The final critique of Foucault is really a question: Is social science, as such, even possible if we take Foucault’s work seriously? Foucault’s work challenges the very assumptions that make social science possible. For Foucault, the difficulty with the social sciences lies in the fact that modern “man” is both the subject and the object of disciplinary knowledge; he is a being defined by his ability to observe and be observed, count and be counted, evaluate and be evaluated, rank and be ranked. Man comes to know himself both as the empirical object and the transcendental subject of knowledge (Dreyfus & Rabinow 1983: 31). Foucault calls this peculiar epistemological configuration the “empirico transcendental doublet” that haunts the history of the human sciences, and it leads Foucault to make one of his most controversial claims: that the era of man is drawing to a close, and eventually man will disappear, “like a face drawn in sand at the edge of the sea” (Foucault 1972: 387).

If Foucault’s claims have any weight, then his own analyses must also be implicated in the conditions of their own production. Foucault acknowledges this, saying that genealogies “are therefore not positivistic returns to a more careful or exact form of science. They are precisely anti sciences” (Foucault 1980: 83). For this reason, Foucault’s greatest influence may be in felt in debates about the future of the

discipline itself. His supporters argue that his work helps pave the way for a post positivist social science.

In his biography of Foucault, Didier Eribon quotes at length Pierre Bourdieu's article in *Le Monde*, written at the time of Foucault's death:

"There is nothing more dangerous," wrote Bourdieu, "than to reduce a philosophy, especially one so subtle, complex, and perverse, to a textbook formula. Nonetheless, I would say that Foucault's work is a long exploration of transgression, of going beyond social limits, always inseparably linked to knowledge and power . . . I would have liked to have said this better—this thought that was so bent on conquering a self-mastery, that is, mastery of its history, the history of categories of thought, the history of the will and desires. And also this concern for rigor, this refusal of opportunism in knowledge as well as in practice, in the techniques of life as well as in the political choices that make Foucault an irreplaceable figure." (Eribon 1991: 328)

frame

David A. Snow

The concept of frame designates interpretive structures that render events and occurrences subjectively meaningful, and thereby function to organize experience and guide action. Within sociology, the concept is derived primarily from the work of Erving Goffman, which is beholden in part to the earlier work of Gregory Bateson. For these scholars, as well as others who use the concept analytically, frames provide answers to such questions as: What is going on here? What is being said? What does this mean? According to Goffman, frames essentially enable individuals "to locate, perceive, identify, and label a

seemingly infinite number of occurrences" within their immediate life situations or spaces.

Frames do this interpretive work by performing three core functions. First, like picture frames, they *focus attention* by punctuating or bracketing what in our sensual field is relevant and what is irrelevant, what is "in frame" and what is "out of frame," in relation to the object of orientation. Second, they function as *articulation mechanisms* in the sense of tying together the various punctuated elements of the scene so that one set of meanings rather than another is conveyed, or, in the language of narrativity, one story rather than another is told. Third, frames perform a *transformative function* by reconstituting the way in which some objects of attention are seen or understood as relating to one another or to the actor. Examples of this transformative function abound, as in the de eroticization of the sexual in the physician's office, the transformation or reconfiguration of aspects of one's biography, as commonly occurs in contexts of religious conversion, and in the transformation of routine grievances or misfortunes into injustices or mobilizing grievances in the context of social movements.

Given the focusing, articulation, and transformative functions of frames, it is arguable that they are fundamental to interpretation, so much so that few, if any, utterances, gestures, actions, or experiences could be meaningfully understood apart from the way they are framed. Indeed, one student of discourse and interaction, Deborah Tannen (1993), has claimed as much, noting that: "in order to interpret utterances in accordance with the way in which they are intended, a hearer must know what frame s/he is operating in, that is, whether the activity being engaged in is joking, imitating, chatting, lecturing, or performing a play."

In light of the relatively routine character of such activities, it is arguable that most frames are culturally embedded in the sense that they are not so much constructed or negotiated *de novo* as individuals go from one situation or activity to another, but exist, instead, as elements of the individual's or group's enveloping culture and thus contain within them situation relevant meanings. It is also the case, however, that one can easily glean from everyday social life numerous direct and indirect ambiguities and situations calling for a more interpretive

and contextual understanding of frames. Not only is some interpretive work required when reading a new situation or encounter and deciding, however instantaneously, what extant frame should be invoked or applied, but these primary frames are themselves also subject to transformation through, in Goffman's language, various "keyings" and "fabrications." In turn, these transformations can be fleeting or enduring, thus suggesting that frames are subject to change over time rather than static cultural and/or interactional entities. Additionally, there are moments and situations in social life in which the relevance or fit of extant cultural frames is likely to be ambiguous or open to question, and thus contestable, as is often the case in the contexts in which social movements arise. Hence, frames can be understood and analyzed from both culturalist and constructivist perspectives.

The concept of frame is one of a number of concepts that are invoked to capture the interpretive and constructed nature of much of what goes on in social life. Other kindred concepts include schemas, ideology, and narrative, but it is arguable that frames are conceptually and functionally distinctive. For example, schemas (knowledge structures consisting of learned expectations about objects of orientation) and frames interact during the course of interaction between two or more individuals, with frames providing an interpretive "footing" that aligns the divergent schemas that participants may sometimes hold. Ideologies can be thought of as broad, often loosely coupled sets of values and beliefs that function as a cultural resource for the construction of frames and which, in turn, can be modified by successfully implemented frames. So frames and kindred concepts like schemas and ideology can be thought of as existing in an interactive, almost dialogic relationship.

The analysis of frames and associated processes has been conducted in relation to various activities and social categories (e.g., advertising, face to face interaction, gender, talk) in a variety of domains of social life (e.g., culture, organizations, politics, public policy). To date, however, the most systematic application and development of frame analysis within sociology can be found in the substantive study of collective action and social movements.

framing and social movements

David A. Snow

Framing, within the context of social movements, refers to the signifying work or meaning construction engaged in by movement adherents (e.g., leaders, activists, and rank and file participants) and other actors (e.g., adversaries, institutional elites, media, countermovements) relevant to the interests of movements and the challenges they mount in pursuit of those interests. The concept of framing is borrowed from Erving Goffman's *Frame Analysis* (1974) and is rooted in the symbolic interactionist and constructionist principle that meanings do not naturally or automatically attach themselves to the objects, events, or experiences we encounter, but arise, instead, through interpretive processes mediated by culture. Applied to social

movements, the idea of framing problematizes the meanings associated with relevant events, activities, places, and actors, suggesting that those meanings are typically contestable and negotiable and thus open to debate and differential interpretation. From this vantage point, mobilizing grievances are seen neither as naturally occurring sentiments nor as arising automatically from specifiable material conditions, but as the result of interactively based interpretation or signifying work. The verb "framing" conceptualizes this signifying work, which is one of the activities that social movement leaders and participants, as well as their adversaries, do on a regular basis.

