other, starting discussions softly, and humor were all associated with greater marital stability. On the other hand, contempt, belligerence, and defensiveness were associated with a greater risk of marital dissolution (Gottman et al. 1998; Hetherington 2003).

EFFECTS OF DIVORCE ON ADULTS

Numerous researchers have found that compared with married persons, divorced persons tend to have more economic hardship, higher levels of poverty, lower levels of psychological well being, less happiness, more health problems, and a greater risk of mortality (Hemström 1996; Amato 2000; Waite & Gallagher, 2000; McManus & DiPrete 2001). Cross national data have confirmed similar findings in 20 countries across the world (Mastekaasa 1994a; Amato 2000). One of the ongoing questions among social scientists is whether the differences between married and divorced individuals are due to selection or the stress of divorce. The

selection explanation suggests that poorly functioning individuals have a high risk of divorce. Thus, characteristics that existed before the divorce produce the low levels of well being rather than the divorce itself. If this explanation is correct, then differences between divorced and married persons could be explained by characteristics that existed prior to the divorce. An alternative explanation is that the stress of divorce lowers people's well being. If this explanation is correct, then divorce would produce significant reductions in well being net of pre divorce characteristics. Although selection can account for some of the differences between divorced and non divorced persons, recent research indicates that divorce appears to have a significant impact on well being that is not explained by selection (Mastekaasa 1994b; Hemström 1996; Amato 2000; Waite & Gallagher 2000).

Although divorce is a stressful event, its impacts vary greatly according to the circumstances and attitudes of the people involved. Some are stressed by divorce but recover over time, while others are devastated and never recover. Hetherington (2003) observed that the majority of the divorced persons she interviewed were able eventually to build reasonably normal and satisfying lives. She identified six different patterns of adjustment to divorce. At one end of the continuum were the *enhanced* who adjusted well to the divorce. They were successful at work, socially, as parents, and often in remarriages. Ten years after the divorce, 24 percent of the women and 13 percent of the men were in the *enhanced* category.

At the other end of the continuum were the *defeated*, who spiraled downward after divorce and were low in self esteem, had elevated scores on depression and anti social behaviors, and often had difficulties with alcoholism or drug abuse. One year after divorce, about one third of the divorced adults Hetherington studied were in the defeated group. Ten years after the divorce, only 10 percent of her sample remained in the defeated group and they were mired in despair, poverty, and depression.

A key question is what helps adults adjust successfully to divorce. Four key factors have been identified in research: (1) income, (2) a new intimate relationship, (3) age, and (4) social networks (Wang & Amato 2000; Hetherington

2003). First, those with adequate financial resources are more likely to adjust to the divorce. Second, those with a new intimate relationship (dating regularly, cohabiting, or remarried) are better adjusted. Third, divorce adjustment is more difficult for older than younger individuals. In most cases older persons have invested more time in the marriage and may have more difficulty finding another partner. Fourth, social networks provide encouragement, support, and other resources. Hetherington (2003) reported that social networks were important for many in her enhanced group.

FUTURE RESEARCH

There are several questions that need to be addressed in future research. First, there is a need for more extensive study of the process of divorce. When individuals divorce they go through a process in which they change their identity from a married person to a single individual. They make a variety of decisions regarding money, residence, and childrearing. Divorce impacts relations with friends and relatives and it involves processing legal documents. Even though there has been extensive study of the causes and consequences of divorce, there has been relatively little study of the process people go through to obtain a divorce.

Another important area for future research is to study different subcultures and cultures. Relatively little is known about divorce rates and trends in other countries. Related to this is the need to examine how various risk and protective factors operate in different countries.

Finally, it would be useful to study the dissolution of other types of intimate relationships. For example, Avellar and Smock (2005) examined the economic consequences of the dissolution of cohabiting unions. We need to know more about the risk factors, the dissolution process, and the economic and social consequences of the dissolution of cohabiting unions.

documentary

Annie Goldson

Documentary has existed as long as film itself. The one reel actualities produced by the Lumière brothers in 1895 and the more complex films that followed these early experiments – for example, *Nanook of the North* (Flaherty 1922) and *The Man with a Movie Camera* (Vertov 1929) – were distinguished by their sense of a “historical real,” the depiction of real people and events (Renov 1986). This apparent ability to capture “reality” has continued to distinguish documentary from fiction; indeed, the genre, with its intimate connection to the physical world, appeals because of its truth claims, whether these exist at the level of fact or image. Documentary stimulates what Bill Nichols calls “epistophilia” or a “desire to know,” conveying an “informing logic, a persuasive rhetoric, or a moving poetics that promises information and knowledge, insight and awareness” (Nichols 2001: 40). The filmmakers above, however, would hardly have known they were making “documentary” at the time they were in production, as the genre had hardly yet been conceived.

It is difficult to give a comprehensive history of documentary, given the variability and flexibility of the genre. Documentary continuously responds to a changing environment. Technological advances, cultural and political

shifts, the production of “break through” documentary texts, and new market opportunities and pressures all impact on the direction and shape of the genre.

It is John Grierson, founder and leader of the highly influential British Documentary Movement, who is most often credited with coining the term documentary, as well as providing us with the first definition of the genre in the 1930s (Grierson 1966: 13). Describing it as “the creative treatment of actuality,” Grierson tended not to dwell on any contradictions implicit within his definition, but the tension between “evidence” and “artifice,” as Corner (1996) suggests, has continued to reverberate. Grierson’s legacy, as Aitken (1998) suggests, is multi faceted – the producer wrote copiously on the art of documentary, dreamed of “putting the working class on film,” but also linked documentary to the pedagogical purposes of instruction and civic education. His “social issue” documentary, which follows a problem/solution scenario and remains a mainstay of the public broadcasting documentary strands today, established a series of documentary conventions, such as an anonymous narration, interviews that reinforce the “voice” of the documentary, and a rhetorical editing style.

During the interwar period, an influential strand of documentary that fused politically progressive or dissident attitudes, with formal innovation, flourished. This transnational movement included films from the Grierson stable – *Drifters* (1929), *Song of Ceylon* (1934) – as well as European classics such as *Land without Bread* (1933) and *The Spanish Earth* (1937), and American films such as *The Plow that Broke the Plains* (1936) and *The River* (1937). This wave of work was curtailed by the onset of World War II as documentary became harnessed to the war effort and, outside spectacular or poetic texts such as *Triumph of the Will* (Riefenstahl 1934) or *Listen to Britain* (Jennings 1942), became predictable in structure and tone.

Ethnographic documentaries, heirs to Flaherty’s complex legacy, continued through this period also. These ranged from “travel” films filled with exotic “disappearing savages,” to more serious works of some ethnographic worth. Despite the value of some, much ethnographic film retained the “I–You” split of the

anthropological gaze, thus replicating the power relationship between colonial powers and colonized peoples. Some films, notably those of Jean Rouch – *Les Maîtres fous* (1955), and *La Chasse au lion à l'arc* (1957–65) – exhibited the strains of failing imperial powers, anticipating more radical anti colonial documentary practices to come. Rouch was to turn his cameras onto his own tribe (Parisian youth) in his groundbreaking film *Chronique d'un été* (1961), which deployed and defined the techniques of *cinéma vérité*.

Although a number of canonical documentaries – *Blood of the Beasts* (1949), *Night and Fog* (1955), and later *The Sorrow and the Pity* (1971) – continued an earlier more poetic, politicized tradition, the majority of documentaries produced in the immediate post war period were made by governmental film boards. Documentary was to aid reconstruction and extolled the efforts of governments in creating jobs and developing infrastructures. The films were forced to adhere to set formulae and agendas and, although some filmmakers attempted to push at the boundaries, the documentaries remained largely forgettable.

The experimental edge displayed by documentary since its origins was further eroded by the establishment of television, which became, and remains, the site for most documentary funding and distribution. Television delivered documentary to audiences who in turn delivered advertising revenue back to broadcasters. Hence, documentary was tightly bound into the commercial contract of broadcasting culture, transmuting in the US (again, with some exceptions such as the fly on the wall films of Direct Cinema) to more sensationalist magazine style programming. Documentary fared a little better in the UK and Commonwealth countries, where a Griersonian notion of public service continued, manifest in such series as *Panorama*.

Today, despite the cultural variations that exist and the volatility of the international broadcast sector, television documentary remains remarkably uniform. Works tend to be gathered into “strands” that run for “seasons.” Variations of these strands appear on public and state broadcasting systems, and commercial and the new specialist channels. Current affairs series and investigative programs, as well as nature, history, and science documentaries, remain

staples and “national interest” documentary strands mandated with shoring up cultural identity appear on state broadcasting systems. Much of television documentary cited above remains “unauthorized,” its form and content largely dictated by the genre and timeslot expectations of audiences and network commissioners alike, although again, there are exceptions – “high end” documentary strands, such as the BBC’s *Storyville* or HBO’s *Cinemax Reel Life* collect disparate and riskier “independent” documentaries, often produced by “auteurs” into a season.

Television documentary has also had to contend with, and itself has been influenced by, the rapid rise of “reality television” or popular factual programming. There are, by now, sub genres of popular factual – from the survivor, celebrity, and dating shows, to the observational programs shot in airports or on the police beat. The critical and filmmaking communities remain divided over reality TV. Some argue that it has revived documentary, encouraging broader audiences to be more receptive to non-fiction programming. Others revile reality TV for destroying what they see as documentary’s educational and political mandate. Certainly, reality TV is shaped by an economic environment that emphasizes competition, entertainment, and the need to garner ratings, which is remote from the existing traditions of documentary.

Although broadcast television has remained the dominant force in funding and distributing documentary, alternative media movements have continued to coexist. Developing rapidly during the 1960s and 1970s, they drew on the new and relatively inexpensive medium of video. Political, leftist, and agitprop collectives such as Newsreel (US) produced Marxist, radical, and feminist documentaries, while anti colonial or Third Cinema films, such as the 1968 Argentinian film *La Hora de los Hornos*, were deeply influential in the developed world. Experimental film and video practices that eschewed the commercial and broadcast circuits flourished in metropolitan centers such as New York, Berlin, and London. With the demise of the organized left wing and Marxist political parties at the end of the Cold War, documentary began to engage with identity based movements: feminism, AIDS activism, and

ethnic liberation movements, as well as environmental struggles and anti globalization. The rise of digital platforms continues this trend and there is active exploration into “digidocs,” often placed within activist and educational websites.

This more political documentary history has influenced a recent phenomenon: the shift of documentary back onto the big screen. If the overt educational and political agendas have faded on broadcast television, they are reemerging in the cinemas. Although not all cinema documentaries are “political,” most engage with educational and cultural questions and issues. High profile works such as *The Thin Blue Line* (Morris 1987) and *Roger and Me* (Moore 1989), and Moore’s later films, *Bowling for Columbine* (2002) and *Fahrenheit 9/11* (2004), proved that documentaries can generate not only controversy and critical acclaim but also large profits. A slew of similarly political documentaries have followed, such as *The Corporation* (2003) and *Super Size Me* (2004), alongside softer, unlikely hits such as *Spellbound* (2002) and *Être et avoir* (2002).

Up until the late 1970s, writings on the documentary tended to be insider accounts that underlined the status of the documentary maker as something of a hero/outsider. With some notable exceptions, the wave of critical theory and film studies that emerged around this period had ignored documentary, focusing most attention on Hollywood classical cinema. However, as theory matured, documentary began to be subject to serious investigation. Its closer alignment to “reality” in fact threw “the problem of realism,” already thoroughly explored in relation to dramatic film, into even sharper relief. The problem with recording reality was that it assumes that “there is a real ‘out there’ in the natural world that can be shown (or that will reveal itself) without the use of linguistic or cinematic signs” (Gaines 1999: 2). This “impossibility” was wedded, in the same theoretical stew, with the Althusserian notion that “reality” is a highly ideological move to begin with. Realist documentary, then, was seen as reinforcing hegemonic belief systems because it appeared to capture “raw truth” while it was really delivering “ideology.” As well as dominating the discussion of documentary, these critiques privileged certain styles of documentary – those

more interactive and self reflexive modes – that are seen to reveal their own “constructedness” and frame.

Documentary theorists took a range of approaches to the genre. Bill Nichols’s influential modal analysis, which provided a loose taxonomy, continues to prevail, while Brian Winston (1995) has taken a more historical than structural perspective, exploring the ambiguities and tensions within the Griersonian tradition. Michael Renov’s (2004) most recent work traces subjectivity in documentary, a genre historically associated with objectivity. Accompanying the publication of monographs is an increasing number of edited collections on the documentary, some of the most useful emerging out of the “roaming” annual Visible Evidence conference. An increasing number of scholars, too, are breaking with the more canonical focus that has prevailed, engaging more with concepts of reception, audience, and more populist variants of television documentary, such as reality TV, docudrama, and mockumentary (Roscoe & Hight 2000; Hill 2004).

Although they tend to “get on with the job,” makers are aware of their role of representing “reality.” Every step in the production process is mediated by a slew of factors and many ethical and political dilemmas are generated on a daily basis. Documentarians measure up their films, or their films, indeed, are measured up, according to some “truth” or “history” that exists out there. Although couched in different language than that of academic debate, many of the same issues generated by the “problem of realism” are grappled with. The controversy around Michael Moore’s “creative” use of timelines, the arguments about the truth or otherwise of reality TV, the rise of the “mockumentary,” and the debates around bias, show that the tension between “creative” and “actuality,” between “artifice” and “evidence,” continues to reverberate in the various documentary communities – makers, audiences, and academics alike.

documentary analysis

Lindsay Prior

To Max Weber, the written order formed an essential building block of that quintessential form of modern organizational life – bureaucracy. Many later sociologists also noted the importance of documents for structuring and facilitating human interaction. Despite this, documents in sociological studies tend to be somewhat taken for granted and more often than not used as a resource for research rather than as a topic in their own right. Indeed, in the frame of research methods, the use and manipulation of documents is often subsumed under the broader category of “unobtrusive” techniques. This is in strong contrast to the study and use of talk and of speech, which is often linked to tailor made styles of analysis such as conversation analysis.

There is no obvious way to account for the contrasting fortunes of speech and writing in social scientific research and only a few social scientists have remarked on such differences. Thus, the anthropologist Jack Goody has frequently referred to and illustrated how writing is a rich, yet neglected, field for research studies. In a similar manner, Walter Ong underlined the ways in which the influence of writing – as against “orality” – has been underestimated in western scholarship. Yet the subordinate role of writing to speech is far from deserved. Text and writing are not, of course, coterminous with documentation and not all documents involve written traces. Architectural drawings, photographs, tapestries, scientific images, X rays, body scans, and various kinds of physical artifacts can all function as documents in a sociological sense. However, a consideration of the written trace will serve as a useful paradigm for this entry.

As already suggested, when documents appear in sociological research they are usually approached in terms of what they contain. That is, the focus is principally on documents as a means of conveying information – as instruments or conduits of communication between, say, a writer and a reader. Documents do, of course, contain information, yet it is also quite clear that each and every document enters into human activity in a dual relation. First, documents enter the social field as a receptacle (of instructions, obligations, contracts, wishes, reports, etc.). Second, they enter the field as agents in their own right. Indeed, as agents, documents have effects long after their human creators are dead and buried (wills and testaments provide a readily available example of such effects). And as agents, documents are always open to manipulation by others: as allies, as resources for further action, as opponents to be destroyed or suppressed (we should not forget that people burn and ban documents as well as read them).

The text (and pictures, plans, and drawings) contained within any specific document can be analyzed using various techniques. These range from simple forms of content analysis to more complicated forms of discourse analysis. The former method, insofar as it focuses on, say, word and phrase counts and numerical measures of textual expression, can offer fundamental

insights into what people consider to be significant and insignificant in the world. In this mode it is possible to study how people represent such things as “disease” or “crime,” or even “self” and “other” in any given context. More sophisticated approaches to document analysis using strategies derived from the analysis of speech transcripts – such as the deployment of second order coding schemes – can also be applied to the written word. However, the most promising lines of inquiry are probably those developed on the basis of discourse analysis.

Discourse is a complicated concept, and it is not always clear what is meant by discourse analysis even in texts that are devoted to explaining what it might be. The best intellectual starting point for a sociologist, however, is in the work of Michel Foucault, who was essentially interested in the ways in which sets of ideas and concepts in science, medicine, and social science often cohered into determinate ways of seeing the world. More importantly, such “discursive formations,” as he called them, were crucially linked to specific forms of social practice. In short, he argued that what is written and said is inextricably locked into what is done. So he assumed an essential connection between documents (and their contents), practical action, and sites of action – all of which express aspects of a discursive formation. With this in mind we can consider three specific moments of documentation in social action. They are, respectively, moments of production, consumption (or use), and circulation.

The production of documents (e.g., statistical and other reports on crime, health, poverty, and the environment) has figured as an object of study in numerous areas of sociology. The standard sociological stance is to use such reports as a resource for further study – as, say, a source of data on crime or health. Following the work of the ethnomethodologists, however, it is quite clear that documents as reports on the world can also be usefully studied as “topic.” In the latter frame the key questions revolve around how reports and accounts of the world are actually assembled by social actors. What kinds of conceptual and technical operations become involved in their production and what range of assumptions are deployed so as to achieve the end result of a “report”? In the sociology of health and illness,

for example, studies have focused on the ways in which such things as death certificates for individuals or mortality reports – for towns, cities, regions, and nations – are produced. In the sociology of science, questions have been raised concerning the ways in which scientific findings and papers are produced. Indeed, in numerous studies of scientific controversy it is clear that demonstrating “facts” about the world depends very heavily on documentation – especially the manufacture of visible traces (via graphs, photographs, and tables) of invisible entities.

As to issues concerning the consumption of documents, these often turn on matters of use and function. In this frame, what is important is a study of the manner in which people use written (and non written) traces to facilitate or to manage features of social organization – whether it be transitory episodes of interaction or the ongoing functioning of a hospital, or a business, or a school. For example, in his renowned study of folders in a suicide prevention clinic, Harold Garfinkel demonstrated how people who drew on such folders often used them for purposes that were not always consonant with the ways in which the files were originally designed. Thus, Garfinkel noted that many items of routine data that should have been contained in the folders (such as the age and occupation of the patient) were frequently missing. In a similar way, reasons for the non acceptance of patients were missing in 20 percent of the folders, while the names of the staff members in charge of the intake conference were missing in just over 50 percent of cases. Clearly, these were “bad” records, and Garfinkel turned to asking why such incomplete records were, nevertheless, assiduously kept. Some of the reasons for poor record keeping were referred to as normal and natural troubles such as clinic personnel forgetting to enter data. More fundamentally, however, Garfinkel argued that clinic personnel often used the records aware of the possibility that the detail contained within them might be called on at some future stage to demonstrate that patients had always got the treatment they deserved. So clinic folders were, if you like, being constructed in a medico legal framework such that it could always be shown that the “right” things were done to the “right” person at the

“right” time. Such a contractual reading of folder contents explained why it was that basic items of data could be missing from the files on the one hand, while marginal notes and corrections and additions to the folder contents could appear on the other. In short, it accounted for why there were “good” organizational reasons for keeping bad records. Similar reasoning can and has been applied to the use of records in numerous other settings, such as school records, surgical records, and police and welfare agency records. Thus, in medical sociology, there have been numerous studies directed at showing the ways in which patient identities and diagnoses are often shored up through the use of written traces in medical “charts” and patient files.

The creation of identity through documentation is, of course, something that has figured prominently in the history of sociology. Thus, researchers in the so called Chicago tradition (or school) of sociology gave voice to many human actors through the construction of “life stories.” In the latter frame, “delinquents,” criminals, and various people seen as outsiders figured largely in such accounts. In parallel mode, anthropologists often sought out autobiographies of those who had played important traditional roles, such as tribal chiefs. These days it is recognized that the work of identity creation and life “storying” is a concern of almost all people in the advanced world. This may be solely through the construction of a curriculum vitae for employment purposes or through a narrative of personal troubles as conveyed to a counselor, or more likely an account at a security check of who one “is” and what one is doing. (Asserting identity is, in the latter case, almost totally dependent on documentation.) Such autobiographical strategies constitute elements of what Foucault had termed “technologies of self” and they form an important cornerstone of everyday life in the modern world.

As for the circulation or exchange of documents – whether these be of good will cards, Christmas cards, memos, or files – it is possible to see in the trace of exchange the development of social networks and the emergence of identifiable human groupings. For example, studies of citations in scientific papers have been used so as to identify styles of interaction between

groups of scientists. Similar work using web crawlers has been used by sociologists to identify emergent medico scientific networks in the field of genomics. It is conceivable that a sociological study of email contacts and text messaging contacts among the ordinary public may also serve to demonstrate how the exchange of text and documentation functions both to define and cement social groupings. In a related mode, advocates of what has come to be known as actor network theory (ANT) highlight the ways in which documents do not simply circulate but how they also often act back and structure their creators or users. In the latter sense some have spoken of the ways in which documents are invariably involved in the *performance* of social organization.

It is evident, then, that documents, and especially written documents, can be taken as a field of research in their own right. In particular, the study of the processes of production and consumption (or use) of written materials is often key to understanding how the social world and the things within it are constructed. Naturally, in the hurly burly of ordinary everyday activity, issues of production and consumption become entwined, and it is not always easy to distinguish clearly between the one process and the other. Nor should issues of document content be overlooked. Rather, it is the ways in which production, consumption, and content relate to each other that should form the basis of sociological investigation.

doing gender

Sarah Fenstermaker

Candace West and Don Zimmerman introduced the concept “doing gender” in an article of the same title in 1987. They were the first to articulate an *ethnomethodological* perspective on the creation and affirmation of gender inequality between males and females in western society. The purview of ethnomethodology includes the study of the socially managed accomplishments of all aspects of life that are treated as objective, unchanging, and transsituational. West and Zimmerman’s treatment of gender began by making problematic the prevailing cultural perspective: (1) female and male represent naturally defined categories of being that are derived from mutually exclusive (and easily distinguished) reproductive functions, and which result in distinctively different psychological and behavioral proclivities; (2) such divisions are rooted in that biological nature, which makes them both fundamental and enduring; (3) these essential differences between masculine and feminine are adequately reflected in the myriad differences observed between women and men and the social arrangements that solidify around them.

In clear contradiction to these notions, West and Zimmerman asserted that sex is founded on the socially agreed upon biological criteria for initial assignment to sex category, but that classification typically has little to do with the everyday and commonsense sex categorization engaged in by members of a social group. They argued that it is not a rigid set of criteria that is applied to establish confidence that someone is male *or* female, but a seamless application of an “if-can” test. If someone *can be seen* as a member of an appropriate category, then he or she *should* be categorized accordingly. Following this assertion, West and Zimmerman were obliged to describe the process by which sex

categorization is construed, created, and reaffirmed. They did this through the concept of “doing gender.”

This concept challenged the current thinking about gender as an attribute, an individual set of performative displays (largely separate from the ongoing affairs of social life), or a response to vaguely defined role expectations. They completed what Dorothy Smith (2002: x) deemed “a ruthless but invaluable surgery” by distinguishing among sex, sex category, and gender. Under this new formulation, gender could no longer be seen as a social “variable” or individual “characteristic” but as a socially situated accomplishment. West and Zimmerman argued that the implication of such ubiquity is that the design and interpretation of social conduct can at any time be made subject to concerns about sex category. Thus individuals and their behavior – *in virtually any course of action* – can be evaluated in relation to a womanly or manly nature and character. This dynamic, situated rendering of gender points to all aspects of social life – behavioral, emotional, discursive – that mark, note, remind, create, affirm, and reaffirm the social conviction that there is something *essentially* male or female that resides within and justifies sex categorization. The powerful gender *ideals* that abound in popular culture, advertising, and the media certainly serve as resources to guide normative understanding of doing gender, but the actual doing of gender requires much more than a regimented list of “appropriate” behaviors. As West and Zimmerman (1987: 135) explain, “Doing gender consists of managing such occasions so that, whatever the particulars, the outcome is seen and seeable in context as gender appropriate, or, as the case may be, gender inappropriate, that is, *accountable*.”

West and Zimmerman maintained that humans might be classified as males or females, but to be treated as competent group members they must learn to feel, behave as if they possessed, and thus *demonstrate*, their essential womanly and manly qualities. By this the authors do not imply necessarily *hypermasculine* or *deportment*, but myriad craftings – according to every conceivable characteristic and expectation of particular settings and situations – that communicate competence as a person *accountably* feminine or masculine.

Moreover, while they allow that it is individuals who “do” gender, “the idiom of accountability [derives] from those institutional arenas in which social relationships are enacted” (Fenstermaker et al. 1991: 294). Categorical attributions like gender (and later, it was argued, race and class) are granted meaning by particular social conditions and are given concrete expression by the specific social and historical context in which they are embedded.

The notion of gender as an accomplishment in response to the ubiquitous dictates of accountability leads away from the notion of static normative ideals, and necessarily focuses attention on gender’s *situated, fluid* character. That women and men believe themselves to be different by nature is a cultural constant; *how* and *in what ways* those differences are observed, granted social meaning, and rendered consequential varies by the situated particulars of social setting, time, and place. This is not to say that the accomplishment of gender need be confined to interpersonal, so called “micro” level interactions. Indeed, this conceptualization does not *narrow* gender’s purview only to individuals, but enlarges it to address the myriad dynamics of any social order, at whatever level they operate.

ELABORATIONS

Following the initial formulation in *Gender and Society*, Candace West and Sarah Fenstermaker clarified and extended the concept of “doing gender.” Their interest widened to focus on the implications of the concept for explicating practices of inequality and on the application of the concept to empirical work. The subsequent theoretical commentary of West and Fenstermaker focused primarily on the relevance of gender to various forms of interpersonal and institutional inequality and to the extension of the concept to include race and class (see below). They were motivated by an interest in the *social mechanisms* by which the various outcomes of social inequality (e.g., job discrimination, sexual harassment, violence against women, hate crime, differential treatment by gender in school, church, and government) are created and legitimated.

In that spirit, West and Fenstermaker asserted that the accomplishment of gender manifests itself at every level of social arrangement: discursive, interpersonal, organizational, and institutional. West and Fenstermaker argued that as representations of collective action, institutions are subject to gendering in the presentation of their “essential” characters, and are thus assessed (and behave *as if* they are assessable) in relation to gender. We need only look as far as the various recent peregrinations heard on “preserving family values,” the United States as a “world cop,” or the “immorality” of big corporations like Enron to get a sense of how institutions take on gendered characters that inform expectations of their actions. The broad sweep of the concept poses myriad possibilities for applications to the empirical world, particularly evident in the extension of “doing gender” to the concept of “doing difference.”

In their article “Doing Difference” (1995), West and Fenstermaker posed a theoretical problem that took them well beyond their earlier preoccupation with gender. At the time, feminist sociological theory was beginning to pose questions about the categorical “intersectionality” of social life. West and Fenstermaker observed that there was little in the existing literature on gender that provided for an understanding of how race, class, and gender could operate *simultaneously* to shape and ultimately determine the outcomes of inequality. If such “intersections” or “interlocking categories” could go beyond metaphor, what was needed was a conceptual mechanism that illuminated “the relations between individual and institutional practice and among forms of domination” (West & Fenstermaker 1995: 19).

To adapt the argument offered in “Doing Gender,” West and Fenstermaker asserted that while the *resulting manifestations* of sexism, class oppression, and racism are certainly different, the mechanism by which such inequalities unfold are the same. That is, “difference” is done (invidious distinctions justified on grounds of race, class, or gender) within individual and institutional domains to produce social inequalities. These practices are influenced by existing social structure, but also serve to reinscribe the rightness of such practices over time.

CRITICAL RESPONSE

The attempt to develop this unitary model of the workings of inequality garnered heated criticism (*Gender and Society* 1995) that captured some of the problematic features of the formulation as well as the ways an ethnomethodological focus on the production of inequality can be misconstrued. First, critics were wary of any formulation that seemed to conflate the distinctive features of class, race, and gender inequality. The implication for some was that this conflation *erased* the very real differences among class, gender, and racial inequalities. Second, critics worried that insofar as the approach rested on analysis of *face to face* interactions, it might be ahistorical as well as astructural, and thus neglectful of the workings of power. Finally, critics charged that in its focus on the constructedness of social life, both stable institutional inequality and the possibility of ongoing resistance to it might be missed.

In response, Fenstermaker and West reiterated that by requiring the locus of production of inequality to be *interaction* (broadly defined), one is directed to the center of the creation of raced, classed, and gendered social divisions. However situated, such divisions are hardly ephemeral; indeed, they bear the weight of history, past and ongoing institutional practices, and the day to day workings of social structure. Finally, they argue that this is also the way in which social change is made, where resistance has meaning and institutional power can be challenged.

The ethnomethodological insistence on placing interaction at the center of social life was seen by critics as problematic theoretically, but was greeted by empirical researchers as an invitation to productively recast the study of gender, race, and class. Since the 1987 publication of "Doing Gender," scores of empirical studies have demonstrated the empirical usefulness of a concept that directs researchers to the actual production of social life. Studies of the creation of class, race, and gender in high schools (Bettie 2003), the construction of culture and patriarchy among Asian Americans (Pike & Johnson 2002), Dana Britton's (2003) study of prison guards, and Barbara Perry's (2001) study of the construction of hate crime serve as only a few exemplars of the valuable work that begins

from an interest in the situated dynamics of inequality.

TOWARD AN INTEGRATED FRAMEWORK

The useful theoretical tensions that now surround the concept "doing gender" speak to the multiple directions of feminist theory in sociology. First, there remains a continued interest in articulating the *simultaneous* management of categorical identities, where for example accountability to gender, race, class, and sexuality are *together* understood as ever available for social evaluation and social consequence. *How* those operate together or vary in individual salience in any given moment of interaction is a question for empirical study. Second are the recent calls to integration where gender is recast as a *social structure* or an *institution*. Here, the accomplishment of gender, race, class, and sexuality is acknowledged to be multidimensional, sometimes interpersonal, and sometimes organizational in character, and consciously builds in the likelihood of social change. It remains to be seen whether such integration can sufficiently direct empirical focus to the actual workings of accountability at all levels of social life. Third, a fruitful area of new study resides in the "destabilization" of social categories (e.g., "trans" gender, "multi" racial) that forces a reordering of both categorical definition and expectations surrounding accountability to them.

domestic violence

Dianne Cyr Carmody

Domestic violence is a pattern of coercive behavior designed to exert power and control over a person in an intimate relationship through the use of intimidating, threatening, harmful, or harassing behavior (Dutton 1995). This rather broad definition includes multiple forms of abuse: physical, sexual, and emotional or psychological. There is a lack of agreement about what should be included in the definition of domestic violence. Some argue for a broad definition that includes sexual and emotional harm, like the one above, while others limit their definition to actions that result in physical injury.

The debate over the definition of domestic violence complicates the already difficult

problem of measuring the actual incidence of domestic violence. Those who use a broad definition report much higher incidences of domestic violence than those using a narrow definition. In addition, most cases are not reported to police and many victims suffer in silence for years.

In spite of these methodological challenges, research on the incidence, causes, and consequences of domestic violence has progressed in recent decades. This research, much of it conducted in the last 25 years, reveals important patterns and concurrent social problems associated with domestic violence. The victims of domestic violence are primarily female; in 1998, women were victimized at a rate 5 times higher than men (Rennison & Welchans 2000). Women face a higher risk of violent attack from intimates than strangers. Bachman and Saltzman (1995) found that women are up to six times as likely to be assaulted by a partner or ex partner than by a stranger and they are more likely to suffer an injury when their assailant is an intimate (Bachman & Carmody 1994). Domestic violence is one of the leading causes of injury to women in the US (Tjaden & Thoennes 1998). Research has also revealed important patterns associated with race and ethnicity. African Americans experience the highest rate of domestic violence (Rennison & Welchans 2000). Domestic violence rates also vary by age and economic status, with highest victimization rates among the poor and females between the ages of 16 and 24 years (Rennison & Welchans 2000).

Domestic violence has also been linked to a variety of concurrent social problems. While victims may want to leave an abusive relationship, many remain out of fear or lack of resources or hope for change. Victims' fear is well founded: studies show that victims face the highest risk of serious or lethal injury at the point of separation (Tjaden & Thoennes 1998). In addition, each year, approximately one third of all female homicide victims are killed by intimates (Bachman & Saltzman 1995). While the victims of domestic violence face clear challenges, even those in nonviolent relationships pay some of the costs associated with domestic violence. A recent report from the National Center for Injury Prevention and Control (2003) estimates that domestic violence costs the nation US\$5–10 billion annually in medical expenses, police and

court costs, shelters, and employee absenteeism. Domestic violence has also been cited as a primary cause of homelessness (United States Conference of Mayors 1999).

While early researchers worked to document the magnitude of the domestic violence problem, more recent studies have focused on prevention and intervention in violent relationships. Some have assessed the impact of mandatory arrest laws (Sherman & Berk 1984; Carmody & Williams 1987; Hirschel & Buzawa 2002) and court ordered batterer treatment programs (Davis & Taylor 1999; Stephens & Siden 2000). Others have emphasized the link between domestic violence and other types of violence: child abuse (O'Leary 1988), dating violence (Makepeace 1981), sexual assault (Russell 1990), and violence among same sex couples (Renzetti 1992). With increased understanding of the dynamics and causes of domestic violence, more effective interventions and preventative measures should emerge. The result will benefit us all.

double consciousness

Rutledge M. Dennis

When W. E. B. Du Bois introduced the concept of "double consciousness" in his literary and autobiographical masterpiece, *The Souls of Black Folk* (1903), the idea of doubleness was already a major motif in the literary works of Dostoevsky, Stevenson, Melville, Conrad, Poe, and Goethe. Likewise, the term had been addressed in the psychological and philosophical writings of Nietzsche, Dewey, and James. For both groups, the merger of doubleness and consciousness often suggested an irrational force and the emergence of a dual and split personality entombed in one physical body. The dual and split nature of this consciousness

suggested that what was in play was the existence of a "true" and genuine self which could be contrasted to a self which was "false" and inauthentic. Du Bois's use of the term would incorporate many of the psychological and, by reference, sociological assumptions associated with the authors above.

A restatement of the salient features of Du Bois's views on double consciousness permits us to focus on both the origins and consequences of this doubleness; such a restatement will also serve as the basis for a reassessment of the clarity of the concept as explicated by Du Bois. In addition, a reassessment permits us to approach the concept from contemporary sociological perspectives in order to focus on its possible utility in the current era. The core of Du Bois's logic on double consciousness is as follows: (1) it denies an objective consciousness; (2) the "other" becomes the eye through which the world is viewed; (3) it creates an internal warfare between black and white values and norms; (4) ultimately, the black and white selves may merge into a more creative and unique self; and (5) the struggle to appease black and white strivings has greatly handicapped an already distraught and oppressed black population.

In his examination of double consciousness, Du Bois places his thoughts and ideas in a sociological *cul de sac*. For example, his assertion of the absence of "true" self consciousness assumes that the self consciousness of blacks emerging from family and community networks, from economic, cultural, and political institutions, and from the dominant society was less than real or true. It was certainly not the consciousness of a free people, but it was a consciousness reflective of their condition and status in the society. For blacks to have had the consciousness of the free, while unfree, would fly in the face of logic and be yet another example of what Marx called false consciousness. That freedom for blacks would have meant another type of consciousness is a foregone conclusion, but the issue raised here addresses the difference between what consciousness would have been in freedom and how the experience of "unfreedom" is a true experience with its own accompanying consciousness, though not the uncomplicated consciousness Du Bois desired.

Du Bois's statement of blacks only seeing themselves "through the revelation of the other world" is simply untrue, and flies in the face of his own empirical research. For example, we now have vivid accounts of blacks during slavery, the Reconstruction, and the beginning of the Jim Crow years. What we see is a picture of a people grounded in the politics of pragmatism and using any and all available resources, strategies, and skills to navigate a system stacked against them. The reality is that they fought against the very idea of "only" seeing themselves "through the revelation of the other." It may seem logical that a people, faced with overwhelming political, military, and cultural power, may have no choice, but that logic is much too simple and does not take into account the highly complex manner in which humans both survive and play a variety of charades and roles in order to retain a positive and normative image of themselves against all odds.

The will to resist negative emotional, psychological, and sociological intrusions from those who wish to destroy one's humanity may be stronger than many believe. But here, one must understand Du Bois's strategy: to alert others, especially those who indirectly oppress, one must paint a picture which captures the horrors of physical, sociological, and psychological oppression and suffering, and these must be sketched in stark and uncompromising ways so that there is no mistaking the awfulness of this existence. Yet there is always the danger of making sufferers cardboard figures devoid of life, fiber, and willfulness, in which they become mere objects, incapable and unwilling to act. The reality of the brutalization of life in slavery and much of the post slave era is now known through the words and voices of those who shared the horrid experiences. What emerges is a picture of victims who were seeing and defining the "other" who victimized them, while they themselves were simultaneously being victimized and defined by the "other." But the victims were also simultaneously defining themselves and placing a sociological and psychological marker between the "real" self group and the self group seen and defined by the other. Thus, the victim-victimizer dance is dialectical and there is a degree of "shadow boxing." Invariably, we must then conclude that the victims

are never completely as weak as victimizers assume, nor are the victimizers ever as powerful as they believe themselves to be.

The second problem with the concept of double consciousness as used by Du Bois and as commonly used by others involves an inversion of logic. For example, if there is double consciousness, there must exist a "single" consciousness, and if the double nature of consciousness suggests the intrusion of the white mind and white thoughts and the conflicts resulting from this psychological and sociological invasion of white into black, the single consciousness must conversely connote a separate black thought tied to singular black experiences. Thus, the single consciousness is the black consciousness rooted in the experiences of blacks and their inner world out of which emerges the norms and values, and culture, around which blacks have, according to Ralph Ellison, created a world for themselves "on the horns of the white man's dilemma." The black, single consciousness, therefore, reflects the real and objective life as lived. However, rather than introducing the double consciousness to reflect, as it seems logical to do, how blacks have gained keen insights into whites and their social, cultural, and emotional world, Du Bois stands logic on its head by inverting the double to mean, not an objective view of the white world and how blacks see and define their actual objective condition, but how blacks look at themselves "through the eyes of others." This inversion of logic has kept the focus on a view of blacks as incapable of constructing an objective view of themselves or their world and almost destined to look at themselves and their world through the eyes of their oppressors. Again, there is little evidence to support this view. What makes Du Bois's position of the double more problematic is that, taken to its logical conclusion, it must mean that blacks have placed themselves completely within the consciousness of whites and thus use this white consciousness to assess black life, values, and concerns.

Sociology would be methodologically enriched if it were to "socialize" the term double consciousness and link it analytically and logically to the social. By doing so, we could better understand consciousness as it relates to specific dimensions of social interaction and

social relations. In this way, Du Bois's inversion of consciousness, the collective seeing of one group through the eyes of another group, is avoided, placing Du Bois upright, as Marx did to Hegel. Such a new definition of doubleness will not be directed toward how the powerless have accepted the view of themselves as perpetrated by the more powerful. Rather, it will entail a shift which focuses the doubleness more vividly on the dominant powerful community, its institutions and organizations. Perhaps more importantly, such an adjustment in the use of the concept will move us away from one of Du Bois's central themes: a concentration on what powerful groups may think of less powerful groups. What does matter is for powerless groups to have an accurate view of who they are and what must be done as they engage the dominant society, and the need to develop a more accurate and objective critique of the dominant society.