The link between framing and social movements was first noted in an experimental study of the conditions under which authority is defined as unjust and challenged (Gamson et al. 1982) and then developed more fully in a conceptualization and elaboration of "frame alignment processes" (Snow et al. 1986). Since then there has been an almost meteoric rise in research on framing and social movements, with much of the work congealing into what is now called the framing perspective on social movements (Benford & Snow 2000; Snow 2004). The analytic appeal and utility of this perspective is based largely on the conjunction of three factors. The first is the neglect of the relationship between meaning and mobilization, and the role of interpretive processes in mediating that relationship, by the dominant perspectives on social movements that emerged in the 1970s – namely, the resource mobilization and political process/opportunity perspectives; the second is the rediscovery of culture and the so called discursive turn that occurred during the 1980s; and the third is the development of a framing conceptual architecture or scaffolding which has facilitated more systematic theorization and empirical assessment of framing processes and effects.

Among the interconnected concepts and processes that have surfaced as the framing literature has expanded, there are at least six that can be thought of as cornerstone concepts and processes in that they provide a conceptual architecture that has stimulated much of the research exploring the relevance of framing to mobilization, both empirically and theoretically. These key concepts or processes

include: collective action frames, master frames, core framing tasks, frame alignment processes, frame resonance, and discursive processes and fields.

Collective action frames are the resultant products of framing activity within the social movement arena. They are relatively coherent sets of action oriented beliefs and meanings that legitimate and inspire social movement campaigns and activities. Like everyday interpretive frames, collective action frames focus attention by specifying what is "in" and "out of frame"; articulate and elaborate the punctuated elements within the frame so that a particular meaning or set of meanings is conveyed; and, as a result, often transform the meanings associated with the objects of attention, such that some situation, activity, or category of individuals is seen in a strikingly different way than before, as when everyday misfortunes are reframed as injustices or status groups like the homeless and cigarette smokers are framed as legitimate targets for social movement protest. But collective action frames differ from everyday interactional frames in terms of their primary mobilization functions: to mobilize or activate movement adherents so that they move, metaphorically, from the balcony to the barricades (action mobilization); to convert bystanders into adherents, thus broadening the movement's base (consensus mobilization); and to neutralize or demobilize adversaries (countermobilization). Much of the research on framing and social movements has focused on the empirical identification of collective action frames and specification of their functions with respect to the movements in question. In the case of the environmental movement, for example, numerous frames have been identified, such as an "environmental justice frame," a "runaway technology frame," a "conservation frame," and a "landscape frame."

Although most collective action frames are movement specific, sometimes those that emerge early in a cycle of protest come to function like master algorithms in the sense that they color and constrain the orientations and activities of other movements within the cycle, such that subsequent collective action frames within the cycle are derivative (Snow & Benford 1992). When the ideational and interpretive scope and influence of a collective

action frame expand in this way, it can be thought of as a *master frame*. Examples of master frames in recent history include the civil rights frame in relation to the resurgence of the women's movement and the flowering of movements accenting the rights of the aged, the disabled, American Indians, and other ethnic groups; the nuclear freeze frame in relation to the peace movement of the 1980s; and the environmental justice frame in relation to various environmental movements (Snow & Benford 1992; Benford & Snow 2000).

The relative success of collective action frames in performing their mobilization functions is partly contingent on the extent to which they attend to the three *core framing tasks* or challenges of "diagnostic framing," "prognostic framing," and "motivational framing" (Snow & Benford 1988). The former entails a diagnosis of some event or aspect of life as troublesome and in need of repair or change, and the attribution of blame or responsibility for the problematized state of affairs. Much research examining the substance of collective action frames suggests that diagnostic framing typically defines or redefines an event or situation as an "injustice" (Gamson 1992; Benford & Snow 2000: 615), but it is not clear that all collective action frames include an injustice component. Prognostic framing involves the articulation of a proposed solution to the problem, including a plan of attack and the frame consistent tactics for carrying it out, and often a refutation of opponents' current or proposed solutions. Such framing, simply put, addresses the Leninist question of "what needs to be done." Research has shown that both diagnostic and prognostic framing can generate considerable debate resulting in "frame disputes" within movements (Benford 1993). The final core framing task, motivational framing, addresses the "free rider" problem by articulating a "call to arms" or rationale(s) for engaging in social movement activity. This has also been referred to as the "agency" component of collective action frames (Gamson 1992).

Frame alignment processes encompass the strategic efforts of social movement actors and organizations to link their interests and goals with those of prospective adherents and resource providers so that they will "buy in" and contribute in some fashion to movement campaigns

and activities. Four basic alignment processes have been identified. They include “frame bridging,” which involves the linkage of two or more ideologically congruent but structurally disconnected frames regarding a particular issue; “frame amplification,” which entails the embellishment, crystallization, and invigoration of existing values and beliefs; “frame extension,” which depicts movement interests and framings as extending beyond the movement’s initial constituency to include issues thought to be of relevance to bystander groups or potential adherents; and “frame transformation,” which involves changing prior understandings and perspectives, among individuals or collectivities, so that things are seen differently than before (Snow et al. 1986). Research on these alignment processes has been quite extensive and has firmly established their importance in relation to mobilization (Benford & Snow 2000; Snow 2004).

The ultimate measure of the effectiveness of proffered collective action frames and the corresponding alignment strategies is whether they resonate with targeted audiences. Those for which *frame resonance* is established facilitate mobilization; those that are non resonant fall on deaf ears, thus failing to inspire or influence the direction of social movement activity. Two sets of interacting factors have been postulated to account for variation in frame resonance. One is the “credibility” of the proffered frame, which is affected by the consistency between claims and actions, the relative empirical credibility of claims and events, and the credibility of the frame articulators, as determined by status and knowledge considerations. The second set of factors affecting frame resonance is the “salience” of the framing to the targets of mobilization, as determined by the centrality of the beliefs and claims to the lives of the targets of mobilization, the extent to which the framing is experientially commensurable with the past or present lives of the targets, and the extent to which the framings have narrative fidelity, such that they are resonant with cultural narrations and myths (Snow & Benford 1988; Benford & Snow 2000: 619–22). Affecting both sets of factors is the failure to attend to various framing problems that can result in the commission of framing errors or mistakes that undermine the prospect of resonance. Four such problems

that appear to confront movements of all kinds include the problem of “misalignment,” as when, in the case of injustice framing, attention is focused on establishing the responsible agents without first firmly establishing victimage; the problem of “scope,” as when framing claims are either too broad and general or too specific and narrow; the problem of “exhaustion,” as when a particular framing has been overused and perhaps taken for granted and is thus tired and spent; and the problem of “relevance,” as when the frame is contradicted by the flow of events and framing efforts are insufficiently attentive to establishing one or more of the conditions of salience (Snow & Corrigan Brown 2005). Such framing problems or vulnerabilities indicate that affecting resonance is a precarious enterprise and ongoing challenge.