Du Bois's metaphor of the double as "two souls, two thoughts, two unreconciled strivings; two warring ideals in one dark body" has been taken by many to refer to the hopelessness of the task facing blacks. The reality was far different from the picture painted by Du Bois. There was nothing in the black body or mind which mitigated against freedom for itself, hence, Du Bois led us sociologically into a blind alley by explaining the issue primarily as an internal battle, an internal war in which the black body was warring against itself. In reality, the war was external to the black body and stitched into the fabric of the social structure. Metaphorically, we can say that there was one soul occupying the black body, but there was another soul occupying the white body, and that soul was in opposition to the black body and the black soul. But just as the white body lacked two souls, the same can be said for the black body. Could the white soul enter the black body? Did whites have a double consciousness born from oppression and domination? Could the black soul enter the white body? Did Du Bois create a false dichotomy?

As problematic as double consciousness might be, Du Bois, when one reads the social contexts in which the concept is used, situated it in a sociology of black life, though he did not draw the obvious conclusions when he used the term. What must be asserted, however, is

the reality that consciousness of whatever type must emerge from the lived experiences of the people. One part of Du Bois's logic is correct: consciousness must originate in the economic and social relations within the society. One of the difficulties of tracing double consciousness is that, like so many examples in Du Bois's sociology, he does not consistently utilize the same terms throughout his empirical and theoretical works. And he does not delineate or even hint at the concept elsewhere in *Souls of Black Folk* outside of chapters 1 and 10. Nor does he use the concept in his subsequent works. This may mean that he really did not consider the concept as a major definer of black life in America. The question must be raised as to the term's sociological relevance, theoretically and methodologically. Was the term merely of metaphorical value to Du Bois, and does it raise more questions than it answers or resolves? Though the concept is widely used today to refer to groups other than blacks – women, homosexuals, and other ethnic and racial groups – we might be faced with the reality that the Du Boisian idea of the double consciousness may best be observed and understood as a legacy developed out of literary works and the legacy of psychology as a discipline which analyzes the internal dynamics of the self. In this manner, the term can be closely allied to the concept of individual and group identity.

drag queens and drag kings

Leila J. Rupp and Verta Taylor

Drag queens and drag kings are men, women, and transgendered people who perform femininity, masculinity, or something in between. Drag in various forms can be found in almost all parts of the world, and increasingly a transnational drag culture is evolving. Traditionally, drag queens have been gay men who cross dress and lip synch to recorded music in gay or tourist venues, but the world of drag has become much more complicated with the emergence of drag king troupes, ballroom in black and Latino communities in the United States, and the participation of transgender, transsexual, and even heterosexual people in drag performances. Much of the scholarship on drag has focused on the question of how much such performances reify or challenge femininity and masculinity. Drag king troupes, influenced by feminism and queer theory, tend very consciously to deconstruct masculinity and femininity in performances, including by “faux queens” – also called “bio queens” – women who perform femininity or femininity as performed by drag queens. But even traditional drag queens, a variety of scholars have argued, undermine the notion of a polarized gender system by displaying the performative nature of gender.

Not all men who dress as women or women who dress as men identify as drag queens or kings. Other categories include transvestites or cross dressers, generally straight men who wear women's clothing for erotic reasons; butch lesbians; preoperative transsexuals; and transgendered people who display and embrace a gender identity at odds with their biological sex. Some drag queens and drag kings also identify as transgendered or are in the process of sex change surgery. Others alter parts of their bodies, as do “tittie queens,” drag queens who acquire breasts through either hormones or implants but have no intention of changing their genitals. Ballroom, a cultural phenomenon with origins in New York over 50 years ago and made famous by the film *Paris is Burning*,

encompasses a variety of categories: “butch queens” (gay or bisexual men who are masculine, hypermasculine, or effeminate), “femme queens” (male to female transsexuals at various stages), “butch queens up in drags” (gay men in drag), “butches” (female to male transsexuals, butch lesbians, or any woman dressing as a man), “women,” and “men” (straight men).

Drag also encompasses a variety of styles of performance. Esther Newton (1972), in her classic study of US drag in the 1960s, distinguished between “stage impersonators,” talented performers who sang in their own voices, and “street impersonators,” more marginal drag queens who lip synched their numbers. “Female impersonators” generally do celebrity impersonation and keep the illusion of being women, in contrast to those who regularly break it by, for example, speaking in their male voices, referring to themselves as men, or discussing their tucked penises. In Germany, this difference is marked by distinct identities: “drag queens” are glamorous female impersonators, while “Tunten,” a reclaimed derogatory term for feminine men, are what in the United States would be called street queens or camp queens who dress in trashy and outrageous outfits and perform political theater. A similar distinction can be found in South Africa, where white “drag artists” who adopt a masculine persona offstage contrast with black or colored “common drag queens,” effeminate men whose performance extends into everyday life. Ballroom features performances judged by “realness,” for example, a gay man dressed as a straight businessman. Kinging involves a wide variety of performances, from impersonation of hypermasculine straight men to campy gay male numbers to enactments of serious political critiques of such issues as rape, hate crimes, and wartime violence.

The term “drag” in the sense of men wearing women’s clothing dates back to the mid or late nineteenth century, when glamorous female impersonators first appeared on stage. But drag also had connections to the subculture of cross dressing men looking for male sex partners; even before the use of the term “drag” there were subcultures of men – known as “mollies” in England – who used feminine attire and mannerisms to express their same sex sexual desire. In the 1920s, throughout the

major cities of the western world, public drag balls and clubs featuring drag performers attracted mixed crowds. During World War II, in both Canada and the United States, male military personnel staged drag shows to entertain their buddies, although in Canada, as military women increasingly took over female roles, men in drag in theatrical productions aroused suspicion of homosexuality. Despite the conservatism of the post war era, drag shows survived, in part by catering to straight audiences. In San Francisco, where the tourist industry touted the city’s reputation for sexual license, gay men and lesbians mingled with heterosexual tourists at the drag shows at Mona’s, “where girls will be boys,” and Finocchio’s. The Jewel Box Revue, although born in a Miami gay bar in 1939, also aimed at a straight audience. Like the tuxedo clad Harlem performer Gladys Bentley, Storme DeLaverié, who emceed the Jewel Box Revue, was a predecessor of today’s drag kings.

As drag changed in dramatic and less dramatic ways up to the explosion of gay and lesbian activism in the 1970s, two things remained constant: drag both built community among gay and lesbian people and challenged, if more or less politely, the dominant gender divided and heterosexual order. José Sarria, who performed in drag at the Black Cat in San Francisco and ran for city supervisor in 1961 as part of the struggle against police harassment of the gay bars, formed the Imperial Court System in 1965, arguably the first drag queen movement organization. The Court System (now known as the International Court System, with chapters scattered over the western part of the country) raises money for the gay community (and other charitable purposes) through drag shows, but more importantly provides a “family” and respect for drag queens, the heart of the Court.

Drag as a way of creating family is central to ballroom as well. The ballroom community is organized into houses, family like structures that sponsor competitive ball events. Each house has a mother (mostly men, but also women or transwomen) and a father who take responsibility for their children. Such familial support is essential for black and Latino youth who have often been rejected by their biological families, communities of origin, and religious

institutions, the structures that generally sustain people of color in US society. Likewise, drag king troupes provide a nurturing environment for masculine and transgender women who face hostility and violence in the larger world. Drag king troupes and individual performers come together at an annual conference, the International Drag King Extravaganza, held in Columbus, Ohio, since 1999, where, in addition to attending academic sessions and performances, those interested can learn how to apply facial hair, bind their breasts, “pack” (wear a dildo or in some other way create a penis), and move like men.

If drag historically has created community, it has also always carried the possibility of challenge. Even the tourist shows at Finocchio’s or the Jewel Box Revue had a potentially political edge. Comic routines called attention to the illusion of femaleness, and even traditional female impersonation worked to arouse sexual desire in straight male audience members. The role of drag queens in the resistance that followed the 1969 raid on the Stonewall Inn in New York is well known. In the years that followed, groups such as Street Transvestites Action Revolutionaries (founded by Sylvia Rivera, a heroine of Stonewall) and Flaming Faggots, along with men who identified as “radical fairies” and “effeminists,” as well as butch women, challenged gender conformity within the movement. But such gender revolutionaries fought an uphill battle with gay liberationists and radical feminists who tended to dismiss drag as politically incorrect. Not until the 1980s, when groups such as the Sisters of Perpetual Indulgence and Church Ladies for Choice took up comic drag in a serious political struggle with the religious right, did transgender presentation again play a more central role in the movement.

Nevertheless, drag queen performances, especially the more “in your face” political variety in which there is no pretense at being women and a great deal of direct discussion of gay life, sexuality, and gender crossing, can be seen as an effective strategy of the gay, lesbian, bisexual, and transgender movement. Drag shows at the 801 Cabaret in Key West, Florida, for example, explicitly challenge audiences composed of heterosexual as well as gay, lesbian, and bisexual people to confront the

question of what makes a man a man and what makes a woman a woman, as well as to experience desires outside of their own sexual identities. Drag king performances tend to be very explicitly political, representing an enactment of feminist and queer theory critiques of masculinity, although some numbers are humorous and simply fun.

Drag also involves the performance of and movement across lines of class, race, and ethnicity. Impersonation of middle- and upper-class men by black and Latino working-class youth is part of ballroom events, and in both drag queen and drag king shows, performers sometimes adopt a racial or ethnic identity at odds with the one they normally embrace. Performance studies scholar Jose Muñoz argues that drag performed by people of color has the potential to deconstruct whiteness, and other theorists agree that drag holds the potential to expose the performance of racialized codes of gender.

Drag at the turn of the twenty-first century has taken on a wide variety of forms, but all of them are foreshadowed in drag history. There are talented artists who impersonate female or male icons or create their own personae; there are street queens who live a marginal life; there are professional and amateur drag queens who lip synch and adopt a range of styles, from female impersonation to campy drag to voguing; there are movement activists who adopt drag for explicitly political purposes; there are mainstream celebrities such as RuPaul and Lady Chablis, who began their careers like other drag queens but became famous. Perhaps nothing illustrates the rags to riches possibilities of drag so much as the fortunes of Wigstock, the Labor Day drag festival in New York that began in 1984 with an impromptu performance by tired drag queens leaving a club at the end of the night and grew over the years into an international extravaganza attracting tens of thousands of spectators and official recognition from the city.

The major scholarly critique of drag queens – that they are more gender conservatives than gender revolutionaries, or that they exercise male power in female form – has not extended to drag kings, although there are no doubt some who would see them as aping, as they criticize, traditional masculinity. Some in the gay, lesbian, bisexual, and transgendered communities are critical of both drag queens and drag kings

for calling attention to gender transgression and thus undermining the argument that gay people are just like heterosexuals in every way except choice of partners. Gender theorists have been very interested in cross dressing and transgender performances for what they reveal about the social construction and performativity of gender and sexuality. Recent empirical research on drag queens, drag kings, and ballroom in different national and local contexts is enriching our understanding not only of the complex gender, sexual, racial/ethnic, and class dimensions of drag performances, but also of what they reveal about the fluidity of gender and sexual identity.

dramaturgy

Peter Kirby Manning

A dictionary definition of dramaturgy is "the art of theater, especially the writing of plays." Roget's *Thesaurus* lists it under drama (599.2) and gives the synonyms theatrics, histrionics, acting, play acting, melodramatics, stagecraft, *mise en scène*, and stage setting. This definition turns attention to the literal process of creating for others a scripted text for its presumed effects. In everyday life the metaphor has its limits and the world is not always a stage, or even dramatic. Most attempts at precise definition of dramaturgy fail because, while it is a powerful metaphor or way of seeing, the concept as employed surfaces differences in emphasis and style.

Dramaturgy points to a family of words associated with the idea of analyzing, or being sensitive to, selective performance to emphasize features of symbolic action, whether they be textual, prose or poetry, or behavior. In social science, dramaturgy is not an actor's perspective or a view with the actor's eyes but a meta perspective that makes sense of action, whether it is carried out by organizations, groups, or actors. Dramaturgy reflects the everyday work of actors, but the perspective does not assume an ironic pose, discount what is done or said, or begin with scientific concepts or theories. As seems apt, dramaturgy assumes neither that we know much more than what we see nor that we understand what lies behind the eyes of actors.

Given this perspective, what does dramaturgy connote about analysis of the social? What is achieved by use of the theatric metaphor and a focus upon how performances are enacted and with what effect(s)? What has an effect must be intelligible to others. In this sense, it requires or assumes feedback and reciprocity from an audience, the process by which claims are validated (verbal or non verbal, written or electronic). Failure to produce feedback and reciprocity requires repair, apology, recreation.

Kenneth Burke, a leading writer on theater and drama, defines humans (as a logical category) thus: "Man is the symbol using animal" (Burke 1989: 56). Symbol use is an expression of emotion or sentiment; it could be called a quest for meaning or emotional grounding.

Emotion, it would appear, is what is being symbolized; symbols touch off meaning, response, and emotion or catharsis in an audience. To state that symbols are “used” by “man” means that they are selectively attended to. Of the many symbols present in an encounter, only some will be used or selected to produce a response in others. In situations, parts or elements of action are revealed, given, and given off, but how they might produce a sequence of actions cannot be known fully in advance. Dramaturgy does not honor any particular repertoire of symbols, symbolic actions, conversational moves, or a given poetics of human conduct. However, it is likely that the power and appeal of dramaturgy rest in its applicability to the increasing number of situations in massified society in which strangers must negotiate encounters in the absence of shared values, beliefs, kin, or ethnic ties.

In this context of high modernity, performances rely on trust, evidenced in ongoing sequences of interpretation, what Goffman, following the philosopher Austin, terms the “felicity condition.” Social interaction is a communicative dance based on trust and reciprocity. Thus mutuality and duality constitute the “promissory, evidential character” of social life. While trust, or acceptance of forthcoming outcomes, is necessary, it may be violated, new contingencies may arise, and a new line of action may unfold. People perform, respond, perform, respond, and thus they symbolize. It is a false and misleading assumption that trust is absent in modern life; it must be made present more in modern life where strangers have fewer cues to establish it in advance.

Goffman’s view is not a full picture of the constraints of social structure. In many respects, the weakness of dramaturgy has been that those who use it casually “overcode” the notion, and apply it widely without qualification, seeing the ordering of life as a kind of bad high school play, or applying it exclusively at the actor’s consciousness level rather than explicating the limits of the idea as metaphor to guide careful analysis.

Dramaturgy, or dramatism as Kenneth Burke called it, as a perspective in social science emerged at the University of Chicago. While Burke was an original scholar and an autodidact, other figures in the movement, Goffman, Gusfield, Edelman, and Duncan, were Chicago-trained PhD scholars. They were influenced by

the ideas of George Herbert Mead, Herbert Blumer, and Charles Morris, who was himself a student of Mead’s. Morris was pioneering and refining an idea related to symbolic interactionism and dramaturgy, semiotics, the science of signs. Burke’s earliest works were subtle deconstructions of the singular Marxist materialist portrait of man particularly popular amongst intellectuals in the 1930s. In effect, asserting the partiality of any view of human conduct, Burke also questioned any full organic scheme such as the popular structural functionalism current until the 1970s.

To understand the contours of dramaturgy, one must consider further dramatists. As scholars, they begin with three assumptions. The first is that behavior is a vast, unfolding, deeply complex matter, for the meaning of which we are given cues by others. This is followed by a second assumption: that the human need for order and ordering is fundamental. This assumption suggests that humans are driven to perform for others in some fashion as a condition of sociality. People are civilized, as Durkheim writes, because they are tied to others. The third assumption is that through symbolic action, words, gestures, postures, and facial expressions, we seek to be understood. Symbolic action creates the possibility that sequences producing order will be sustained. While social scientists have seized on interaction as their materials, others have worked on texts, plays, plastic and visual arts, and the sequences of concern need not be face to face encounters.

Kenneth Burke and Hugh Dalziel Duncan were critics of written texts. Burke, like William Empson, was an insightful observer of that poignantly ambiguous symbolic action, poetry. Poetry is metaphor in the guise of metonymy. This concern with forms of speech and aesthetics aligns dramaturgy with classic rhetoric (Aristotle in particular), accounts, or vocabularies of motive, as well as any persuasive performance. “Motive” in dramaturgy is a rhetorical form: an account for an action choice when it is questioned. This is how motives are revealed. The underlying and unifying idea is that once tradition and continuity in human relationships are attenuated, meaning must be sought and pointed to again and again rather than assumed. Because complexity of action remains, what is seized

upon for analysis, if not in everyday life, is what is *said* about what was done, will be done, or might be done. All renditions of interactions, including responses and interpretations of them, are endlessly partial. This proposition, refined by C. Wright Mills, brings us to the matter of metaphor and other figures of speech, for they provide recipes used to gloss longer sequences and order requests and responses. Strings of words may be extended into stories, allegory, myth, or other narrative genres. All representations are re representations, and thus are paradoxical, partial, misleading, and open to interpretation and response. Thus, no metaphor, even dramaturgy, can capture the full richness of behavior *mis en scène*.

If we hold these points loosely in mind, several refinements set the scope of dramaturgy. These include the role of the self, of pragmatism, conversational analysis, and the role of the audience. These are critical distinctions, because they account for the tensions between symbolic interactionism, dramaturgy, and ethnomethodology. Dramaturgy does not require a self or selves as central meaning producing mechanisms. All responses are interpretations, but they need not pass through a master self like processor. It does not rest upon pragmatism or the social psychology of Mead, Blumer, James, or Peirce. Pragmatism presumes intentions and purposes of some sort which are revealed and refined over the course of interaction. Most attempts to clarify the perspective play on an assumed pragmatism: actors (writers, painters, poets, everyday citizens) seek to convince others (an audience) of what they claim to be by selective presentation of symbols. Life is not captured to be reshowed on a VCR or DVD and cannot be rerun, even though it may be understood after the fact. The modern tradition of linguistics, conversation analysis included, posits a range of possible meanings in an interaction, whilst not considering the state of affairs chaotic. Sequential interpretations unfold, but cannot easily be used to reveal intent, purpose, or perspective. Perspective suggests consistency of project that is characteristic over time. Audiences are alert to efforts by others to make claims and to respond. Gusfield's gloss on Burke (Burke 1989: 10) makes the persuasive function of such symbolic action a part of the conflict and reflection inimical to human conduct. Readings

of "conflict" and "order" are done by the theorist, not by those who are embedded in the sense making. Ethnomethodology and conversation analysis resemble dramaturgy, but differ in the role they attribute to the ordering of conversations according to tacit conventions, and in the degree to which order is problematic. In many ways, dramaturgy opts for a kind of surrealism or search for meaning, while ethnomethodology assumes order prevails.

Dramaturgy burst on the scene soon after the publication of Goffman's reworked, ethnographically based dissertation, *Presentation of Self in Everyday Life* (PSEL 1959). It was first published in 1956 as a research monograph by the University of Edinburgh. Goffman argues very tersely on p. ix: "I shall consider the way in which the individual in ordinary work situations presents himself and his activities, the ways in which he guides and controls the impression they form of him, and the kinds of things he may or may not do while sustaining his performance before them." In this sentence, Goffman states that dramaturgy is about the actor's impression management. His strong connection to dramaturgy in spite of variations in emphases in his career is signaled best by the organizing metaphors he employs, many of them taken from the theater – front and back stage, script, and role. PSEL stimulated both efforts to summarize it and a number of collections.

PSEL has sold well and remains in print after some 40 or so years; it has been very influential on two generations of graduate students. The book is controversial because it renders interaction as a puzzle resolved only in and through interaction, not via a priori concepts such as personality, values, norms, or social systems. Goffman struggled to show how actors display order and ordering conventions in many situations, with an eye always to ways humans adapt, interpret, read off, and make sense of others' behavior. This does not assume life as chaos, nor does it require positing people as "puppets" with attributed feelings, aims, goals, and a repertoire of strategies and tactics. It does assume that they act to display for others and to elicit a response. Goffman was associated with dramaturgy, but his work evolved, evading easy understanding or simplification.

The complexity of his ideas, as well as his abiding significance as a scholar, lead many to

agonize over his concepts, seeking to fit them to this or that scheme; rendering his work as a cynical dismissal of modern life; attempting to embed his ideas in a sociohistorical context; dismissing them as trivial; seeing them as a paradigm of modern life or an impenetrable enigma. None of these is fully accurate. Tom Burns, an early colleague of Goffman's at Edinburgh, perhaps most accurately dismisses attempts to discover a single consistent theory in Goffman's writing. Philip Manning disagrees, arguing for an emergent puzzle composed of constituent parts.

Scholars have struggled with the basic notions of dramatism with varying success, some shaping it in line as a version of symbolic interaction; performance ethnography that emphasizes the "performative" nature of human action; post modernism; quasi organizational theory; of quintessential democratic interactions, and as politics as a grand spectacle arising from the need to dramatize and manage conflicts. The most troubling connections are to structuralism and semiotics, as Goffman cites scholars such as Bakhtin and Russian linguists, and refers to signs in several of his publications. A few salient and useful attempts at exegesis exist.

Criticisms of dramaturgy as theory often come from unsympathetic sources (Brissett & Edgley 1990 summarize these). The point most frequently made, that dramaturgy asserts ontological assumptions about the reality of life as theater, is clearly wrong. It is one among many possible perspectives; it is not a perspective on perspectives. A second common criticism is that it is not a theory of the deductive/propositional sort. This perhaps hinges more on a definition of "theory" than on whether dramaturgy qualifies. A third trenchant criticism is the view that the extensive accommodation and impression management of the modern citizen is an indication of normality, not deviance. This modern citizen, sensitive to impressions and their management, seeking to be liked, is an ideologically captured consumer, a shadow of more powerful economic and political forces. Modernity is perhaps more than this, but not less. In this way, Goffman echoes ideas of Robert Musil, Ortega y Gasset, Sartre, and Camus.

dropping out of school

Ralph B. McNeal, Jr.

Dropping out of school in a post industrial society comes with many risks. In the United States, as with most industrialized societies, education is a key factor for predicting social mobility; dropping out clearly undermines one's prospects of moving up the socioeconomic ladder. Dropping out of high school is also accompanied by many other negative outcomes or consequences, including an increased propensity for subsequent criminal behavior, lower

occupational and economic prospects, lower lifetime earnings, an increased likelihood of becoming a member of the underclass, lower levels of academic skills, and poorer levels of mental and physical health than non dropouts.

In addition to the negative consequences for the individual dropout, areas with high concentrations of dropouts also suffer. Areas with higher concentrations of dropouts have decreased tax revenues, increased expenditures for government assistance programs, higher crime rates, and reduced levels of social and political participation. Given all of these negative consequences, what do we know about high school dropouts? Who are they? Why do they fail to complete high school?

Before answering any of these questions, we should first define *dropout*. This is not as easy as it might appear. Oftentimes, attempts to define high school dropouts and actually measuring this status in the many available data sources are at odds. In the purest sense, a high school dropout is *anybody who fails to acquire a high school diploma*. There are two major national studies that are often used to conduct research on high school dropouts, High School & Beyond (1980) and the National Education Longitudinal Study (NELS, 1988). These two databases account for the lion's share of what we know about dropping out of high school during the past two decades, but each data source has its own limitations. In High School & Beyond, dropouts are those students who drop out of school between the tenth and twelfth grades; this clearly misses a large number of dropouts who either leave school prior to the tenth grade (one estimate is that between 10 and 20 percent of dropouts leave school prior to the tenth grade) or those who are still in school in the twelfth grade, but eventually drop out. In NELS:88, high school dropouts are often defined as those who have left school during or after the eighth grade and still have not returned to school or acquired a high school diploma as of two years post the anticipated graduation date (a six year window). NELS is far more inclusive, but still leaves some students out of the definition because they return to complete their high school diploma outside of the allotted window. Thus, while the abstract definition of a high school dropout is very clear, the actual measurement of who

has, or has not, dropped out is questionable. To help clarify the various statuses, any number of terms have been applied, including "stopouts," "dropouts," "early leavers," and "returnees," just to name a few (Pallas 1986).

To further complicate matters, researchers often define high school dropouts differently than do educators. In some instances, educators actively track students who have left their school and do not include the student as a dropout if he or she enrolls in an alternative education or adult learning program. In other instances, educators do not track the student once he or she has left the school but classify the student as a dropout if that individual withdraws from school and there is no accompanying request to forward the student's academic record to another educational institution. Regardless of how it defines a student who has left school, it is often in the school's best interest to record the lowest possible dropout rate since it is one measure of school quality. Somewhere in the midst of these various operationalizations lies the truth – those students whose educational careers fall short of acquiring a high school diploma.

WHO DROPS OUT AND WHY?

It is not difficult to paint a portrait of the typical high school dropout. There have been a plethora of studies trying to determine who drops out (or does not). Racial and ethnic minority students – in particular blacks and Hispanics – are more likely to drop out than white students. Students of lower academic ability are more likely to drop out than are high ability students. Lower socioeconomic status (SES) students are more likely to drop out than higher SES students. Being older than one's peers and/or from a single headed household have also been linked to higher likelihoods of dropping out. Gender prominently factors into the dropout equation; teenage pregnancy is more likely to lead to dropping out for women, whereas acquiring a full time job has a greater increase on the likelihood of dropping out for men. Beyond demographics, researchers have also examined other individual level measures including student involvement in extra curricular activities and adolescent employment. Students who are

more involved in extra curricular activities are less likely to drop out; students who work more than 20 hours a week during the school year have an increased likelihood of dropping out.

Many of these individual level effects were established by researchers in the 1980s and 1990s using a variety of theoretical models, including the participation identification model, the social control model, the rational choice model, various integration and process models, and zero sum models. During the past decade, various elements of social context have also been incorporated into theoretical models, including peer group, family, school, and community factors. In terms of family based explanations, parents' level of education and/or occupational standing, select aspects of the home environment such as the availability of cultural capital resources, and the relevant social support system (e.g., social capital) have been found to significantly affect a student's likelihood of dropping out. Students with parents or older siblings who are dropouts are at higher risk of dropping out, as are students with uninvolved parents.

More recent research further expands the boundaries of meaningful social context(s) by examining the school's role in producing high school dropouts, as well as the influence of various neighborhood characteristics. Research has consistently found that school size, level of social integration or involvement within the school, resources, and various indicators of school climate all affect whether a student drops out of school. Studies have also shown that spatial/context measures such as higher dropout rates and greater rates of poverty have a disproportionate effect on an individual student's likelihood of dropping out. The majority of studies examining school or community context use some variant of opportunity theory, coupled with the assumption that adolescents are rational actors in the educational decision making process, to explain dropping out within a multilevel framework.

In summary, research to date has examined an exhaustive number of predictors of dropping out of school at the individual, familial, peer group, school, and community levels. Most of the aforementioned concepts can be thought of as "pushing" or "facilitating" factors. An

alternative set of factors can be viewed as "pulling" or "attracting" measures. Previous research established that students often leave school early because they wish to obtain the status of various adult roles, such as mother or worker. These two findings are clearly gender related. For many young women, pregnancy is a key contributing factor to their decision to drop out of school; scholars contend that the attraction of motherhood draws young women out of school to start families. For many young men, the lure of full time employment is sufficient for them to prematurely terminate their education; this is especially true in impoverished neighborhoods where full time jobs are a rare commodity. The so called "tipping point," the point where school year employment becomes detrimental to a student's chances of completing high school, seems to be approximately 20 hours a week. What distinguishes both of these effects (pregnancy and employment) from other predictors is the strong possibility of a selection effect. In other words, the research clearly establishes these links, but there is disagreement on the direction of causality. Proponents of adolescent work contend that students who are already disengaged from school choose to work; opponents of adolescent work contend that greater than part time work draws otherwise engaged students out of school and into the workplace. Similar arguments are made concerning teenage pregnancy. Does the desire to assume adult roles come before or after the student's disengagement from schooling? The truth is, we do not know, because studies have yet to systematically control for the student's adult role orientation, making it impossible to draw a definitive conclusion.

FUTURE RESEARCH

Given what we know about the consequences of dropping out, and the major predictors, what is yet to be determined concerning high school dropouts? Future research should focus on one of four broad areas: defining and measuring dropout, disentangling early childhood attitudes and behaviors and determining their effect on dropping out, studying dropouts from non public school settings, and addressing the long term costs and consequences of dropping out.

As for the first broad need, there are several specific tasks that should be completed. First, there needs to be a clearly articulated and widely agreed upon method of defining, and perhaps more importantly of measuring, dropout. Most previous research tends to define school dropout in relation to high school, but many students drop out of middle school and are not captured in most studies. Additionally, the category of "dropout" should be more fully refined to recognize that not all dropouts are the same. For example, there are dropouts who fail to acquire any further education, dropouts who return to get their high school diploma, dropouts who earn an equivalency certificate (e.g., GED), and dropouts who continue on to attain college or post graduate degrees. Future research should strive for better clarity when professing to study "dropouts" and address the subtle, but likely very important, differences across these groups.

The second broad need is to disentangle early childhood attitudes and behaviors, and to determine their effect on dropping out. Some preliminary research has examined how early childhood predictors such as attitudes toward school, exposure to delinquent behaviors, and early childhood parenting practices affect adolescent delinquency and drug use. This is a line of social psychological research that should be applied to dropping out of school since items such as early childhood school readiness, literacy, and elementary school experiences should be critical for understanding dropping out of high school. After all, dropping out often is the final step in a very long and gradual process of disengaging from school.

The third broad area where future research might prove fruitful is the investigation of dropouts from non public school settings. To date, the lion's share of research has focused on dropouts from public high schools. Research is clearly needed on who drops out of private schools (religious, non religious, and alternative/charter schools), and why. As with most other educational processes studied during the last 40 or more years, there will surely be differences between public and private schools in this regard. The lack of current research on this matter seems to imply that dropping out of school is only an issue faced by public schools, and this is clearly not the case.

Finally, research should more clearly conceptualize dropping out in a longitudinal framework. Too often research on dropouts looks at predictors approximately two years prior to dropping out and outcomes approximately two to four years after dropping out. Given the importance of educational credentials in a post industrial society, research should place dropping out of school into the context of the life course perspective and investigate how this act is related to a wider variety of predictors in childhood and outcomes in later life. Such studies should clearly define dropout, including its many subcategories, and investigate the similarities and differences in a variety of outcomes in the later stages of the life course such as life satisfaction, lifetime earnings, and mental and physical health (to name a few).

drug use

Larry Gaines

Drug addiction and abuse constitute a major social problem that is interlaced throughout our society. Each year it costs billions of dollars in terms of interdiction, prevention, enforcement, treatment, and lost productivity. Moreover, the drug problem exacerbates a number of other social problems including poverty, homelessness, crime, and family discord. Historically, society addressed the drug problem, as well as other social problems, using a generalized, simplistic response. However, if the drug

problem is better understood in terms of who is using drugs and what types of drugs are being used, tailored responses can be developed that in the end may be more effective and beneficial.

American society is bombarded constantly by all sorts of messages advocating the use of drugs. Pharmaceutical companies and vendors have inundated society with drug advertising. Few people can open their email accounts without having at least one message that attempts to sell some type of drug. Many of these vendors have their own physicians who can prescribe drugs in absentia. A significant proportion of television advertising is now devoted to prescription drugs, and they all end by urging viewers to ask their physician about some drug that will enhance their lives by making them feel better, look better, or have enhanced sexuality. There are approximately 3 billion prescriptions written annually, and the Center for Disease Control and Prevention (CDC) notes that each year physicians write about 1.5 prescriptions per office visit, demonstrating a substantial amount of medicating in the United States (Cooper et al. 1993; NIDA 2004).

In some quarters of our society, the same pressures exist for using illicit drugs. Young people are enticed to use drugs as a result of cultural norms and expectations. Ample friendship networks exist to deliver club drugs such as Ecstasy, cocaine, and Rohypnol. For many youth, drugs are solidly embedded in the culture, and they desire to be accepted as one of the group. Since alcohol and tobacco consumption is high for young people, it is rather easy for them to slip into using drugs. Research indicates that adolescents who use alcohol and tobacco cigarettes are significantly more likely to use illegal drugs than adolescents who abstain from these legal drugs.

The vast majority of efforts attacking the drug problem are concentrated on illegal drugs, but it must be understood that prescription drugs are just as problematic, although they receive less notoriety. Quantities of prescription drugs are diverted to the street and abused. Nicotine and alcohol are the two most widely used drugs in society, but because of their legal status most people do not see them as such, although this has been moderated somewhat as

government and public groups have attempted to negatively label their use and abuse. Substances that are psychoactive, that is, influence the workings of the mind – and therefore the behavior of organisms that take them – are legally governed in the United States by the Controlled Substance Act of 1970. This Act divides substances into “schedules” according to their medical utility and their potential for abuse. Those substances the federal government regards as having “no medical utility” and a high potential for abuse are Schedule I drugs: it is illegal to possess or sell Schedule I drugs. They include heroin, LSD, marijuana, and Ecstasy. (It must be pointed out that bodies other than the United States government regard a number of Schedule I drugs – marijuana most notably – as having considerable medical utility.)

Many in our society are concerned with America’s drug problem. However, America does not have a single drug problem; it has multiple drug problems. Although marijuana is the drug of choice across the social spectrum, different constituencies or groups have a propensity to use or abuse other drugs. Young people tend to abuse marijuana, Ecstasy, and Rohypnol and inhalants. Methamphetamine is predominately a rural drug, while crack cocaine and heroin are associated with inner city youth and young adults. Middle and upper class professionals tend to use powder cocaine at a higher rate relative to other groups. Synthetic narcotics such as Lortab, Dilaudid, and OxyContin are more likely to be abused by middle aged and older Americans, and a number of prescription drugs are abused by housewives. Although there is overlap in terms of drug consumption, there is a measure of stratification of drug usage within the overall population.

There are different levels of drug usage. Legally, the use of any illegal drug or prescription drug in a manner not recommended by the physician is considered abuse, but some people have more problems with drug use than others. Goode (2005) notes that the drug problem cannot be fully understood without considering the amount of drugs that individuals consume. Abdinsky (2004) has developed a continuum of drug use that better illustrates the point. First, there is experimental use where a

drug is tried to see what happens. Individuals may experiment with a drug once or a few times and never use the drug again. This is a fairly common occurrence. Second is culturally endorsed use where an individual's culture or peer group has adopted or accepted the use of a drug or set of drugs as normative behavior. When this occurs there is pressure on the deviant non drug user to conform to the norms of the group. Such pressures are extremely enticing and many youngsters and teens have difficulty resisting. The same can be said of many marginalized neighborhoods where drugs are an everyday part of life. Recreational use is the third category, and this is where drugs are consumed more frequently. Drugs are used increasingly in more social contexts, and the abuser tends to look for opportunities or excuses to consume drugs. Finally, compulsive use is where individuals have developed a physiological or psychological dependence on the drug. Many more life events center around the acquisition and use of drugs as opposed to work or family responsibilities. The Department of Health and Human Services (2003) estimates that there are 22 million Americans classified with substance dependence or abuse, which includes alcohol as well as illicit drugs. This constitutes 9.4 percent of the population aged 12 and older.

Although compulsive drug use begins with experimentation, it is not true that all drug experimenters end up as compulsive drug users. Indeed, many people do not venture beyond the experimentation stage of drug use. For example, the National Survey on Drug Use and Health, which is conducted by the Department of Health and Human Services, provides data on lifetime and past month drug usage. In 2002, 46 percent of the American population aged 12 or older had used an illicit drug in their lifetimes, but only 8.3 percent had used an illicit drug in the past month. While 8.3 percent of the population perhaps showed a pattern of drug usage, about 38 percent of the population appeared to be infrequent drug users or people who were experimenters. Thus, the vast majority of drug users do not become compulsive users.

It is informative to examine drug usage patterns when attempting to understand the

amount and patterns of drug consumption in the United States. To this end, there are a variety of surveys that can be enlightening. In 2002, the National Survey on Drug Use and Health survey found that approximately 19.5 million Americans were current drug users. The most widely used drug was marijuana with a use rate of 6.2 percent. There was an estimated 2 million cocaine users with a little over 25 percent being crack cocaine users. This represented less than 1 percent of the population. Cocaine use declined in the early 1990s for youth, but the trend has reversed and in 2002, an estimated 2.7 percent of the population had used cocaine at some point. There were 1.2 million hallucinogen users, and a little over 50 percent of the hallucinogens being abused was Ecstasy. Ecstasy has been driving an increase in hallucinogens for several years. There were 166,000 heroin users in 2002, and the rate of usage has been steadily climbing since the mid 1990s, although these figures are suspect since many heroin users such as the homeless are not counted in the household survey. A substantial proportion of the increase is attributable to young people whose rate of usage has increased 400 percent in the last seven years (DHHS 2003).

There is a substantial portion of the population that is abusing psychoactive prescription drugs. Approximately 2.6 percent of the population or 6.2 million people reportedly are current users of psychoactive drugs for non medical purposes. The most commonly abused prescription drugs are pain relievers, followed in order of use by tranquilizers, stimulants, and sedatives. As an example, OxyContin, a synthetic narcotic and a relatively new drug, has about 2 million abusers, which is similar to the number of cocaine users in the United States (DHHS 2003). Psychoactive drugs are diverted from pharmacies and medical providers, manufactured in clandestine labs, and smuggled into the United States from foreign countries.

As noted above, drug use is interlaced with a variety of problems. The relationship between drugs and crime is of most importance and drives a substantial proportion of the concerns with drug abuse. Thus, it is cogent to examine drug use in the criminal population. However,

before examining these statistics, it is important to note that there is considerable debate on the degree to which drugs cause crime. Although drug use is attributable to some crime, many experts agree that the drug problem commingles with the crime problem and that criminals reside in a culture that is conducive to drug use. These experts argue that it is not a clear cut causal relationship (McBride & McCoy 2003; Faupel et al. 2004).

To this end, three models explaining the crime–drug relationship have evolved (Goode 2005). First, the enslavement model posits that individuals become addicted to drugs as a result of some life situation or happenstance. They become trapped in their addiction and must resort to crime to support their drug needs. Proponents of the enslavement model see legalization of drugs as a viable method of reducing drug related crimes. Second, the predisposition model states that criminals are deviants or anti social people who have a predisposition to commit crime and take drugs, and reside in a culture where drugs are accepted and plentiful. Drugs and crime become an accepted part of life. Finally, the intensification model basically states that drug usage intensifies criminal behavior. This is supported by the fact that when addicts desist from drug usage, the number of crimes they commit declines precipitously (Ball et al. 1983). Inciardi (1992) sees drug use as intensifying an already existing criminal career.

A significant proportion of those arrested regardless of crime are abusing drugs. The Arrestee Drug Abuse Monitoring Program (ADAM) examines drug use rates in 39 large and medium sized cities in the United States. Essentially, jail inmates are interviewed about their drug use and asked to provide a urine sample, which is analyzed to determine if drugs are present and the kinds of drugs inmates were taking at the time of their arrest. Screening concentrates on illegal drugs and a limited number of prescription drugs: cocaine, opiates, marijuana, methamphetamine, PCP, barbiturates, benzodiazepines, methadone, and propoxyphene. ADAM is an important program in that it provides access to drug use information about the criminal population, which assists in the development of more effective criminal justice policies.

In terms of male arrestees, the median percentage of arrestees testing positive for one of the above nine drugs in 2003 was 67, and the median percentage for females was 68. The 2002 National Survey on Drug Use and Health reported that 11.6 percent of the population aged 12 or older had used an illicit drug in the past month. Although ADAM and the National Survey use different methodologies, the differences between arrestees and the population are striking and demonstrate that drug usage among the criminal population is significantly higher. The median use rate for female arrestees across cities was one percentage point above the male rate. Females used crack cocaine, cocaine, and heroin at a higher rate, while males used marijuana and methamphetamine at a higher rate (Zhang 2004). The difference in usage rates between males and females may be the result of sample characteristics or police discretion when deciding to make an arrest as opposed to actual use rates. The police may apply laws more strictly to the males. Regardless, the data show that drug usage and abuse is high among all arrestees with some differences across cities.

The ADAM statistics reveal that for the most part, cocaine and marijuana primarily are being used by those arrested. PCP appears in the drug testing fairly infrequently, and methamphetamine and heroin use, although widespread, seem to be regionalized with some locations having moderate numbers of users, while other locations have minimal numbers of users who are arrested.

If drug usage statistics were examined in detail for a period of several years, it would reveal that there is an ebb and flow of drug problems. Drugs of choice, to some extent, vary by region of the country, age of the population, and city. Historically, society and government have not recognized that there are multiple drug problems, and for the most part have developed prevention, suppression, and treatment programs that may be applicable to one part of the country or one type of drug, but have less utility for other parts of the country and other drugs. The drug problems must be fully understood in terms of patterns of usage, and more effective programs must be fashioned that address specific populations and types of

drugs. This can only be accomplished by monitoring drug usage patterns and researching programs at the micro level. An understanding of what works and the conditions that facilitate success must be understood. Only then can effective responses to the drug problems be implemented.

drugs, drug abuse, and drug policy

Emma Wincup

The term “drug” has been both broadly and narrowly defined. At its simplest, it is reserved for substances which are prohibited under criminal law. Deploying this definition, the range of substances classified as drugs varies across time and across jurisdictions. However, typically, it refers to substances such as heroin, cocaine, ecstasy, and amphetamines. At the other extreme, more inclusive definitions of the term have been adopted. In addition to outlawed substances, in these instances, drugs can refer to alcohol and tobacco, plus substances such as solvents, prescribed medication, and over the counter remedies used illicitly. When developing policies, countries are most likely to utilize a narrow definition and focus attention on illegal drugs.

The terms “drug abuse” and “misuse” are frequently used in policy documents to describe the most harmful forms of drug use which warrant attention. However, there is an emerging consensus that these terms should be avoided because they are highly subjective and judgmental descriptions of patterns of drug use. Instead, the term “problem drug use” is preferred, which typically describes patterns of use which create social, psychological, physical, or legal problems for an individual drug user. Although many problem drug users will be classified as emotionally or physically dependent on drugs, this is not inevitably the case. Instead, their drug use can be regarded as problematic because they engage in high risk behaviors (e.g., injecting drugs or consuming large quantities in one session). It is important to note that unambiguous distinctions between patterns of drug use are difficult to draw, not least because at one level all drug use can be viewed as problematic due to its potentially negative implications for an individual’s health and well being.

Problem drug use has been defined as a law and order, social, medical, and public health problem. Defined as a law and order problem, policy attention is likely to be focused on

strategies to reduce the supply of drugs through tackling drug markets or to decrease the demand for drugs through attempts to break the link between drugs and crime. This link is often viewed simplistically as a causal one, with drug users committing crime to finance their drug use. Consequently, policies such as coercive drug treatment are advocated to break the link.

Problem drug use has also been understood as a social problem. A challenge for sociologists is to explore why problem drug use has been defined in this way and who has done the defining. The policy implications which flow from understanding problem drug use as a social problem are not readily apparent. On the one hand, it could lead to a policy agenda which tries to overcome the social exclusion experienced by problem drug users by understanding the social structural factors related to problem drug use. However, on the other hand, it could lead to policies based on the premise that problem drug use is the result of the personal characteristics of individuals who experience it, further marginalizing them from society.

Approaching problem drug use as a medical problem involves equating it with a disease. The development of a medical model for understanding problem drug use was influential in moving understanding away from moral failure. Policies which flow from conceptualizing problem drug use in this way emphasize particular forms of treatment, and have been criticized for failing to appreciate the social causes and consequences of problem drug use.

Perceiving problem drug use as a public health problem stems from a concern about its effects on health and well being for individuals and the communities they live in. For example, community members may be exposed to used drug paraphernalia. Consequently, advocates of this approach suggest the need to pursue a harm reduction strategy, which includes practices such as operating needle exchange schemes and prescribed substitute medication.

Different conceptualizations of the type problem drug use presents have influenced, at different times, the policy approach adopted by individual countries. For example, during the 1980s and most of the 1990s, the UK adopted a

public health approach to drug use. This was a response to the realization that unsafe injecting practices could transmit HIV. As the new millennium drew near, a criminal justice approach to drug policy was adopted: problem drug use and offending became increasingly interlinked. This can be perceived as an example of policy transference, with the UK following – in part – policies adopted in the US. On both sides of the Atlantic critics have suggested that pursuing a law and order approach to tackling drug use amounts to a war on drug use and a war on drug users. Contemporary drug policy in the UK, as in other countries, is best described as based upon a range of different conceptualizations of the type of problem drug use poses, which results in a wide range of policies being adopted. These policies are implemented by a varied group of organizations (e.g., criminal justice, health care, and social work agencies). In reality, this may mean that drug users are exposed to seemingly contradictory policies; for instance, policies which have the effect of criminalizing growing numbers of drug users can be pursued alongside policies which increase opportunities for drug users to give up drug use or to use drugs in a less harmful manner.

drugs and the law

Brian K. Payne

At the broadest level, law can be defined as a written policy designed to control human behavior. Drug laws, then, are written policies designed to control drug using behaviors. The aggressive response to drug using behaviors, however, is a relatively modern phenomenon in the United States. A series of early American drug laws precipitated current efforts to control drug related behaviors. These laws included the Pure Food and Drug Act of 1906, the Harrison Narcotics Tax Act of 1914, and the Marijuana Tax Act of 1937. In fact, between the early 1900s and 1969, hundreds of federal drug laws were passed in the United States.

Perhaps the most influential piece of drug legislation framing the current response to drug using behaviors, the Comprehensive Drug Abuse Prevention and Control Act of 1970 repealed all prior federal drug laws and placed all drug laws under this broad, encompassing law (Payne & Gainey 2005). One of the significant aspects of this law was that it created a mechanism by which drugs could be categorized into various "schedules" based on the drug's medical utility and harm. Schedule I drugs (e.g., heroin, methaqualone, LSD, marijuana, and hashish) are considered to have no medical use and a high potential for abuse. Schedule II drugs (demerol, methadone, cocaine, PCP, and morphine) are those that do have currently accepted medical uses but also have high potential for abuse. Schedule III drugs (opium, vico dan, Tylenol with codeine, and some other amphetamines and barbiturates) have an accepted medical use and a medium potential for abuse. Schedule IV and V drugs have medical uses and a low potential for abuse. These schedules are significant, not just for a classification scheme, but because of the fact that criminal penalties parallel the drug's schedule. Offenses involving Schedule I drugs would warrant the stiffest penalty, followed by Schedule II, III, IV, and V drugs respectively.

The Comprehensive Drug Abuse Prevention and Control Act of 1970 also included a civil asset forfeiture clause which allowed for seizure of drugs and items used in the drug trade. It

was expanded in 1986 with the "Substitute Assets Law," which said the government could take the suspect's property if the drug assets are no longer available (Blumenson & Nilsen 1998).

Asset forfeiture is justified on punitive, deterrent, and economic grounds. Problems that have arisen with these policies include the use of the asset forfeiture as revenue, changing priorities in the drug war, goal displacement, and systemic failure (Payne & Gainey 2005). In terms of asset forfeiture's revenue generating phenomenon, there is reason to believe that some police departments have come to rely on asset forfeitures as a form of revenue needed for the department to survive at the most basic levels. In fact, a survey of 1,400 local law enforcement agencies found that the department depended on a significant amount of civil asset forfeiture funds "as a necessary budgetary supplement" (Worrall 2001: 171). With regard to the changing priorities of the drug war, it is believed that rather than taking efforts to control and prevent crime, police may select cases which can generate the largest profit with little regard for the social benefit of the case (Miller & Silva 1994). On a related point, goal displacement occurs inasmuch as "revenue generation becomes a sub goal of the criminal justice response to illicit drug activity" (Payne & Gainey 2005: 128). Finally, systemic failure occurs when asset forfeiture policies keep the justice system from attaining its goals (Vecchi & Sigler 2001a, b).

Though drug laws vary from the federal to the state level and across the states, today, at least five types of drug laws exist (US Department of Justice 1993). First, *possession laws* are those drug laws that stipulate it is illegal for individuals to possess certain types of substances. *Trafficking laws* are those drug laws which aim to control the movement and distribution of drugs. The difference between possession and trafficking laws usually has to do with the amount of drugs possessed. If an individual possesses a large amount, it could be regarded as a trafficking offense, regardless of whether that individual intends to distribute or sell the drugs. Penalties attached to trafficking offenses are much more severe than those attached to possession offenses.

Use laws are those drug laws that stipulate that individuals cannot use certain substances.

For example, if an individual tests positive for marijuana use after being pulled over for a traffic violation, he can be arrested and prosecuted for using the drug even if he does not possess it. In contrast, *misuse laws* are those laws which regulate the amount of a particular substance individuals are permitted to use. Driving while intoxicated laws are an example. Finally, *paraphernalia laws* are those laws which regulate the possession and sale of items that can be used to promote the use or distribution of controlled substances.

Penalties attached to drug offenses have received a great deal of scrutiny and criticism. In particular, some argue that the drug laws assigning penalties for cocaine and crack cocaine are racist and unfair. Individuals convicted of cocaine possession tend to be more affluent while those convicted of crack possession tend to be poorer. The effects of the two drugs are believed to be similar, but the penalties for crack offenses are much more severe than the penalties for cocaine offenses.

drugs/substance use in sport

Ian Ritchie

In the *Commission of Inquiry into the Use of Drugs and Banned Practices Intended to Increase Athletic Performance* (Dubin 1990), commissioned by the Canadian government in the aftermath of the infamous Ben Johnson drug scandal at the 1988 Seoul Summer Olympic Games, Chief Justice Charles Dubin stated that the problem of drug/substance use represented the single greatest moral crisis in high performance sport today. His statement was prescient in that there is probably no other issue that is seen by either the general public or authorities in major sport organizations to be a greater threat to the integrity of international sport than the use of banned drugs/substances. Certainly no other issue warrants the same commitment of resources and bureaucratic effort, especially since the creation of the World Anti Doping Agency in 1999, which now oversees anti doping efforts worldwide. The problem of drug use in sport also presents for sociologists and those in related academic disciplines in sports studies an opportunity to study the deviant subculture of drug use, the social and political dynamics of modern sport, and even more generally to explore the sociology of deviant behavior and the social construction of “normal” and “pathological” categories in a major sphere of social life.

An intriguing aspect of the use of banned substances and methods in sport is the fact that, according to historical evidence, it was only at a relatively recent moment in history – the International Olympic Committee formally banned drugs in the Olympic Games in 1967 – that certain substances and methods have been

defined as unethical or deviant. Athletes have used a variety of performance enhancing substances during many time periods and in diverse cultural contexts, including the ancient Greeks who had few qualms about the use of performance enhancers in the ancient Olympic Games. So referring to incidences as “cheating” in sport’s now distant past is more a reflection of transposing contemporary sensibilities onto history than it is the reality of those practices and morals. During multiday, ultra marathon cycling races and the late nineteenth century pedestrianism craze, for example, there were few attempts by athletes or trainers to hide the use of various performance enhancing concoctions, except to keep the composition of the mixtures undisclosed to competitors.

Given its recent construction as a “deviant” or “unethical” practice, then, the use of banned substances and methods, and the various organizational efforts to create and enforce “anti doping” policies, provide an opportunity to study first hand the creation of deviant behavior and a deviant category, and more general issues of power and control over the ongoing construction of what is considered normal versus pathological behavior in sport.

Four streams of thought and research have emerged in sociology and related disciplines in sports studies to consider this important social problem. First, in the philosophy of sport, debates regarding the ethical arguments that underlie the prohibition of drugs have been ongoing, especially since the early 1980s at the height of Olympic Cold War sport when the organized and systematic use of drugs in various national high performance sports systems became impossible to ignore. More specifically, three main arguments, which have been most commonly used to warrant the prohibition of banned substances in official policy statements, have been debated: that drugs are harmful to athletes; that drugs corrupt the ideal of the “fair playing field” in sport; and finally, that drugs corrupt the central ideals, ethos, or “spirit” of sport. While debates regarding these fundamental issues are ongoing, and while the philosophical arguments have become more sophisticated over time, the justifications themselves continue to be plagued by often obvious contradictions of performance enhancing techniques, technology, science, and the like that

are permitted but still contradict the central arguments used in support of anti doping prohibitions.

The second stream of research falls within policy studies, which considers the efficacy of procedures to detect and deter athletes; the power, structure, and legitimacy of organizations that attempt to control drug use; and, more recently, the rights of athletes and their involvement – or lack thereof – in the policy creation and implementation process. Most policy analysis has concentrated on three important organizations: the International Olympic Committee, the various International Sport Federations that oversee policies for separate sports within the Olympic Movement, and the World Anti Doping Agency.

Third, studies in the sociology of deviance and deviant behavior consider the issue from the perspective of the creation of deviant subcultures in which substances are both latently and manifestly encouraged, and more generally from the perspective of the general social construction of deviance, including issues of organizational power that have come to play in defining certain substances as deviant or unethical.

Finally, critical historical accounts have attempted to understand the specific social and political circumstances out of which the widespread use of performance enhancing substances and methods – banned or otherwise – emerged. Here efforts have concentrated on the post World War II era, and specifically the development of bureaucratically organized national high performance sports systems in the Olympic Movement, because it was in this context that the scientifically, technologically, and medically assisted pursuit of the linear record became the *sine qua non* of international competitive sport. The most obvious example was the former German Democratic Republic, which for approximately three decades maintained a state run system of “supplementary materials.” However, performance enhancers became integrated components of the high performance sports systems of many East and West bloc countries during the Cold War era, and these practices continue today.

The latter two disciplinary streams are the most important for sociologists and their attempts to understand the drug/substance use issue. In terms of critical historical accounts, a

seminal text is John Hoberman's *Mortal Engines* (1992). Hoberman traces the birth of performance enhancement in sport back to the original development of relationships formed between biomedical scientists and athletes in the late nineteenth century. Interestingly, however, scientists had little interest in helping athletes boost performances; the real interest was merely studying athletes – because of the physical extremes to which they pushed their bodies in training and competition – to discern biophysiological “truths” about the human body as a whole. Only later in the 1920s and 1930s did the idea begin to emerge that athletes’ bodies might have unlimited physical potential. From that point on, biomedical scientists were joined by a cadre of other self proclaimed experts who attempted to use virtually any means possible to enhance athletes’ abilities to train, compete, and push the body to ostensibly endless limits. This trend only accelerated during the Olympic Cold War years as national sports systems vied for gold medals and national ideological aggrandizement. Hoberman convincingly demonstrates that the push toward the use of increasingly sophisticated scientific and technological means of enhancement developed into a mania of sorts in the last half of the twentieth century, during which time drug use became only the more visible symptom of this uninhibited obsession. Hoberman cautions, then, that we need to think carefully about the ultimate purpose of this obsession, because while science and technology have almost limitless possibilities, the human body does not.

With respect to understanding substance use from the perspective of the sociology of deviant behavior, a landmark study is Robert Hughes and Jay Coakley's “Positive Deviance Among Athletes” (1991). Adding to Robert Merton's classic typology of modes of individual adaptation to cultural goals and institutional means, the authors maintain that in the right environment athletes “overconform” to a “sport ethic” – a set of value orientations that guide the decisions and actions of serious athletes. The ethic's criteria – unwritten but nevertheless extremely pervasive in athletes’ lives – include making sacrifices, taking physical risks, and refusing to accept limits in the pursuit of performance potentials and goals. With respect to drug use, the implication of the model

developed by Hughes and Coakley is that the constellation of criteria that determine the sport ethic constitute for serious athletes a very different line of demarcation between what is normal versus pathological than what the general public or, for that matter, many sports authorities might consider it to be. The sport ethic – and not just drug use per se – will, the authors claim, have to be taken into account before the “moral crisis” of drug use can be resolved.

These studies reflect two major streams of inquiry that are crucial in developing a more complete understanding of the drug/substance use issue. First, a better understanding of the historical development of modern high performance sport as a whole is necessary. While Hoberman's work has brought attention to the important role the development of biomedicine played in the general emphasis on performance enhancement, surprisingly little is known about the specific social and political environments out of which the use of drugs has emerged. Today, while the decision taken by an individual athlete agent to use a banned substance may appear to be an isolated and perhaps voluntary one, in reality that decision takes place within the context of a large, complex set of historically created and socially situated actions and relationships. The use of performance enhancers reflects, at minimum: the general historical forces and relations that have comprised the real world of high performance sport as it has developed in the twentieth century, especially since World War II and during the Olympic Cold War years; the particular set of political circumstances that motivated nation states to develop sophisticated and well funded sports systems in the pursuit of the linear record and gold medals, utilizing virtually any available scientific and technological means necessary, including drug supplementation; and the general emphasis on and triumph of instrumental rationality in modern life, which affected high performance sport as much as, if not more than, any other sphere of social life.

Second, there is a glaring lacuna in the sociological literature in that very little is understood about the real lived experiences of high performance athletes, their training and working conditions, and the processes through which their athletic identities are created. To

a much greater degree sociologists have studied the socialization processes that lead boys and girls into sport and physical activity, and to a lesser but nevertheless still significant degree the social and psychological process of serious athletes retiring or disengaging from sport and the athlete identity. However, there is little understanding of the experience of becoming a competitive, national or world class athlete and the processes through which methods of performance enhancement – banned or otherwise – become part of an athlete's identity and his or her everyday, lived experience.

These two macro and micro streams of analysis are crucial when trying to explain the moral crises in high performance sport to which the Canadian *Commission of Inquiry* referred. The existence of the World Anti Doping Agency reflects the legitimacy of efforts to rid sport of drug and substance use but it also attests to the fact that the problem persists unabated. Like all similar elements of social life defined as deviant and regarded as major social problems, the issue of substance use in sport will continue to play an important role in the development of provocative streams of sociological thought and research, especially as the use of drugs and other performance technologies in sport intensifies on a global scale.

Du Bois: "Talented Tenth"

Rutledge M. Dennis

At crucial moments in a people's history, the question "What is to be done?" is raised. Along side this question, additional questions will follow, such as "Who will do it, when, and how?" When one explores such works as Plato's *Republic*, Machiavelli's *The Prince*, Comte's *Course in Positive Philosophy*, and Marx's *Communist Manifesto*, one is deeply aware of the sense of crisis expressed by the writers and the urgency with which they raised the questions posed above. One must therefore understand the responses to group or national crises and the urgency of responses to such crises before fully understanding W. E. B. Du Bois's own urgent response to the national crisis of race, and to the many ways in which the crisis was more pronounced and devastating to blacks.

Du Bois first proposed a highly visible role for the educated segment of the black population in an article entitled "The Talented Tenth" (1903), and throughout his long life, at least until the 1950s, his life and the organizational and institutional networks he constructed both amplified and represented the importance of the role of the educated. But what was successful in practice was, however, not quite as successful when it came to justifying the theory. In fact, Du Bois's theory was

attacked from two main quarters. First, Booker T. Washington criticized the usefulness of those who had devoted much of their life to book learning, and he doubted their proficiency in dealing with real people and their problems. Secondly, the very idea of an elite stratum, even one devoted to a good cause, did not sit well with many. Indeed, the elite theme was one closely associated with white supremacy, white privilege, and black exclusion. But a careful scrutiny of Du Bois's logic surrounding an educated elite would lead one to disavow and refute both criticisms.

The justification for such a stratum was deeply rooted in the economic, cultural, and political realities of the United States, especially the South, during the last quarter of the nineteenth century. Du Bois urgently wanted to jump start and accelerate racial and social change within black communities as well as open the larger society to black participation in all realms, especially the political. In this sense, the educated cadre had a dual mission, one of which would be addressing internal black matters such as education, health, and economics; the other, that of addressing the resistance to freedom, democracy, and justice which permeated white society. What is often missing from the criticisms leveled against the concept was the heightened sense of dedication, sacrifice, and special mission of this stratum that was at the core of Du Bois's rationale for such an elite. The "Luke theorem" could be presented as a justification for expecting much from this educated stratum. The theorem found in Luke 12:48 asserts that: "For unto whomever much is given, of him shall be much required: and to whom men have committed much, of him they will ask the more." Du Bois would certainly have disavowed any grounding of his idea in scripture given his general agnostic views, but the theorem clearly states the terms in the manner in which Du Bois often stated why the educated stratum had an obligation to assist the black community: with its talent, skills, and opportunities, this stratum, Du Bois believed, comprised the natural leadership of black America.

Du Bois embedded his talented tenth concept in an array of organizational and institutional structures. This point becomes obvious in any analysis of the organizations Du Bois assisted in founding: the Negro Academy, the Niagara

Movement, the National Association for the Advancement of Colored People (NAACP), the various Pan African Conferences and Assemblies, and the Atlanta University Studies. In addition, there were the journals and periodicals: *Crisis*, *Phylon*, *Moon*, and *Horizon*. Du Bois viewed these organizations and periodicals as essentially tools to be used in propagandizing the population, blacks and whites. For blacks, the tools represented vehicles for presenting a more accurate and objective view of themselves, their successes and failures, but also their hopes and aspirations for new and rewarding racial and social advancements. For whites, Du Bois wanted to dislodge racial stereotypes and feelings and to present a picture of the New Negro, a term made popular by the anthology edited by Alain Locke (1969 [1925]).

The idea of a viable and unique educated cadre would decline in importance in the 1950s, partially due to Du Bois's disappointment at the lack of support for him among educated blacks when he was arrested and charged with treason during the McCarthy era, and perhaps partly due to a slow movement by Du Bois into the international communist movement. He formally joined the party in 1961, but even before doing so, he ceased to view black Americans as a possible beacon of strength and devotion to the cause of their own liberty, believing instead that freedom from the worst vestiges of segregation and terror only enabled blacks to follow whites down a path of worshipping money and success rather than a devotion to struggles for their liberation. But this view coincided with an increasing emphasis on the class factor in contemporary life.

A review of Du Bois's concept of a talented tenth does not suggest that he wanted this cadre to lord over blacks, as Washington and others suggested. Rather, his rationale was a simple recognition that there were individuals with skills, talents, and interests who were willing to place their economic, educational, and cultural assets where they might be more useful to an entire population for its collective benefit; that there were those whose leadership skills would serve, from Du Bois's perspective, as the natural bridge between the black and white worlds. What Du Bois wanted, above all, was a fighting cadre, one which would confront people

and issues and fight the good fight for blacks, just as he had been doing himself.

Du Bois would agree with the assertion that the talented tenth is alive today, though many who comprise this group would refrain from using the term. They are organized into many professional, educational, political, social, and cultural groups. The Congressional Black Caucus would constitute such a group, as would groups such as the Association of Black Sociologists, associations of political scientists, psychologists, historians, anthropologists, and the various Black Studies Associations, and literally hundreds of other professional organizations and associations. Included in this group would also be the numerous black fraternities and sororities, as well as other interest groups. When one reads the goals and objectives of these organizations and associations, it is clear that the shadow of Du Bois lurks over them, because they all speak of a need to address and redress issues in black life. Black Americans were not unique in having one of their great scholars and leaders enunciate a theory of leadership to address pressing social issues. What was unique was the timing of such a leadership strategy and its emergence in an evolving American democracy during the last quarter of the nineteenth century when the nation, especially its black population, was in great emotional, political, social, economic, and cultural disarray. What was also unique was the enunciation of such a scheme in a society in which blacks were hated by many, greatly disliked by others, and largely ignored by still others. Du Bois's concept of black leadership continues to be a viable and necessary feature of the American reality as long as race and the black presence continue to be a bone, as de Tocqueville so clearly stated it, in the throat of white America.

Du Bois, W. E. B. (1868–1963)

Rutledge M. Dennis

W. E. B. Du Bois was a sociologist and historian, born in Great Barrington, Massachusetts. Though he wanted to attend Harvard after high school, the lack of funds and the advice of a few of his teachers dissuaded him, so, instead, he attended Fisk, where he received his BA in 1888. He received a second BA from Harvard University in 1890, from where he was also awarded an MA (1891) and a PhD (1895) with the dissertation "The Suppression of the African Slave Trade to the United States of America, 1638–1870." Between 1892 and 1894 Du Bois was a graduate student at the University of Berlin, made possible by a combination gift/loan from the Slater Fund. This experience would have enduring consequences on both his personality and his scholarship, though, as he stated in his classic *Souls of Black Folk* (1903), his experiences at both Fisk and Harvard had already shaped some of his views on race, class, and philosophy.

Du Bois's sociological significance rests on three major themes: (1) his role as one of the early sociology pioneers; (2) his role as a sociologist of race; and (3) his role as a scholar activist. As one of the early modern pioneers, along with Durkheim, Weber, and Simmel, Du Bois viewed the connection between theory and research as inextricably linked to the alleviation of social problems and as contributors to overall societal reform. This was important to Du Bois because so little data had been collected in areas in which scholars allegedly knew so much. For his first major social research project Du Bois used some of the methodologies culled from Charles Booth's famous London study. Indeed, Du Bois was the first American scholar to use

sociological methods – questionnaires, interviews, and participant observation, use of city directories, and church and civic organizational records – to study the social structure and behavioral characteristics of a minority group within a larger majority and dominant class and amid a racially exclusive urban setting. This study provided much insight into the significance of the black church as a religious and social center in black life. The result was the classic urban community study, *The Philadelphia Negro* (1899). Earlier, he conducted a study of a small Virginia town, *Farmville Negro* (1897). These two studies, one of the North, the other of the South, permitted Du Bois to delve into comparative analyses between the black North and the black South, some of which are seen in *The Souls of Black Folk* and in a series of articles (which were in fact sociological essays) written for Northern newspapers and later collected by others and published as *The Black North* (1901). The research–reform dialectic can also be seen in Du Bois’s editorship of the Atlanta University Studies which sought, via research, to study almost every facet of black life and culture in the US, and to use the results to push for societal reform, especially along racial and class lines. But his youthful faith in science, knowledge, and truth as obviating factors in prejudice and discrimination would be greatly shaken by the realization that knowing the truth would not offset the great economic, political, and sociocultural advantages groups derived from oppressing other groups.

Even as Du Bois fought mightily to believe that science and objectivity would make a difference in matters of race, class, and social justice, his scholarly and sociopolitical activities illustrated that he would be the Great Dialectician, whose mind, interests, and concerns might reflect shifting intellectual modes and themes. So, even as theme (1), science and research, was in operation, as a good dialectician he was already into theme (2) with its focus on a sociology of race. For example, his paper “The Conservation of Races” (1897) was a justification for maintaining certain racial/cultural values, even as blacks sought greater entry into the larger society. Today, such a claim is understandable under the rubric of social and cultural pluralism. This article and a later one, “The Study of the Negro Problem”

(1898), but especially *The Souls of Black Folk*, would make race analysis, its shape, depth, and contours, as important for many as Marx’s class analysis had been and continues to be. It is here as a sociologist of race that later generations of scholars and students would find sociological richness in concepts such as the talented tenth, double consciousness, the color line, the veil, racial solidarity, and masking.

Du Bois’s prescient assertion in *Souls* that “the problem of the twentieth century is the problem of the color line” was a bold prediction for what was in store for the western world, but also presaged a lifetime struggle for himself, as he vowed to lend a hand in the destruction of that color line. The very title, *The Souls of Black Folk*, would be an exploratory search and revelation as Du Bois would lay bare, for whites to see, the heart and soul of a people. What was also patently visible was the heart and soul of the young scholar Du Bois, for even before C. Wright Mills asserted his version of a sociological imagination, Du Bois, in *Souls* (p. 87), had inserted himself personally into a larger national and international sociology and history. He was to define himself through his race, and conversely he wanted to define his race through his exemplary bearing, behavior, and sense of self worth: “I sit with Shakespeare and he winches not . . . I summon Aristotle and Aurelius and what soul I will . . . So, wed with truth, I dwell above the Veil.” It was clear in *Souls* that Du Bois would not only be a part of the great history he foresaw for the twentieth century, but would also make and shape that future history. This was no clearer than in his great debate with and attack on the preeminent black leader of the early twentieth century, Booker T. Washington. The intellectual skirmishes, flank attacks, and the subtle and not so subtle innuendoes from both men and their respective camps reflected the belief of each that he had the key to the black present and future. Neither succeeded. That is why the profound issues in the Du Bois–Washington debate – the importance of industrial vs. higher education, the priority of economics vs. politics and civil rights, and the style and type of leadership needed for black America – continue to resonate today, often with the same vigor and emotion as they did during the height of the debate.

The more one researches the life of Du Bois, the more it becomes abundantly clear that neither his life nor his intellectual and scholarly activities can be neatly compartmentalized, and his ideas are found in so many intellectual niches and corners. So profound were his scholarly output and the causes for which he fought that one could objectively view his era as the Age of Du Bois, and it is in theme (3), the scholar activist, that this is best expressed (Dennis 1996, 1997). With the increasing loss of faith in science Du Bois began to define himself as a scholar activist – he uses the term “propagandist” – and would become, as the chief “propagandist for the race,” the scholar as organizer: organizer of four Pan African Congresses; founder and general secretary of the Niagara Movement; one of the founders of the NAACP; founder and editor of *The Moon*; founder and editor of *The Horizon*; founder and editor of *The Crisis*; founder and editor of *Phylon*. And during this same period he writes sociologically significant books, books reflecting his markedly leftward political shift: *John Brown* (1909), *Black Reconstruction* (1935), *Dusk of Dawn* (1940), and *The World and Africa* (1947). *In Battle for Peace* (1952) was written after he had been indicted, placed on trial, and acquitted for being an unregistered foreign agent of the Soviet Union, as a result of his leadership in various peace movements and organizations. Given his pronounced political preferences and pronouncements throughout the 1940s and 1950s, it was not surprising to many when in 1961 Du Bois joined the Communist Party of the United States. In a masterful stroke marking him as a true dialectician, Du Bois, that same year, accepted an invitation from President Nkrumah to go to Ghana to complete his Encyclopedia Africana Project, a project which would be a version of the Encyclopedia of the Negro, which Du Bois initiated in 1909. In 1963 he renounced his American citizenship and became a citizen of Ghana. He died on August 27, 1963 on the eve of the historic March On Washington. Four autobiographical works (Du Bois 1903, 1920, 1940, 1968) aptly document Du Bois the scholar, the intellectual, the academician, the social activist, the organizer propagandist, and the international political spokesman. Each volume also provides more than a glimpse of Du Bois the sociologist.

Du Bois is a man of many parts, and these parts are significant to many laypersons and scholars in a variety of disciplines. Since the 1960s – when he was largely the “forgotten sociologist” – we have entered an era in which there is increased attention on Du Bois the sociologist, who historically tended to be overshadowed by Du Bois the activist. A brief perusal of today’s introductory texts and books on theory illustrates the strides many have made in fighting to ensure Du Bois’s rightful place in the sociological pantheon among the other great pioneers.

dual-earner couples

Pamela Aronson and Sara Gold

Dual earner couples are romantically involved (either married or unmarried) and each contribute to the financial support of their household through their work outside the home. The presence of dual earner couples has increased over the last 40 years, as there has been a shift away from the traditional male breadwinner and female homemaker family type. The breadwinner homemaker model waned in prevalence as women entered the workforce in large numbers, especially after the 1950s. For example, in 1976, 31 percent of women with infants under 1 year old worked outside the home; by 2002, 54.6 percent did so (US Census Bureau 2002). These figures are significantly higher for women with school aged children and women who are not parents. The influx of women into the workplace occurred for a number of reasons, including more equal access to education and occupations, greater demand for workers in the service sector of the economy, and social changes brought on by the women's movement. As a result, an increasing number of women provide significant financial support to their families (Gornick & Meyers 2003).

Families with lower incomes have historically been more likely than those with middle or higher incomes to rely on the earnings of two workers. Today, however, advantaged women (such as middle class, white, married women) are increasingly likely to contribute to their family incomes. Dual earner couples are more common in part because of the declining value of men's wages. Women's earnings have been extremely important in helping families maintain their standard of living, especially for working class and lower middle class

couples (Bianchi & Spain 1996). Although women's wages have risen over time, women still earn substantially less than men for nearly all occupations (US Census Bureau 2000).

Dual earner couples are diverse in their family situations and experiences. They can be married with children, married without children, cohabitating heterosexual couples, or cohabitating same sex couples. The experiences associated with having two workers in the household also vary depending on one's stage of life. For example, dual earner couples with young children face different rewards and challenges in balancing work and family than "empty nest" couples who are looking toward retirement (Moen 2003). Despite this diversity in experience, dual earner couples often encounter particular benefits, strains, and tensions as they integrate and balance two careers with a romantic relationship and home life.

Dual earner couples often make decisions about when and whether to have children with the concerns of balancing two careers and a family in mind. Dual earner couples are increasingly delaying having children until their career paths are established. In 1960, 60 percent of women aged 20 to 24 and three quarters of women aged 25 to 29 had become parents (White 1999). Forty years later, the percentage of women with children in these age groups had declined to 33 and 55 percent, respectively (US Census Bureau 2002). In addition to delaying children, some dual earner couples choose not to have children.

Dual earner couples frequently must decide whose career will receive a higher priority. Decisions that advance one member of the couple's career may, at the same time, put the other's career on hold. In the past, priority was almost always given to the husband's career. Presently, though this approach remains a common strategy, these couples are less likely to place a higher priority on the husband's career and are more likely to take a variety of factors beyond gender into consideration.

Dual earner couples must redefine what their breadwinner/homemaker counterparts have already classified as measures of success. Traditionally, a breadwinner husband is successful when he financially supports his family and a homemaker wife is successful when she emotionally supports her family and takes care

of their home. Dual earning affords both members of a couple opportunities to feel successful by fulfilling both home and work responsibilities. Moen et al. (2003) report that feelings of success are not dependent on a tradeoff or balancing act between the two realms of home and work, but on a sense of living a well rounded life. The benefits of the dual earning situation include financial stability, the potential for greater gender equality, and positive mental health.

To meet their personal and professional needs, dual earner couples rely on a number of strategies to structure their work and home lives, such as carefully negotiating schedules or number of work hours. Those with children are more likely to have a large discrepancy in the number of hours that each parent works, whereas couples without children typically have similar work hour arrangements. Mothers are still much more likely than fathers to scale back or rearrange their work hours in order to take care of children. This gender difference reveals that dual earner couples' choices are often "neo traditional" in character (Moen & Sweet 2003). Many of these families with children work different shifts – such as weekends or nights – in order to minimize the amount of necessary childcare. One study, for example, found that one third of dual earner couples with preschool aged children worked such a "split shift" (Presser 1999).

The absence of a full time homemaker makes it necessary for these families to employ a variety of strategies to achieve a well managed household, as they must fit the responsibilities of running a household into their often limited time at home. The total amount of time spent doing housework in America has been declining, especially among employed wives. Many families hire outside help to fill this time gap. Although some dual earner couples strive for an egalitarian division of labor, others do not. As a result, women are more likely to take on the "second shift" responsibilities at home (Hochschild 1989). That is, despite labor force participation, women are more likely to take on a managerial role in the home and perform about twice as much of the housework as men. The "time bind" that results from combining long work hours with home responsibilities can be a source of stress for many families. As work offers greater

external rewards than home, many families report feeling more successful and relaxed at work, while time pressed at home (Hochschild 2000).

Dual earner couples often experience what is known as "spillover:" "the transfer of mood, affect, and behavior between work and home" (Roehling et al. 2003: 101). Spillover can be both positive and negative. For example, positive work to family spillover occurs when feelings of success at work lead to a relaxed attitude at home. Conversely, when stress at work causes a parent to lose patience with a child at home, negative work to family spillover may be to blame. An example of positive family to work spillover occurs when workers are more productive on their jobs as a result of experiencing a satisfying family life. An example of negative family to work spillover includes family intrusions on work time. Workplaces that are supportive of employees' home commitments and that offer higher levels of worker autonomy tend to result in less negative spillover. The opposite is true of jobs with lower levels of support or flexibility. For dual earner couples, negative spillover can have a significant impact, as both partners are negotiating similar work and family commitments. Negative spillover tends to be less of a problem for those couples who work similar, and fewer (less than 45), hours per week (Roehling et al. 2003).

The benefits, strains, and tensions of the dual earning situation are commonly thought of as personal matters. This perception persists even though there is a widening gap between workers' needs and governmental and workplace policies. For example, the Family and Medical Leave Act of 1993 guarantees many workers up to 12 weeks of unpaid leave to care for an immediate family member during a time of serious illness. While this policy is helpful for many workers, not all employees are covered under the law and its unpaid nature makes it difficult for many workers to take leave from their jobs. Workplace policies, the most common of which is flextime, do not adequately recognize the demands facing dual earner couples. For example, employers often expect workers to place all home life responsibilities on their spouses. Issues pertaining to childcare, health care benefits, and the number of hours that employees must work to be considered

“full time” are all ripe for new policy innovation to support the most common working arrangement among American families. Whether policy makers will push for more changes to bring work life policies in line with home life realities remains to be seen.

dual labor markets

Tony Elger

The concept of labor market dualism was first developed by institutionalist economists critical of conventional analyses of the labor market (Peck 1996). They argued that different categories of workers faced contrasting management policies, as white male workers were preferentially recruited to jobs offering training, pay gains, promotion, and job security. This meant access to organizational job ladders which constituted “internal labor markets” governed primarily by organizational rules. Meanwhile, women and minority ethnic groups generally had access to insecure, low paid jobs without internal training and promotion prospects, and were confined to the external labor market constituted by such jobs. This analysis contested neoclassical economic models of the allocation of individual workers across a spectrum of jobs according to individual skills and preferences, and emphasized the ways in which organizational structures and management decisions generated a division between primary and secondary labor markets which operated according to different logics.