The generation and modification of collective action frames occur primarily through the *discursive processes* of frame articulation and elaboration. Frame articulation involves the discursive connection and coordination of events, experiences, and strands of one or more ideologies so that they hang together in a relatively integrated and meaningful fashion. Frame elaboration involves accenting and highlighting some events, issues, and beliefs or ideas more than others, such that they become more salient in an array of movement relevant issues (Snow 2004). Historically renowned movement leaders, such as Gandhi and Martin Luther King, Jr., were masters at frame articulation and elaboration. Gandhi’s principles of *satyagraha* and *ahimsa* were based, in part, on his articulation of beliefs derived from Hinduism, Buddhism, and Christianity, and Martin Luther King’s potent civil rights frame derived, in part, from his articulation and elaboration of strands of Christianity, democratic theory, and Gandhi’s philosophy of non violence.

The processes of frame articulation and elaboration occur during the course of conversations, meetings, and written communications among movement leaders and members within broader enveloping cultural and structural contexts variously called *discursive fields* (Steinberg 1999) or discursive opportunity structures (Ferree et al. 2002). Discursive fields evolve during the course of debate about contested issues and events, and encompass cultural materials (e.g., beliefs, values, ideologies,

myths) of potential relevance and various sets of actors (e.g., targeted authorities, social control agents, countermovements, media) whose interests are aligned, albeit differently, with the contested issues or events, and who thus have a stake in what is done or not done about those events and issues. The discursive processes of frame articulation and elaboration draw selectively upon these cultural materials and are conducted in relation to the various sets of actors that constitute the discursive field. This suggests that the development of collective action frames is facilitated and/or constrained by the cultural and structural elements of the discursive field, further suggesting that collective action frames constitute innovative articulations and elaborations of existing ideologies or sets of beliefs and ideas, and thus function as extensions or antidotes of them. From this vantage point, social movements are viewed not as carriers of preconfigured, tightly coupled beliefs and meanings, traditionally conceptualized as ideologies, but as signifying agents actively engaged in the production and maintenance of meanings that are intended to mobilize adherents and constituents, garner bystander support, and demobilize antagonists.

Although the connection between framing and social movements has generated considerable theorization and empirical research, there are a number of issues that have not been adequately addressed. One cluster concerns issues specific to framing processes and their consequences. Much research has identified movement specific collective action frames, but comparatively little research has examined systematically the discursive processes through which frames evolve, develop, and change. The conceptual cluster of frame articulation and elaboration and the theorized discussion of the discursive fields in which these processes are embedded provide the conceptual edifice for research on frame discursive processes, but to date the actual occurrence of systematic research on framing processes (see Gamson 1992; Ferree et al. 2002; Snow 2004) has not kept pace with the calls for such research (Steinberg 1999; Johnston 2002; Snow 2004). A second cluster of issues that has not been sufficiently explored concerns the relationship between collective action frames and framing processes and relevant cultural and social psychological factors

such as narrative, ideology, collective identity, and emotion. Clearly, these are overlapping concepts that interact in ways not yet fully understood.

And last, our understanding of social movements will be advanced if more attention is devoted, both theoretically and empirically, to how framing intersects with the issues and processes examined via the theoretical lens of resource mobilization, political opportunity, and cultural perspectives. These perspectives should be seen not so much as competing but as shedding light on different aspects of the character and dynamics of social movements. The framing perspective emerged not as an alternative to other perspectives on social movements, but to investigate and illuminate what these other perspectives glossed over, namely, the matter of the production of mobilizing and countermobilizing meanings and ideas.

franchise

David B. Bills

Franchising is a business arrangement in which a parent company contracts with one or more smaller firms to grant or sell to them the right to distribute its products, implement its processes, or use its trade name. The recent development of franchising in the US and elsewhere is characterized by steady to rapid growth in the number of franchised establishments, their increased levels of employment and sales, and their proliferation beyond the restaurant and retailing sectors in which they have been historically most prevalent into virtually all areas of post industrial economies.

The relationship between franchisors and franchisees is based on a contract that specifies the legal responsibilities and mutual expectations of each party to the contract. Still, the fact that the franchise relationship is so nearly an exclusive one means that the franchisors and franchisees share many common interests. Franchisors acquire a generally reliable means to expand their businesses, while franchisees acquire a measure of independence, sense of ownership, and reduced risk. Franchising permits the exploitation of efficiencies from scale economies. It allows the establishments of a parent company to share the overhead costs of such factors as marketing, advertising, and monitoring. These costs are often prohibitively expensive for a free standing establishment. About 80 percent of the time, the franchisee buys the business or a share of the business, but often the parent company retains ownership. This pattern varies a great deal across industries.

There are two principal types of franchising: product franchising and business format franchising. The US Department of Commerce defines product and trade name franchising as “an independent sales relationship between supplier and dealer in which the dealer acquired some of the identity of the supplier.” It defines business format franchising as “an ongoing business relationship between franchisor and franchisee that includes not only the product, service, and trademark, but the entire business concept itself – a marketing strategy and plan, operating manuals and standards, quality control, and a continuing process of assistance and guidance.” Product franchising (such as beverage bottling) is older and larger in sales value in the US than business format franchising, although the share of franchise sales in the product franchising sector is declining. Business format franchising, the most common kinds of which are quick service restaurants, lodging, retail food, and table/full service restaurants, is, however, more widespread than product distribution franchising, producing about four times as many establishments and jobs.

The roughly three quarters of a million franchised businesses in the US generated about \$1.5 trillion in sales in 2004. This figure represents about 10 percent of the national product of the US. Franchising’s share of total sales is

much higher in some industries. For example, franchises generate more than a third of retail sales. About 9 million Americans are directly employed in franchises, and about that many more work in jobs generated in some way by the franchise sector.

Frazier, E. Franklin (1894–1962)

Mary Jo Deegan

Groundbreaking scholar on the African American family, social classes, youth, and community, Edward Franklin Frazier was born on September 24, 1894 in Baltimore, Maryland. He was the son of a former slave, Mary Clark, and James Edward Frazier. His father died when he was 10 years old, and his mother and three siblings worked together to survive this familial and financial loss.

Frazier graduated *cum laude* with an A.B. from Howard University (1916), and in 1920 he completed his master's degree in sociology from Clark University in Worcester, Massachusetts. After training at the New York School of Social Work (1920–1), he accepted a fellowship (1921–2) to study Danish folk high schools. He then taught sociology at Morehouse College in Atlanta, Georgia, and directed the Atlanta University School of Social Work. After Frazier published "The Pathology of Race Prejudice" (1927) in *Forum*, a controversy ensued and he was forced to leave Morehouse.

Frazier next received a fellowship from the University of Chicago where he earned his PhD under Ernest W. Burgess. The publication of his dissertation, *The Negro Family in Chicago* (1932), brought him to the forefront of scholarship on the black family. He taught at Fisk University from 1929 until 1934 under the supervision of Charles S. Johnson. Frazier and Johnson agreed neither politically nor personally and Frazier was relieved to move to Howard University, where he worked from 1934 to 1951. In 1948 he became the first African American elected as the president of the American Sociological Association.

In 1939, he published *The Negro Family in the United States*. It immediately generated fierce debate about the significance of illegitimate births, single parents, female headed households, neglected children, social disorganization, family pathology, and matriarchal and patriarchal issues in black families. The book was forgotten by the general public until Daniel Patrick Moynihan, in his 1965 policy paper *The Negro Family: The Case for National Action*, used it to assert that the black family was at the root of the "tangle of pathology" in African American urban communities. This highly criticized report brought Frazier's work into contemporary debates.

He published another provocative book, *Black Bourgeoisie*, in 1955. Here he criticized the color line within the black community and its leaders' failure to take more political and courageous stances on racial issues. Many African American leaders and Marxists debated its findings. Despite these criticisms, *Black Bourgeoisie* forced many black college students of the 1950s and 1960s to reexamine their upwardly mobile goals and responsibilities to the community. Frazier trained many black students at Howard University who became leaders and civil rights activists, including Stokely Carmichael (who later became Kwame Toure).

Frazier directed the Division of Applied Social Sciences UNESCO (1951–3), where he analyzed interactions between different races and the effect of these interactions on communities.

Frazier died on May 17, 1962 in Washington, DC as the modern Civil Rights Movement was beginning to fundamentally change American life and laws.

Freud, Sigmund (1856–1930)

Steve Dorné

Sigmund Freud's pioneering focus on unconscious motives arising from infant experiences offers a distinctive approach to understanding human motives. His focus on how the super ego internalizes societal demands offered a way of understanding how social norms affect individuals. His approach has had an enduring influence in sociology, shaping important research especially in gender, family, and religion.

Freud was born to a middle class Jewish family in Moravia. Freud, who had two half brothers from his father's previous marriage, was the favored first son of his mother, to whom he was strongly attracted. Freud recalled strong jealousies toward his younger brothers and contempt for his father, who was two decades older than his mother and whom Freud perceived to be intellectually weak and unable to confront anti-Semitism. Freud spent most of his life in Vienna, where his family moved when he was four. After studying medicine, philosophy, and science at university, he worked as a physician studying neurology. In the late nineteenth century he rejected the medical emphasis on chemical imbalances as the cause of hysteria, focusing instead on how mental processes cause physical problems. For the rest of his life, he used his psychoanalytic work with patients to develop a theory of the mind that is his lasting contribution.

Freud emphasized that the motives that impel action are unconscious. Behind every sociological theory rests some understanding of human motives. Symbolic interactionists focus on how meanings drive action; rational choice theorists focus on individuals' conscious weighing of costs and benefits; and ethnomethodologists see action as driven by habit and taken for granted knowledge. Freud insisted, based on his psychoanalytic work with his patients, that unconscious motives drive human action. He discovered the unconscious through his analysis of dreams, mental illness, jokes, and slips of the tongue. His psychoanalytic work suggested that unconscious desires arise from childhood relations with parents. For Freud, the self so represses infantile and childhood desires that they cannot enter the self's consciousness. Yet they nonetheless drive adults' actions.

Freud's account of psychic structure recognizes how cultural norms root themselves in the human psyche. For Freud, the "id" or "it" represents the unconscious drives that demand satisfaction. The psychic structure's "super ego" or "over I" represents the internalization of cultural norms espoused by parents. The super ego is an ego ideal in which part of the psyche (unconsciously) takes on the parents' admonishing role, punishing other parts of the self. For Freud, the "ego" is the "I" which mediates between the demands of id, super ego, and external reality. One of Freud's fundamental contributions to sociology is the recognition that the psyche itself internalizes social demands. The super ego, he says, is the "special agency" in which "parental influence is prolonged." (Freud 1969: 3).

Freud applied his psychoanalytic insights to understanding social phenomena. In considering religion, he argued that "in all believers . . . the motives impelling them to religious practices are unknown or are replaced in consciousness by others which are advanced in their stead" (Freud 1963: 22). For Freud, it is the "infant's helplessness and the longing for the father aroused by it" that is the ultimate source of "religious needs" (p. 19). This focus on unconscious motives that derive from childhood experience is Freud's fundamental contribution to sociology, which continues to have influence in fields as diverse as the sociology of

religion, the sociology of gender, and the sociology of family.

friendship during the later years

Rebecca G. Adams

Gerontologists were responsible for much of the early scholarship on adult friendship and continue to focus more attention on it than other researchers do. This is probably due to their historical preoccupation with theoretical questions regarding older adults' social integration, engagement, and psychological well being. Friends are, however, important during later adulthood in many other ways as well, serving as sources of affection and social support and contributing to physical health and even to longevity.

Early studies of older adult friendship tended to focus on the effects of quantity of social contact, but more recent ones focus more on predictors of friendship patterns, including their dyadic and network processes and structural characteristics. Also in contrast to the early research on older adult friendship, more

recent research focuses on its negative aspects as well as on its positive aspects.

Many of the original studies of older adult friendship were either ethnographies or surveys of small samples of older adults. Contemporary researchers now commonly compare the friendships of adults of various ages and sometimes examine friendship patterns longitudinally. Knowledge of why friendship patterns change over time is still limited, however, because researchers often use the variable "age" as a proxy measure for stage of life course and developmental maturity without distinguishing between these two aspects of aging. Furthermore, researchers have not yet conducted large longitudinal studies of the friendship patterns of multiple cohorts.