Dual labor market theorists nevertheless differed in their analyses of the organizational logic of dualism. Some linked it to the contrast between large oligopolistic employers and small competitive enterprises. Since large employers themselves differentiated between primary and secondary workforces, however, others argued that managers constructed primary labor markets to retain relatively skilled workers, especially after investing resources in firm specific training. Finally, radical commentators suggested dualism was often the result of management tactics of divide and rule, rather than technical calculations about protecting investment in training.

These analyses were primarily designed to explain the *persistence* of labor market dualism, but recent organizational restructuring has involved a reduction in stable routes of career progression and a growth in less secure forms of employment (Grimshaw et al. 2001). Meanwhile, areas of skills shortage, combined with equal opportunities policies, have opened *some*

doors for qualified but hitherto excluded groups. One dual labor market analysis which addressed change rather than stability was the “flexible firm” model, which contrasted core “insiders” providing functional flexibility with peripheral “outsiders” characterized by numerical flexibility (Kalleberg 2003). The core experienced horizontal movements within teams or across tasks more than vertical advancement, while the periphery included part time, temporary, and subcontract work. However, this model was more a prescription than an analysis, recommending that employers and the state codify and develop their employment practices in this way. It was criticized for (1) imputing a coherent strategic orientation to management, when such policies are often ad hoc, reactive and constrained; (2) conflating distinctive forms of numerical flexibility, such as part time, casual, and consultancy work, with quite different labor market implications for those involved; and (3) ignoring substantial sector differences (Pollert 1988).

Debates from the 1980s have prompted the development of more complex analyses of labor market *segmentation* by institutionalist economists and economic sociologists (Rubery & Wilkinson 1994; Peck 1996). Descriptively this has involved identifying multiple labor market segments rather than a simple dualism. Distinctions have been made between professional and managerial segments involving vertical progression through moves within and between employers; semi professional and craft segments involving predominantly horizontal moves between relatively secure positions with different employers; white collar and manual segments involving modest internal job ladders within specific organizations; relatively secure non career jobs often associated with part time work; and persistently insecure forms of employment. Such segments are not seen as entirely stable, but rather as modified and remade. They involve shifting clusters of opportunities and insecurities, sometimes linked to changing sources of labor supply, rather than a uniform movement towards flux and insecurity.

Such segmentation analyses have been underpinned by discussions of both the social organization of the demand for labor and the social organization of the supply of labor (Peck 1996). While management decisions are pivotal

on the demand side, changing family and household relations are central to the supply side, while state policies help to structure both. The elaboration of this conceptual framework has provided leverage in the analysis of differences in the social organization and regulation of labor markets over time and between different states, as they embedded in distinctive social institutions of capitalism.

Durkheim, Émile (1858–1917)

Anne Warfield Rawls

Émile Durkheim, often referred to as the founder of sociology, was born April 15, 1858 in Épinal, France. Appointed to the first professorship of sociology in the world, he worked tirelessly over three decades as a lecturer and writer to establish sociology as a distinct discipline with its own unique theoretical and methodological foundation. After an illustrious career, first in Bordeaux and then after 1902 in Paris at the Sorbonne, Durkheim died in

November 1917, still a relatively young man, never having recovered from grief after most of the young sociologists he had trained, including his own son André, were killed in World War I.

Durkheim's basic argument was that the human rational being is fundamentally a creation of social relations. His related arguments against all forms of individualism, and for a distinct sociological object and method, stand at the heart of sociology as a discipline. Motivated from the beginning by a recognition that the organization, rationality, and morality of modern societies are different from traditional belief based social forms in fundamental ways, he argued that these differences pose serious challenges to contemporary society. He credited Rousseau and Montesquieu with inspiring his emphasis on the social origin of the individual, an emphasis he holds in common with other classical social thinkers (e.g., Comte, Marx, Weber, and Mead). The individual as a social production, and the centrality of social phenomena in all aspects of human experience, are ideas that distinguish sociology from other disciplines' approaches to social order, social action, modernity, economic exchange, mutual intelligibility, and justice.

Durkheim's arguments have played a central role in the development of almost every aspect of sociology since its inception. His position was popularized as functionalism by Talcott Parsons in the late 1930s, and as a focus on symbolic systems by Lucien Lévy Bruhl and Claude Lévi Strauss from the 1920s to the 1960s. Postmodernism and poststructuralism, which developed in the 1960s and remained popular through the turn of the century, are both reactions to the way these two earlier conflicting interpretations of Durkheim's arguments developed over time.

Durkheim's innovative use of statistics in *Suicide*, and his articulation of a sociological method of measuring what he called "social facts" in *The Rules of the Sociological Method*, remain a foundation for sociological methodology even today. His arguments with regard to the social origin of ideas inspired the development of the sociology of knowledge and, more recently, cultural sociology. His arguments regarding universes of discourse have also been taken up by the sociology of science

where they rival those of Wittgenstein in their importance with regard to various sociologies of practice.

Durkheim's emphasis on practices, first articulated in *The Division of Labor in Society* (1893), then elaborated in *The Elementary Forms of the Religious Life* (1912), stands as one of the most modern approaches to social order of its time and continues to pose challenges to the sociological understanding of modernity. In that work, what would later emerge in the arguments of Wittgenstein and others as problems with the conception of meaning and rules took shape as Durkheim sketched out the problem of meaning in a modern context of differentiated multicultural exchange. He formulated a distinction between two forms of society, one modern and based on differentiated labor, the other traditional and based on shared beliefs. The contrast between the two, he argued, involved a contrast between rules that self regulate and rules that depend on external beliefs and sanctions for their efficacy. Only the former, he argued, could sustain order and meaning in a modern context. The latter belonged strictly to traditional social forms. The way Durkheim used different types of law to illustrate his argument about the new form of rules inspired sociological studies of crime and law.

Durkheim argued that a confusion about the difference between traditional and modern social forms and a tendency to try to apply traditional forms of law/rule to modern societies were responsible for many social problems. Arguably, the tendency of Durkheim's interpreters to confuse the two social types has had a detrimental effect on the field's development. His emphasis on the distinctiveness of the modern is an essential part of the sociological legacy.

Durkheim's position was modern in crucial ways. For instance, whereas Freud's *Totem and Taboo* (1913) reflected the prejudices of the times by likening the primitive mind to the mentally ill, Durkheim's *The Elementary Forms of the Religious Life*, published a year earlier, insisted that aboriginal social forms and their corresponding beliefs were as rational as their modern counterparts. This was a surprisingly modern stand against the explicit and politically accepted ethnocentrism of Durkheim's time. He regarded

reason as a social product, rendering nonsensical distinctions such as mentally inferior or superior, and infusing his sociology with a fundamental egalitarianism – a new moral philosophy grounded in social facts, and a new sociological epistemology with universal applicability.

Students of Durkheim's who survived the war – the most famous of whom was his nephew, Marcel Mauss – contributed to anthropology rather than to sociology. Because of Durkheim's early death, the long and influential careers of Mauss and others of these students constitute Durkheim's main influence in France. In *The Gift*, Mauss introduced the idea of gifts as reciprocal and symbolic exchanges that create networks of mutual obligation, an idea that challenged the established contrast between "pure" gift and economic exchange. Like Durkheim, Mauss disputed the prevailing individualism of an economic approach to exchange, imbuing it with a thoroughly social character.

For many years Durkheim's popularization in sociology was left to Parsons, resulting in interpretations of Durkheim that were consistent with Parsons's own structural functionalism. It was only with the increasing unpopularity of structural functionalism in the 1960s and 1970s that sociologists began to look for alternative interpretations of Durkheim's work. Thus, there was a revival of Durkheim studies at the end of the century.

Feminists sometimes argue that Durkheim's work ignored women, or adopted an insensitive stance toward them. He certainly did not theorize about women in any depth, but very few men were aware of women's issues at all in the 1890s. Even so, it is significant that Durkheim not only argued for the rational status of aboriginal people, but also had some awareness of the position of women. For instance, in *Suicide* he noted that there seemed to be a fourth form of suicide which he called "fatalistic," particularly prevalent among women. While noting that he lacked sufficient evidence, he suggested that marriage, while beneficial to men, may have a negative effect on women. Durkheim also noted in *The Division of Labor* that studies of aboriginal people suggest women were once as strong as men and that the development of society, and the positions women hold in modern societies, have made women weaker. Given the turn of the century tendency to view women as innately

gentle and weak, Durkheim's opinion in this regard is noteworthy.

PERSONAL HISTORY

Durkheim married Louise Dreyfus in 1887, the year he first accepted teaching duties at Bordeaux. Her family was from Alsace and her father owned a business in Paris. Not much has been written about Louise, but by all accounts theirs was a very happy marriage in which she acted as a companion in work, as well as household manager. Lukes (1973: 99ff.) quotes from a letter written by Mauss that Louise "never left his side, and that, being well educated, she even collaborated with him in his work; she copied manuscripts, corrected proofs and shared in the administrative and editorial work of the *Année sociologique*."

There were two children from this marriage: André Armand and Marie. André studied with Durkheim at the Sorbonne and had just completed his aggregation when the war broke out. He was sent to the Bulgarian front late in 1915 (Lukes 1973: 555). Marie's husband also was drafted by the army, as were five of Durkheim's nephews. Of the 342 students at the École Normale Supérieure called up for service, 293 went to the front and 104 were killed (Lukes 1973: 548), and many more would suffer crippling physical and emotional wounds.

For Durkheim, the loss of his son André was particularly acute for they had been close intellectual companions. Durkheim wrote in his son's obituary that "for a long time I was his sole teacher and I always remained closely associated with his studies. Very early he showed a marked interest in the researches to which I have devoted myself and the moment was near when he was about to become a companion in my work. The intellectual intimacy between us was thus as complete as possible" (1917: 201).

Sociology was a family enterprise for the Durkheims. As in the marriages of other major figures at the time, notably that of Marianne Weber (a scholar in her own right who compiled the posthumous papers of her husband Max), Louise shared significantly in Durkheim's intellectual labors. Not only his son André, but also various nephews and their friends studied sociology with Durkheim. André in particular seems

to have been present for the lectures on pragmatism (Durkheim 1960 [1913–14]). Long hours spent with students and extended family, lecturing, editing, and discussing, would have made sociology a congenial focus of family relations. Thus, the personal losses of the war for Durkheim also devastated French sociology precisely because it had been such a collaborative effort among close friends and family.

The damage to French sociology caused by World War I was compounded when the Nazis invaded Paris in World War II. Durkheim's daughter Marie, who had inherited his papers, was forced to flee and the entire archive of his papers and notes, kept carefully in a separate room, was destroyed by the Nazis (Mestrovic 1988).

Like other classical social theorists, often referred to disparagingly as “Dead White Men,” Durkheim was not a member of the ruling elite in France, holding instead the marginal status of a Jewish minority. Born on the border between France and Germany and descended from a long line of rabbis, Durkheim experienced anti-Semitism and his social situation was always fragile. The idea of “whiteness” and of “white men” as a dominant social group is a peculiarly American idea. In Europe, distinctions on the basis of class, religion, and ethnicity always rivaled those of race in importance.

Durkheim would have carried his Jewish origins with him always and would never have enjoyed the privileged status of a white male in America. Shortly after the death of his son in the spring of 1915, while overcome with grief, Durkheim was subjected to several serious public incidents of anti-Semitism. His French residency was challenged and defended in the Senate, the dispute finding its way into the papers. On January 19, 1916 in the *Libre Parole*, Durkheim was called “a Boche with a false nose” and accused of working for the Germans (Lukes 1973: 557). Given the battle he was waging to regain focus after the death of his son, these incidents would have weighed heavily on Durkheim and likely contributed to the stroke he suffered later that year.

Durkheim's argument in *Division of Labor* that justice is required by the self-regulating practices of modern states, and that modern social forms that do not achieve justice are abnormal and cannot persist over time, is

illustrated in a letter he wrote about the war on September 15, 1914: “Never had the ideal to which we are all attached shown its strength more clearly . . . Prussia and Austria are unnatural aggregates, established and maintained by force, and they have not been able gradually to replace force and compulsory subjection by voluntary support. An empire so constructed cannot last. The geography of Europe will be remade on a rational and moral basis” (Lukes 1973: 547–8). In the midst of the war, Durkheim found confidence in his own argument that modernity required a new form of moral solidarity. Germany might rail against the new egalitarian and democratic forms of society and resist by force, and many of Durkheim's students and family members might be killed, but in the end it could not work. The cost in terms of the war would be great, but the outcome always was certain.

MAJOR SUBSTANTIVE CONTRIBUTIONS

According to Durkheim, the transformation of the individual biological being into a social being cannot be explained by either individual biology or psychology. Biological capacities exist, but they require redirection and reformation by social processes. Durkheim argued that dualism, a popular philosophical argument referring to the distinction between mind and body, really represented the distinction between the pre-social animal being and the social human being. The former, he says, is not a rational being. There is no innate human reason or personality. Reason is a result of social processes. In fact, he argued that particular social processes and forms of association, or social bonding, are required to create and maintain social individuals. There are no social individuals except in the context of particular social configurations. Consequently, any position that begins with the individual, such as psychology, economics, or philosophy, and tries to explain social phenomena on the basis of aggregations of individual actions will miss exactly what is important about society.

Durkheim elaborated these ideas in four major works, *The Division of Labor in Society* (1893), *The Rules of the Sociological Method*

(1895), *Suicide* (1897), and *The Elementary Forms of the Religious Life* (1912). Each was designed to illustrate a different point. In addition, Durkheim wrote a second thesis on Montesquieu, countless articles for *l'Année sociologique* (which he also edited), and gave lectures on pragmatism, socialism, moral education, and Rousseau. Taken together, these substantively different sociological studies make up a unified, empirically based theoretical view.

It was Durkheim's position that social processes create entirely new dimensions of persons and associations between persons, creating social configurations in ways that add up to more than the sum of the individual parts. He explored the differences between two social forms, which he associated with traditional and modern society in *The Division of Labor*. There Durkheim explained the need of social beings for particular sorts of social bonding, which could only be maintained by fulfilling certain basic *functional requirements*. Social entities have a coherence in their own right that makes demands on participants. For this reason, Durkheim argued that it is necessary to focus on the effects of social processes on individuals, not the other way round, and that a new discipline was needed. The concrete nature of these social processes manifests in institutions and practices that can be studied empirically. Durkheim called these *social facts*. He outlined the new discipline of sociology and its methodology in *Rules* and referred to sociology as the study of social facts.

Social facts have a coherence that does not result simply from an aggregation of individual parts, and cannot be studied by a focus on the parts. The study *Suicide* was designed to demonstrate that even this most personal of acts could be explained on the basis of the ways in which persons were associated with one another and bonded together socially. What appear as individual feelings, thoughts, and values, he argued, are the products of social participation.

In *Elementary Forms*, Durkheim lays out an argument connecting social forms to individuals. The social experience of the sacred is the moment at which social connections are born and also gives rise to the individual social being. Reason is a result of this process. Symbols also first acquire shared meaning through

totemism and its enacted rituals. Durkheim employed his analysis of totemic rites in formulating a challenge for all individualist approaches.

THE DIVISION OF LABOR: FUNCTIONALISM, PRACTICES, AND JUSTICE

Durkheim's brand of functionalism was first elaborated in *The Division of Labor*. It addresses equilibrating processes in two very different kinds of large systems. In the first of these, *mechanical solidarity*, equilibrium is created and sustained through shared beliefs. In the second, *organic solidarity*, self-regulating rules provide for stable and coherent social contexts through shared practices. Because shared beliefs require the authority of a common and enforced morality, equilibrium based on shared beliefs can only succeed if beliefs and values can be controlled by force and constraint. This social form results in a conventional morality that varies from social group to social group and requires a repressive form of law. When the equilibrium of societies is based on shared practices, however, different beliefs and values can be accommodated, and laws guaranteeing the autonomy of these contexts and their contracts emerge. Participation in self-regulating practices requires trust, reciprocity, equal access, and other qualities only possible in a system based on freedom, equality, and justice. Durkheim's functionalism proposed that justice becomes a requirement as reciprocity in self-regulating practices replaces the external constraints of traditional social forms.

Durkheim illustrated this functional argument in two ways. First, throughout the body of the text he contrasts the way legal sanctions developed and are applied in traditional and modern social forms. Modern contractual economic exchange, he says, requires a legal support that protects contracts and the autonomy of self-regulating practices, whereas traditional belief-based systems of ritual reciprocity require a legal system that protects and enforces the harmony of shared beliefs that sustain it. Durkheim's assessment of the relationship between law and society remains important and was the foundation for the development of both criminology and legal studies in sociology.

Durkheim's second way of illustrating the difference between traditional belief based and modern practice based social forms consisted of contrasting professional groups based on self regulating practice – particularly scientific practice – with religious ritual and belief. Both produce solidarity and make intelligibility possible, but in very different ways. Only the self regulating practices of professional groups, he argued, are compatible with differentiated labor, science, and truth.

While functionalism is often associated with political conservatism, in Durkheim's analysis it is only conservative with regard to traditional social forms. In a modern practice based system, Durkheim's functional argument supports a strong egalitarianism. It is his position that even the practice of inheritance, which most scholars consider to be an integral part of a modern property based system, is a holdover from earlier collective social forms, and as such threatens the necessary equality. "Every form of superiority has repercussions on the way in which contracts are arrived at," he says (1984 [1893]: 319). "If therefore it does not depend upon the person of individuals and their services to society, it invalidates the moral conditions of the exchange . . . In other words, there can be no rich and poor at birth without there being unjust contracts."

One source of confusion is that Durkheim's functionalism consists of two corresponding sorts of arguments. The first way of thinking about functionalism involves Durkheim's use of examples drawn from the human body. The brain needs the heart to pump blood to it. But, the heart also needs the brain to signal the muscle to contract. There is a functional interdependence between the two. This form of functionalism tends to be associated with a conservative relativism: things may be bad for individuals, but nothing can be changed without damaging the whole society.

Durkheim's functionalism could also be described as an *if/then* statement, however. *If* the brain depends on oxygen, *then* in order to stay alive it needs to get oxygen. Many of Durkheim's arguments are of this form. *If* a social form depends on shared belief, *then* in order to sustain it shared beliefs must be maintained. *If* a modern social form depends on shared practices and not on shared beliefs, *then* that which

shared practices require becomes necessary. This latter form of functional argument is not subject to the usual criticisms. It also overcomes the contingency usually associated with social phenomena, allowing for a degree of philosophical necessity with regard to practice based societies.

In the context of modern differentiated societies, Durkheim's functionalism does not emphasize either conflict or consensus. He argued that modern practices require freedom, equality, and justice. Therefore, in a modern context the functional prerequisites of practices are, not coincidentally, the same thing individuals strive for. Conflict occurs only in abnormal forms where freedom, justice, and equality have not been achieved. Furthermore, shared beliefs, which place contingent moralities before individual good, are no longer necessary in a society based on justice, and the coercion they require to produce consensus is problematic because it interferes with the development and maintenance of self regulating practices.

RULES AND SUICIDE: METHODS, SOCIAL FACTS

In his classic study *Suicide*, Durkheim introduced the sociological use of statistics, demonstrating that different suicide rates could be explained on the basis of differential patterns of social connectedness when they could not be explained on the basis of individual psychology. For instance, individual characteristics do not explain why older men commit more suicide, but their unmarried – unconnected – status does. In addition to introducing the use of statistics, Durkheim also used various qualitative and archival methods, particularly in his research on law and religion. Durkheim's method, whether statistical or qualitative, focused on the character of forms of association and on the consequences of those associations for the health of the social individual and/or group. By contrast, statistics in contemporary sociology are generally used to measure relationships between the demographic character of individual actions and various institutional constraints (values, goals, sanctions). This has been the predominant sociological method since the 1940s and is often equated with "macro" sociological concerns. It

is, however, a later interpretation of Durkheim's method, influenced by structuralism and not entirely consistent with his own approach.

Durkheim used statistics as indicators of social facts. For Durkheim, social facts in a modern differentiated society consist of forms and patterns of association, not beliefs and values. What matters are the ways in which members of various groups are associated with one another, not their orientation toward valued courses of action, which had been important in earlier social forms. Where statistics such as suicide rates provide indicators of these associations, they may be of use to sociologists.

Durkheim's approach did not correlate individual characteristics with value oriented behavior, however. He used statistics to indicate the strength and character of various forms of association. For instance, if the forms of association in a group were very weak, then people in the group could be expected to have a greater number of moral and psychological problems. If the forms of association in a group were too strong, then people could be expected to sacrifice themselves for the group whenever necessary. The tricky part is specifying the ideal forms of association. Durkheim argued that this varies across societies. *The Division of Labor* worked out the difference between two forms of social solidarity whose forms of association were entirely different, and *Suicide* demonstrated that the conditions under which ties to the group would be too weak or too strong also differ. Suicide in traditional and modern societies would therefore have to be understood in entirely different terms – for Durkheim, more proof that suicide was a function of social relations.

This approach differs from that of many contemporary sociologists who use statistics to measure and predict the behavior of individuals as effected by their orientations toward social goals, values, and sanctions. The focus on individuals and their relationship to social factors runs counter to the method Durkheim proposed: demonstrating the impact of social facts, assessing solidarity mechanisms, and measuring the group level effects of beliefs and values.

Furthermore, the popular characterization of Durkheim as a quantitative macro sociologist implies a disinterest in qualitative approaches. In fact, *The Division of Labor* is based largely on

an analysis of historical changes in the law, and *Elementary Forms* both adopts and advocates a qualitative approach. In the latter, Durkheim argued repeatedly that if order cannot be found in a single case, then it cannot be established however many cases are examined.

It was Durkheim's position in *Rules* that sociologists should focus on the social facts of recurrent institutional and orderly social forms. He treated social order as a central topic for sociology and argued that methods should treat the social as primary, avoid individualism, and be broadly scientific (i.e., consist of practices recognizable to other scientists). He did not argue for methodological hegemony and in Durkheim's work the character of particular social facts, and not some a priori prescription, seems to have determined the methods he used.

ELEMENTARY FORMS: DUALISM, EPISTEMOLOGY, UNIVERSES OF DISCOURSE

In *Elementary Forms*, Durkheim argued that it is through participation in religious practices that social beings acquire the basic forms of human reason: space, time, classification, force, causality, and totality. He argued that the concept of classification has logical primacy. The first emotional experience of the distinction between sacred and profane gives birth to this category and makes possible the enactment of the rituals that create the other categories.

In his conclusion Durkheim outlined the view that all concepts, or *collective representations* as he calls them, have a social origin. Concepts adhere in universes of discourse and a proper understanding of reason, language, and mutual intelligibility would require a study of the way various words/concepts have meanings in the context of the social forms of association in which they are used.

The argument that religion developed to serve functions that were primarily social, rather than society developing to serve religious functions, would have been very unpopular in 1912 and remains so today. To the religious, the meaning of religion has nothing to do with sustaining social orders. Durkheim does not deny that religious beliefs may be true. But for him their "truth" lies in their capacity to

motivate ritual practices. Beliefs alone do not explain the development of organized religions. Frequently they serve to coerce and constrain individual faith so as to support traditional social forms.

External constraint is part of the social control function of religion in traditional societies. In modern societies, however, this function is no longer required and religious diversity becomes possible. Thus, religion does not fulfill exactly the same functions in modern and traditional societies. Rituals create and sustain shared practices in both, but the need for homogeneity differs. So, while religion still fulfills epistemological functions, it is no longer connected with social orders in the same way.

For Durkheim the essential first human moment came with the creation of the first distinction between sacred and profane, and because of the importance of this moment it permeates the argument of *Elementary Forms*. In his view, it is essential that social connections and symbolic meanings are established through ritual practices. Only in this way can individual social actors be created in the first place. Without engagement in ritual practices humans are only animals, he says, and can only think like animals.

In giving the social primacy over the biological or individual rational being, Durkheim was also taking a position on the equality of all persons. He regarded *reason* as the *function* of social forms and all successful societies must produce it. Differences in the apparent reasoning powers of people, therefore, were not due to differences in innate intelligence, but rather to the different needs of the societies in which people lived and the varying ways in which reasoning was socially structured.

Durkheim's position was remarkable given the pervasiveness of the belief in racial and gender inequality, not only in his day but extending into the present. One early American critic dismissed Durkheim's sociology for proposing the allegedly absurd view that if "Negroes or Eskimos" were to live in the same society with whites they would become their equals. Not until the late 1960s would the developing public awareness of human equality begin to catch up with Durkheim's position. We can only imagine how large a price sociology paid for the inability of popular opinion to

appreciate Durkheim's position in this regard at the time. According to Durkheim, popular opinion with regard to racial and gender inequality was simply wrong. It was only in their social forms, and the ways in which persons were transformed by participation in those social forms, that human beings differed. Thus, Durkheim gave sociology a distinctively democratic and egalitarian foundation.

MAJOR INTERPRETATIONS, INFLUENCES, AND CONTROVERSIES

There have been five major streams of interpretation of Durkheim's work. From the 1930s onward Talcott Parsons, who incorporated Durkheim into structural functionalism, became the primary interpreter of Durkheim's work in English. As a consequence, a positivist and functional interpretation of Durkheim became prevalent in the United States. In France, by contrast, his work was taken up by anthropologists, the best known being Lévy Bruhl and Lévi Strauss, who elaborated his argument regarding the relationship between the development of concepts, ideas, and societies, developing symbolic anthropology on this foundation. Each of these two early interpretations distorted the original work by capturing only parts of it. The movements that emerged against structural functionalism and symbolic anthropology – poststructuralism and postmodernism – thus also have certain shared roots.

In the wake of these intellectual revolutions, there was a revival of interest in Durkheim in both the humanities and social sciences. In the US the "cultural" side of Durkheim that had been eliminated by structural functionalism began to come to the fore and was elaborated by Jeffrey Alexander in particular. There was also an effort, beginning with and inspired by Randall Collins, to draw out the connections between Durkheim and contemporary interactionism, notably the work of Erving Goffman and later Harold Garfinkel. This interpretation also made its way into the sociology of science where it found affinities with the arguments of Ludwig Wittgenstein. Among Marxists there have been a number of persuasive articles emphasizing the radical political character of Durkheim's work (e.g., Sirianni; Parkin) that

challenge the Parsonsian view of Durkheim as a conservative.

In the wake of this renewed interest, some of Durkheim's work has been retranslated and republished. Durkheim's "Sens Lectures," previously unavailable in English, were published in 2004.

While at the Sorbonne, Durkheim studied philosophy and wrote a dissertation on Montesquieu before completing his final thesis on the division of labor. Montesquieu and Rousseau were important for Durkheim because both treated social forms and processes as prerequisites for the social person. He studied with neo Kantians like Renouvier, studied for a year in Berlin, and was caught up in the interest in the work of William James that swept through Paris at the turn of the century. It is clear from Durkheim's 1913–14 lectures that he saw pragmatism as another individualistic argument, and thus sharpened his own vision of a science of social facts against the philosophy of James.

When Durkheim arrived at the Sorbonne, sociology was associated with the work of Auguste Comte (1798–1857), Saint Simon (1760–1825), and Herbert Spencer (1820–1903). Spencer's was an evolutionist sociology that soon fell out of favor. Comte and Saint Simon, on the other hand, influenced such disparate thinkers as John Stuart Mill (1806–73) and Karl Marx (1818–83). It was Comte's position that as the shared beliefs and values of an earlier age diminish through the effects of progress they need to be replaced. Comte proposed a general philosophy as a more enlightened and scientific ideology that could serve the purpose. Early on Durkheim associated this position with socialism, and was critical because of the central role accorded to beliefs and ideology.

It was Durkheim's position that modernity produces new social forms, bound together not by ideology but by forms of association and self regulating practices. Social solidarity was a product not of shared beliefs but of the diversity of interdependent positions in the division of labor. Where social solidarities formerly depended on shared beliefs enforced by strong sanctions, new forms of association produced a form of self regulation requiring no external sanction. Durkheim argued that in modern society the state needed to support,

rather than sanction and impede, self regulating practices.

Durkheim's first example of self regulation in *The Division of Labor* was scientific laboratory practice. When he published the second edition in 1902, he added a preface on professional groups that offered a more extensive example of how social solidarity in modern differentiated social forms is based on many different sets of shared self regulating practices rather than on shared beliefs.

Because he studied with Renouvier and wrote about the dualism of human nature, many scholars have associated Durkheim with Kant. Certainly Durkheim was well versed in Kant's arguments and mentions him frequently in his writings, but he was generally critical. There are also many references in Durkheim's work to Hume and James, with whose arguments he also was well versed but critical.

At the time Durkheim began his studies there were no sociologists per se. Although Comte is sometimes called the first sociologist, Durkheim was the first to officially hold that title. His training would have consisted primarily of courses in philosophy, political economy, psychology, and anthropology, disciplines which treat social phenomena as the secondary, or aggregated, result of individual action. From the first it was Durkheim's objective to replace these perspectives with a new, more scientific way of working that replaced the inherent individualism of the other disciplines with a study of social forms and processes as primary phenomena. In *The Division of Labor*, he introduced this argument and the original introduction presented sociology as a new form of moral philosophy. The same theme of replacing philosophy with sociology can be seen clearly in his last work, *Elementary Forms*. Durkheim was trying to deliver firm imperatives about justice on the basis of social argumentation – to remove the contingencies from the social.

Because philosophers consider anything social to be contingent, Durkheim's efforts to establish a moral philosophy on social facts are generally interpreted as relativistic. Furthermore, because of the emphasis he placed on the universal and positive character of his findings, he is often taken by philosophers to have contradicted himself. This was true for the earliest of his American critics (Elmer Ghelke;

Charles Schaub) and consistently has been reflected in his reception among philosophers.

What Durkheim argued is that a universal sense of justice can be established on the basis of the social facts of self regulating practices in modern societies. He does not accept the assumption that anything social is contingent. One of the points of Durkheim's functionalism is that if a social form needs a particular thing in order to survive, then its survival implies that it must have achieved that thing. These are statements of necessity, not contingency, and in his view are not teleological.

One of the more important issues confusing the reception of Durkheim's work is his rejection of philosophical individualism and his argument that the social comes before the individual. Durkheim's position is that those elements of reason that distinguish persons from animals, particularly moral reasoning, are not inborn. His position, which he attributes to Rousseau, is that only in society is there a need for moral reasoning and therefore only as participants in social processes do people develop this capacity.

This was a complete shift in thinking away from individualism. One of the many difficulties the argument has faced is that it continues to be appraised by people who take an individualist position, believing the social is therefore contingent, then applying individualistic criteria in its evaluation. This leads to labeling Durkheim falsely as an idealist, positivist, subjectivist, objectivist, rationalist, and so on. It has also often led to the view that there are two Durkheims – or that he has contradicted himself. But, the rational individual simply does not exist for Durkheim. In this he is in agreement with other classic sociological thinkers like Marx and Mead, and with more contemporary thinkers like Goffman and Garfinkel.

RELEVANCE TO THE HISTORY OF CONTEMPORARY SOCIOLOGY

Durkheim created a blueprint for the discipline of sociology that defined it in entirely new terms. Understanding social theory, and engaging in the practice of sociology without contradiction, entails giving up philosophical

positions like individualism from which the sociological object, as Durkheim defined it, is rendered absurd.

As sociology has struggled over the decades to define itself against philosophical individualism and to establish the social at its center point, Durkheim has always been the inspiration. Structural functionalism, cultural anthropology, cultural sociology, postmodernism, poststructuralism, sociological studies of science, sociology of knowledge, and legal studies were all inspired by Durkheim's arguments, some negatively and some positively. The work of Garfinkel, Goffman, symbolic interaction, and social constructivism is similarly indebted. Durkheim's arguments with regard to social character of the individual self, the importance of concrete forms of association between people, and the special characteristics of self regulating practices in modern social contexts are an important foundation of these contemporary arguments.

The true importance of sociology as Durkheim envisioned it was not to play hand maiden to philosophy and to submit empirical studies for philosophical appraisal and evaluation. He envisioned a sociology that evaluated social facts on their own terms. He rejected the idea that social facts were contingent and wanted to establish that certain social forms and processes were necessary or, put another way, that certain social needs must be fulfilled in order for society to go on. Once this is established, those necessities become the non contingent social facts against which arguments can be anchored.

Durkheim would have objected to the idea of theory as a perspective of dead white men or anyone else. It was his idea to deconstruct the individualism that comprised the Enlightenment perspective, and he did so from a position that was both scientific and marginal. If we cannot see what we take for granted, then we need incongruities to crack open the surface of the taken for granted so that we can see beneath. It is science, the practices of observation and analysis of what incongruities make available to us, that makes this a worthwhile exercise for sociology.

Durkheim would have resisted allowing individualistic perspectives or disciplines to judge the validity of sociological arguments. He also would have disagreed with the

currently popular position (Coleman) that the problem with sociology is that it does not focus enough on individuals and on individual reason. Other disciplines would regard sociology more favorably if it did so, but the whole point of sociology from the beginning has been to challenge them in this regard. Sociology begins with the premise that individualism is wrong. To argue that it could become more popular by adopting an individualist view is to argue that sociology should surrender that which defines it as a unique and viable discipline. There would be no sociology if the individualism of philosophy, economics, and psychology were accepted. Only if the social is primary does sociology have a reason to exist as a discipline in the first place. On this foundation, Durkheim hoped to ground a sociological understanding of the requirements for justice in modern society.

Durkheim, Émile and social change

Edward A. Tiryakian

One may look in vain in Durkheim's oeuvre for an explicit discussion of social change, to be found neither in his major texts nor as a rubric in the 12 *Année Sociologique* volumes published in his lifetime. *Social change* does not figure in Durkheim's major divisions of sociology. Yet, like the Scarlet Pimpernel, it is here, it is there, it is everywhere. No consideration of Durkheim can be considered complete without taking into account his immanent social realism: societal systems structurally change from within, ultimately from qualitative and quantitative changes in social interaction (a presupposition widely shared with Marx and Weber, albeit for different primary factors). This seeming paradox can be best understood if one takes into account that the nineteenth century which provided the context for Durkheim was the modern period's crucible of enormous economic, political, cultural, and technological transformations of the social order, with Durkheim's predecessors and contemporaries all seeking to ascertain the major features, causes, and outcomes of the transformation. If Durkheim did not write explicitly about social change, he and his immediate followers (the "Durkheimians," who will be briefly mentioned here) were indeed very cognizant and attentive to addressing social change. This was at least partially recognized long ago by Robert Bellah in a seminal article (1960) pointing to the significance of history in Durkheim's epistemological and substantive thought.

Ultimately, following the general dictum of Durkheim that to explain social facts one must

seek recourse to social processes, to account for social change one needs to consider changes in the thickness or density of social interaction in time and space (i.e., in the frequency and extent of social interaction). This paramount focus is to be found in at least three major works, where social change takes on different manifestations.

As Lukes noted in his landmark intellectual biography (1977: 167), Durkheim proposed in his doctoral dissertation *The Division of Labor in Society* a misunderstood theory of social change invoking a morphological key variable: an increase in the "moral" or "dynamic density" of society. The division of labor and its concomitant "organic solidarity" are advanced by demographic factors of population increase in urban areas and by technological factors of increased means of communication and transportation. This perspective has been at the core of much of the initial modernization theory of the 1950s and 1960s stressing structural differentiation as change internal to social systems. As such, Durkheim's theory of societal change as structural differentiation is not altogether novel, since elements of it are to be found in Spencer. However, Durkheim proposed not only the mechanisms of change but also the problematic of the (normative) integration of societal systems in the wake of structural differentiation. This of course involves the question of *anomie* in the modern social order, which is treated in a separate entry.

Much of the treatment of long term social change in Durkheim as well as other social scientists of the nineteenth and early twentieth centuries rests on the evolutionary paradigm. An understanding of the contemporary present forms of society and their interrelationships was viewed in the optic of biological evolution, by tracing the development of origins from simpler to more complex forms of social organization: the more complex, the more organized a social species, the more advanced it is in the evolutionary ladder. While Durkheim analyzed social change in such evolutionary terms (Durkheim 1978 [1899–1900]: 154), he rejected a linear view of the succession of societies (and of institutions), and even more of social Darwinism, which lent itself to colonialism and imperialism in justifying the rule of "advanced" societies over those seen to be more "primitive."

Durkheim's deployment of an evolutionary perspective, utilizing historical data, is evidenced in his various analyses of long term institutional change. Among these may be mentioned his study of (1) the evolution of penal institutions, formulated in terms of laws of quantitative and qualitative changes in punishment (1978 [1899–1900]); (2) the evolution of individualism in its interrelation with the evolution of the state and political society (1957); and (3) the evolution of the institution closest to Durkheim's heart, higher education (1977 [1938]). The last named represents his most elaborate tracing of the development of an institution critical to modernity, written at a time when France in a period of turmoil and uncertainty was grappling with the course to take in educational reforms (p. 7).

Durkheim maintained in positivist fashion that secondary education needed a sound theoretical foundation based upon knowledge of how educational theory and its applications developed over time. The strengths and weaknesses of these theories in different epochs should be uncovered so as to inform policy makers and public opinion and connect proposed legislation and decrees with reality. We need not detail the evolutionary historical path Durkheim drew in going back to the origins of modern education to Rome as the initial starting point of modern higher education, and then following it forward at various stages. It is a richly textured organizational analysis of the emergent university system, seeking to cull what features in an evolutionary perspective appear to have lasting merit and hence deserving to be part of the contemporary educational system, and which do not and should be discarded (p. 160).

Durkheim's rejection of linear progress in evolutionary change is manifest in his redressing of the negative image of the Middle Ages (as an era of coarseness, harsh discipline, and little educational merit of the Scholastics); instead, he argued, this was a dynamic setting for educational development, bringing forth virtually from scratch "the most powerful and comprehensive academic organism which history has ever known" (p. 160). On the other hand, later educational systems had shortcomings: the Renaissance, with its overwhelming stress on classical education and self centeredness, or the

later Renaissance, with Jesuits in charge who made discipline and control more important than students exploring and discovering on their own.

Durkheim's study of the evolution of education, and in particular of the university system, is still of twofold merit, besides an important congruence between Durkheim and his great contemporary educator, John Dewey, with whom he shared the view that educational reforms should promote and facilitate the development and creativity of the student. First, because *The Evolution of Educational Thought* documents that at different periods of modernity, the university and secondary education have felt the need to reinvent themselves. Durkheim's study presents here comparative materials that may provide a perspective for the twenty first century, where higher education is subject to new challenges (multiculturalism, new fiscal constraints, and so on). Second, because it lays to rest the criticism that the functionalist mode of analyzing complex modern social institutions does not address the question of social change.