For many years, gerontologists accepted the folk wisdom that as people age, their number of friends decreases. Recent research, however, suggests that friendship circles increase or decrease depending on the characteristics of the older adults and the contexts in which they live. In some cases, the role changes that people undergo can create further constraints, and in other cases, they can be liberating. For example, men tend to have more friends than women during midlife, but older women tend to have more friends than older men and this gap continues to increase as people age. Researchers have offered various explanations for this reversal in the gender difference in size of friendship network, including men's retirement from the labor force coupled with women's reduction in domestic responsibilities. Also compelling is the argument that because of differences in the types of activities that men and women engage in with friends (i.e., women talk and men participate in physical activities together), women are more likely than men to be able to continue to meet their obligations as friends.

As during other stages of the life course, older adults tend to have friendships with people who are similar to them in terms of sex and age. Older men's friendship networks tend to be less sex homogeneous than women's, a midlife gender difference that persists into old age and is also exacerbated by the differential survival rates of men and women. In other words, there are fewer older men available as friends due to men's shorter life spans. The studies of the age homogeneity of older adult friendships

are not conclusive, but suggest that if there are gender differences, women are more likely than men to continue to have friendship networks high in age homogeneity at older ages, possibly for the same reasons that women have more friends in old age and a higher proportion of same sex friends.

Although research on older adult friendships continues to be more common than research on the friendships of adults at earlier stages of life, even it is becoming less common than in the past. This may be in part because of changes in federal government funding priorities (i.e., less interest in social support) or because many of the original questions that inspired researchers seem to have been adequately answered. Nonetheless, theoretical challenges still remain for gerontologists interested in the friendships of older adults. For example, most of the studies of older adult friendship have been conducted on primarily middle class Caucasian populations residing in North America. Although a great deal is known about gender differences in older adult friendships, virtually nothing is known about class discrepancies or racial and ethnic variations, let alone about how less commonly studied variables such as sexual orientation affect social life in old age. Furthermore, due to the lack of studies conducted outside the US and Canada, little is known about how structural and cultural context affects older adult friendship patterns. Even more broadly, scholars need to consider the implications for older adult friendship patterns of characteristics of this period of history such as the culture of individualism, the privatization of social life, and the development of communications and transportation technologies.

friendship: interpersonal aspects

William K. Rawlins

Friendship refers to a broad category of positively disposed interpersonal relationships characterized by varying degrees of equality, mutual good will, affection and/or assistance. People employ the word *friend* to describe a recent acquaintance, a longtime co worker, a family member, a romantic partner, or an irreplaceable individual they have known for years. Friendship also complements, fuses with, competes with, or substitutes for other personal and social relationships. For example, friendship can complement the professional relationship of two co workers, but compete with the demands of a superior/subordinate relationship. Friendship can fuse so completely with spousal or sibling relationships that it is difficult to identify whether persons are acting as spouses or siblings or as friends. Finally, without close kin, friends may substitute for one's family. The range of uses of the word friendship in North American culture finds

summary definitions altered according to social circumstances. Across situations, however, friendship typically invokes benign connotations and social ideals of shared good will, pleasure, assistance, and moral comportment dating back to Aristotle's treatment of the topic.

Five characteristics defining dyadic friendship – voluntary, personal, equal, mutual, and affective – occur to differing degrees in particular relationships. First, friendship is *voluntary*. While social structural factors place people in the functional proximity necessary for friendships to develop, individual persons choose to treat each other as friends. The manner and degree to which they actually act as friends is both voluntary and negotiated. This voluntary attribute of friendship contrasts with blood ties to kin that persist regardless of personal choice. Similarly, marital bonds are sanctioned legally and religiously. Persons cannot simply drift away from a spouse, as occurs with friends; legal measures like divorce and sometimes religious procedures are necessary to end a marriage. Economic contracts and external obligations regulate work relationships and partnerships instead of the volition of the parties involved. In contrast to relationships continued primarily through their connections to the social structure, persons actively communicate in mutually expected ways to sustain their friendship.

Second, friendship is *personal*. Friends are regarded as particular individuals rather than occupants of roles or members of categories. Suttles (1970) referred to the “person qua person” orientation of friendship. Third, friendship is *equal*. Friendship functions as a leveler despite personal attributes and social statuses that create hierarchical relationships. Friends search for ways to speak and treat each other as equals. Fourth, friendship is *mutual*. Over time it requires fairly symmetrical inputs into the relationship and to each other's welfare. Fifth, friendship is *affective*. The affections of friendship range from a positive concern for the other's well being to a heartfelt liking and even love for friends. While friends may feel profound love for each other, the love of friendship is usually distinguished from sexual or romantic loving, with their overtones of possessiveness and exclusivity. Sexual or romantic

relationships, however, may also include or aspire to the attributes of friendship.

Through the late 1970s only scattered social scientific attention was devoted to friendship. Much work addressed friendship in the context of social attraction studies, emphasizing personality variables or residential propinquity. Friendship also appeared as a residual category of social participation in demographic and sociometric studies, contrasting friendships (often implied by the questionnaire choice, “other”) with family and work relationships. Two developments expanded these conceptions. First, scholars in a variety of disciplines began examining the unique character of friendship. Moreover, various thinkers voiced the need for a more developmental perspective on the emergence, maintenance, and decline of interpersonal relationships. This view assumes that what brings people together may not keep them together. Static conceptions of relationships say little about what makes friendships “work” or why their continued interaction holds mutual significance for them. Other scholars emphasized that the dyadic development of friendships interacted with constraints and opportunities of different periods in the life course. Overall, limited findings or integrated theory existed regarding the interpersonal communication involved in forming, maintaining, and dissolving friendships across life.

Subsequent work identified four interactional tensions that shape and reflect the interpersonal challenges facing friends throughout life. The tension between the freedom to be independent and the freedom to be dependent describes the patterns of availability and obligation characterizing the voluntaristic basis of friendships. Sustaining friendships requires reconciling the autonomy and interdependence of self and other within specific relationships, as well as the demands that friends make upon each other within embracing social configurations. The tension between affection and instrumentality describes the concerns arising between caring for a friend as an end in itself or as a means to an end. All friends rely on each other for a range of emotional and practical assistance. Different meanings of friendship are implied when persons feel befriended primarily for their utilitarian assistance than in relationships where those capabilities are

incidental or stem from a more fundamental mutual regard.

The tension between judgment and acceptance involves the recurring dilemmas in friendship between providing objective appraisals of a friend's activities versus unconditional support. People expect acceptance and encouragement from their friends, but also look to them for tough truths and wise counsel. A compassionately objective reaction combining evaluation and support is often viewed as constructive criticism. While reliance on a friend's opinions is a valued aspect of friendship, friends may tolerate detrimental tendencies or interpret vices as virtues. In doing so, friends may create private cultures that undermine the larger community or the common good. Criticizing or accepting friends constitutes a moral presence in social life.

Finally, the tension between expressiveness and protectiveness addresses the contrasting tendencies to speak candidly with a friend and relate private thoughts and feelings, and the simultaneous need to restrain one's disclosures to preserve privacy and avoid burdening one's friend. Throughout life people consider the ability to confide as a privilege distinguishing their closest friendships. Personal vulnerability arises from revealing sensitive information, and the responsibilities imposed on others not to misuse intimate knowledge of self make confidence and trust problematic achievements. Trust develops to the extent that friends manage the tension between expressiveness and protectiveness. Each person must limit his or her own vulnerability and strive to protect the friend's sensitivities while expressing personally crucial thoughts and feelings.

Although scholars disagree about the precise nature and extent of the differences, there are gender linked patterns of friendship's benefits and tensions across the life course. Some argue that the emotionally involved and interdependent friendships modally associated with females are more fulfilling than the activity based and independent ones modally associated with males. Others argue that these patterns describe qualitatively different forms of friendship that may result in equivalent satisfaction for the parties involved. Second, specific friendships involving members of either gender may

deviate considerably from the norms and modal patterns discussed here. Depending on their particular friendship practices and social circumstances, women's friendships may resemble the modal patterns associated with men and vice versa. Third, the contrasts lessen in women's and men's closer friendships as friendships of both genders approach the practices and ideals of the communal friendships modally associated with females. Fourth, these patterns are based on social scientific research primarily addressing white, North American, middle class participants. Until recently, Robert Brain's *Friends and Lovers* (1976) presented one of the few surveys of cross cultural and ethnic variations of friendship.

Women friends tend to interweave their lives and value interdependence in confronting the tension between the freedoms to be independent and dependent. Men do not like to feel dependent upon their friends, expecting and enacting more independence in their friendships. Relatedly, women experience cross pressures between affection and instrumentality in their friendships. Women describe themselves as more affectionate and report more emotional involvement with their friends than men do. Juggling multiple household, professional, and recreational activities, women place high demands on each other for instrumental help. The persistent requirements of caring and mutual reliance can be a source of strain in women's friendships. In contrast, men's friendships seem less emotionally charged in these areas. They do not demonstrate affection for each other in the ways and to the degree that women do. But they do offer and receive instrumental assistance with various projects, while striving to maintain their independence through reciprocity. Readiness to help without excessive sentiment is a feature of many men's friendships.

Women's friendships are energized by the potentially volatile interplay between judgment and acceptance. Because women care about and expect so much of their friends, they are more inclined to communicate their evaluations when friends disappoint them. By comparison, men seem less concerned about and more accepting of their friends' behaviors. Finally, women tend to be more expressive with their friends and to

discuss and trust each other with confidences. Seemingly less willing to make themselves vulnerable or burden their friends with personal concerns and doubts, men are more reserved and protective with their friends.

Other consistent findings complement this discussion of life course patterns, gender, and friendship. Females repeatedly rate their same sex friendships higher than their friendships with males. In contrast, males typically value their cross sex friendships more than their same sex friendships. Most married men report that their wife is their best friend. While many married women view their husbands as a good friend, they have a woman friend whom they consider as close or closer. Studies indicate that in later life women have more friends, a greater variety of friends, and closer friends than men. Finally, depending on their wives for close friendship in later life, many men retreat from wider participation or initiatives in making new friends.

People pursue varying degrees of closeness in their friendships. Some individuals prefer a limited number of exclusive relationships, carefully chosen, deeply validating, and precious. Others prefer easy going but superficial connections with many people, readily making and relinquishing such friends. Still other persons pursue a combination of these involvements with others. It is unclear whether a specific style of friendship better facilitates emotional well being. Later adults, for example, differ in their preference for multiple companions versus select, intimate friends. It may be that persons become accustomed to a style of friendship that best suits their emotional needs.

Several contemporary areas of inquiry about friendships are emerging. Returning to Aristotelian conceptions, scholars are examining the ways in which friendship facilitates moral growth and can lead persons astray during childhood and throughout life. What are friendships' contributions to the moral quality of our lives? The capacity of dyadic friendships to open outward and provide a basis for community development and meaningful political participation is being examined. How does communication function in initiating, sustaining, and ultimately leaving friendships? How voluntaristic are friendships versus their emergence

primarily as byproducts of social structure? There are increasing investigations of friendships spanning and enriched by differences of religion, ethnicity, socioeconomic status, race, age, gender, and sexual orientation. Scholars are probing the value and nature of friendship in educational and work settings, and the interplay among friendship, romantic relationships, and marriage. The comparative value of intimate friends versus companions for relieving loneliness and serving life satisfaction is an important concern for gerontologists. Finally, how do narratives of friendship shape our life expectations and experiences of self, relationships, and society?

friendship, social inequality, and social change

Graham Allan

While friendship evokes a good deal of interest in popular culture, there has until quite recently been little interest in it among social scientists. Sociologists in particular have failed to pay much heed to friendship, apparently accepting a conventional view that it represents an individual, and consequently idiosyncratic, relationship rather than one structured by social organization or having much social (as distinct from personal) consequence. Recently, though, this has begun to change, partly as a result of the rise of "the personal" in interpretations of the changes that are occurring in what has been termed late or postmodernity. In particular, changes in the demographic patterning of marriage and partnership, including the rising incidence of cohabitation, gay partnerships, and divorce, have led to sociologists showing increased interest in the ways informal ties of friendship are socially constructed and the part they play within contemporary social formations.

FRIENDSHIP AND INEQUALITY

Until the 1980s, a sociological concern with friendship was most evident in community studies. The focus of these studies on the character of local social relationships meant that often they paid heed to the extent and patterning of informal ties of sociability. While the information they contained was generally very limited, they served to highlight the social differentiations that were evident in the informal solidarities that developed. In particular, studies concerned with status divisions often drew on patterns of informal association to illustrate the boundaries constructed by and around different status groups. There was also evidence in this literature that the ways people organized their informal relationships varied depending on their material and social circumstances. This

was important because it indicated that friendships and other ties of informal sociability were not free floating, individually ordered relationships, despite the popular ideologies surrounding them. Instead, they were relationships which built upon other aspects of people's lifestyles and consequently reflected their social and economic identities.