There is a third sort of social change in Durkheim's work, one which has as its focus short term, intensive transformation of the social whole. Some elements of the analysis in *The Elementary Forms of Religious Life* (1995 [1912]) are surprisingly similar to the analysis of long term structural differentiation in Durkheim's first period, yet the accent is on what may be termed "dedifferentiation" rather than "differentiation." In common with *The Division of Labor*, written 20 years earlier, Durkheim posits that increased interaction and the density of actors interacting, in a concentrated time and place, underlie changes in social consciousness. Brought about by religious rituals in the case of the Australian aborigines or by extraordinary events as in the case of the all night meeting of the French National Assembly in August 1789, or by similar "effervescent social milieux" in our own times from Managua and Tehran in 1979 to Eastern Europe in November 1989 (Tiryakian 1995), what is at stake is the renovation of collective solidarity at a critical moment. Durkheim sees such extraordinary moments of interactive intensity unparalleled in ordinary quotidian life. They are moments of destructuration or dedifferentiation, moments of collective enthusiasm,

attended by a collapse of hierarchical status distinction and even, on occasion, of antinomian behavior. While Durkheim drew his theory of the genesis of the sacred in the extraordinary interaction setting involving the whole social group, he also pointed out that social life oscillates between two poles: colorful, festive periods of “hyperexcitement” and periods of “secular activity” of “utter colorlessness” (Durkheim 1995 [1912]: 221). Short term intensive change gives way to “normalcy.” In modern society, the contrast, as Durkheim noted, is more muted, although the need for periodic assemblies and reaffirmation of collective sentiments remains.

Various of Durkheim’s collaborators dealt with social change, some with traditional and some with modern society. As an instance of the former, Mauss and Beuchat, in advance of *The Elementary Forms*, published a monograph on the social life of the Eskimo in two major seasonal cycles, winter and summer (Mauss & Beuchat 1979 [1904–5]). A study in social morphology, it analyzed variations in social organization and density of interaction. In the summer, the group is disbanded and the cultural life that integrates Eskimo society is at a minimum, as individual families are on their own. In the winter, they come together and cultural life is thick with the renovation of “a genuine community of ideas and material interests” (p. 76). Quantitative changes in interaction produce qualitative changes of increased group solidarity and consciousness, sometimes even leading to sexual license. Finding similar seasonal patterns in other North American native settings, Mauss and Beuchat proposed a general law: social life goes through cycles (phases) of increased and decreased intensity, of activity and rest, of dispersion and concentration, at the individual and collective levels (p. 79). Essentially, changes in the cultural life of a group correlate with changes in the form of a group.

François Simiand, a collaborator of the *Année Sociologique* who, with Maurice Halbwachs, was in charge of the major rubric “Economic Sociology,” also developed a long term, cyclical view of change, one applied to economic cycles (Simiand 1932). After extensive historical studies of the movements of prices, wages, economic production, and other indices of economic life, Simiand proposed that there are fluctuations with two major cycles: a

cycle of general expansion – the major A cycle – and one of contraction – the major B cycle. Writing in a period of global economic crisis, Simiand analyzed it as the early phase of a B cycle and criticized patchwork economic solutions that failed to realize the complex set of factors that make up economic life, including as a critical variable the social psychological reality of confidence or trust in economic conditions (1932: 113). The reality of economic progress, economic development, Simiand argued, is A + B, and mistaken are those theories or models of society that ignore fluctuations and believe they can organize a static economy. There is no general panacea for economic ills, but various options are present that require a knowledge of previous economic conditions in periods of transition from A to B or B to A.

Simiand’s two phases have been utilized in world systems theory, which has developed cycles complementing long term (secular) growth of global capitalism. However, more attention has been paid to a Russian contemporary of Simiand, Nikolai Kondratieff, whose theories of alternating “long waves” of expansion and contraction did not fit in the Soviet model of a planned economy. A comparative assessment of Simiand and Kondratieff would provide an important chapter in the history of political economy.

dyad/triad

Dan E. Miller

The smallest and most elementary social unit, a dyad is a social group composed of two members while a triad is a social group composed of three members. The study of dyads and triads is significant in two respects. First, dyads and triads form the most basic elements of sociological analysis. That is, most structural conditions and social processes can be found in dyadic and triadic interaction. Second, the analysis of dyads and triads clearly demonstrates the poverty of strict psychological reductionism, and calls into question the validity of methodological individualism. These issues and others were first addressed by Georg Simmel (1950) in his pioneering work on pure social forms.

A dyad differs from other quantitative social groupings in that each member interacts with only one other. Thus, in order to maintain the group both participants must construct reciprocal interaction with a high level of involvement with each other. Subsequently, a dyad is more fragile and precarious than other social units. If one person leaves or if one's attention is diverted elsewhere, the dyad dissolves. Because dyads are characterized by reciprocal interaction and relatively equal involvement, they tend

to become egalitarian over time. This egalitarian element is enhanced by the tendency for each member to relate to the other as an individual and not in terms of a categorical identity. In addition, the intensity and necessary constancy of interaction create the conditions in which intimacy can develop between the dyad's members. A dyad's intimacy is dependent on the exclusivity of shared knowledge and experience, on the fact that whatever is shared is shared only by the two and stays within the dyad. In such circumstances the dyad's members may become devoted to each other, a quality found in close friendships and romantic love.

Three distinct types of dyads can be identified. In *pure dyads* both members are free of other obligations and responsibilities. Each is responsible only to the other for the maintenance of the relationship. The world external to the dyad, including the passage of time, tends to evaporate in pure dyadic interaction. With *representative dyads* one or both members have allegiances to other social units. How they act and respond to the other is, in part, based on their identities as representatives of the larger social units. For example, sales managers from two companies meeting over lunch to discuss a possible business arrangement constitute dyadic interaction, but their interaction differs significantly from the pure form of two lovers having lunch, lost in each other's company. Dyads (and triads for that matter) need not be made up of individuals. *Supra individual dyads* are comprised of larger social units such as families, organizations, tribes, or societies. That is, larger social networks take on dyadic qualities when they communicate with each other. In this way we can understand how two businesses compete, two governments cooperate, and political party coalitions form.

It is common in the opening phase of dyadic interaction for new participants to engage in reciprocal self disclosure in order to get to know each other. This shared knowledge is instrumental in the formation of a bond between the two, opening up the arrangement to further possibilities. The two members may form a cooperative social unit in order to accomplish a common goal, or the two may disagree with each other, argue, and develop a conflict relationship or a rivalry. The participants may enter into polite

conversation, or they may decide to play a game with each other.

On the other hand, participation in dyadic interaction may be disagreeable for one or both parties. This disagreeableness often is accompanied by a sense of being stuck with no easy way to escape. Ironically, in pure dyads, leaving is relatively easy in that only one other person stands in the way. The knowledge of impending freedom from the constraints of dyadic interaction can be liberating. These qualities are not evident in representative dyads whose members are constrained to keep the dyad intact at least until practical matters are accomplished.

In its most elementary form a dyad comes into being when one member enters another's perceptual space. Interdependence develops when each becomes aware of the other's presence, attention, and responsiveness. Once copresence has been established, both members of the dyad take into account the anticipated response of the other as they construct and regulate their own behavior (Goffman 1963). Two people sitting on adjacent park benches notice each other, quickly establish eye contact, and return to their previous activities. Each is accessible to the other. In order to minimize the potentialities of sensory accessibility both must act in a way that will communicate that, while they are aware of each other's presence, neither person is available for more focused interaction. Identifying each other as non threatening strangers the dyad most likely will settle into a minimal degree of interrelatedness, one of civil inattention. In this situation each accommodates the other by not interfering, while maintaining a degree of attention with minimal responsiveness. The two, constrained by their interrelatedness, inhibit untoward and potentially embarrassing behaviors.

When two people who know each other establish copresence, they may join together to become a couple. Being a couple is a more complex and focused form of dyadic interaction than mere copresence (Goffman 1971). People who constitute a couple maintain ecological proximity allowing easy access to each other, including the intimate element of touch, while at the same time restricting availability to outsiders. Unlike a copresent dyad, couples are more attentive and responsive to each other. Their interactions can range from minimal

involvement, as when they are reading together in a library, to walking together down a street or to being highly involved in conversation with each other.

Moving from situations of copresence and couples to cooperative social action requires an increasingly focused and complex form of interaction. In order to construct cooperative social interaction the following elements of interrelatedness must be established and maintained by the members of the dyad. Both must attend to the other, acknowledge that attention, and become mutually responsive to each other's behavior. On this foundation members must establish congruent situated identities and agree on the shared focus of their interaction. Finally, the dyad must designate a social objective (a desired future state) if the purpose of the cooperative interaction is to accomplish some goal (Hintz & Miller 1995). A couple sitting in a coffee shop discussing an upcoming vacation must establish and maintain the aforementioned elements of interaction if they are to successfully complete their vacation plans. If any of the dimensions of interaction are not established or maintained, then the interaction will cease, in which case the dyad will dissolve or the couple must repair the structure before they can continue.

When a third member joins a dyad, forming a triad, not only do the interpersonal dynamics of the dyad change, but also a new array of possible social relationships emerges. The addition of a third member creates a supra individual quality to the group. That is, if one member leaves, the group continues. Other members can be recruited and socialized with little interference in the group's activities. When a third person enters a dyad's copresence the dyad's behavior becomes public. The special character of the dyad is lost. Intimacy is compromised. A couple with a new child loses much of the intimate reciprocity that previously dominated their relationship. The new parents must focus a great deal of their attention and actions toward the needs of the child. No matter how civilly inattentive the third party behaves, the dyad has acquired an audience that at once inhibits certain actions and alters others. The members of the dyad take the presence of the third into account as they construct their actions. If the third party is a stranger and merely copresent, then an

element of surveillance or voyeurism emerges. If the third party is known to the other two he may be invited to join, or he may be treated as an unwanted intruder who is not only excluded but also alienated from the dyad and the interaction.

In his brilliant essay "Quantitative Aspects of the Group," Georg Simmel (1950) describes three forms of interaction that emerge with the formation of a triad – *divide et impera* (divide and rule), *tertius gaudens* (the third who enjoys), and the impartial mediator. Divide and rule is a form in which a third party engenders conflict between a solidary dyad, thus dividing them and then gaining advantage over them. A well known example in the social sciences and in crime dramas is the prisoner's dilemma. In a prisoner's dilemma (Axelrod 1990) two suspects to a crime are arrested, brought to the police station, placed in separate interrogation rooms, and questioned by a detective. After a time the detective informs each suspect that the other is beginning to talk and that the suspect's punishment will be much lighter if he confesses. The dilemma is whether to talk or not. Both suspects will go free if neither talks, but talking means a shorter sentence. Faced with this dilemma most suspects cooperate with the detectives and confess. By employing the strategy of divide and rule, the detective was able to gain the necessary advantage.

In *tertius gaudens* triadic interaction the third member turns a disagreement (or competition) between the other two to his or her advantage. Unlike divide and rule, in *tertius gaudens* the other two are not a solidary unit. For example, a gasoline price war between two rival oil companies is advantageous to the consumer, who enjoys a break in high gasoline prices. Similarly, a child of a divorcing couple may enjoy the attention and gifts received from parents competing for the child's affection. In another situation two job candidates competing for the same position in a tight job market allow the employer to offer a lower salary and a smaller benefits package.

The third triadic form described by Simmel is that of the impartial mediator whose interaction with the other two is intended to bring them together to settle their differences. Marriage counselors exemplify the impartial mediator with the married couple and the counselor entering into cooperative interaction. However,

the impartiality of a mediator is not always a certainty. It is not uncommon for a marriage counselor or a therapist to unwittingly align with one party in a dispute, thus altering the relationship and further dividing the dyad. A variation on the role of impartial mediator is that of the arbitrator. Whereas the impartial mediator brings people together to help them settle differences through cooperative interaction, the arbitrator in an authoritarian role decides how the dispute will be settled. When contract negotiations between labor and management break down with little chance of reaching an agreement, an arbitrator may be brought in to settle the dispute in a fair and just manner. In a more elementary situation, a father may intervene in an argument between his two children over who controls the television by turning it off and instructing the children to not turn it on.

Coalitions are formed when two parties join together for the purpose of gaining advantage over a third party (Caplow 1969). Coalition formation in triads is about control – majority control. The tendency for coalitions to form in triads constitutes a social fact and, thus, is not reducible to the characteristics of the individuals who form them. In a revolutionary coalition a control hierarchy is overthrown when the member with the least power joins with the party with the second degree of power to wrest control from the most powerful party. With a conservative coalition the power hierarchy is maintained. A more prosaic form of coalition interaction arises when two people (a majority) formally or informally demand conformity on the part of the third person under the threat (or fear) of exclusion.

A coalition is unstable if the two parties who control the third have relatively equal power. In such situations the one with the least power can exert considerable influence by the known possibility that the low power party may join with one of the coalition members to gain control over the deposed other. For example, a small political party may gain numerous concessions by joining with one or the other more powerful parties. More interesting is the situation in which the majority parties modify their own policies in order to mollify the minority party who, each fears, may form a coalition with the rival majority party.

Triads forming one to two situations are commonplace. In one to two triads differentiation is established identifying the "one" as distinct from the others – as a leader or representative. The "one" defines and acts toward the others as a unit – as an audience, as students, as followers, or as captives. In one to two situations responsibility for the actions within the triad falls to the "one." A public speaker commands the attention of the audience, a tutor controls the focus of attention and behavior of her two pupils, and a tyrant controls his subjects. One to two triads are asymmetrical, ranging from the modest asymmetry of a one on audience situation to the increasingly asymmetrical arrangements found in authority relations, followings, and tyrannies.

The study of dyads and triads is relevant in many areas within the social sciences, including: bargaining and negotiation studies; counseling and psychotherapy; courtship, marriage, and family; conversation analysis; leadership; obedience and compliance research; and politics.

E

early childhood

Harriett Romo

Early childhood includes infancy, preschool, and the early years of formal schooling. Sociologists are interested in early childhood for a number of reasons. The children in a society will continue the social organizations, values, and mores of that society. Moreover, the ways a society cares for and socializes its children tell much about the structure and nature of that society.

Ariès (1962) documented the ways childhood has been viewed over time and how those views have changed over different centuries in western society. He studied depictions of children in medieval art and other historical documents to show that the concept of childhood as we recognize it today did not exist in those times. Instead, children were dressed and treated as little adults. Then thirteenth century artists portrayed children as sweet, innocent angels quite different from adults. Perceptions shifted again when sixteenth and eighteenth century moralists argued that childhood was a period of immaturity when children must be trained and disciplined in preparation for adulthood. Ariès claimed that modern society has focused on social problems of children, such as abuse and neglect, and separated children from the adult world. Although Ariès's work has been criticized for his generalizations, his analysis provided convincing evidence that children and childhood are perceived differently in different time periods.

Sociologists are also interested in childhood because child socialization and childrearing practices differ across cultures (Ochs & Schieffelin 1986). Childhood socialization involves children acquiring language skills, forming the

core of personality, and learning the central norms and values of the adults of their society. The parent-child relationship has been studied extensively, especially the interactions between the mother and the child. Attention has also been given to how others in society, including fathers, extended family, siblings, peers, and other significant adults, influence the growing child. Corsaro and others (Corsaro & Miller 1992; Corsaro 1997) have argued that the socialization of children is a collective process that occurs in the public as well as a private realm. They emphasize the importance of language and cultural routines in children's socialization. As children participate in cultural routines, they acquire social skills and knowledge and also creatively contribute to the production of culture through their interactions with adults and other children.

Concerns about the separation of children from the world of family and adults appeared in much of the sociological research on families and children during the 1970s as more parents and other adults worked longer hours, and families struggled to find appropriate care for their children. Issues of quality and adequacy of childcare became crucial for mothers who pursued careers opened up as a result of the women's movement.

As very young children had greater contact with institutions outside the family, more attention was paid to their social, moral, and educational development outside the family. Preschool in many societies has become a common solution to the problem of how to care for, socialize, and educate children between infancy and the start of formal schooling. In the US, early childhood education has been a response to the changing patterns of men's and women's work, high divorce rates, and the needs of single parent families (Tobin et al. 1989). Researchers in the twentieth century

emphasized that children are shaped by their own personal histories and experiences, and they are also actors in the shaping of their experiences and of their environment and culture (Corsaro 1997). For example, children socialize their parents into how parents should behave. Infants demand attention by crying and initiate contacts with adults in interactions. In social learning, children observe the behavior of others, repeat behavior that is rewarded, and avoid behavior that is punished. Children organize and interpret experiences for themselves and make judgments about behaviors. The work of Corsaro has suggested that sociologists can learn much about the daily lives and mores of adults in a society by observing and analyzing the behaviors of children and what they say.

As children spend greater amounts of time in educational institutions, sociologists have focused on the socialization and stratification that occur in schools and classrooms. Peer and media influences on children, the social problems of children, and the effects of changes in family composition on early childhood have also been topics of research. Contemporary research in psychology and education has suggested that infants and toddlers have many more cognitive capacities than previously realized, and a multitude of new research has been generated on infant brain development, cognition, the importance of play in children's lives, peer and family relationships, and emergent literacy.

The research focused on children's educational development has meant a greater awareness of the serious gaps in achievement between children from different socioeconomic, racial and ethnic, and linguistic backgrounds. As more and more US children attend preschool programs, a growing gap exists between children who arrive at formal schooling with extensive preschool experience and those who have not had access to early formal learning. Early childhood represents a critical opportunity for children to develop language and emergent literacy skills that constitute the foundation for more sophisticated literacy skills (Tabors & Snow 2002). Increasingly, children arrive at the first grade of schooling knowing how to write their names, count and recognize numbers, and recite the alphabet. Skills formerly taught in early kindergarten programs are now

taught in preschool programs for 3 and 4 year olds, giving children who have access to such programs an advantage in learning formal school skills.

Immigrant children are the fastest growing sector of the US population. Roughly one in six children in the US today lives in an immigrant headed household. The effect of immigration and the experiences of second generation US born children are topics of increasing research interest. A number of distinguished scholars have argued that immigration is structured by forms of transnationalism, suggesting that families and children often live in more than one nation state simultaneously. Children may be born in the US but schooled in their native community, or vice versa. Immigrant children may be raised by relatives in the native community while their parents work in the US and then join their parents in the US when they reach school age. Large numbers of immigrant children find themselves increasingly segregated from white, English speaking children (Portes & Rumbaut 2001). Some immigrant children do quite well in US schools, surpassing native born children in performance on standardized tests and attitudes toward education. Other immigrant groups tend to achieve below their native born peers. Successful adaptations among immigrant children may relate to cultural values or patterns of economic and social capital. Immigrant parents often struggle to maintain social control of their children as their offspring enter the formal US school system. Recent research suggests that length of residence in the US may be associated with declining health, school achievement, and aspirations. Many parents find it difficult to encourage their children to maintain their home language or their cultural values as they interact with others outside their home and family. Segregation or exposure to American society, English language skills, place of birth, age upon arrival, length of residence in the US, and the social and economic resources of their family influence the adaptation of immigrant children. Outcomes of adaptation are also influenced by where the immigrants settle, the type of childcare or school they attend, and the group of peers with whom they associate. Children with poorly educated parents often find themselves growing up in underprivileged

neighborhoods, poor schools, and a generally disruptive social environment.

There has been much emphasis on the impact of poverty on children. Families from racial and ethnic groups are disproportionately represented among the poor in the United States. Duncan and Brooks Gunn (1997) compiled research on the effects on children of growing up poor. They emphasized key transitions or turning points in child development that might alter behaviors or contexts for children and may be affected by income poverty. Nutrition in the prenatal and early infancy period can affect birth weight and later outcomes in school achievement and behavior. Infants from poor families are less likely to have immunizations or early health care and often receive childcare of lesser quality than that provided for families of different income levels. Persistent poverty has very negative effects on all children's achievement scores and verbal abilities.

A number of social policies and programs have aimed at interventions to assist children during this key period of early childhood. Fruitful strategies have been to improve the school readiness and cognitive ability of young children. Head Start is a preschool program for low income 3 and 4 year olds and Early Head Start reaches mothers, infants, and toddlers. Other effective strategies include helping parents read more to their children and teaching parents about effective parenting and stimulating learning activities they can do with their children.

earner–carer model

Joya Misra

The earner–carer model is a fundamentally gender egalitarian welfare state approach, which assumes that men and women equally engage in both caregiving and paid employment (Gornick & Meyers 2003). Welfare state structures always rest on gendered assumptions about men's and women's roles in the family and workplace. Through social policies, such gender ideologies reflect but also reinforce supposed roles of men and women as citizens, workers, and carers.

The dominant vision of the western welfare state during the twentieth century was the “male breadwinner–female caregiver” or “family wage” model (Sainsbury 1999). According to this model, families were presumed to be composed of a man working outside the home, a woman providing care within the home, and children. In order for this model to operate effectively, men needed to earn a wage large enough to support all of the members of this family. The welfare state would only intervene to replace the male breadwinner's wage in case of unemployment, disability, sickness, or old

age, or occasionally to support women's caretaking within the home (Fraser 1994). However, by the late twentieth century, it became increasingly clear that the male breadwinner model, which had never been accurate for most working class and poor families, was no longer tenable for even middle class families – both because few jobs pay enough to support an entire family, and because most women are now also labor market participants (Crompton 1999). Scholars suggest three main models to replace the family wage model: the universal breadwinner model, the caregiver parity model, and the earner–carer model.

The “universal breadwinner” model posits a society in which both men and women are equally invested in labor market participation. Rosemary Crompton (1999) refers to this model as the “dual earner/state carer” or “dual earner/marketized carer” model. In such a model, the welfare state should work to eliminate differences between men and women by engaging women in the paid labor force. Such a model requires workplace reforms aimed at equalizing women's opportunities, state or market provision of childcare, eldercare, and other care services, and the development of high quality full time positions that carry full social insurance benefits for women workers. This model would require either state or market provision of care, so that women are free to pursue paid employment (Fraser 1994).

The “caregiver parity” model posits a society in which women are valued and rewarded for providing care. In such a model, the welfare state should recognize gender difference and value care (Sainsbury 1999). Rather than encouraging women to pursue employment patterns that mimic men's, a caregiver parity strategy would make the difference between men's and women's employment patterns cost less to women, by supporting the time and effort women spend on care. Such a model would require the state to provide generous caregiver allowances in order to support informal carework, as well as workplace reforms such as parental leaves and flextime that make it easier for women to pursue care and paid employment. Rather than shifting care to the market and state, such a model emphasizes the family as the primary site for the provision of care (Fraser 1994).

The “earner–carer” model rejects both of these strategies to suggest a new vision, in which men and women both must balance informal carework and labor force participation. In this model, feminists pursue a strategy that encourages men's lives to more closely resemble women's lives, and requires social institutions to adjust to meet the needs of men and women who do not specialize in either formal work or informal care, but instead are involved in both formal work and informal care. Such a model would require all jobs to assume workers who are both earners and carers, with shorter workweeks, and employment enabling services. Unlike the universal breadwinner strategy that privileges state and market provision of care, the earner–carer model assumes that care will take place both inside and outside of households. Unlike the caregiver parity model, the earner–carer model attempts to break down gendered norms of care and employment (Fraser 1994; Crompton 1999; Gornick & Meyers 2003). However, this model remains difficult to institute effectively. As Anne Lise Ellingsaeter (1999) and Diane Sainsbury (1999) suggest, despite efforts to institute a more flexible combination of employment and care in Norway and Sweden respectively, gendered models remain. However, as Sainsbury (1999: 196) notes, “The lack of far reaching change . . . should not blind us to the merits of policy construction which integrates market work and care work in the home and simultaneously grants equal entitlement to men and women.”

ecofeminism

Noel Sturgeon

Ecofeminism refers to theories and political practices that make connections between feminisms and environmentalisms. Basically, ecofeminists claim that the oppression, inequality, and exploitation of certain groups (people of color, women, poor people, LGBT people, third world people, animals) are theoretically and structurally related to the degradation and overexploitation of the environment. Ecofeminism involves a double intervention: the claim that feminist issues need to be part of environmentalist agendas and analyses; and the claim that environmental issues need to be part of feminist agendas and analyses. Outside of this basic insight, there is little agreement over the specific character or mechanism of the connection between social inequalities and environmental problems.

Both an activist and an academic phenomenon, ecofeminisms can be found in most parts of the world and in many disciplines, especially women's studies, philosophy, literary criticism, religious studies, history, sociology, geography, cultural studies, and ethnic studies. Several major areas of theoretical and political conflict and disagreement exist. One of the major areas of conflict is how to conceptualize the "woman/nature" connection. Are women the majority of grassroots environmental activists because the gender division of labor puts them in charge of domestic responsibilities such as familial health,

food purity, community viability, and – especially in the global South – access to potable water, availability of fuel, and small scale agricultural sustainability? Or are women concerned about the environment because they are associated ideologically with nature, the body, and animals – especially in western cultures? These aspects, however, are not necessarily opposed, but can be conceptualized from constructivist or essentialist positions. Still, one of the major internal and external critiques of ecofeminism has been of the apparent biological essentialism of some (especially early) ecofeminist arguments that women have a special role to play in environmentalism (Sturgeon 1997).

The set of interconnected ideas called ecofeminism (that nature and women are similarly exploited by the patriarchal system's disregard for life, health, and equality; that access to clean water, air, and food is part of a broader feminist concept of human rights) has served as an inspiration for many activists since the late 1970s. Different versions of ecofeminism have been articulated over time by activists in the anti nuclear, anti militarist, anti colonialist, and anti corporate globalization movements, as well as in environmental movements involving species extinction, wilderness preservation, animal liberation, environmental justice, sustainable agriculture, and anti GMO foods. Ecofeminism cannot be manageably characterized as one social movement, but appears more or less simultaneously in a number of political arenas in the late 1970s and the early 1980s, especially in the context of feminist anti nuclear activism in the US (Starhawk 1982), England, Australia, and the South Pacific. The label, often attributed to François D'Eaubonne, a French activist and writer who used the term in 1974, is more likely a neologism produced by feminist activists from a number of different environmental movements (King 1990). Questions of racism in white feminism, and ethnocentrism in northern/western hegemonic feminism, were also contentious issues for ecofeminist politics.

In the international context, beginning at the 1980 World Women's Conference in Nairobi, many feminist activists from the global South insisted that environmental issues such as deforestation, desertification, and water purity were central parts of women's struggle against

poverty and colonialism. They argued for more materialist analyses of the relation between environmental and women's issues than was common in western ecofeminist activism, which in the 1980s had a strong spiritualist and ideological strand (Agarwal 1992). The label "ecofeminism" was criticized (in both political and academic interventions) as standing in for universalistic, essentialist conceptualizations of the "woman/nature connection" that did not account for unequal power and privilege in the distribution of exposure to environmental problems. The development of this critique accompanied the growing interest in environmentalist feminism in the NGO and UN political arenas, sometimes going under the name "gender and development" (Braidotti et al. 1994). NGOs such as DAWN, WEDO, WEED, and the Committee on Women, Population, and the Environment, as well as movements such as the Green Belt movement in Kenya (headed by Wangari Maathai, awarded a 2004 Nobel Peace Prize for her work) and the Chipko movement in India, constituted a loose set of affiliations that brought environmental issues to the attention of international feminist organizers, and vice versa (Sturgeon 1997).

Ecofeminist arguments have had a noticeable effect on both environmental and gender policy (Buckingham 2004). At the 1992 UN Conference on Environment and Development in Rio, the final document, Agenda 21, contained a chapter on women's stake in environmental issues; and in 1995, at the UN Conference for Women in Beijing, the environment was prominent in the list of women's concerns. Ecofeminism is not just a western movement: for instance, the activism and writing of Indian ecofeminist Vandana Shiva has raised the profile of new issues, such as corporate ownership of genetic materials, as both feminist and environmental concerns within a global political economy, despite what some feminist critics of Shiva see as her essentialist and ahistorical vision of women subsistence farmers. Since the 1970s, the journal *Women and Environments International*, located in Toronto, has published accounts of different environmental feminist activist efforts around the world.

In the academy, a burst of ecofeminist publications has made it difficult to keep pace, especially given that the literature spans so

many disciplines. As indicated above, the label "ecofeminism" itself is now controversial, so much contemporary scholarship tends to use the terms environmental feminism, ecological feminism, or feminist environmentalism, or other more specific emendations of the label such as ecowomanism, environmental justice ecofeminism, or materialist ecofeminism. Early writing that was important to the first theorizations of the field, such as Sherry Ortner's anthropological article "Is Female to Male as Nature is to Culture?" (1974), Annette Kolodny's historical and literary *The Lay of the Land* (1975), Susan Griffin's literary *Woman and Nature* (1978), and Carolyn Merchant's historical *The Death of Nature* (1980), demonstrated the disciplinary variety present at the outset, as well as the theoretical problems of establishing connections between feminism and environmentalism. *The Death of Nature* was not just an inspiration for ecofeminists, but also an important foundation for feminist science studies, which has had an interestingly intertwined but sometimes antagonistic relationship with ecofeminism. All four of these works demonstrate the power of an analysis that simultaneously addresses the means by which sexism and environmental overexploitation are reproduced and maintained, but they also demonstrate some of the dangers of such an analysis. The temptation to lump all women together without cultural, racial, class, and historical distinctions leads to universalisms that are politically and theoretically problematic. Merchant's later work, *Ecological Revolutions* (1989), *Earthcare* (1996), and *Reinventing Eden* (2004), constitutes a detailed historical environmental feminist treatment that carefully accounts for race and class differences, ranging from the European conquest of the US to the present.

Early ecofeminist scholarship located the twin problems of the oppression of women and the exploitation of the environment in a western dualism that separated and unequally valued men/women, culture/nature, reason/emotion, mind/body, white/black, and human/animal. Ecofeminist philosophers Karen Warren (2000) and Val Plumwood (1994) have separately developed a detailed critique of this dualist framework and implicated it in a number of structures of domination, not just those

affecting women and nature, but also in racism, colonialism, and speciesism. Other ecofeminist theorists such as Greta Gaard (1997) and Catriona Sandilands (1999) have examined the ways in which heterosexism is also upheld by dualist structures of domination as well as other problematic concepts of nature. Carol Adams (1990), among others, has written extensively on the relation between the exploitation of animals and sexist/heterosexist ideologies. Vandana Shiva (*Staying Alive*, 1988), Maria Mies (*Patriarchy and Accumulation*, 1986; Mies & Shiva 1993), and Mary Mellors (*Breaking the Boundaries*, 1992) have written about the dangers of capitalist and colonialist economies for both women and the environment. Joni Seager (*Earth Follies*, 1993) has argued that the patriarchal structures of corporations, governments, and militaries are implicated in these institutions being the three major causes of environmental problems.

As a corrective to the narratives and practices of domination identified by this wide ranging scholarship, Warren (2000) and Merchant (2004) have offered the idea of a partnership ethic, a way of understanding nature not as other, or as resource, but as active agent in a process of co construction of reality with human beings. These ideas are close to those of Donna Haraway (*The Companion Species Manifesto*, 2003; *The Haraway Reader*, 2004), who has allied herself with a thoroughly non essentialist version of ecofeminism in several places (Sandilands 1999), though she never uses the language of partnership with nature, but rather the notion of "naturecultures" as a way to shake up notions of binary difference and to see nature as composed of multiple, interdependent actors. Chris Cuomo (1998) has written about another way of conceptualizing a more positive social and environmental ethics, using the complex and promising concept of "flourishing" as a guidepost to constructing social and environmental relationships that are just, flexible, and sustainable.

Sociological work on the relationship between feminism and environmental issues has analyzed particular movements, explored overlap between feminist and environmental values, and surveyed ecofeminist theoretical arguments (Norgaard 1996). Overviews of environmental movements sometimes include

ecofeminism as a variant (Merchant, *Radical Ecology*, 1992) but ecofeminism is often ignored or excluded by social movement historians or theorists, despite, or perhaps because of, ecofeminism's widespread manifestations in a number of different environmental political contexts (Sturgeon 1997). Robert Gottlieb (*Forcing the Spring*, 1993) and Dorceta Taylor (1996) have both done interesting and useful work in challenging standard environmental histories that emphasize wilderness preservation and white male founders such as John Muir. Instead, Gottlieb and Taylor have emphasized working class (occupational health), female (progressivism and social welfare), and African American (urban reform and civil rights) movements as historical antecedents to the common concerns of feminist environmentalists and environmental justice advocates.

Environmental justice and ecofeminism movements have similar foci, operating from slightly different but related frameworks, with ecofeminism stressing gender, and environmental justice stressing race. Both positions, however, end with emphasizing the interconnections of race, class, gender, and class inequality with environmental issues. The exploration of the relationship between ecofeminism and environmental racism, however, is a fraught discussion, given that the label ecofeminism has been associated early in its existence with white feminists not necessarily allied with the issues of race and class important to environmental justice activists (Kirk 1997). Yet, there is a set of historical, political, and theoretical interrelations here worth exploring, given the large number of women who have been activists in grassroots environmental justice organizations, and some of the struggles they have had with sexism in these organizations (Di Chiro 1992). Laura Pulido (*Environmentalism and Environmental Justice*, 1996) and Devon Peña (*Chicano Culture*, 1997) also recognize the importance of gender as well as race and culture in constructing and analyzing environmental justice movements. A recent attempt to bridge the divide between environmental feminisms and environmental justice is the collection edited by Rachel Stein, *Environmental Justice: Gender, Sexuality and Activism* (2004).

The future of activist ecofeminism might very well lie in directions that will cause the

label to disappear entirely. Ironically, as the label becomes less used, the cornerstone of ecofeminism, the interconnections of the issues of social inequality and environment, is an analysis widely accepted by the global justice movement, and scholarly approaches which deploy environmentalist and feminist analyses together are becoming more critical as tools in understanding a broad array of social and cultural phenomena. Joni Seager (2003: 950) identifies four areas in which "the best of the recent feminist environmentalist scholarship engages with and extends transnational, postcolonial, and poststructuralist deconstructions and challenges." These four areas, according to Seager, are the work being done by feminist environmentalist scholars on animal rights, public health, global political economy, and population issues. More and more environmental feminist work includes the ecofeminist critique of dualist structures, but also looks more generally at the use of ideas of nature and the natural as tools of legitimation in a global political economy (Sturgeon, *The Politics of the Natural*, 2006). This expanded theoretical agenda provides a broader scope on the world's present problems, in which the interrelated issues of growing inequality and planetary environmental crises are central.

ecological models of urban form: concentric zone model, the sector model, and the multiple nuclei model

Kent Schwirian

Ecological models of urban form describe and explain the spatial patterns taken by the distribution of people, buildings, and activities across a city's terrain. This orderly set of spatial arrangements is known as the city's land use pattern or spatial form. Through the years ecological researchers have identified three major models of the geometry of city form: concentric zone, sector, and multiple nuclei. While the three models are conceptually distinct, in the actual development of most cities various elements from the three models become uniquely combined into a spatial pattern that gives each city its own individual spatial geometry. Each of the three models was developed to explain urban morphology in industrial cities of the twentieth century. The concentric zone model was presented by Ernest Burgess in 1925. The sector (Hoyt 1939) and multiple nuclei (Harris & Ullman 1945) models were presented later as alternatives to the concentric zone model. Through time the three have become intellectually linked and widely considered as "the classic models of urban land use." They are "classic" in the sense that the three models have stood the test of time and have proven to be catalysts of research on cities in both developed and developing societies.

The three models share common assumptions: (1) that the city is growing in population and expanding in economic activities; (2) a relatively free land market that is responsive to the economic principles of supply and demand with little in the way of government regulation; (3) an economic base that is mainly a mix of industrial commercial activities; (4) private ownership of property; (5) specialization in land use; (6) a transportation system that is fairly rapid and efficient, and generally

available in terms of cost to the majority of the population; and (7) freedom of residential choice, at least for the higher socioeconomic strata. Even though sharing these assumptions, the three models predict different spatial geometries (see Figure 1).

CONCENTRIC ZONE MODEL

For the Chicago School sociologists (1914–45), Chicago was the prototypical growing industrial city. What was true for Chicago, they argued, was true for most others. Chicago was both their window on city life and their laboratory for community study. The concentric zone model described Chicago, they argued, and, in essence, described other cities as well.

The concentric zone model, attributed to Ernest Burgess, posits a city undergoing rapid population and economic growth. As different population groups, industrial enterprises, and organizations come to the city, an enormous land market competition develops for highly prized locations. The groups with the most available resources (e.g., business and industry, the upper class) are able to obtain the locations they desire while those with fewer resources (e.g., impoverished immigrant groups) have to make do elsewhere. In 1929 Robert Park called the city, through the operation of its land market, a "great sifting and sorting mechanism . . . so that every individual finds, eventually, either the place where he can, or the place where he must live" (Park 1952: 79).

Central location is valued most highly since the old industrial city had but one vital downtown center. Central location minimizes transportation costs to all other locations in the city. Consequently, land values at the city's center soar and can only be afforded by the most resource laden groups – typically, business and industry. The *central business district* (CBD) forms the organizing node of the city and is identified as Zone 1 of the model. It includes banks and other financial institutions, corporate offices and headquarters, large department stores and specialized retailers, museums, hotels and night clubs, bars and restaurants, theaters and other entertainment venues, and government administrative offices.

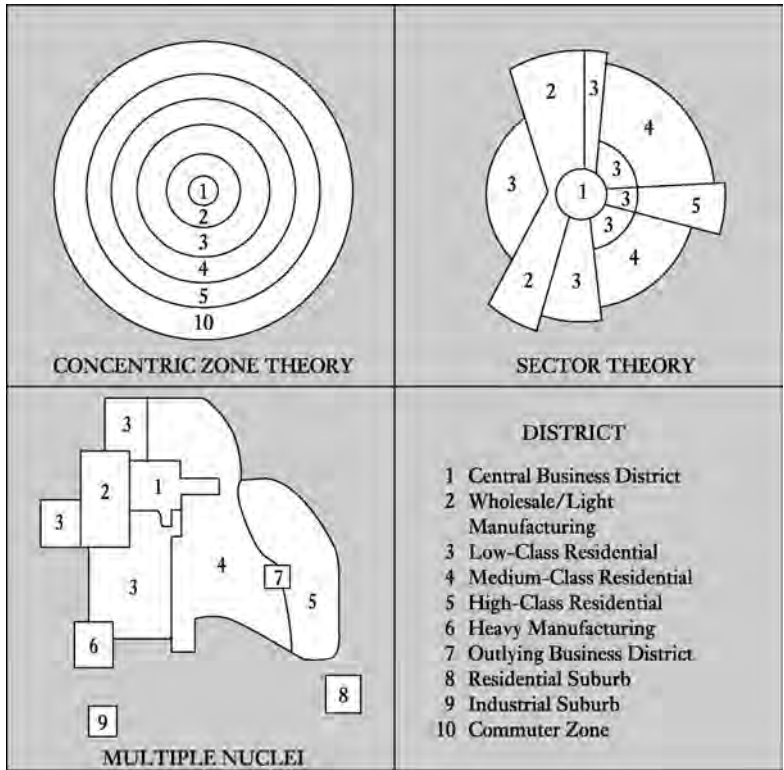

Figure 1 Classic models of urban spatial geometry.