Middle class friendships were found to be relatively free ranging, with friendships being enacted in different settings. Working class sociability, on the other hand, seemed to be more constrained, with non kin ties often restricted to particular social contexts and understood as consequent on interaction in those settings. Allan (1998) argued that this pattern of sociability was a way of sustaining balance in relationships in circumstances of poverty and economic shortage. Other researchers emphasized other social divisions, with gender differences in friendship in particular becoming a topic of significant debate within sociology (O'Connor 1992). Numerous studies suggested that men's friendships tended to be more instrumental than women's, with women's being more expressive. This was generally related to theories of gender socialization, as well as to the idea that women acted as relationship "experts" in many settings, including the home. The friendship experiences of older people were also a significant topic of sociological interest, partly driven by social concerns over the dangers of isolation in later life. In contrast to aging and gender, the relative absence of sociological studies of ethnicity and friendship is noticeable.

Cultural understandings of friendship are generally premised on the notion that it is a relationship of equality. This has a number of dimensions. First, the organization of friendship is one in which hierarchy, in terms of authority or power, is typically understood to play no part. Within the relationship itself, friends normally perceive each other as being of equal standing, even if there is difference recognized in personality and temperament. Second, friendship is normally understood to be equal in terms of the typical exchanges that take place. It is, in other words, a reciprocal relationship. While there may be short term imbalances, in the mid term efforts are generally made to ensure that neither friend can be

seen to be "taking advantage" of the other. Indeed, if there is an inappropriate lack of reciprocity, the friendship is liable to end, either through conflict or more gradual withdrawal. Third, friendship is generally equal in terms of the social and economic characteristics of those who are friends. While not inevitable, there is a marked tendency for friendships to be characterized by "status homophily." In other words, those who are friends are usually of a similar age, have equivalent occupations, are in the same life course position, and share other similar structural characteristics with one another.

At one level the reasons for this are obvious. Not only are those who meet in sociable arenas likely to be broadly similar to one another, but also friendship is, by definition, a tie between people who share interests and feel a degree of liking and compatibility for each other. These factors alone are likely to result in friends occupying similar social locations to one another. However, the reciprocity characteristic of friendship is equally important in these processes. In particular, reciprocity is far easier to manage when the resources and commitments of the friends are broadly similar. For example, if one of the friends has more money or more time available for leisure activities than the other, keeping the friendship balanced is likely to become that much more difficult.

Friends are also important in consolidating our identities. They do this through shared activities and conversations and by acting as a resource for helping with whatever mundane or exceptional contingencies we face. Typically, we see such talk and activity with friends as expressions of our individuality; these interactions are based on our personal rather than our social characteristics. Yet much of our talk and many of the contingencies we face emanate from the social positions we hold (i.e., our structural location). In other words, friendship interactions confirm our individuality, yet that confirmation is generally built upon, rather than distanced from, the role positions we occupy (Jerome 1984). Consequently, through their content, friendships build on and confirm the significance of those very identities from which they appear to be independent. These processes of identity confirmation involved in friendship are themselves reciprocal. In other words, the friends each tend to confirm the

identity of the other through their interactions. Thus, the more similar the friends in terms of their social location, the more likely they are to share common experiences and the more readily they can appreciate the issues, dilemmas, and contingencies the other faces. Conversely, the further apart they are structurally, the more problematic such shared, taken for granted understandings become.

CHANGES IN FRIENDSHIP

If existing friends do come to occupy different social locations, this often results in their friendship waning. Despite ideologies of friendship that suggest that "real" or "true" friends are lifelong, the reality of most friendships is that they do change over time. At particular periods in life, some friendships will be more active, but, as circumstances change, they are liable to become less central. Other friendships will become more active, and in this sense take their place. In general, this is an unremarkable feature of the routine organization of friendship. However, it becomes more noticeable at times of significant change in people's lives, in line with the arguments above about friendship "homophily." When, for example, people divorce, there is often a shift in their friendship networks (Terhell et al. 2004). Typically, they begin to interact less with some of their previous friends, especially those who continue to be partnered, and instead gradually spend more with others who are also separated. A major reason for this is the difficulty of sustaining reciprocity within these previous friendships, given the material and social differences that now exist. Moreover, having faced the consequences of divorce themselves, the newer friends are better able to understand and facilitate the adjustments required to being newly "single." In the process these friendships help to consolidate the new identity of "divorced" in the ways discussed above.

While individual friendships change, so too the ways in which friendships are patterned varies over time. In his important article, Silver (1990) argues that the possibility of friendship as it is now understood arose as a consequence of the development of commercial society in the eighteenth and nineteenth centuries. Unlike

previous societies, this generated a legislative and normative culture in which trust could develop outside of kin ties. Other researchers have shown how the social and economic circumstances which characterize a society – or a particular segment of that society – shape the forms of friendship which develop. Oliker (1998) provides a good example of this in her discussion of nineteenth century women's friendship patterns in the US. Recent socioeconomic changes have also had an impact on the general organization of friendship networks. In particular, the declining significance of locality in people's lives, new patterns of mobility, the growth of individualization, and shifts in the permanency of relational commitment have all fostered a greater diversity in personal networks.

This is an issue discussed at length by Pescosolido and Rubin (2000). They argue that in late modernity a "spoke" model of personal networks is tending to replace the more densely configured networks that were common previously. In other words, rather than networks in which many of those involved also know one another, now it is somewhat more common for networks to comprise relatively discrete, non overlapping clusters of others. This is very much in line with other theorizing about late modernity, in particular Giddens's (1991) arguments about the greater freedom people have to generate different lifestyles. This pattern of network configuration is likely to facilitate the types of process discussed above through which people establish new identities as their circumstances alter. In particular, it makes it easier for them to shift the extent to which different friendships are prioritized. Equally though, it makes it possible for individuals to emphasize different elements of the self in different contexts (Allan 2001). A classic illustration of this arises when gay/lesbian identities are revealed to some people in the personal networks, but not to others (Weeks et al. 2001).