Zone 2, the *zone in transition*, is located around the CBD on all sides. It is in the process of shifting from residential to industrial commercial land uses as the growing CBD spills its various activities into it. It is an area of intense land speculation and profit taking by property owners. The area's increasing blight and deterioration drive out the middle and working class residents. Their leaving makes the zone an available place of residence for those groups that cannot obtain housing elsewhere – the segregated racial and ethnic minorities, the socially stigmatized, the downwardly mobile, and those seeking impersonality, anonymity, and seclusion. Slums, prostitution, crime, mental and physical illness, and the drug war flourish in the zone in transition. It is a socially distressed area inhabited by socially distressed individuals.

Just beyond the zone in transition is found Zone 3, the *zone of workingmen's homes*. It is a

blue collar neighborhood inhabited by stable families where “respectability” is a driving ethos. The housing is neat and tidy and the residents are alert and “on guard” against incursions of minorities from the zone in transition. Residential invasions of the poor and ethnic minorities are usually met with resistance. Blockbusting realtors operate in the zone to open housing opportunities for those minority group members moving up socioeconomically and out spatially. Once a “tipping point” has been reached and immigrating minorities flood the zone, the working class residents flee further out, typically into the adjacent Zone 4, the *zone of better residences*, which houses the middle class. In turn, the middle class moves further out in response to the perceived downgrading of its neighborhoods by the newcomers. It relocates to the next adjacent zone, the *commuters' zone*, which at one time housed the city's upper crust. Later Burgess identified

two additional zones in the metropolis – the agricultural districts and the metropolitan hinterland (Burgess 1930).

The shifting of people and activities from one zone to another according to this model resembles the pattern that is observed when a pebble is tossed into a lake. The concentric ripples it creates follow and run into each other in their outward rush. The turnover rate of urban neighborhoods from one population type or activity type to another is governed by several factors. First is the rate of growth in people and activities that demand housing or buildings. Second is the rate of construction of dwellings, industrial buildings, and commercial confines. Third is the investment decisions made by developers, financial institutions, and political regimes. If construction lags behind population and economic growth, stagnation and the piling up of people and activities take place. Demand for developed land increases and the prices for developed parcels escalate. If construction exceeds population and economic growth, vacancy rates rise and land prices decline, but new opportunities are created that may serve to attract future growth. Or, in the extreme, with high vacancies and little growth, a collapse of the local development economy may take place which sends the city into economic depression.

SECTOR MODEL

On the basis of studying 142 American cities, Homer Hoyt (1939) argued that, contrary to the concentric zone model, the city's urban geometry is better described by a sector pattern of land development. The distributions of rents and the city's socioeconomic status groups are organized in homogeneous, pie shaped wedges or sectors that run from the city's CBD to the periphery. The characteristic land use, activity mix, and population composition for any sector are different from those sectors adjacent to it. The implication is that if one were to drive from the CBD to the periphery while remaining in the same sector, one would remain in generally the same type of land use, resident population composition, and activity mix. The concentric zone model provides the driver with a much different view of the city. As one travels

from the CBD to the periphery, regardless of direction, one passes through the same gradation of an ever increasing status composition of neighborhoods.

The sector model is based on an axial conception of the city. It incorporates Richard Hurd's (1924 [1903]) idea that growth and development first take place along main transportation routes from the city's center to the hinterland; these include rail lines, highways, and navigable bodies of water. At some point, it becomes cheaper in travel time and money to develop the open land between the axes than to continue the outward push along the axes. As the area between the axes becomes filled, another cycle begins with development shifting to the axes again and pushing out along them into the undeveloped hinterland.

In a city with a sector spatial geometry, sectors of industry, warehousing, and poor quality land tend to be surrounded by sectors of low income and working class residents. Middle class housing sectors tend to buffer those of upper status from the sectors of low income, industry, and noxious activities. The high status populations command the most desirable sites in the city. The high rent sectors tend to occupy high ground that is free from risk of floods and deluxe apartment areas tend to be established near the business centers in old established residential areas. Low rent areas and the areas occupied by the poor and marginalized race and ethnic groups tend to be located on the opposite side of the city from the high income sector.

The location and movement of the sectors occupied by the wealthy and upper socioeconomic groups have a major impact on the location of the other sectors. Hoyt's model argues that high rent residential growth tends to proceed from its given point of origin along established lines of travel or toward another existing nucleus or trade area. The high rent sectors tend to spread along lake, bay, river, and ocean ports where the waterfronts are non industrial. High rent residential districts tend to grow toward open country, away from "dead end" sectors that prevent expansion by natural or artificial barriers, and toward the homes of the community leaders. The growth of high rent neighborhoods continues in the same direction for a long time. Real estate developers may

bend the direction of high grade residential growth, but they cannot negate or reverse the effects of the general principles embodied in the model.

MULTIPLE NUCLEI MODEL

Unlike the other models, the multiple nuclei model of Chauncy Harris and Edward Ullman (1945) does not view the city as being organized around the CBD. Rather, it postulates that there are a number of different growth nuclei, each of which exerts influences on the distribution of people, activities, and land uses. Each nucleus specializes in markedly different activities, ranging from retailing through manufacturing, education and health services to residential. Nuclei vary in size. Some are large, such as the industrial sites; other are small, such as a strip shopping center. Thus, the city's spatial geometry is much like a patchwork quilt of differing nuclei that are not organized around a single center. The CBD is but one of several functionally important nuclei.

The multiple nuclei model uses four basic principles to explain both the emergence of separate nuclei and the change in them through time. (1) Certain activities require specialized facilities located in only one or a few sections of the metropolis, as seen in the case of manufacturing plants requiring large blocks of undeveloped land located near rail lines. (2) Certain like activities profit from adjacent congregation, as seen in the clustering of retail establishments into malls and shopping centers. (3) Certain unlike activities are antagonistic or detrimental to each other, as seen in the case of manufacturing plants and upper class residential developments. (4) Certain activities are unable to afford the costs of the most desirable locations, as seen in the case of low income residential areas and high land with a much sought after view.

The number and mix of nuclei in a city vary greatly. Larger cities have more nuclei than do smaller places, and they tend to be more specialized in the larger community. For example, a small city may have a retailing nucleus, but in a larger city the separate retail activities may spin out into their own nucleus, as seen in the "diamond" district in New York City. Some

nuclei have existed from the origins of the city, as seen in the CBD; others developed as the city grew, such as ethnic enclaves established by arriving immigrant groups, and through urban redevelopment as one land use supplants another, as in the case of an arena project being built on the site of a former prison.

MODELS IN COMBINATION

In examining the comparative utility of the three models, researchers have found that in many cities socioeconomic status tends to vary by both sector and distance. That is, some sectors tend to contain a larger percentage of the affluent than do others, and there is a general tendency for the socioeconomic standing of neighborhoods to increase with distance from the CBD. Studies have also shown that housing types and values often vary by sector. Regardless of the extent to which a city's spatial geometry approximates concentric zones or sectors, overlaying the whole pattern tends to be numerous nuclei devoted to such things as educational campuses, medical complexes, race and ethnic group ghettos and enclaves, industrial plants, parks, and historic districts.

In applying the models to other societies, researchers have identified elements of the three models in the geometry of spatial structure of their cities. A main difference between the geometry of cities in developed and developing societies is that in the developing societies, socioeconomic status tends to be inversely related to distance from the core, while in cities in developed societies, status tends to have a direct relationship with distance. Some have suggested that as cities in developing societies increasingly become part of the global network, they experience economic, social, and political changes and those changes are manifest in the transition of their spatial geometries to a pattern consistent with the patterns of cities in developed societies (Schwirian 1983).

Increasingly, researchers have argued that the spatial geometry of post industrial cities such as Los Angeles does not conform to the classic models. Their origin lies not in the industrial centralization of the twentieth century as assumed by the classic models, but, rather, in the decentralized and dispersed multicentric

metropolitan region of the postmodern age (Dear 2001).

ecological problems

Peter Preisendorfer and Andreas Diekmann

Although human beings have overused natural resources and local environments throughout history, today's ecological problems such as the greenhouse effect, the reduction of biodiversity, overfishing of the oceans, or shortages

of clean drinking water are relatively recent phenomena. They started with the period of industrialization in the first half of the nineteenth century, and had their real takeoff after World War II. Serious warnings about impending global ecological disasters were first issued in the 1960s by scientists like Rachel Carson (1962), Paul Ehrlich (1968), Garrett Hardin (1968), and Dennis Meadows et al. (1972).

Given Durkheim's view that sociology should concentrate on social facts and their social origins, sociologists were long reluctant to deal with the environmental challenge and to incorporate it into their discipline. Although the Chicago School in sociology pioneered urban "ecological" studies in the first half of the twentieth century, it took a relatively long time before a specialty called environmental sociology was established. Today, an environmental sociology devoted to describing, explaining, and contributing to the solution of ecological problems is an institutionalized subsection of sociology. It has its own textbooks and review articles (e.g., Berger 1994), and is part of the teaching program at many universities. There are at least three major areas of research in which environmental sociologists are active: theories of the emergence of ecological problems, environmental attitudes and behavior of the general public, and environmental behavior of corporate actors (business firms, environmental movement organizations, and the state). Other research topics deal with the social diffusion of environmentally friendly technologies, the perception of ecological risks, and the social distribution of ecologically harmful emissions ("environmental justice").

THEORIES OF THE EMERGENCE OF ECOLOGICAL PROBLEMS

Overwhelming majorities of people answer in surveys that they want to live in a sound and healthy environment – one without noise, air pollution, toxic waste, traffic jams, and the like. However, such unpleasant collective effects occur, and the question is why. Theories of ecological problems developed in answer to this question fit neatly into the four general paradigms of sociological theory: functionalism/system theory, conflict theory/the political

economy perspective, rational choice theory, and interactionist/constructivist approaches.

Approaches developed in the tradition of functionalism/system theory locate the reasons for ecological problems in the complexities of systems, both ecosystems and social systems. Systems usually consist of many elements and the relations among them, which may be understood to a better or worse extent. Changes in one or a few system elements can have far reaching and unexpected consequences. The discernment of such contingencies is hampered by the existence of feedback processes, interactive linkages, positive and negative loops, and the fact that, while some changes have short term consequences, others have only long term consequences. Caught in simple "cause and effect" thinking, human beings have difficulty perceiving and predicting the dynamic system effects of their actions, so they endanger and destroy the equilibrium of well adapted and finely tuned ecosystems. The most prominent examples of such a system theoretic approach to environmental problems are the "limits of growth" scenarios from the Club of Rome and its members (e.g., Meadows et al. 1992). One of sociological system theory's core ideas is that modern societies are characterized by functional differentiation, i.e., that they consist of a set of relatively autonomous subsystems (political, economic, and legal subsystems, and so on). All these subsystems have their own "codes" and their own logic, and maintain efficiency at the cost of a certain amount of one sidedness. The problem of environmental protection affects several different societal subsystems, which is seen as an impediment to a reasonable solution of this problem in functionally differentiated societies (e.g., Luhmann 1986).

The conflict theory/political economy perspective, which has its historical basis in Marxist theory, blames mainly the logic of the capitalist and/or neoliberal economic system for the environmental crisis. In a neoliberal world, successful businesses and prosperous economies require permanent growth, which involves new products and innovations, short product cycles, and a rapid process of creative destruction. The built in dynamics of industrial production (the industrial metabolism) relies not only on the exploitation of workers and human resources, but to an even greater

extent on that of natural resources. The profit seeking exploitation of resources is not confined to the industrialized countries, but has instead expanded to the whole world during a process of mainly economic globalization. Proponents of the political economy perspective of ecological problems are authors in the tradition of the neo Marxist world system theory, prominent anti globalization activists, and scientific writers like Allan Schnaiberg who have often focused on the "treadmills of production and consumption" in western countries (e.g., Schnaiberg & Gould 1994).

The first contribution of rational choice theory to the explanation of ecological problems is the elementary assumption that, if environmental behavior is not optimal, something must be wrong with the incentive structure. People might not act in an environmentally responsible way because environmentally responsible behavior would cost them something they value, for instance, because prices of ecoproducts are too high or because driving a speedy (but fuel inefficient) car enhances social status. Rational choice theorists insist that environmental behavior cannot be well understood if it is conceptualized as altruistic behavior, but only if it is seen as subjectively rational, self interested behavior. One of the important reasons why incentives to pro environmental behavior are often distorted stems from the fact that many environmental goods and services are public goods. A defining element of such goods is that no one can be excluded from their use, which induces people both to overuse these goods and to withhold their own contribution to their production (the problem of free riding). Market prices are often poor signals of the real value not only of such public goods, but also of the value of private goods, because they do not include the true costs of negative externalities (e.g., the water pollution caused by the production of these goods). In other words, rational choice theory states that ecological problems often have the structure of a social dilemma such as a "commons dilemma" or a "prisoner's dilemma." In a social dilemma, the rational individual strategy is non cooperation, i.e., in this case pursuing one's own interests at the expense of the environment. For a public good, individual and collective rationality diverge, lowering cooperation among actors.

A solution to a social dilemma is establishing enforcing institutions to help change the incentive structure so that cooperative behavior will be in the self interest of individual actors. A well known study reflecting this line of reasoning is Elinor Ostrom (1990).

Proponents of interactionist/constructivist approaches emphasize that environmental problems – like all other societal problems – are socially defined and culturally patterned. The social construction of the environmental crisis can be demonstrated by looking at historical differences in the definition of the problem and by cross national comparisons of problem solving preferences. Given this focus, constructivist theorists are interested primarily in the social and political processes through which ecological problems are placed and kept on the problem agenda. Groups with vested interests in environmental issues and the presence or absence of pro environmental movements play a crucial role in the modern construction of the environmental crisis, as does the focus of the mass media. Douglas and Wildavsky (1982) are the authors of a classic study on social and cultural influences on the definition of environmental problems (and especially on the perception of risk).

Another analytical tool is provided not by those four theoretical approaches but by a useful conceptual scheme, the IPAT formula suggested by Ehrlich and Ehrlich (1991). According to this “accounting scheme,” ecological impact (I) is the product of the population (P), the pro capita consumption level (affluence A), and technology (T). As an example, consider the impact of carbon dioxide emissions from private cars. Impact measured in tons per year results from the population P times the average number of miles a person drives per year (A) times the average CO₂ emission per mile (T). There are two main ways to reduce environmental impact: less consumption (the “sufficiency strategy”) or better technology (the “efficiency strategy”). Programs aimed at uncoupling economic growth and energy consumption or “factor x programs” (those intended to enable affluence with lower overall energy input) follow the latter strategy (Weizsäcker et al. 1998). Economic and sociological theories such as modernization theory or social diffusion theory try to explain how social and

economic conditions affect lifestyles, the consumption level, and the development of more environmentally efficient technologies.

ENVIRONMENTAL ATTITUDES AND BEHAVIOR IN THE GENERAL PUBLIC

Moved to action by alarming scientific studies, in the 1960s a growing part of the general public began to develop an attitude summarized by the term “environmental concern.” This concern was first observed in the US, but it spread to other countries in a rapid social diffusion process. Today, we can speak of a global or worldwide environmental concern (Dunlap et al. 1993). Judging by the results of surveys in different western countries, environmental concern increased to a peak around 1990, but has since decreased or at least stagnated. Those who retain an attitude of environmental concern are more likely to be young, female, highly educated, have a higher income, and hold a progressive/liberal political worldview. Comparing different countries, a higher GNP is associated with more widespread environmental awareness. The positive correlation between income/GNP and environmental concern has often been interpreted as an indication that the quality of the environment is a luxury good, important primarily to the rich.

There are two main expectations in focusing on environmental concern in attempting to resolve ecological problems. First, that it can put pressure on the political system to take action in favor of the environment. Second, that it can directly affect citizens’ environmentally relevant behaviors. The first mechanism has some intrinsic appeal, but is difficult to validate. The second, that environmental attitudes strongly influence environmental behavior, has been proven shaky because the relation between environmental concern and behavior reported in numerous studies is of only modest strength. Although there has been some lamentation about the discrepancy between environmental attitudes and behavior, this discrepancy is typically observed in attitude-behavior research in general. The disconnect between environmental attitudes and behavior has roots similar to inconsistencies in other areas of study. Environmental attitudes

are simply one of many factors influencing environmental behavior.

Empirical studies on the behavioral effects of environmental attitudes are regularly confronted with the problem of measuring and conceptualizing "environmental behavior." If we define it only as behavior that affects the natural environment, most behavior belongs to the category. It is therefore necessary to rank different kinds of behavior according to their impact on the environment. Concentrating on those behaviors with the largest impact leads to "indicators of sustainable household consumption" (Lorek & Spangenberg 2001). These indicators can be used to provide the public with recommendations on how to improve their environmental performance. Mobility/transport (the use of cars, airplanes, public transportation), housing (size of one's home, the presence of a heating system or air conditioning), and nutrition (local ecofood, the consumption of meat) are the three areas in which individual behavior has the strongest environmental consequences. Common wisdom about and public attention to what constitutes environmentally relevant behavior tend to diverge from these scientifically established facts.

Starting from the premise that ecological problems are (also) caused by maladaptive individual behavior, much research focuses on the question of which factors determine this behavior and how environmentally harmful behavior can be changed. There are two opposing schools of thought on that issue: attitudinal approaches and structural approaches. Whereas psychology tends to give priority to influencing attitudes (through moral suasion, value change, environmental education, and so on), sociology and economics have a clear preference for structural settings (convenient access to preferred alternatives, legal restrictions, financial rewards for desirable behavior, and the like). These two views may be reconciled through the hypothesis that environmental attitudes are important when stakes and/or inconvenience of a certain behavior are low (low cost condition), but lose their influence in favor of structural circumstances when stakes and/or inconvenience is high (high cost condition). Diekmann and Preisendörfer (2003), along with others, have presented findings supporting this low cost hypothesis.

ENVIRONMENTAL BEHAVIOR OF CORPORATE ACTORS

Modern societies consist not only of individual actors, but also of corporate actors. The interests and behaviors of these corporate actors are as important for the quality of the environment as those of individual citizens. The activities of business firms and corporations have tremendous effects on the state of the environment, both direct and indirect. They use natural resources as inputs in their production process, they decide which types of goods and services they produce and how they produce them, they have the capacity to influence the consumers and to direct their wishes and their demand for certain products, and often they use the environment as "waste sink." Given all these forms of potential impact, it is important to monitor and to explain firms' environmentally relevant activities. Empirical studies by environmental sociologists investigate which industries cause the most serious environmental damage, under what conditions firms are motivated to improve their ecological performance, which instruments or strategies they use to do so, and what barriers prevent a successful implementation of technological devices developed to reduce negative environmental impacts (e.g., Schot & Fischer 1993). Empirical evidence demonstrates that most pro environment policies pursued by firms and industries are forced upon them by governmental regulation (ecological push incentives, as opposed to ecological pull incentives). Even though there are some dedicated entrepreneurs deeply motivated by environmental considerations, the typical firm engages in voluntary environmental action only if there is (the expectation of) a positive financial payoff. Economically successful businesses have been observed to invest more in pro environmental behavior than less successful firms. Most studies on the causal order of this relation between firm performance and pro environmental activity indicate that good performance induces firms to engage in pro environmental action, and not vice versa (or at least to a lesser extent).

Corporate actors directly fighting for an improvement of environmental conditions (those such as Greenpeace, the WWF, or Robin Wood) have grown out of the so called environmental movement that began at the end of

the 1960s in many countries. These environmental organizations have traditionally varied in the radicality of their strategies (and continue to do so), follow somewhat differing ideologies, and concentrate on different kinds of ecological problems. Sociologists have established a separate line of inquiry called social movement research, which is also dedicated to the environmental movement and to environmental NGOs. This research now has its own theoretical approaches (resource mobilization, political process, and framing theories), and it has a core set of substantive research questions (e.g., Rucht 1991; Giugni 1998). These include the social profile of movement entrepreneurs, the individual decision to join a movement or the organizations involved (even though they are engaged in producing a public good, namely, better environmental quality), causes of cross national variation in the strength of environmentalism, the mobilization strategies adopted by different groups, and the temporal processes of the institutionalization of a social movement. As is the case with environmental concern in the general public, the environmental movement seems to be on the decline in many parts of the world.

One reason for the shrinking importance of the environmental movement in rich countries is that many claims and proposals originally articulated by environmental activists and organizations have found acceptance in the conventional political system and are now part of the programs and platforms of mainstream political parties, governmental agencies, community councils, and so forth. This means that corporate actors in the political arena have become the dominant players in the field of ecological problems. On the national level, governments have founded their own ministries for the environment, enacted numerous environmental laws, and initiated many other policies aimed at the protection of natural resources. Despite disagreement over strategies and measures of success, most governments today declare "sustainable development" to be the guiding principle behind their environmental policies. Of course, in many countries there is still a large gap between official environmental goals and the actual state of the environment. Ecological problems are also an object of regular negotiation among countries. Whereas these processes

have been relatively successful in the case of stopping the depletion of the ozone layer, progress is very slow in the case of the reduction of carbon dioxide emissions, preserving biodiversity, providing clean water in developing countries, stopping deforestation, averting soil degradation, and preventing the depletion of resources like ocean fish.

On a global scale, a large proportion of the world's population is excluded from living in an intact and healthy environment, and in some rapidly growing economies such as China the state of the environment will deteriorate in coming years. Within a given country, the poorer population is usually the group exposed to higher environmental and health risks such as noise, pollution, and toxic substances. Since the 1980s the "environmental justice movement" has addressed the social problem of an unequal distribution of the environmental impact among members of different social classes or income categories. A large amount of empirical research, particularly in the health sciences and to a lesser degree in sociology, demonstrates the existence of a "social gradient," i.e., a negative correlation between socioeconomic status and various environmental risks (Evans & Kantrowitz 2002; O'Neill et al. 2003). There is also evidence that environmental risks have a larger detrimental impact on health among the poor than among wealthier people.

According to the well known Brundtland Report (Brundtland 1987) which elaborated and disseminated the idea of sustainable development on the international stage, such a development can and should guarantee that future generations will have a chance to fulfill their basic human needs in a sound and healthy environment. Two decades after the release of this report, it is safe to say more remains to be done in order to narrow the gap between sustainability goals and the actual condition of the environment.

ecological view of history

Harumi Befu

An ecological view of history has to do with how history is accounted for in relation to the ecological conditions in which civilization is situated. The Japanese have developed a unique approach to the understanding of this issue. The idea that ecology has an impact on culture and history and the philosophical underpinning of the particular Japanese approach have their history in the pre World War II era. A short review of the genealogy of this concept is called for.

The distinctly Japanese ecological approach is closely associated with the Kyoto School of thought. This school encompasses philosophy, history, civilization, evolution, and other fields. The best known scholar of this school is arguably Kitarô Nishida (1870–1945), a philosopher who amalgamated western philosophy, notably that of Henri Bergson and the neo Kantians, with Zen philosophy and developed his own unique philosophy, the representative work being *Inquiry into the Good* (1990). One important element of his philosophy is his concept of self, which sees the self and its environs – other beings, nature, and the universe – as an integrated whole, rejecting the dichotomy between self and its environs – an approach accepted in western philosophy.

This conception of oneness of self and the universe was inherited by Tetsurô Watsuji (1889–1960), a major figure in ecological history. Watsuji is probably the first in modern Japan to systematize the interrelationship between environment and culture. His work was first published in *Fudo* (1935) and later translated into English (1961, 1988). Having studied in Germany, Watsuji was heavily influenced by German philosophy, in particular that of Herder and Hegel. It is important, in terms of the sociology of knowledge, that he was moved to construct his theory in direct response to the western theory of the relationship between nature and humans. Watsuji reviews the genealogy of scholarship on the human–nature relationship in western intellectual history from Hippocrates on. He homes in on Herder's conceptualization of the human–nature relationship in terms of *Geist* (spirit). Watsuji sees Hegel as the inheritor of Herder's theory, which places western civilization as the latest and crowning achievement in human history. Watsuji, however, unsurprisingly takes exception to Hegel's claim of Europeans as "the chosen people." Thus Watsuji's ecological theory was developed in reaction to the western supremacist bias he saw in Herder and Hegel.

Watsuji also rejects the basic stance of western philosophy where humans and nature are distinguished and pitted against each other. Watsuji additionally rejects scientific causality and determinism, where environment determines human action, culture, and civilization. In this conception of *fudo*, environment and humans are not separate entities defined by a causal relationship between them, as Berque (1996) explicates. Watsuji instead develops the idea of oneness of humans and nature (Befu 1997). This fusion is expressed in the very term *fudo*, the title of his major work. To Watsuji, *fudo* refers to humans and their environment as one, not to be analytically separated into various conventional components such as the individual, social groups, natural environment, and so on. Berque (1990) has coined the term "*médiance*" to refer to Watsuji's concept of *fudo*.

Watsuji develops a tripartite ecological classification of (1) monsoon type, (2) desert type, and (3) pasture (German *Wiese*) type. The first "monsoon" type is represented in Asia, East and South. Its salient meteorological characteristic

is humidity, which according to him is expressed in just about every aspect of human life. The Middle East represents the second type, climatically characterized by aridity as the major metaphor for its civilization and as a way of life. The third "pasture" type is represented by Europe, which combines the humidity of the monsoon type and the aridity of the desert type. In this classification, Africa is curiously missing, except for North Africa, which might be classified in the desert type. Likewise missing in his classification is the western hemisphere.

Watsuji's main focus is on the first type, especially as it affects Japan. Japan's uniqueness within the monsoon region arises from the fact that although impacted by the monsoon in the summer, it is also subjected to a severe winter climate originating in Siberia, traversing the Japan Sea, and ultimately enveloping the whole island chain of Japan. It is manifested, according to Watsuji, most directly in human character and the pattern of subsistence economy in Japan, which is based on rice cultivation. This in turn affects village organization and the family system as well as the aesthetics of a people. Ultimately, as he develops his ideas in subsequent publications, this ecological argument is expanded to the levels of the national polity (*kokutai*) of Japan and to its imperial system.

His argument persuaded generations of Japanese scholars all through the war period and into the post war era, setting the stage for legions of younger scholars to select themes from his theory and develop their own. For example, rural sociologists like A. Tamaki (1978) and H. Tsukuba (1969) cite Watsuji in discussing village structure and peasant personality. Even business management specialists such as K. Odaka (1981), an erstwhile dean of industrial sociology (now glossed as "management science"), and M. Tsuda (1977) explained the reputed Japanese management style by deriving it ultimately from the rice growing rural community structure. Nippon Steel Corporation, in its handbook for employees destined for foreign posts, also derives the Japanese management style from the rice growing rural community structure.

Another giant in the intellectual genealogy of the Kyoto School is biologist Kinji Imanishi, who developed his own unique, explicitly anti-Darwinian theory of biological evolution. A key

concept in his theory is *specia*, in which a species and the social organization it constitutes are treated as a unitary, indivisible unit of evolution (Imanishi 2002). Here again one sees a rejection of opposition and dichotomy between an object and its environment in diachronic development.

The last in this genealogy of intellectual giants in the ecological view of history is Tadao Umesao, one of Imanishi's direct intellectual descendants and the acknowledged doyen of the anthropological profession in Japan. His views were made well known initially through his 1957 work, which has been revised and updated several times. The latest version has been translated into English, with a new chapter added (Umesao 2003). Umesao shares his intellectual stance with his predecessors in the Kyoto School. He too starts by rejecting western thinking. His treatise on ecological history was in fact triggered by Arnold Toynbee's theory of civilization, and is an explicit rejection of it.

Umesao does not acknowledge his debt to Watsuji. But Umesao's ecological theory does show some critical similarities to Watsuji's. For instance, Umesao, like Watsuji, divides the Eurasian continent into three sections. He acknowledges the arid middle zone, which he calls *Chuyo*, or "mediant." Moreover, Umesao also more or less ignores Sub Saharan Africa and the western hemisphere. But similarities end here. Rather than seeing the eastern and the western portions of the Eurasian continent as being different, as Watsuji does, Umesao collapses the two regions into one type.

Also, rather than working out just three arche types, as Watsuji does, Umesao fine tunes the variable civilizational characteristics of regions bordering the central "mediant" and the two zones lying east and west of it through contingent historical interactions between them. He sees the middle region, the mediant, as one in which historical ravages of one war after another, one conquest after another, in its hostile arid environment, have created a situation inimical to civilizational development. In the zones at the eastern and western extremes of the Eurasian continent, on the other hand, the relative geographical protection made for an environment in which civilization could modernize. In both regions, civilizations developed in a similar fashion, both going through the feudal age and industrialization with relative ease.

When Umesao's theory first appeared in 1957, it immediately received wide acclaim in the intellectual community. Since its publication, this work has impacted generations of Japanese and has now become a classic. It was selected as the fourth most important book, pre or post war, fiction or non fiction, for its intellectual influence on modern Japanese history by a jury of 58 leading Japanese intellectuals in all fields, including politics, the arts, literature, and business.

As early as 1957, like his intellectual predecessors, Umesao rejected the hegemonic status claimed by the West vis à vis Japan, a position which is increasingly acknowledged by Asian as well as western scholars in the past few decades. One thing that characterizes all these efforts at understanding the nature of human ecology is that Japanese theorists are all reacting against the West's hegemonic claim of knowledge and proposing alternative views. In these alternative views, humans are conceptualized as an integral, and even indivisible, part of the universe and nature, rather than being pitted against them. In opposition to western metaphysics, Japanese intellectuals are staking out a claim that historical and evolutionary changes take place through integrated transformation of the whole, rather than by one segment causing change in another.

ecology

Marc M. Sanford

Ecology generally refers to the scientific study of an organism or community of organisms and their relationship to each other as well as to the environment. The ecological framework is used in biological sciences, social sciences, botany, zoological sciences, and other research areas and is applied to myriad subareas including human ecology, cultural ecology, organizational ecology, plant ecology, population ecology, spatial ecology, and more. Early writings on ecology were influenced by the works of Malthus and Darwin. This can be seen in ecology's use of natural selection and the presence of other competing species in the race for survival.

The concept was developed by famous phytogeographers such as Humboldt and Grisebach in the first half of the nineteenth century. However, many acknowledge that the term's modern meaning became fixed in a publication by Hæckel in 1865, in which he coined the term "oekologie" and defined it as the relation of an animal to its organic and inorganic environment. Despite the widespread credit given to Hæckel for coining the term,

there are sufficient claims that the term ecology was in use at the same time by at least seven other biological researchers. One researcher on the topic credits the very first use of the term to Henry David Thoreau in 1858.

Many early studies in botany and biology employed the term "plant geography" and ecology. Early writings on plant ecology looked at vegetation in different climates and discussed how each type was determined by climatic and edaphic factors. Botanists, biologists, and zoologists in the late nineteenth century were interested in the interdependent nature of life, or the "web of life" that intertwines all living creatures. They were interested in recording the mutual adaptations of one species as it depended on another for its survival. Later research on the subject matter of animal ecology, at least through the mid twentieth century, focused on the individual organism, the population of organisms, and the community.

Social scientists borrowed the ecological framework directly from the biological and plant sciences. Ecology's quantitative approach influenced both the conceptual approach to the human community and the methodological one. The term "human ecology" was used in the social sciences by Charles C. Adams in 1913. However, ecology as a social scientific approach received systematic formulation around 1915 from Robert Park. The classical human ecologists writing in the 1920s and 1930s applied to the interrelations of human beings a type of analysis previously applied to the interrelations of plants and animals. The human ecologists claimed that although the conditions that affect and control the movement and numbers of populations are more complex in human societies than in plant and animal communities, they exhibited extraordinary similarities.

Robert Park (1936), Ernest Burgess (1925), and Roderick McKenzie (1929) applied biotic principles of competition, differentiation, and invasion/succession to ethnic groups, class groups, and other subcultures in the city of Chicago. Competition operates in the form of communities vying for land and housing. The highest land values are found in the central shopping district and central banking area. From these points land values decline and determine the locations of other social institutions and businesses. As the city expands, the

pressures of businesses and social institutions steadily increase at the center. This pressure is then diffused to every other part of the city and acts to sort businesses and population groups. Differentiation occurs through population groups settling in areas that do not match official administrative boundaries. These areas became known as "natural areas." Throughout the ecological process, generally, we expect increased functional differentiation or specialization of populations and communities. Invasion and succession occurs when population groups move into areas where they were not present beforehand.

Custom, tradition, and culture also occupy a central role in human ecology. Robert Park hypothesized that the individual is both incorporated and subordinated to the local community and local social order. This community and social order is comprised of ecological, economic, political, and moral components. The move away from the biotic was further emphasized by Roderick McKenzie. McKenzie claimed that "human ecology is the study of the spatial and temporal relations of human beings as affected by the selective, distributive, and accommodative forces of the environment." Although McKenzie continued to speak of invasion and succession, he tied the ecological approach to specific divisions of space and developed a typology of city functions: the primary service community, the commercial community, the industrial town, and the community which lacks a specific economic base. The human ecology perspective focuses on the form and functions of populations, communities, and cities and carried a great amount of weight until the early 1960s.

Another application of ecology in the social sciences is organizational ecology. Organizational ecology emerged from economic and general systems theory and places a distinct emphasis on selection mechanisms. Organizational ecology generally focuses on the environmental and organizational determinants of the formation of the firm, including organizational life cycle transitions and the competitive and demographic structures of industry. Organizational ecology considers the implications of changes in the firm's environment that are a result of organizational actions. Organization theory often focuses on firm level

demographic processes, including entry, exit, and reorganization.

Within organizational ecology organizational structures are affected by the social conditions at the time of their creation. An organization's structure and organizational goals are historically shaped. Both a firm's organization and historical conditions influence its organizing activities in various social environments and entrepreneurship. Organizational ecology also speaks to whether firms should specialize or generalize depending on the uncertainty of the business and economic environment. In uncertain environments, organizations should become more generalist in their orientation in order to survive.

Criticisms of the ecological approach within the social sciences include whether change can originate from within the socio ecological system and whether communities and environments can be analyzed as truly being closed systems. Furthermore, recent use of the ecological framework in the social sciences is scarcely influenced by the original biological analogy. Despite the wide variation in the use of the term "ecology," the term for sociologists often becomes a synonym for "spatial" and loses much of the systematic interplay between environment and community.

ecology and economy

David John Frank

For sociologists, the consideration of ecology – and thus ecology’s role in the economy – is relatively new to the agenda. In a semantic sense, this is necessarily the case. The word “ecology” and its apparatus of meaning only recently entered the vocabulary. But sociology’s ecological turn is much more than the result of semantic invention. It embodies a profound shift in the institutionalized model of nature itself (Frank 1997).

From roughly the mid nineteenth through the mid twentieth centuries, what we now call “ecology” barely existed in the social imagination. Nature appeared in the public realm mostly in the narrowly rationalized form of resources – particular material goods, with status external and subordinate to human society. For instance, in the guise of natural resources, trees materialized as timber and cows took form as livestock. The ecology–economy relationship was uncomplicated accordingly. The ecological system served both as store of natural inputs – raw materials to economic production – and sink for outputted wastes (Berger 1994). In utilizing this system, humans exercised their rightful dominion over earth.

Especially in the West, this resource model of nature grew deeply institutionalized – i.e., taken for granted in culture and organization. Most importantly, perhaps, the resource model helped fuel the twin expansions of industrialism and capitalism, both of which required the exploitation of natural goods on historically unprecedented scales. Even at the world level during this period, natural resource views gained precedence over the alternatives, expressed for instance in the 1911 International Fur Seal Convention, which set conservation measures aimed at maintaining the commercial exploitation of North Pacific fur seals.

By and large in this era, sociologists took the terms of discourse at face value. This means that to the limited extent they noticed at all, sociologists interpreted ecology’s role in the economy in straightforward resource terms (Buttel 2002). Certainly, sociologists recognized that societies differed in relative shares of nature’s bounty and varied by advances in the means of utilization. But seldom did sociologists challenge the central imagery itself, in which ecology referred to natural resources, meaning basic economic provisions.

During the latter twentieth century, much of this changed. To a striking and extraordinary extent, scientists extended and intensified nature’s rationalization well beyond the resource frame. What had formerly been defined in terms of inputs and outputs acquired a host of new meanings, which rendered nature as ultimately valuable and functional to human society. Scientists reconceived nature as an interconnected ecological “environment” – a planetary life support system. In this resource to ecology shift, for example, trees transcended the meaning of timber and came to appear as oxygen producers, greenhouse gas sinks, species habitats (endangered and otherwise), and themselves essential nodes in the web of life.

Of course this broad redefinition of nature hardly meant that resource imageries disappeared. On the contrary, scientists participated in the invention of technologies that opened vast new natural territories to utilization. Still with the rapid profusion of the environment’s life sustaining properties, the warehouse imagery of nature quickly lost dominant standing.

Within the new paradigm, the old one way road from ecology to economy got widened,

bringing new focus to the reverse economy to ecology relationship. Most strikingly, there appeared widespread public concern over the ways economic systems damaged ecological systems, thereby threatening not only material goods but also earth's life bearing capacities (Berger 1994).

The emergent ecological model of nature gained institutionalization most rapidly in the West, where scientific authority stood tallest. There it catalyzed, for example, changes in the longstanding conservation movement, participants in which began to pose economic activity as the antagonist of environmental vitality. And even at the world level, the new imageries acquired legitimacy, as exemplified by the 1972 founding of the United Nations Environment Program, around the mission "to provide leadership and encourage partnership in caring for the environment."

As they had previously, sociologists operated within the set parameters of discourse. Most importantly, sociologists offered analyses of the logics and mechanisms whereby different economic configurations caused more or less ecological damage (e.g., Schnaiberg & Gould 1994). Capitalism in particular came under scrutiny. Researchers showed, for instance, ways the profit motive and private ownership combined to exacerbate ecological ills. For the private owner, maximized profit meant maximized exploitation, extracting nature's commodity values without regard to environmental consequences, as exemplified by the clear cut forest. Likewise for the private owner, maximized profit implied minimized amelioration, privileging the least costly means of exploitation, even when those means wreaked the greatest ecosystem havoc, as illustrated by the strip mine. Furthermore for the private owner, maximized profit rewarded the disposal of "wastes" into the commons, polluting those aspects of nature (notably air and water) shared by the public at large, as in the case of smokestack industries. In virtually all such sociological analyses, the revised ecological definition of nature took priority over the old resource one.

Of course changing conceptions of "nature" continue apace, spurring ongoing reconsideration of the ecology-economy linkages. Along with society at large, sociologists now

increasingly notice that economic activity need not be antithetical to ecological well being. Indeed, some sociologists have recently called attention to the environmental benefits of economic activity, which may cause birth rates to decline and environmental values to rise (Inglehart 1990). As the new ideas take hold, such concepts as sustainable development – promising the union of robust economies with healthy ecologies – seem less like pipe dreams than previously. A new ecology-economy partnership may be forging in the public eye.

In some quarters, of course, nature continues to be seen through the resource lens – in simple input-output terms. In other quarters, meanwhile, any economic rise still indicates certain ecological fall. Both views increasingly, however, seem simplistic and divisive (as seen, for example, in conflicts between wealthy northern and poor southern countries at recent environmental conferences [Shiva 2000]). In the contemporary world, the aspiration to economic betterment seems unwavering and universal. And in the same world, environmental protection is becoming ever more rule like. The satisfaction of both ends will require ingenuity and compromise. In this middle ground, the sociological study of ecology and economy may be most promising.

economic determinism

J. I. (Hans) Bakker

The concept of economic determinism refers to monocausal determinism by material, economic factors. The idea is often associated with Karl Marx's "historical materialism," but it is not clear that Marx himself was a strict economic determinist, or even a materialist (Gouldner 1980; Simmel 1990 [1900]; Landry 2000). The Romantic strain in the work of the early Marx did not disappear entirely, which is evident in terms of his view of species being and the teleology of communism. Some commentators differentiate between economic determinism and dialectical materialism, where dialectical materialism allows for more flexibility and may even include a feedback mechanism. Rigid versions of economic determinism are often associated with Marxist Leninism and Stalinism. In Marxist parlance, the forces of production determine the relations of production in any mode of production. Sometimes that statement is modified to include the disclaimer that such economic determinism is only true in the final analysis. But precisely what "in the final analysis" means is rarely specified exactly. Closely related is the concept of economic reductionism (Robertson & White 2005: 355–7), where emphasis is placed on the idea that the economy is closely intertwined with all forms of the culture of consumerism. Thus, for example, advertising images can be viewed as ideological constructs that are the product of economic forces working on decision makers in corporations. Concern with capitalist globalization has

been premised in part on the theory that economic globalization is determinative of all aspects of civil society, not just consumption. Studies of the origins of the "capitalist world system" have moved the classical Marxist argument about economic determinism from relations of production within nation states to a global arena that involves the interaction among societies. Wallerstein (1974, 1980, 1989) "emphasized the causal significance of economic material factors, relegating other aspects of epiphenomenal status" (Robertson & White 2005: 357). There are also counterarguments which stress "civilizational" or "cultural" factors as determinative (e.g., Huntington 1996). Weber's 1904–6 thesis (2002: 125) concerning the Protestant ethic is often misinterpreted as a one sided idealist argument, but he explicitly points out that it is not his intention to replace a one sided economic determinism with an equally misleading, one sided idealist (ideological cultural) determinism. There are few sociological writers who take a strictly economic determinist view, but there is a strong movement to go beyond the labor theory of value and classical and neoclassical economics models and to recognize the importance of multivariant and reciprocal social factors within economic institutions.

economic development

Thomas D. Beamish and Nicole Woolsey Biggart

Economic development studies are concerned with how societies have, could, and should pursue improvement in the quality and quantity of life for their inhabitants. Since the decades following World War II when development studies began and were implemented as policies, there has been neither consensus on how to pursue the goal of economic and social improvement nor unqualified improvement in the quality of life for most of the world's population. Nonetheless, the politically and socially important pursuit of economic development continues and involves academics, nation states, regional and international organizations, non governmental organizations, and philanthropic foundations.

Development scholarship arose out of the major social, political, and economic changes that accompanied the end of World War II and the restructuring of the global geopolitical map. As a consequence of the war, there was both a felt need to reconstruct the destroyed economies of Europe and Japan, and to supply financial assistance to the newly freed colonial possessions of losing states. Early efforts focused on the construction of critical industrial goods and state owned infrastructures, and the overall modernization of political and economic institutions. Rebuilding activities were based on assumptions of social and economic "convergence": a belief that all societies progress in a stepwise fashion from traditional social orders toward increasingly modern social and economic systems as manifest by western industrial states.

The most stubborn development problem to defy eradication is the unequal relationship that

remains between developed and underdeveloped regions. Events such as the fall of the Soviet Union and the dissolution of the tripartite breakdown of global nation states – first world, communist world, and third world or neutral countries – brought a new set of social and geopolitical issues that theories of the post World War II modernist tradition, as well as those critical of modernist assumptions, could not adequately address. Continuing economic hardship in Asia, Latin America, and Russia called into question the economic strategies of global development organizations such as the World Bank and the International Monetary Fund. Standardized protocols for development did not stimulate the expected convergence of the underdeveloped and developed economies and rarely sustained development in undeveloped regions.

Proposed economic treatments for laggard economies tended to reflect a common belief that all economies are fundamentally the same and operate on a universal set of economic principles that when violated lead to suboptimal outcomes. Economic policies were premised on the assumption of a neoclassical market ideal where firms are dispersed and contracts assured by a regulatory state. Deviations from this ideal are assumed to need restructuring to better approximate the ideal market model, the basis for Anglo American economies.

Critics argue that economic differences are not necessarily imperfections of an ideal market economy. Rather than assume that all economies are the same and destined to converge as they modernize, critical development scholars cite important differences on which economic competitiveness can be built. These differences – the result of history, social traditions, and institutionalized political structures – allow nations to organize themselves politically, culturally, and economically in ways that are culturally meaningful and that enable them to successfully leverage their capabilities and social predispositions in the economy. For example, research has shown that French, German, Japanese, British, and American firms (among others) excel at different things in the global economy because of their different social structures and endowments.

During the early period, economic development theories were largely based on the belief

that all societies developed through a set of stages that ultimately would lead to a modern nation state and industrial economy. This evolutionist approach urged political and social reforms that would develop “primitive” or “backward” societies into modern economic systems like those in the West. This approach is rooted in western cultural beliefs about progress. It encouraged individualism and western style institutional structures, such as constitutional democracies, even in places based on radically different social arrangements such as lineage structures and group based economic institutions. New institutions and practices were taught by development specialists who worked with governments and educational ministries in developing countries, and were reinforced by economic incentives that tied loans and funding packages to reforms.

By the mid 1960s ideas about evolutionary progress and convergence toward a single model had been formalized in scholarly research and development policy such as modernization theory. Modernization theory (Rostow 1969) reflected three geopolitical trends that characterized this period: (1) the rise of the US as a superpower and with it Anglo American style capitalism; (2) the simultaneous rise of the Soviet Union and its influence over Eastern Europe, China, and North Korea; and (3) the disintegration of the European colonial empires in Asia, Africa, and Latin America. The threat of communist expansion produced generous funding and attention to development research. Social science theorizing that supported western industrial practice and the expansion of capitalist social and economic forms played a key role in producing a body of thought to counter the influence of socialist development schemes.

By the 1970s, another state centric view of development emerged to counter the modernist view. An outcome of the turbulent experiences of Central and South America, Asia, and Africa as states there attempted to mimic first world economies and states, scholars such as Frank (1969) noted that developing countries, far from improving their economic circumstances, continued to be both dependent on and increasingly impoverished because of their relationship with western industrial states. Called dependency theory, these theorists pointed out

that the underdeveloped world reflected colonial pasts that had not been substantially changed despite decades of development attempts to alter institutions and practices through economic loans and subsidies. According to dependency theorists, direct political domination under pre World War II colonialism had merely been exchanged for post World War II economic dependence on former colonizers. Third world states were dependent on first world states for economic opportunities, financing and development loans, new technology and training, and access to first world markets, all of which retarded the third world from developing.

By the early 1980s, however, it became increasingly evident that state centric ideas, whether of the modernization or dependency schools, could not entirely capture the whole of development outcomes for the rich and especially the poorer parts of the world. Attention by Wallerstein (1980) and others to global exchange structures painted a picture of a capitalist world economic system where economic outcomes are not determined by the actions of any one state. All states are part of a networked capitalist system and the prospects of any one state are influenced by its place in that system and its relation to other states.

During the 1980s and continuing into the 1990s, a resurgence in economic theorizing had an especially strong influence over global development institutions, especially lending institutions and donor countries. The World Bank and International Monetary Fund promoted neoclassical economic precepts, including laissez faire trade policies such as low tariffs, few import controls, no export subsidies, and free labor markets through loan conditions and repayment terms. Taken together as a neoliberal policy agenda, these practices are known as the Washington Consensus and include the willingness of a developing nation to conform to fiscal discipline, lower taxes, a competitive exchange rate, liberalized foreign direct investment policies, privatization, property rights, and deregulation. These conditions have been a prerequisite for developing nations receiving funds from global development bodies.

Critics of the Washington Consensus point out that these policies and programs create an

environment favorable to transnational firms wanting to do business in developing countries, and do not place the social and economic needs of those countries first.

In the late 1970s and 1980s, with the rise and economic success of the “East Asian Tigers” – Japan, Taiwan, Hong Kong, and Singapore – state centric scholarship resurged as the “developmental state” approach, a belief that development outcomes could be explained in part on the role of states as active participants in the economy. According to this theory, the success of these East Asian states reflected key interventions by quasi authoritarian states. The economic principle that state intervention retards capitalist development was not validated by the empirical record of the industrializing East. The developmental states argument stands in marked contrast to the *laissez faire*, “hands off” state model advocated by traditional economics, but it also complicates ideas of earlier dependency, modernization, and world systems theories that do not consider individual state actions as central to development outcomes.

Finally, resurgence in the 1990s of institutional analysis also affected development studies. For example, Biggart and Guillén (1999) identify three important premises that neo institutionalism brings to development: (1) that institutional arenas, such as developing societies, are internally coherent and based on organizing logics that inform action and meaning; (2) that economic and managerial practices and actions not consistent with the institutional logics of a society, even if they are in the abstract “technically superior” or more “efficient,” will not be readily recognized or incorporated; (3) that organizing logics are not merely constraints on development as traditionally conceived, but provide the basis for successful economic activity because they represent social and culturally based repositories of distinctive capabilities and competencies. This scholarship points out that in pursuing uniform policies and single minded development strategies that ignore the unique experience of each society, developing countries lose the possibility of building on the existing strengths of any “institutional endowments” they may have developed over time. Ignoring the import of the social, historical, and cultural

basis of a society, according to institutionalists, is tantamount to ignoring what specialized capabilities and talents that society brings to development, and the legacy on which any customized development plan might be premised.

Economic growth typically has been measured in terms of an increase in the size of a nation’s material output. Gross domestic product, which supplanted the use of gross national product in the 1990s, is the most frequently used index of both the size and health of a domestic economy. Calculating a nation’s GDP involves adding domestic consumption rates with investment, government purchases, and net exports. Increasingly, consumption has become the largest component in this measure.

While GDP details gains of economic significance, according to development scholars critical of this metric, it masks declines in the quality of life experienced by a good portion of the world’s population, instead mostly capturing gains for elite countries and specifically the elites within those countries. Critics have devised a number of more inclusive measures of “well being,” such as Osberg and Sharpe’s (2002) Index of Economic Well Being (IEWB), Redefining Progress’s Genuine Progress Indicator (GPI) (Cobb et al. 1995), and the United Nations Development Program’s Human Development Index (HDI) (UNDP 2001), among a growing list of such efforts (Hagerty et al. 2001). In addition to the traditional economic indicators of growth, “Quality of Life Indexes” typically try to move toward a fuller representation of both economic and non economic well being and include measures of “social health” such as education rates, income distribution, and national health. In some instances, indexes go so far as to include crime rates, measures of social benefits and safety nets, and rates of pollution, resource depletion, and long term environmental damage. Advocates contend that these metrics better assess the overall health of a nation, not just the state of its material economy.

These measures also provide a very different picture of development trends than does GDP. Using social, economic, and environmental indicators, GPI shows there has been an overall decline in quality of life in the US since World War II and Osberg and Sharpe (2002), using the IEWB (a more conservative model), found

that gains were also much flatter than those represented by US GDP. Ultimately, such quality of life measures have sensitized development scholars to the reality that social and environmental deterioration can accompany robust economic growth. This has been almost entirely missed by traditional development policies and policymakers, which have been dominated by assumptions of social and economic convergence, and traditional economic measures of growth as proxies for social health and environmental well being.

In the early twenty first century development studies have been concerned with forces opposed to western ideas of progress and economic success. Ethnic awareness and the resilience of cultural identity in many parts of the world have created strong local opposition to policies that favor western institutions, programs, and culture, and to regimes that favor western alliances. At the extreme, religious fundamentalism has spurred the development of anti western terrorist organizations. At the minimum, there is skepticism that economic riches are available to all countries, or that one standard of quality of life need be universally applied. Environmental movements are increasingly powerful actors in development debates, arguing that unbridled consumption, of the sort at the foundation of modern industrial economies, is economically and socially unsustainable.

economic geography

Jurgen Essletzbichler

According to Lee (2000), economic geography is “the geography (or, rather, geographies) of people’s struggle to make a living.” Economic geography is concerned with spatial variation in the organization of production, distribution, and consumption of commodities and the influence of externalities, place specific institutions (on various spatial scales), and cultural practices on economic activity. As in other disciplines, the research foci of economic geography shifted as a result of exogenous changes and as a consequence of internal discourse, cooperation, and rivalries among members of the discipline. And although the discipline has never been homogenous and progressing towards some “preordained epistemological mission” (Scott 2000), it is possible to trace out a set of paradigm shifts that have occurred in the discipline over time (Livingstone 1992; Barnes 1996, 2001; Martin 1999; Scott 2000).

Geography’s origin as an academic discipline was tied to the needs of colonialism in the nineteenth century, the exploration and exploitation of new territory and, in the case of economic geography, the mapping of resources and transportation routes. The first disciplinary crisis resulted from the apparent end of colonial and polar exploration and the closure of continental frontiers that seemed to leave geography with out a purpose. Two world wars provided ample

work for geographers, however. Until the end of World War II, economic geography adopted idiographic methods of investigation and was concerned with regional description and synthesis. Theoretical and methodological changes that occurred in other disciplines – such as a move towards logical positivism in the social sciences and a shift to general equilibrium modeling in economics and to rational choice theory in sociology – had, at first, little or no impact on the direction of the discipline.

At the end of World War II the discipline was once more confronted with a serious identity crisis. Although a number of the disciplinary rank and file defended the idiographic approach, theoretical and methodological changes outside geography, practical problems posed by the needs of a fast expanding economy, and the rise of young, ambitious faculty eager to apply their quantitative skills to address those problems triggered the “quantitative revolution” and ushered in a new phase in economic geography, best described as spatial analysis and/or regional science paradigm (Johnston & Sidaway 2004). This new generation of quantitative economic geographers was strongly influenced by the old German location theorists and regional scientists who aimed to incorporate distance as a major variable in neoclassical economics and demanded that “geography as a whole must become an analytical, law finding discipline conjoined with quantitative methodologies” (Scott 2000). While regional science reached its peak in the late 1960s in the US and diffused to the UK in the mid 1960s, it was unable to penetrate French or German geography. By the end of the 1960s, the external circumstances shifted again. The slowdown of the economy, rising rates of unemployment and inflation, and the gradual abandonment of the Keynesian welfare state combined with political and social upheaval to pose new problems and opportunities that required new theoretical and methodological approaches.

Regional science and the underlying equilibrium models had little to say about social and spatial inequality, the rise and persistence of poverty, job loss, deindustrialization, and regional decline. On the contrary, the methodological individualism underpinning its models and claims to objective truth delivered

by quantitative methods were considered increasingly as smoke screens to hide structural inequalities produced through capitalist accumulation. As a result, the applications of Marxist approaches to explain the evolution of the capitalist space economy started to dominate research in economic geography in the 1970s and early 1980s. While the immanent crisis of the 1970s necessitated the engagement with the destructive aspects of capitalism, in particular the causes and implications of the decline of old industrial regions, the early 1980s witnessed the emergence of new, formerly “backward” regional production systems in Italy, Southern Germany, and California that were inhabited by different kinds of industries, characterized by different labor processes and forms of industrial organization, and appeared to be strongly embedded in particular cultural and institutional practices.

Economic geography in the 1980s then turned to examine and explain the economic, organizational, cultural, social, and political characteristics of these new industrial spaces. Different research groups emphasizing Marshallian industrial districts, vertical disintegration and local linkages, flexible specialization, or innovation driven regional growth, emerged. This research was in part influenced by French Regulation Theory used to tie region specific changes to broader economic and sociopolitical shifts. It became obvious that national and regional variation of economies could not be explained through economic principles alone, but that differences in governance systems, conventions, culture, and institutions had to be introduced to account for existing variation. The success of this research area may be attributed to the importance attributed to “place” as explanation of economic success. Rather than treating place as a container where socioeconomic processes unfold, social interaction between agents embedded in a common, region specific institutional environment was said to result in emergent properties at the level of the region that would not emerge from interaction of actors in networks that span over long distances. The work on regional economies constituted probably the last identifiable core research area of economic geography.

While the region provided a focus for economic geography, it also meant a branching out

and fragmentation of the discipline. Recognizing the importance of “non economic factors” such as culture and institutions, meant a move away from economics (orthodox or Marxist) and alignment with other disciplines such as anthropology, cultural studies, management, sociology, or evolutionary and institutional economics. For Barnes (2001), this fragmentation also signified a more fundamental move from “epistemological” to “hermeneutic” theorizing, a move away from foundationalism to theorizing as social practice, a “cultural turn” in economic geography.

Economic geography has arrived, once again it seems, at a critical juncture to decide its future disciplinary trajectories. However, contrary to earlier periods where the lack of a core research area triggered an identity crisis, the present absence of a well identified core has resulted in a flourishing of theoretically and methodologically diverse approaches addressing a variety of research questions that would not have been classified as economic geographic only 15 years ago. Instead of a single core, a number of theoretical avenues pursued by economic geographers can be identified.

Regional science has been resurrected and rebuilt on “solid” microfoundations in the form of the “new geographical economics,” modeling equilibrium landscapes and urban hierarchies (Martin 1999). The main addition is the incorporation of increasing returns at the regional level allowing for multiple equilibria and unequal development.

Political economic approaches continue to emphasize the operation of structural forces that enable and constrain economic actors, but have become more sensitive to space/time contingencies that influence the crystallization of these processes in unpredictable ways. The bodies of research produced in this mold include work on the scalar reconfiguration of governance systems, the relationship between nature and society, work on neoliberalism and the new imperialism, the dynamics of regional growth and decline, labor geographies, political ecology, and gender studies.

The work on regional worlds has evolved into a series of research areas, including work on global city regions as motors of the globalization process; the analysis of culture, conventions, and untraded interdependencies to promote or

obstruct regional development; and research on clusters, regional innovation systems, and learning regions. This work borrows heavily from economic sociology (in particular, Mark Granovetter) and reaches back to Polanyi’s work on tacit knowledge.

A relatively new research area in economic geography borrows from evolutionary and institutional economics to understand the relationship between variety of individual behavior, firms, sectors, and institutions in a region on the one hand and the aggregate pace and direction of regional growth on the other; path dependent regional development; and the emergence and evolution of industry regions. The inclusion of cultural practices is not restricted to analysis of the commodity producing sectors, but penetrates work on consumption and retailing, the financial sector, and cultural products.

Economic geography is not confined to market transactions, but is increasingly interested in alternative forms of exchange, household economies and, more generally, the reproductive sphere.

Work on the body bridges the productive and reproductive sphere and is linked to a variety of issues ranging from consumption to prostitution and performance.

Diversity in research topics also fuels a variety of theoretical approaches ranging from positivism on the one end to non representational theory on the other. While inspiration is still drawn from Descartes, Popper, and Marx, much of the recent work in economic geography is influenced by Foucault, Derrida, Deleuze, and Latour. Not surprisingly, this diversity in theoretical frameworks is also reflected in the methodological approaches employed by economic geographers who conduct secondary data analysis, interviews and focus groups, textual and visual analysis, and experiment with creative writing and visualization to capture complex and dynamic problems. The majority of practitioners interpret this development as a sign of a viable and active discipline that builds bridges with other disciplines where necessary and appropriate and understand it as the way forward in a world of increasing complexity, where disciplinary boundaries start to wither away. On the other hand, the dissolution of a core identity and the diversity of subjects covered might result in a widening gap among

members of the discipline, each group trapped in its theoretical, methodological, and linguistic worlds that they share with colleagues outside the discipline, but that prevent them from communicating with other economic geographers. Economic geography has become hard to define and the discipline is likely to maintain its diversity of research questions, theoretical frameworks, and methodologies in the near future. But if the history of economic geography has taught us anything, it is the inherent unpredictability of the future disciplinary trajectory entailed in a dynamic, fast changing environment.

economic sociology: classical political economic perspectives

Milan Zafirovski

Classical political economy broadly understood is the stage and branch of economics during the period from the late eighteenth century to the second half of the nineteenth century. In a narrower specification (by Schumpeter) it encompasses the "publications of the leading English authors from 1776 to 1848," specifically from Adam Smith's *Wealth of Nations* to J. S. Mill's *Principles of Political Economy*. In addition to Smith – usually considered the "father" of (classical) political economy – and Mill as its codifier, its other prominent representatives include David Ricardo, Thomas Malthus, Jean Baptiste Say, and William Senior, as well as Karl Marx (described as a "dissident") and John Cairnes (deemed the "last" classical economist). Following Smith's implied definition, its representatives typically define classical political economy as the study of the production, distribution, exchange, and consumption of wealth.

In general, classical political economy can be divided into two broad branches: pure economics or the theory of a market economy (catallactics), and social economics or economic sociology. For example, Smith's political economy is sometimes described as a blend of market theory (catallaxy) and economic sociology or sociological economics, as are its versions in Say, Mill, and Marx. Presumably, the theory of a market economy is primary and foundational within classical political economy and of

more interest to pure economists, and social economics secondary and supplementary, but more interesting for economic sociologists.

Classical political economy involves a number of versions and elements of social economics or economic sociology understood as an analysis of the societal setting of economic life, frequently intertwined with those of pure economics or market theory. The archetypical instance is what some economists identify as the "economic sociology of Adam Smith" (Schumpeter 1949), concentrating on the institutional social structure of the economy, or Smithian "sociological economics" (Reisman 1987) that, interlaced with his market theory, attributes comprehensiveness to his political economy and makes him a broad "sociological economist" (Reisman 1998). Moreover, others state that "precisely" on the account of this comprehensiveness, specifically his "concentration on structural institutional change, Smith deservedly won acclaim as the father of Political Economy" (Buchanan 1975: 171).

Another version of economic sociology or social economics within classical political economy is provided by Say, Smith's continental (French) follower. Say can probably be credited with inventing the concept of "social economy" (Swedberg 1998), as acknowledged and adopted by Mill later. Further, Say proposes social economy as a more appropriate conception and designation than political economy for economics on the grounds that this is a science involving observations on the "nature and functions of the different parts of the social body," specifically the "economies of societies." Notably, Say implies that social economy treats economic laws as special instances of the "general laws" or "general facts" of society (i.e., of sociological uniformities) as the domain of sociology (the "science of politics and morals").

Mill furnishes still another version of economic sociology within classical political economy. For instance, Schumpeter estimates that about a third of Mill's magnum opus *Principles of Political Economy* contains elements of economic sociology – a remarkably high proportion by the standards of contemporary economics – which are mixed with the two thirds of market theory. The influence of Comte's sociology on Mill is mostly responsible (along with that of

Say's social economy) for the presence of such elements. Moreover, reportedly Mill, "when he came to write his *Principles*, abandoned his ambition to work out a purely abstract theory and adopted a broader view of the scope and method of political economy under the [sociological] influence of Comte" (Bladen 1941: 18). In general, Mill proposes a "science of social economy" defined as a study of the "laws of society," "laws of human nature in the social state," "conduct or condition of man in society," or "natural history of society," thus as essentially equivalent to Comte's sociology. Further, Mill considers political economy, understood as the study of "acquiring and consuming wealth," an "important division" or "branch" of the science of social economy, apparently influenced by Comte's consideration of economics as part of sociology.

Economic sociology within classical political economy centers on, generally, the "social framework of the economic course of events" (Schumpeter 1949: 61), particularly the impact of society on the economy, and comprises a number of elements. For example, the "division of labor, the origin of private property, increasing control over nature, economic freedom, and legal security – these are the most important elements constituting the economic sociology of Adam Smith" (Schumpeter 1949: 60). A particularly important element of Smith's and other economic sociology in classical political economy is recognizing the impact of institutional arrangements, as an integral part of the social framework of economic life, on the latter. This impact includes institutional political influences on economic welfare, for example. Thus, Smith observes that there are many social institutions (and laws) tending to enhance the "public welfare," noting in particular that those of civil government may tend either to "promote or to disturb the happiness both of the individual and of the society." Similarly, so does Say, remarking that the state often provides a "powerful stimulus" to individuals' economic activities (e.g., through "well planned public works") and so their well being. The economic impact of social institutions also involves institutional influences on wealth distribution, as Senior suggests in observing that the latter is affected by the "peculiar institutions of

particular Countries,” such as slavery, legal monopolies, and poor laws. Developing and reinforcing this observation, Mill states that wealth distribution “is a matter of human institution only” in the sense of being dependent on the “laws and customs of society.” Notably, he adds that the institutional rules which determine wealth distribution “are what the opinions and feelings of the ruling portion of the community make them,” thus echoing Smith and even anticipating Marx. In particular, following Smith and Ricardo, Mill describes private property as the “primary and fundamental” institution which underpins the “economic arrangements of society.”

In addition, Smith and Mill suggest that the institutional or political regulation of prices and markets is a salient instance of the influence of social institutions on the economy. For instance, Smith notices that particular policy regulations can hold the market prices of many commodities for a long time a “good deal” above their “natural” value (i.e., labor cost). He finds another example in the prohibition of interest (as the “price” of money) in medieval Europe and “Mahometan nations” on extra economic, especially moral religious grounds. Mill especially emphasizes the effects of traditions on markets, prices, and wages, observing that in early society “all transactions and engagements” are under the “influence of fixed customs.”

Another prominent element of economic sociology in classical political economy is identifying and examining the role of social classes in and as part of the societal setting of the economy. This includes in particular what Schumpeter (1954) identifies as the “connection between the social rank of a class and its function” (and rewards) in the economy. Thus, Smith observes the existence of “different ranks and conditions of men in society,” specifying that “three great, original, and constituent orders of every civilized society” are landowners (“those who live by rent”), laborers (“those who live by wages”), and capitalists (“those who live by profit”). Notably, he admonishes that no capitalist society can be “flourishing and happy” if laborers – the “far greater part” of its members – are “poor and miserable.” In particular, he deplores the “rich and powerful” (“men of rank and fortune”) for merely selecting from the “heap what is most precious and

agreeable,” lamenting that their “sole end” is gratifying their “own vain and insatiable desires” from the labors of those they employ. Also, Smith says that “whenever the legislature attempts to regulate the difference between masters and their workmen, its counselors are always the masters,” thus anticipating Mill’s “ruling portion of the community” and even Marx’s ruling class.

Elaborating on Smith’s ideas, Ricardo (considered the most able classical economist) posits that wealth is distributed among “three classes of the community” (landowners, capitalists, and workers) in the form of rents, profits, and wages as respective class rewards. Further, Ricardo implies that social classes have a central economic role by arguing that discovering the laws governing wealth distribution is the “main problem” of political economy.

Building on but also going beyond Smith, Ricardo, and Mill, Marx’s ideas about the role of social classes in the economy, notably capitalism, are so numerous, manifold, and controversial, as well as (un)popular, that they require a separate treatment. At this point, suffice it to mention that Marx treats the totality of class (or property) relations as the “economic structure of society – the real foundation, on which legal and political superstructures arise and to which definite forms of social consciousness correspond.”

Still another important element of economic sociology in classical political economy pertains to the social conditions or requisites of production, consumption, and related activities. An instance is the effect of the (societal and technical) division of labor, another element of the social framework of the economy, on economic productivity, as analyzed and celebrated since Smith. Smith famously contends that the “greatest improvements” in productivity result from the elaborate division of labor and that in civilized society individuals are “at all times in the need of cooperation and assistance of great multitudes.” Another instance involves the impact of overall social conditions on economic laws, including those of production and distribution. This is what Cairnes suggests in viewing the laws of production and distribution of wealth as the effect of the “combined operation” of political social conditions (along with the “principles of human nature” and the

“physical laws of the external world”). So does he, alternatively, by acknowledging that the production and distribution of wealth have their causes in the social political (and physical) “laws and events” of the “external world” (alongside the “principles of human nature”). An additional instance of the above element of economic sociology is treating the process of production as a specific social condition or relation involving individuals and groups (classes). This is particularly characteristic for Marx, who treats material production as (also) a “social relationship” between its participants, specifically, workers and property owners. Thus, he states that producers establish “definite social and political relations,” which indicates the “connection” of social political structures with productive processes in the sense that a certain “mode of production” connects to a “certain mode of cooperation or social stage” (as a productive force). Notably, Marx treats economic capital as a “social relation of production” (i.e., a sum of “social magnitudes” like exchange values), more precisely a “bourgeois relation of production, a relation of production of bourgeois society.”

Still another case of the social conditions of production and consumption concerns the sociocultural origins, multiplicity, and development of economic (and other) preferences and wants, as Mill, Cairnes, and Marx suggest. Thus, Mill posits the social multiplicity of preferences in stating that many economic activities actually ensue from “a plurality of motives,” not only the “mere desire of wealth” (though he concedes that political economy usually makes “entire abstraction of every other human passion or motive”). So does Cairnes, who even goes further by suggesting not only this multiplicity of motives, but also the social formation and development of material wants and tastes. He does so by observing that the “desires, passions and propensities” influencing actors in their pursuit of wealth are “almost infinite” and, notably, “may be developed in the progress of society,” citing the role of customs in “modifying human conduct” in this pursuit. Marx suggests that preferences are subject to societal formation and historical evolution, stating that human tastes or wants (and pleasures) have their origins in society, which gives them a social (and so relative) character.

Lastly, some other explicit or implicit elements of economic sociology within classical political economy may include the long run interaction between population and the economy (Malthus), institutional and other non market restrictions on market competition, including free trade (Smith, Mill, Cairnes), the economic implications of “moral sentiments” like sympathy, justice, and benevolence (Smith pre 1776), and so on.

economic sociology: neoclassical economic perspective

Milan Zafirovski

Neoclassical economics is the stage and branch of economic science since the 1870s through the 1930s and beyond. It was mostly the product or sequel of what economists (Schumpeter

1954) call the Copernican marginalist revolution in economic theory during the 1870–90s. Specifically, the crux of marginalism was a marginal utility theory of exchange value and its extensions (e.g., marginal productivity principle of income distribution) in reaction and contrast to the labor cost conception in classical political economy. The founders or pioneers of marginalism are commonly considered to be William Jevons (England), Carl Menger (Austria), and Leon Walras (Switzerland/France), who almost simultaneously in 1871–4 “discovered” marginal utility value theory as a putative revolutionary alternative to its labor-based versions in Smith, Ricardo, Mill, Marx, and others. (For instance, Jevons specifically attacked Ricardo and Mill’s theories, prompting neoclassical economists like Alfred Marshall to rise in their partial defense.) The term neoclassical economics was invented by Thorstein Veblen (Groenewegen 1995), a heterodox institutional economist, in the early 1900s to indicate that marginalism (e.g., marginal utility theory) was, in virtue of utilitarianism and hedonism, essentially continuous with and so “scarcely distinguishable” from classical political economy (which apparently overlooks the opposition of the marginalist revolution to Ricardo et al.’s labor theories of value). In this sense, the terms marginalism and neoclassical economics become interchangeable, though the first term is probably more accurate and precise for describing this stage and type of economic theory. Moreover, historians of economics such as Schumpeter (1954: 919) object that “there is no more sense in calling the Jevons Menger Walras theory neoclassic than there would be in calling the Einstein theory neo Newtonian.” This suggests that neoclassical economics is essentially marginalism (with partial exceptions like Marshall), but not conversely: the marginalist revolution is not newly, but counter classical (that is what makes it presumably “Copernican”).

In addition to Jevons, Menger, and Walras, some other prominent representatives of marginalist or neoclassical economics include Philip Wicksteed, Eugen Böhm Bawerk, Friedrich von Wieser, Knut Wicksell, Francis Edgeworth, Vilfredo Pareto, Marshall (in part), Irving Fisher, and John B. Clark. Although narrower in analysis and more formal (mathematical) in

method than classical political economy, neoclassical economics also comprises two general branches: pure economic theory premised on the principle of marginal utility and social economics or economic sociology. For instance, Jevons proposes incorporating what he (perhaps for the first time in social science) terms economic sociology into the divisions of economics, alongside pure (marginal utility) theory. So does Walras, who seeks to integrate what *à la* Say he calls social economy with “pure” political economy. If pure (marginal utility) market theory is a primary and defining division of neoclassical economics and in the focus of most economists, economic sociology is a secondary and supplementary one, yet more appealing to sociologists as well as to social economists.

Some pertinent formulations or anticipations of economic sociology within neoclassical economics include the following. A remarkable (and perhaps surprising) moment is that an ostensibly pure marginalist economist, Jevons, probably invented the term economic sociology (Swedberg 1998), though under the likely influence of Comte (filtered through Spencer and Mill). Notably, within marginalism and beyond, Jevons provides the first explicit proposal for economic sociology as an integral branch of (neoclassical) economics. Moreover, he proposes that “it is only by subdivision, by recognizing a branch of Economic Sociology . . . that we can rescue our [economic] science from its confused state.” Jevons implicitly defines economic sociology as the “Science of the Evolution of Social Relations” in relation to the economy (apparently adopting a Spencer type definition of sociology in general). Jevons’s early follower, Wicksteed, carries this proposal even further by suggesting, under the acknowledged sociological influence of Comte, that economics “must be the handmaid” of sociology, which implies an idea of economic sociology. So does the project of Edgeworth (also Jevons’s follower) for what he calls mathematical sociology (or “mathematical psychics”). Moreover, he states that marginal utility theory (“Calculus of Variations” in utility) is the “most sublime branch” of sociological analysis, invoking Comte’s view of economics as the branch “most applicable to Sociology.”

Walras’s counterpart to Jevonian economic sociology is social economy, a concept he

probably adopted from Say and Mill. Walras specifically defines social economy as the “theory of the distribution of social wealth” in contrast to “pure” political economy defined as the “theory of price determination under the hypothetical regime of absolutely free competition.” Moreover, Walras goes a step further than Jevons in implementing the proposal for economic sociology by writing a book on social economy in a deliberate attempt at its integration with pure (and applied) economics. Closely following Walras, Wickseil adopts the idea of social economy defined as an “investigation of the issue how economic laws and practical precepts would be properly applied for getting the most possible social gain, and what changes in existing economic and legal structure of society are necessary for this end.” Like Walras, he seeks to integrate social economy thus understood with pure or theoretical (and applied) economics within economic science as a whole. So does Clark, who considers what he calls social economic dynamics as a proxy for dynamic economic sociology, economics’ “third division” to be integrated with its other “natural divisions.” Notably, he establishes these divisions of economics on the basis of “sociological evolution.” Also, Walras’s successor, Pareto, implies an idea and approach of economic sociology by suggesting that economists “have to consider not just the economic phenomenon taken by itself, but also the whole social situation, of which the economic situation is only a phase.” Pareto therefore implicitly conceives economic sociology in terms of a consideration of the “whole social situation” of the economy as its integral part.

Still another proposal for economic sociology within marginalism is implicit in Wieser’s project of social economics, mostly prompted and influenced by Weber. Wieser (a sociologist turned marginalist economist) implicitly defines economic sociology as an analysis of the “social relations of the economy” or the “sociological problems of economic theory” (which reveals Weber’s influence). He suggests that economists should describe and explain economic processes with “sociological phenomena,” citing exchange value as one of those “sociological fields” which makes possible “more rapid and certain progress” in analyzing the economy than do others. Also, Marshall’s neoclassical

economics implies some ideas or intimations of economic sociology. For instance, Schumpeter (1941) comments that, reminiscent of Mill, Marshall’s *Principles of Economics* contain (“behind, beyond and all around the kernel” of pure market theory) an “economic sociology of nineteenth century English capitalism which rests on historical bases of impressive extent and solidity.” Other economists also notice that, like Smith, Marshall produces “sociological insights” and displays a “sociologist’s awareness that approbation and self approbation are relevant even in the economic marketplace” (Reisman 1990: 264).

Like that of Smith and other classical economists, Jevons et al.’s economic sociology identifies and examines the social character and context of the economy (Schumpeter 1949: 61). First, some neoclassical economists acknowledge that the economy represents a social category by virtue of existing and functioning within society. This is what Walras does by observing that economic relations, including market transactions, necessarily take place in society. So does (more strongly) Pareto, who argues that the “states” of the economy are “particular cases of the general states of the sociological system,” described as “much more complicated”; he considers, consequently, economics as an “integral” part of sociology in which “complications are greater still and by far.” Moreover, he adds that in many situations economic problems are “subordinate” to the sociological; for example, material interests and rational actions to sentiments (“residues”) and non rational conduct. Also, Menger describes the (national) economy as the “social form” of economic activity or simply a social economy, and economic processes as instances of “concrete social phenomena.” His follower Wieser provides an instance in this respect by observing that every actor interprets the (marginalist) economic principle of attaining the highest total utility at the lowest cost “in the light of his social environment.”

Walras and Menger and Wieser imply what Wicksteed states explicitly: the reason the economy is a social phenomenon is that it “compels the individual to relate himself to others,” which makes economic laws the “laws of human conduct” – so psychosocial rather than physical ones. Marshall presents a case of such relations

in which market actors can create “particular” markets involving “some people or groups of people” in “somewhat close touch” with each other, such that “mutual knowledge and trust” lead to favoring these insiders at the expense of strangers, thus perhaps anticipating the social embeddedness conception of modern economic sociology. Similarly, Clark observes that the “socialization” of the economy leads to social differentiation by arranging producers (and consumers) into differentiated and unequal social groups and subgroups. Also, he essentially treats economic change or dynamics as a particular dimension of “sociological evolution,” as do later neoclassical economists like Schumpeter, who places economic development within a “theory of cultural evolution” on apparent Durkheimian grounds that the “social process is really one indivisible whole.”

Second, neoclassical economists recognize the impact of society, including politics and culture, on economic life. Thus, Clark acknowledges that many economic phenomena (e.g., “hired labor” or “loaned capital”) are dependent on “social organization.” In particular, Walras, while advocating the *laissez faire* doctrine, admits that an economy cannot properly operate without “interference” from some political and other authority. Further, Wicksteed observes that, due to political and other interference, the market “never has been left to itself,” even suggesting that it “never must be,” which provides an empirical rationale to his proposal for making economics the “handmaid” of sociology. Wicksteed thereby adopts and generalizes Jevons’s observation that in many cases market transactions “must be settled upon other than strictly economical grounds” (e.g., bargaining power), as well as that the future supply and demand in markets often hinge on the “political considerations of the moment.” In addition, some neoclassical economists register the impact of cultural phenomena, like traditions or customs, on economic agents and behaviors. Specifically, evoking and developing Mill’s views on the economic impact of rigid traditions in early society, Marshall emphasizes what he describes as the cumulative inhibiting effects of customs on the “methods of production and the character of producers.”

economy, culture and

Marion Fourcade Gourinchas

In traditional academic discourse, “culture” and “economy” have long been regarded as separate analytical spheres: on the one hand, the realm of shared cognitions, norms, and symbols, studied by anthropologists; on the other, the realm of self interest, where economists reign supreme. Though the two disciplines overlap occasionally (in economic anthropology mainly), radical differences in the conceptual and methodological routes each field followed during the twentieth century have prevented any sort of meaningful interaction.

By contrast, the interaction between culture and the economy has always been a central component of sociological analysis. All the founding fathers of sociology were, one way or

another, interested in the relationship between people's economic conditions and their moral universe. In his famous presentation in the *Preface to a Contribution to the Critique of Political Economy*, for instance, Marx described "forms of social consciousness" essentially as an epiphenomenon of material relations. Later interpretations, however, have suggested that even for Marx and Engels the relationships between "material base" and "superstructure" were far from deterministic. The "western" Marxist traditions that developed in Europe after World War I proposed a somewhat more sophisticated analysis that emphasized the integration of culture into the apparatus of domination – either because the hegemony exerted by bourgeois culture induces the masses into implicitly consenting to their own economic oppression (Gramsci 1971), or because the incorporation of culture into the commercial nexus of capitalism leads to uniformity of spirit and behavior and the absence of critical thinking (Adorno & Horkheimer 2002). Still, in these formulations, culture remains wedded to its material origins in capitalist relations of production.

Partly reacting against what they perceived to be a one sided understanding of the relationships between base and superstructure in Marxist writings, Weber and Durkheim both sought to demonstrate the greater autonomy of the cultural realm, albeit in quite different ways. Both insisted that people's behavior is always infused with a meaning that is not reducible to their material positions. Weber, more than anyone else, demonstrated the influence of preexisting ideas and, in particular, religious worldviews on the economic conduct of individuals. For instance, even though their actions may look rational from the outside, the behavior of early Protestant capitalists was quite illogical from the inside: anxiety about salvation, rather than self interest, motivated them to accumulate (Weber 2002). In other words, their search for profit was not based on instrumental rationality, but it made *psychological* sense given the religious (cultural) universe in which they lived. In fact, Weber considered that all religions condition individual attitudes toward the world and therefore influence involvement in practical affairs – but they, of course, all do it differently, so that the "economic

ethics" of individuals varies substantially across social contexts.

It is Durkheim, however, who best articulated the *collective* basis of our meaning making orientation: groups of individuals share certain understandings that they come to take for granted in their routine dealings with each other. Hence how people behave, including in economic settings, is not a priori reducible to a set of predetermined individual preferences and the interests they support. Rather, most of people's actions are motivated by habit and routine; and preferences, as well as the institutions they support, are informed by cultural norms (Meyer & Rowan 1977). In each society, then, culture and institutions act in tandem to shape individual consciousness and thereby representations of what is understood to be "rational." This is what DiMaggio (1994) calls the "constitutive effect" of culture. Because these mental maps are widely shared, they have much greater efficacy than others that would be out of place, or misunderstood, in the same context.

THE CULTURAL SHAPING OF ECONOMIC INSTITUTIONS

As a system of representations that exists separately and independently of individuals, culture may shape economic behavior in many different ways. It may be more or less institutionalized. Corporate cultures, for instance, are often highly formalized, even bureaucratized, but the rules that underlie bazaar interactions, though obviously codified, remain very informal (Geertz 2001). Second, the effect of culture may be more or less profound: Meyer and Rowan (1977), for instance, have famously suggested that many organizational rules are adopted in a purely ceremonial way but have little impact on actual practice – a claim that has been notably supported by research on educational institutions and hospitals. On the other hand, substantial evidence has come out of cross national studies of a deep patterning, not only of economic values and norms (Hofstede 1980), but also of economic institutions and organizations (e.g., Dore 1973; Hamilton &

Woolsey Biggart 1988). The critical question, then, is whether the two are related, and how.

NATIONAL CULTURES AND THE ECONOMY

One possible answer has been provided by Dobbin's (1994) suggestion of the existence of an elective affinity between economic and political culture (see also Beckert 2004). In his comparative analysis of the development of the railway sector in the nineteenth century, Dobbin shows that public officials in three countries sought to achieve economic growth in very different ways, and were influenced in doing so by their cultural perceptions about the nature and sources of the political order in their own nation. In the United States, they strove primarily to protect community self determination; in France, they oriented themselves toward centralized planning by the state in an effort to avoid logistical chaos; and in the United Kingdom, they were mainly concerned with protecting the individual sovereignty of firms. Ultimately, then, the economy of each country ended up "reflecting" the polity it originated from.

Some sociologists, however, would argue that there is no such inherent consistency to national cultures. Biernacki (1995), for instance, finds that the process of their formation is eminently fragile, almost serendipitous. In his comparative study of textile mills at the onset of the industrialization process, he finds that the concept of "labor" had a substantially different meaning in Britain and Germany, but that these differences originated in on the ground practices by workers and employers rather than in some preexisting mental categories. These practical conceptions, derived from the material context of industrialization in each country, tended then to crystallize into full fledged meaning making systems, which became eventually codified in writing – by political economists and other intellectuals. Through this process they acquired a great cultural depth, and ended up shaping a whole set of outcomes in the development pathways of the two countries – such as the wage calculation system, disciplinary techniques

within factories, forms of workers' collective action, and even industrial architecture. Yet even then, the systems remained vulnerable to a change in practices (which eventually took place in the early twentieth century).

THE EMERGENCE OF CULTURE WITHIN THE ECONOMY

Biernacki's study illustrates particularly well the fact that we should think about the role of culture primarily through its inscription in *practices*. Economic settings, therefore, do not simply display, or reflect, preexisting cultural understandings, but should be regarded as places where distinctive local cultures are formed and carried out. There are two main ways in which this point has been articulated in the sociological literature. The first emphasizes the social meanings people produce (whether voluntarily or involuntarily) through their use of economic settings and economic objects, and is best illustrated by consumption studies. The second suggests that some form of social order – i.e., regulating norms and practices – emerges out of the interpersonal interactions that take place within economic settings, particularly for mal organizations and markets.

Consumption

The first set of questions goes back to Veblen's and Simmel's analyses of consumption, and was most noticeably extended by Bourdieu (1984). The fundamental idea here is that consumption is not about individual parameters (preferences, income) but is profoundly *relational*. Consumption practices are the site of a competitive struggle whereby individuals seek to position themselves vis à vis other individuals in the social space. For Veblen (1994 [1899]), it is essentially about vertical hierarchy – leisurely elites seek to demarcate themselves from those below them by wasting money and time on perfectly useless purchases and activities. For Bourdieu, the structure of the social "space" is more complex: education and socialization into high culture (or not) play as much a part as money in determining taste and, beyond, consumption practices. What structures consumption

practices (as all forms of action), then, is what Bourdieu calls “habitus” – a system of dispositions that is formed through the individual’s trajectory in the social space (understood, again, in a relational manner vis à vis other individuals).

The study of consumption practices thus provides an extraordinarily rich terrain for analyzing how people relate to one another, both structurally and cognitively. In a creative variation on this theme, Zelizer (1994) has shown that these relational meanings are not only expressed through *what* people purchase, but often in *how* they pay for it – cash, gift certificates, checks, food stamps. People, in fact, constantly personalize, differentiate, and earmark money in ways that can be understood as metaphors about social relations and identity. (Whether the *how*, like the *what*, is also subject to the logic of habitus remains to be studied systematically.)

Organizations

The second question – the cultural universe produced within and by economic institutions – has also given rise to a diverse and extremely rich literature. We may illustrate this point with three examples: antitrust law; financial markets; and the McDonald’s corporation. Fligstein (1992), most prominently, has studied the way in which the legal environment shapes the formation of distinctive economic cultures. Corporate managers, he argues, act on the basis of “conceptions of control” – shared understandings about how a particular market works. These conceptions evolve in close connection with changes in the legal regulation of corporate competition, which tip the balance of power toward management groups with certain organizational cultures at the expense of others. In the course of the twentieth century, for instance, the American corporation was a contested and historically evolving cultural terrain, where conceptions of control shifted from production to sales and marketing, and finally finance and shareholder value. In this case, organizational culture fundamentally emerges out of a combination of institutional forces and power struggles.

Of course, such tacit understandings and patterned practices may emerge in a more decentralized way, out of interpersonal interactions in corporations, factories, workshops, and markets, including the most “rational” ones. Sociologists, for instance, have revealed the existence of all kinds of rituals, beliefs, customs, and informal control structures that regulate social life in the financial markets – the very heart, supposedly, of instrumental action. In fact, the economic potential of culture has not been lost on corporations, many of which try actively to “engineer” predictable behaviors and commitments on the part of their employees through the use of quasi religious rituals and the enforcement of strict codes regulating social interactions.

The organizational innovations introduced by the McDonald’s corporation are probably among the most potent examples of the cultural effects of corporate logics. As Ritzer (2004) has shown, they had a dramatic effect on human experience and social organization well beyond the boundaries of the firm of origin – helping spread the values and practices of efficiency, calculability, predictability, and control to various organizations and social institutions (education, medicine, or the criminal justice system), both in the United States and abroad. The sheer success of this model is thus a precious reminder that instrumental rationality – as Weber worried – is also a very powerful “culture” in and of itself.

THE ECONOMY AS THE CULTURE OF MODERNITY?

The example of McDonald’s suggests a broader point, then: the constitution of economic categories themselves is through and through a social process. Consequently, what gets incorporated (or not) into the sphere of the market place reveals much about how we understand ourselves, about our “culture.” As Polanyi (2001 [1944]) argued long ago, the hallmark of post eighteenth century modernity was the emergence of a distinctive social order dominated by market relations. Following nineteenth century critics (among them Marx,

Weber, and Simmel), Polanyi articulated the dehumanizing effect of modern capitalism and calculative rationality on personality and human relations, whereby individuals come to be seen as commodities and means to an end rather than as ends in themselves.

Empirically, however, there is quite a bit of debate about whether such effects really exist: recent economic experiments in small scale societies, for instance, have suggested that market integration is *positively* correlated with human cooperation (Henrich et al. 2004), thereby vindicating earlier commentaries about the civilizing (Hirschman 1977) and socially integrating effects of commerce. It is also unclear whether the penetration of markets has been as universal and far reaching as some skeptics believe. Modernity certainly does not mean that everything has been engulfed into the sphere of the marketplace: for instance, the study of the conditions under which boundary “objects” such as children, death, organs, or art are subject to economic exchange has revealed a quite varied landscape. Hence, as sources of economic benefit, children were *removed* from labor markets around the turn of the twentieth century in the United States (and countries that continue to authorize such practices today face grave political and economic pressures). On the other hand, as sources of emotional and social benefit, they were commodified in ways that were not foreseen in the nineteenth century, mainly through the adoption, insurance, and consumption markets (Zelizer 1985).

The intellectual challenge, then, is twofold: to specify the distinctive nature of the moral order capitalism relies upon, and to understand how it is produced. Perhaps this challenge is nowhere as obvious as in the current emergence of a new and eclectic vocabulary that seeks to overcome the conceptual divide between culture and economy, and focuses instead on the always inextricably moral dimensions of economic discourses and practices (Amin & Thrift 2004). Particularly noticeable is the work on logics of moral justification, which identifies the recent appearance of the discursive figure of “connectivity” as a new regime of justification conceived in and for the post industrial capitalist economy (Boltanski & Chiapello

2005). Dezalay and Garth (2002) explore another exciting avenue in their analysis of the mutually reinforcing, profoundly entangled, discourses of economic and political individualism – e.g., human rights and the market – and their worldwide diffusion under US hegemony. Finally, Callon (1998) and others have investigated the *performative* nature of the knowledge forms that sustain the development of capitalism, mainly economics and accounting. They have shown that through their language, techniques, and representations, these disciplines produce a world of “calculative agencies” and create a host of new institutions in which these agencies may exercise their calculative power – thereby formatting, little by little, our cultural selves onto the model fiction of *homo economicus*. This outburst of work seems to signal that sociology is finally ready for a real engagement with economics that will demystify it as a cultural form, as the discursive rationalization and active formatting, by capitalism, of itself and for itself – not merely the science of how the economy “works.”

economy, networks and

Gordon Walker

The intersection of economic and social behavior has long been an interest of sociologists. Since Simmel's (1955) seminal work on affiliation, it has become clear that the extent, kind, and structure of relations in a society have a potentially crucial impact on how well it functions, and by implication how much wealth it creates. Two current research programs are outlined here, small worlds and interfirm networks, which are related broadly to market creation and robustness. Both of these research programs capture core aspects of Granovetter's (1985) concept of embeddedness and suggest new directions for examining the sociological roots of economic behavior.

An economy runs on its volume of transactions, both between businesses and between businesses and consumers. An increase in transactions is generally considered a sign of economic health; a drop in volume a sign of weakness. One of the most important mechanisms that stimulates transaction volume is the fabric of institutional and social relationships that connects potential transaction partners with each other. Such a network, extending broadly across the economic, demographic, and class strata of a society, is essential for the creation and distribution of wealth through market forces. The more constrained the range of network ties, the greater the limitation placed on economic growth and ultimately on the viability of the economy. To understand the probity of this assertion, one need only consider the severe long term problems faced by command societies or the huge short term loss caused by the national shutdown in the United States after September 11, 2003.

Perhaps the best developed model of an extensive network is the small world. Milgram's (1967) early experiments showed that individuals in a referral chain can use simple social markers to home in on a targeted person, even across wide geographical distances. The average chain in his study was composed of six people, connected in sequence, hence the title

of John Guare's play *Six Degrees of Separation*. But if we are all tied to each other through just a few ties, how is it that we are surrounded mostly by people whom we know and who frequently know each other?

Watts and his colleagues (Watts 1999) have developed a variety of models of small world structure that answer this question. Their basic model has two salient components consistent with intuition. The first component is high local clustering (my friends are also friends of each other), and the second is a low global path length (it only takes a few steps to get from my position to someone on the other side of the network). Many networks with important economic implications have been found with such a structure, including the Internet, interlocking boards of directors, and interlocking groups of corporate owners (see Kogut & Walker 2001).

Where do small worlds come from? What determines them? The classic answer to this question is the following. At first, a population of potential transactors is segmented into discrete groups, like cavemen clustered in isolated tribes. Then, one or a few members of each tribe strike out on their own and make contact with other groups, establishing relationships, even as the tribes themselves remain highly internally related. Interestingly, Watts (1999) finds that just a few of these intergroup connections are sufficient to tie the network together, consistent with Milgram's results, and preserve the inbred relationships of the tribes. Although this story of global network development is appealing, it has problems.

The first concerns why isolated tribes connect with each other. A reasonable intuition is that they are looking for things they don't have. That is, without the promise of gain, there is no economic motivation to leave home. So trade across the network, not just with neighbors, implies a search for value enhancement. Unfortunately, the distribution of information in the network has to be just so in order for a broad search process to be efficient; and as this distribution departs from the optimum, search becomes highly inefficient very quickly. In most networks, then, search alone will not be a feasible explanation of small world development.

What other mechanisms might lead to the emergence of a small world? There are two possibilities. One is that relationships are

formed randomly, since chance encounters can surface opportunities. However, Watts and his colleagues have shown that randomly generated ties ultimately destroy local clustering, which violates the small world model where strong neighborhood relations endure. Moreover, casual observation suggests that not all contacts among individuals or firms are random; the fact that those that are make a strong impression proves that they are exceptional. A second possibility is that relationships between tribes emerge as their members meet in one or more secondary social or economic institutions, such as schools, professional associations, social clubs, governing boards, and places of work. These groups constitute a sociologically distinct dimension from the local clusters, since in the tribes first model clustering occurs before the network is integrated. Thus, networks become integrated as small worlds when social institutions develop or are made available to link up isolated tribes.

An important characteristic of small world properties of networks constructed through common memberships in institutions is that these networks can be highly dependent on the size distribution of the groups that individuals belong to. Larger groups obviously provide more individuals with exposure to each other. In fact, for some networks, both the degree of clustering in local neighborhoods and the number of ties to span the overall population have been shown to be completely dependent on group sizes.

Therefore, in order to understand the formation of a small world, one needs to attend more closely to the opportunity structures that bring individuals together. Without a sufficient set of opportunities for gathering individuals with differing backgrounds, the network is fragmented, search is frustrated, and the volume of transactions remains small. Where these institutions originate depends on the network being integrated. However, it seems unlikely that an isolated set of tribes would be able to establish ties with each other through common membership in institutions that they themselves would have to develop. A more likely possibility is that institutions enter the tribes' domain from the outside, suggesting that small world development cascades across networks from the more to the less developed, bringing with it greater

integration and the potential for an increased transaction frequency and economic growth.

Another problem with the caves first model is that not all networks start off as fragmented. That is, some networks are integrated first and develop local clusters second. The US venture capital syndication network, for example, was highly integrated nationally very early in the history of the industry. The network only slowly developed an identifiable structure of clusters, based on the common geographical location of the firms in cities or regions, such as New York, Boston, Northern California, Dallas, Minneapolis, and Chicago. What stimulated the rise of such a local focus is not known, but some possibilities are that: common preferences arose within a region to invest in local startup firms as the volume of opportunities increased; regional specialization in local startup industries increased (Silicon Valley – semiconductors; Boston and San Diego – bio technology), leading to venture capital firm specialization and co venturing; and venture capitalists became more mobile across firms within the same city or region. All of these represent opportunities for expanding local search and hence for the development of regional syndication clusters. Such a pattern indicates that economic motivations may spur the development of clusters just as they may influence building ties between them.

To understand a small world, then, one needs to identify and analyze the relevant social and economic trends and structures that infuse it. These create and shape the opportunities individuals and firms have to form relationships and therefore for network development overall. In this regard, it would not be inappropriate to explain the emergence of regional production clusters, which have attracted so much study over the last 30 years, as a creative combining of geographically bounded technological, social, and demographic factors that together enable a local interfirm network with small world properties. Focusing on relationships alone is insufficient to understand how the small world develops to facilitate economic behavior. These ties need to be motivated and sustained by substantive opportunities and venues for interaction.

In addition to the effect of small worlds on the volume of transactions throughout an

economy, other kinds of network structure have important economic consequences by affecting behavior within industries (see Burt 1980). We have evidence of network influence on five areas of economic activity: technological innovation, financial performance, investment behavior such as venture syndication and acquisitions, entry into an industry, and further development of the network itself. These cases vary in the types of network structure and linkages among firms that constitute the network. Some of these structures can be embedded within the small world, but they differ in their consequences, depending on the industry in which they occur. Interestingly, we observe interfirm alliances in almost all sectors, including extractive industries, financial services such as investment banking and venture capital, high technology, discrete manufacturing, and large scale processing industries. So industry networks in general are pervasive and important for the overall economy.

A frequently stated assumption about an interfirm network is that it is a complex pathway for the flow of information, and within the network the position of the firm determines the information available to it (see Podolny 2001). A common additional assumption is that the information a firm receives from partners that are related to each other in a cluster is to some extent redundant, since these partners are likely to share it in their relationships with each other. Thus, the more information a firm receives through its alliances with organizations that are not related to each other, the broader the firm's exposure to market and technological trends and opportunities. A broader exposure in turn leads to a higher rate of innovation (Ahuja 2000) and, in moderation, to higher rates of firm survival (Uzzi 1996). In some cases, greater exposure to information may also increase firm performance.

Redundant information can also provide an economic benefit. Tight clustering among firms through their alliances can lead to technological spillovers, which increases the rate of innovation. Alternatively, clustering can impose normative constraints on behavior (Coleman 1988), which induces firms to cooperate and raises the likelihood of future partnering (see Ingram & Roberts 2000). Thus, the most effective structure for a firm's alliance network seems to be

partners that are closely connected to each other but not tied to the same firms outside the local neighborhood.

Occupying a central position in a network of alliances (Gulati & Gargiulo 1999) also provides more information, with a variety of possible economic consequences for firms. In the semi-conductor industry, central firms experience stronger firm growth; and centrally positioned banks tend to diversify more extensively. Further, venture capital firms that are central in the industry's network of syndications are more likely to invest in startups that are geographically distant. Finally, because they are closer to more potential partners, central firms are more likely to enter into more alliances. This broad range of centrality benefits shows clearly how network position affects firm behavior and through it the distribution of assets in the overall economy.

Just like firms, an industry wide network may be more or less centralized, and higher centralization indicates that one or a few firms dominate the industry through their alliances, possibly because their technologies have become standard. In fact, by reflecting the competition for standards dominance, the trend in industry centralization affects the pattern of entry by suppliers to the competing firms. It has been observed that potential suppliers tend to enter the industry when its level of centralization is rising, indicating that some firms are winning the standards competition and therefore that they are safer as long term partners. When standards competition is fierce and industry centralization is falling, it is less clear who the eventual winners will be; so suppliers, in the interest of not choosing a failing customer, hold off and do not enter. In technology based industries, the signaling role of network structure can thus have an effect on the structure of adjacent markets and therefore indirectly on the economy.

Local interpersonal and interfirm networks provide the normative context for exchange. But they also influence the economy through extensive, global structures, such as the small world, that facilitate the efficiency and increase the volume of transactions. The creation and persistence of these global networks, often through societal institutions, therefore expand

economic behavior. Moreover, in a developed economy, networks of alliances within industries influence many important economic variables, including the rate of innovation, firm performance, and investment behavior. These may have an indirect, but ultimately powerful, effect on the growth and overall robustness of a nation's economy.

economy, religion and

Rachel M. McCleary

The modern study of religion and economics begins with Adam Smith's *An Inquiry into the Nature and Causes of the Wealth of Nations* (1776). Smith applied his economic analysis to several aspects of religion that researchers since developed with quantitative research. Smith's fundamental contribution to the study of religion was that religious beliefs and activities are rational choices. As in commercial activity, people respond to religious costs and benefits in a predictable, observable manner. People choose a religion and the degree to which they participate and believe (if at all).

In the 1970s, the rational choice approach to religion, or the economics of religion, reinvented social science investigation of religion (Young 1997). The first formal model of religious participation was developed by Corry Azzi and Ronald Ehrenberg (1975). Laurence Iannaccone's (1998) literature survey of economics attributes to Azzi and Ehrenberg the framework that served as the basis for future research on religion. Using Gallup survey data, Azzi and Ehrenberg found that the opportunity cost of time influences religious behavior. Within a given household, women whose wages are typically lower will spend more time in religious activity. Likewise, individuals whose real wages increase over time can be expected to participate less in religious activities. Education, just as wages, plays an important role in participation in religious activities. Edward Glaeser and Bruce Sacerdote found that the level of education of believers influences their choice of religion. The payoff for higher educated people is social capital in the form of networking rather than stronger religious beliefs. Benito Arruñada found that more education increases the costs of participating in the institution of confession. Individuals with higher education tend to engage in moral "self policing," relying less on priests for such enforcement.

The family and its dynamics, a popular subject of anthropology, sociology, and psychology, are currently undergoing reinterpretation by rational choice theorists. Evelyn Lehrer

(1999), using data from the National Survey of Families and Households, looks at how religious upbringing influences the number of years of schooling a person attains. She also explores how a woman's religious preference influences her choice of marriage or cohabitation. Maristella Botticini and Aloysius Siow (2003) reexamine the dowry institution and seek to explain parental choices in using different forms of intergenerational transfers.

Religious extremism, both in non violent and violent forms, is explained according to rational choice theory for similar reasons. Iannaccone's cost benefit analysis of strict religions led to the development of a theoretical model of the evolution of organized religion. Taking Ernst Troeltsch's (1931) sect–denomination distinction, Iannaccone applied a cost induced commitment to organized religion. He argued that denominations and extremist sects can be construed as distinct modes or "clubs" of religious organization based on consumer (believer) preferences. Using the club model of religion, Iannaccone sought to explain the success of strict religions (cults, sects). Using a cost benefit analysis, Iannaccone argued that people choose to undergo stigma and self sacrifice and engage in unconventional behavior to eliminate free riders, thereby increasing the commitment of believers and benefits to members. Iannaccone's economic analysis provided a rational explanation for behavior that other professions categorized as brainwashing or a form of pathological behavior.

Eli Berman (2000, 2003) applied the club model to Israeli Ultra Orthodox Jews, as well as to Hamas, the Taliban, and the Jewish underground militias. Berman found in the case of the Israeli Ultra Orthodox community that the benefits of remaining in the group outweighed the costs of sacrifice and stigma. For the Taliban, the sacrifices demanded by the group, seemingly gratuitous acts of violence, destroyed outside options and, thereby, increased group loyalty.

Scholars who investigate the demand side of religion tend to favor the view that religious preferences change over time for both the individual and social groups. Sociologists Roger Finke and Rodney Stark (1992) maintain that individual preferences remain constant. Finke

and Stark contend that the supply of religious goods changes over time, not the demand for them. Analyzing membership data beginning in the American colonial period, Finke and Stark argue that religions begin small, supplying the religious goods that consumers want. As the religion grows and more members join, the religion accommodates the variety of membership demands by becoming less strict until it loses its religious relevance and declines.

However, religious strictness can reach an optimal level, after which it becomes detrimental to a religion. Extreme religions deter people from joining. A common example is the Shaker movement that practiced celibacy. Because of its inability to attract new members, it became obsolete. Religious strictness is not the only reason a religion declines. Adam Smith argued that state subsidies to organized religion create a dependency upon a regular and enforceable income. State subsidized religion tends to change in two ways. It devolves, losing those aspects of religious devotion that are relevant to people practicing their faith and the authority of its doctrine. Second, it tends to become a religion for elites, and to the degree that the clergy itself becomes an elite group in society, of elites. By contrast, those religious groups that depend solely on voluntary contributions must continually address the religious needs of their congregants to stay in existence.

Smith extended his analysis to the evolution of organized religion. Observing the nonconformist religious groups – “upstarts” – Smith noted that the spiritual, imaginative, and emotional bases of the new religious movements successfully challenge state sanctioned religion. As a reaction to popular criticism of its elitist ways, state religion resorts to coercion, repression, and even violence to maintain its financial, political, and social arrangement in society. Religion, Smith concluded, is more vibrant where there is a disassociation between church and state. The absence of state religion allows for competition, thereby creating an environment for a plurality of religious faiths in society (Smith 1791 [1776]). By showing no preference for one religion over others, but rather permitting any and all religions to flourish, the state encourages an open market in which religious groups engage in rational discussion.

This competitive but non coercive environment supports an atmosphere of “good temper and moderation.” Where there is a state monopoly on religion or an oligopoly among religions, one will find zealotry and the imposition of ideas on the public. Where there is an open market for religion and freedom of speech, one will find moderation and reason.

Correcting Adam Smith’s argument, it has been contended that the relaxing of state regulation on religion unleashes competitive forces in the economic marketplace but not necessarily competition among religious faiths (Jeremy 1988). The focus of this variant argument lies with the legal recognition in England during the Industrial Revolution of nonconformist religious groups – the upstarts. These groups challenged the dominant religion – in some cases state religion – with different views of the linkages between salvation and economic activity. Although these nonconformist religious groups did not necessarily increase in membership to challenge the dominant position of the state religion or mainstream faiths, they contributed to and altered economic activity. Thus, state inclusion of nonconformist religious groups can have a positive effect on the economic productivity of society without seriously challenging state religion. This variant view is compatible with what Smith said the effect of religious pluralism would be: the continual subdividing of sects into numerous ones and small units so that a single religion does not dominate (Smith 1791 [1776]).

Economic historians have applied economic analysis to religious institutions. For example, Robert Ekelund, Robert Hebert, and Robert Tollison treat a religious organization as an economic firm to explain the rent seeking practices of the medieval church. More recently, they assess the competitive entry of Protestants into the medieval religion market (Ekelund et al. 2002). They analyze the Roman Catholic Church’s response in the form of the Catholic Reformation. Timur Kuran (2004) investigates the effects of Islamic legal institutions on economic growth and the distribution of goods. Kuran finds the institutions that generated evolutionary bottlenecks include the Islamic law of inheritance, which inhibited capital accumulation; the absence in Islamic law of the concept

of a corporation and the consequent weaknesses of civil society; and the *waqf* – the religious endowment of property for specific, usually philanthropic, purposes to the exclusion of all other uses – which locked vast resources into unproductive organizations for the delivery of social services. All of these obstacles to economic development were largely overcome through radical reforms initiated in the nineteenth century. Nevertheless, traditional Islamic law remains an impediment to economic growth.

A recent application of economic analysis to religion and religious beliefs is the cross country quantitative analysis of Robert Barro and Rachel McCleary (2003). Using international survey data on religiosity for a broad panel of countries, they investigate the effects of church attendance and religious beliefs on economic growth. They find that religious beliefs are more important for economic activity than religious participation. Rene Stulz and Rohan Williamson, using data on financial markets of various countries, find that a country's principal religious preference is relevant for predicting creditor rights. The improvement of data collected on various religions as well as aspects of religious preferences and institutions will continue to spur research on religion, particularly from an international perspective. The more important data sets used are described below.

The World Values Survey (WVS), directed by Ronald Inglehart at the Inter University Consortium for Political and Social Research (ICPSR), offers four waves of surveys (1981–4; 1990–3; 1995–7; 1999–2001), now covering over 50 countries. Each survey includes a series of questions on religious beliefs, activities, commitments, and values, as well as a variety of economic, political, and social variables. For discussions and uses of these data, see Inglehart and Baker (2000).

Another useful data set is the International Social Survey Program (ISSP), which is a cross national collaboration of surveys (including the General Social Survey or GSS for the United States). The 1991 and 1998 waves are dedicated to religion, the latter for 30 countries. As with the WVS, the ISSP includes an array of other variables. For discussions and uses of the ISSP data, see

International Social Survey Program 2002 (available at www.issp.org/data.htm).

Gallup International has collected cross national survey data on religion for many years. The Gallup Millennium Survey has useful indicators on church attendance and religious beliefs for over 50 countries in 1999; see Gallup International Millennium Survey 2002 (available at www.gallup-international.com/survey15.htm). Currently, these data are not easily accessible to researchers, although negotiations with Gallup International are underway.

Jonathan Fox and Shmuel Sandler (2004) are assembling a religion and state database (RAS) in which they classify the relation between religion and state into four broad groupings: separation of religion and state, discrimination against minority religions, restrictions on majority religions, and religious legislation. They examine religion and state separation between 1990 and 2002 in 152 states with populations of over 1 million.

The American Religion Data Archive (ARDA), under the leadership of Roger Finke at Penn State University, will prove beneficial. The ARDA (available at www.thearda.com) is widely used as a source of data on religion for the United States and Canada. It provides additional software enhancements for selected ecological files. For the most heavily used files, such as Church and Church Membership Surveys, the site offers “Mapping” and “Report” options. Here state or national maps on church membership totals or rates can be constructed for any denomination in the data file. Users can also get a profile of religious denominations for any state, county, or metropolitan area selected.

economy (sociological approach)

Thomas J. Fararo

The general problem of how to conceptualize and explain the relations of the economy to wider contexts of human behavior has been one of the main themes of major theorists in the sociological tradition. In the classical phase of the tradition, Marx, Weber, and Durkheim each treated the problem. In the writings of Marx, what has been called the base–super structure model rests upon the concept of a mode of production that includes social relations of production and forces of production, corresponding approximately to economy and technology, respectively. Social classes consist of persons who occupy the same position in the social relations of production, such as lord and serf in the feudal mode of production and capitalist and wage laborer in the capitalist mode of production. The dominant class employs its power advantage to shape a superstructure consisting of non economic institutions along with a dominant ideology reflecting the interests of the ruling class. This model is associated with a theory of social change, as in *The Communist Manifesto*, in which Marx and Engels analyze the historical dynamics of the rise and fall of capitalism in terms of revolutionary change involving conflicts among aristocrats, who represent the declining feudal mode of production, and the bourgeoisie, who in ushering in the capitalist mode of production are also giving birth to their own “gravediggers,” the class of wage laborers.

One implication of this analysis is that cultural phenomena are reflections of economic and political interests, whether in support of the status quo or antagonistic to it. In the writings of Weber, however, we find cultural orientations playing not just a reflective role relative to the economy. In *The Protestant Ethic and the Spirit of Capitalism* (1904), unintended consequences of religious ideas arising out of the Protestant Reformation are hypothesized to have been an important factor in the rise of modern rational capitalism in the West.

Calvinists were motivated by their religious ideas to seek economic success in the world and yet to maintain an ascetic lifestyle, a combination quite favorable to the formation of a bourgeois class. Eventually, however, as some of the religious spokesmen of the time feared, the religious element of the ethic was undermined by its very success in stimulating material gain. The result is the culture of modern rational capitalism, which no longer has or needs a religious meaning. In this and other studies, Weber set out a wide ranging sociology of the economy that included, in particular, complex and historically variable relationships between culture and economy. For Weber, the emergence of modern rational capitalism is only one instance of a wider historical process in which other institutional forms of rational social organization developed, especially bureaucracy. Indeed, he emphasizes that the modern capitalist enterprise, no less than the modern state, is a bureaucratic structure within which all action is organized in terms of norms of efficiency.

Durkheim made another type of theoretical contribution pertaining to economy and society. In one of his major works, *The Division of Labor in Society* (1893), he produced a new type of analysis of the division of labor. More than a century earlier, Adam Smith, in his treatise *The Wealth of Nations* (1776), had demonstrated the economic function of the division of labor in terms of gains in productivity. By contrast, Durkheim traces out its *social* function in the sense of social integration. He argues that simpler societies with little division of labor are held together mainly by the similarity of sentiments and ideas of their members, while complex societies with an extensive division of labor are held together by an organic form of solidarity, i.e., by the effects of the extensive interdependence of the differentiated members. Thus, in a somewhat oversimplified statement, we can say that just as Weber's study illuminated the relation between the economy and its cultural environment, Durkheim's study illuminated the relation between the economy and what the later social theorist Talcott Parsons called "the societal community," a system of social relationships among individuals and groups.

The approach that Parsons took was to place the economy in its larger setting of human

action and society in such a way as to delineate its various environments and how they constrained and enabled economic action. This approach is grounded in an action frame of reference and in a methodology of functional analysis. Any system of action has four functional problems: adaptation to its environment (A), definition and attainment of its goals (G), the integration of action elements (I), and the maintenance of meanings that are presupposed in the various actions (L). This AGIL scheme is applied recursively starting from the most general level of human action in which there is a non action (biophysical) environment. Behavioral systems, personality systems, social systems, and cultural systems respectively arise as solutions to the AGIL problems at this general action level. In particular, a social system has a structure that consists of institutionalized normative culture, e.g., the definition of rights and obligations.

From this analytical standpoint, the biophysical environment of the action system as a whole includes the living bodies of the members of the social system and the nature of the habitat in which they are collectively embedded. Thus the social system's adaptation problem – which we may denote IA – is one of gaining some degree of institutionalized control of these environmental states. For instance, human bodies have their own functional imperatives, such as adequate food, water, and shelter. The habitat may enable but also constrain how these needs can be satisfied. Thus, provision of these primary needs in the given biophysical environment and of other needs of personalities that arise in and through action processes within a cultural tradition constitutes a functional imperative of the social system to which its economy is the ongoing institutional solution, perhaps quite inadequate from a normative point of view in the sense that what prevails may be a condition of widespread hunger and/or alienation.

As a subsystem of the social system, the structure of the economy is defined in terms of differentiated institutionalized normative culture in the sense of socially sanctioned rights pertaining to ownership, contract, employment, and the like. The actions of the members of the social system also may be analyzed, not only in terms of how the social system "solves" its

adaptation (IA) problem but also in terms of how it produces some solution to its political (IG) problem, its social integrative (II) problem, and what Parsons later called its “fiduciary” (IL) problem of maintaining social value commitments.

Parsons and Smelser in their volume *Economy and Society* (1956) treat each of these problems and solutions in terms of their system model, so that a social system includes an economy, but also three other functional subsystems, namely a polity, a social community, and a fiduciary system, respectively, which form the *social* environment of the economy. Its wider *action* environment consists of behavioral, personality, and cultural systems. Parsons and Smelser also attempt to delineate the nature of intra economic processes in terms of the AGIL scheme as applied to the economy as a system with its own four functional problems, e.g., adaptation of its social environment with its political, social integrative, and fiduciary features. Concretely, these features may include, for instance, a weak or strong state, a weak or strong legal tradition, and an educational system that provides more or less appropriate skills and motivation for participation in productive activities. That these variable features profoundly constrain and/or enable productive economic activity is illustrated by the contemporary difficulties of establishing a market economy in a social environment in which there is an unstable polity, little by way of enforceable laws protecting private property, and an educational system that discourages individual initiative.

Functional analysis has certain conceptual implications. Parsons and Smelser (1956: 14) note, for instance, that “the whole society is in one sense part of the economy, in that all of its units, individual and collective, *participate in* the economy. . . . But no concrete unit participates *only* in the economy. Hence, no concrete unit is ‘purely economic.’” This is best illustrated by reference to collective units. Schools (fiduciary specialists) participate in the economy as purchasers of needed facilities, services, and supplies. In a capitalist system, firms (economic specialists) participate in the fiduciary system that reproduces capitalist values simply by hiring workers, making profits, distributing dividends, and the like, all of which contribute to retention of value orientations supportive of

capitalism. As Weber noted, modern capitalism no longer requires religion for the reproduction of the culture of capitalism. It should be noted, however, that financial scandals involving corporations are dysfunctional in terms of the fiduciary function, undermining faith in the virtues of capitalism.

Many of the interactions in a differentiated social system are functionally specialized exchanges of various sorts and, in the aggregate, produce market or market like phenomena. For instance, the labor market connects the economy to the fiduciary system in that the latter produces actors who can take positions in some context of production that enables them to enact the corresponding roles in relation to others. At the micro level, two people may engage in an exchange process, one of whom is in a representative role for a firm while the other may be connected to a household as one of its employed members and whose income performs a significant function in the context of that social subsystem of the system under analysis. At the macro level, this is but one exchange among numerous others that together form what Parsons and Smelser call an “interchange system,” which connects the economy and the fiduciary system.

Since the Parsons–Smelser model is abstractly general, it can have applications at various levels. As one example, consider the social system of the world, “world society.” Its polity is a fractured one, consisting of numerous sovereign states with competing claims and incessant outbursts of violent conflicts. Its social integration is proceeding rapidly, however, via the impact of increasingly faster and more efficient modes of communication as well as the formation of collectivities that transcend nation state boundaries. In this context, there is the world economy with its increasing globalization of production and consumption as well as numerous markets still enclosed within more local sectors of the world society. This world society is embedded in a world system of human action that includes cultural systems such as value systems, religions, ideologies, and sciences. World fiduciary processes in the form of education, for instance, reproduce particularistic values associated with national or other identities but also, although not uniformly, other more universalistic values

that are incompletely realized in world institutions such as the United Nations. Globalization, in large part driven by economic actions, is a historical process that has increasingly come under analysis by sociologists as they interpret the world economy as embedded in a larger system of action that includes world culture, world polity, and so on.

Although the model proposed by Parsons and Smelser is of considerable value in addressing the question of how the economy relates to its environments, issues relating to lack of clarity and rigor in the formulation of the model have limited its usefulness to other analysts of economy and society. Perhaps for this reason, the tradition of economic sociology went into a kind of hibernation for about two decades before being revived in the mid 1980s. At about that time, a number of research programs that involve both theory and empirical investigations were initiated. Taken together, these programs have been called "the new economic sociology" by Granovetter (1985) in an influential article that stimulated the rebirth of the field.