Friendship has not been a topic that has been researched widely by sociologists, though, influenced by ideas of social capital, there is an increasing recognition of its importance in influencing people's well being. There is also a growing recognition that friendship as a form of relationship is becoming more central within social organization, partly as a consequence of contemporary changes in family solidarities and

household composition. This has led to an interest in the patterning of personal networks and the different contributions friends and kin make in people's lives. However, despite this increased interest, our knowledge of friendship remains quite limited. Specifically, there is a need for more studies of friendship involvement for those in midlife, including the ways couples manage joint and individual friendships. There are studies of friendship in childhood, youth, and old age, but fewer of intermediary periods. We also need to have more longitudinal studies. As noted above, we know that friendships change over time in both content and personnel, but there is a need for far more detailed information about the ways in which this happens. Finally, there is also a need for rather more detail of the ways in which friendships are drawn upon and used. This calls for a diversification of research methods. It would be particularly useful to have more qualitative and ethnographic studies of friendship that allowed researchers to understand better the dynamics of friendship.

friendship: structure and context

Rebecca G. Adams

Although since the days of Aristotle, Cicero, and Plato philosophers have been pondering the qualities of ideal friendship, proposing typologies of categories and functions of friendship, and analyzing the role of friendship in maintaining a stable society, very few sociologists conducted empirical research focused specifically on friendship before the late 1960s (for an exception, see Williams 1959). The friendship literature has thus developed during a scholarly period in which interdisciplinary collaboration has been more common than in the past. Nonetheless, cooperation on friendship research across disciplines has been rare, and while psychologists and communications scholars have mainly studied dyadic processes, sociologists and anthropologists have focused their research on network structure. Much of the early work in both of these traditions focused on individual variations in friendship patterns, but psychologists were concerned with how psychological disposition shaped what happened in friendship dyads, while sociologists were concerned with how social structural location affected friendship network structure. More recently there has been a general concern in the friendship literature about how context shapes relationships (Blieszner &

Adams 1992; Adams & Allan 1998). Sociologists, then, have contributed to the friendship literature by examining how friendships vary according to individuals' locations in the social structure, studying the structural characteristics of friendship networks, and theorizing about how friendships are affected by the contexts in which they are embedded.

EFFECTS OF SOCIAL STRUCTURAL LOCATION ON FRIENDSHIP

Gender is the most frequently studied antecedent of friendship patterns, though researchers do not often specify whether the effects they identify are the result of disposition or social structural location. The most robust finding reported in the literature on gender and friendship is that adult men's friendships tend to be activity based whereas women's friendships are more likely to involve self disclosure, reciprocity, social support, affect, and strong emotions (Adams & Ueno 2006). Given these findings, it is not surprising that compared to women, men tend to put more emphasis on having friends who are similar to themselves, and are therefore more likely to engage in the same activities with their friends and to view friendship as less important as a result of less intense involvement. Researchers have conducted very few studies comparing men's and women's friendships across the life course, so it is not clear how these gender differences change as adults age. It does appear, however, that as men age, they have less contact with their friends than women do, a finding that indicates a reversal of a midlife gender difference. During midlife men have more friends than women, but evidence suggesting that this difference also reverses in later life is not conclusive. Unlike women's friendship networks, the gender diversity of men's friendship networks increases with age and the age homogeneity of them decreases. In combination with men's emphasis on similarity and shared activities, these age shifts may explain why some researchers have reported that friendship becomes less meaningful to men as they age or at least as their health declines and constrains their types of involvement.

In contrast to the large literature on gender and friendship, very few studies focus on the

effects on friendship of race or ethnicity, socioeconomic status, or stage of life course (Ueno & Adams 2006). In surveys of general populations, samples include very small numbers of racial and ethnic minorities, and race or ethnicity is included as a control variable in analyses, if at all. Some studies focus on friendships within specific racial or ethnic groups or treat racial and ethnic homogeneity in friendships as an indicator of segregation. Oddly enough, given how well developed the literature is on class differences in neighboring, the literature on socioeconomic differences in friendship patterns remains undeveloped. Some studies suggest that friendship is more important to the middle class than to the working class and others show that people in different classes value different aspects of friendship (Allan 1989; Walker 1995), but there are many potential class differences in friendship patterns that remain entirely unstudied. Although studies of adult friendships within various age groups continue to be common, studies comparing friendships across stages of the life course remain rare. Even studies that do compare friendships across stages of the life course are usually cross sectional, and thus it is not possible to distinguish life course stage, period, and cohort effects. Furthermore, these studies tend to focus on changes in friendship patterns as people move through the dating, marriage, and parenting phases of the family life course (e.g., Kalmijn 2003), rather than on other life course changes such as in the occupational realm.

STRUCTURAL CHARACTERISTICS OF FRIENDSHIP NETWORKS

Sociologists have studied the structure of friendship networks much less exhaustively than psychologists have studied their internal processes, perhaps because interviewing respondents about their networks is time consuming and therefore expensive or because the network literature tends to focus on social networks in general, without distinguishing family, neighbors, co workers, and friends from each other and from other types of associates. Researchers have conducted fewer studies of friendship network structure during the past decade than during the previous one, though studies of

dyadic friendship processes have become more common during the same time period.

Early friendship researchers often asked respondents how many friends they had (i.e., the size of their friendship network) as one variable to be scaled with other measures of social integration or engagement, but now the focus is often more on the quality of relationships than on their quantity. Many of the studies in which friendship network size is reported are of subgroups of a general population. Even in studies of general populations that include measures of friendship network size, the researchers often fail to report an average or frequencies of responses in each category. It is therefore difficult to answer questions about whether the size of friendship networks varies across subgroups or has changed over time.

Studies of friendship network density (i.e., the percentage of all possible links among friends in a network that do in fact exist) are very rare and their foci vary according to what age group is studied. Research on college student friendship network density focuses on its relationship with conformity and commitment to the larger group. For example, researchers have found that networks of college students who participate in deviant activity are relatively denser than those of students who do not, and that college students in dense networks within larger groups are not as committed to the larger groups as the members of embedded networks which are lower in density. Perhaps the two best known studies of adult network density are Laumann's (1973) analysis of Detroit Area Study data and Fischer's (1982) report on the Northern California Study. Laumann, who only examined density among his respondents' three closest friends, found that 27 percent of them had networks that were completely interlocking (100 percent dense), 42 percent had partially interlocking networks, and the rest had radial networks (0 percent dense). Fischer reported that the average density of the network of associates was 44 percent and that the more kin and the fewer non kin in the network, the denser it was. This suggests that friendship network density, if he had reported it, would have been lower. Research on older adult friendship network density illustrates how age homogeneity of context and physical health can influence friendship network density; studies

demonstrate that nursing home residents have the highest friendship network density, residents of age segregated apartment buildings have the next highest, and residents still living in age integrated communities have the lowest.

Perhaps because philosophers have often defined friendship as a relationship between equals, researchers have almost completely ignored the hierarchical aspects of friend relations. Some recent studies, however, have shown that although the majority of friendships are perceived to be equal, not all of them are. For example, Neff and Harter (2003) reported that only 78 percent of college students' friendships were perceived to be equal. Similarly, Adams and Torr (1998) reported that the older adults they studied described only two thirds of their friendships as equal in terms of power and of status. In other studies, researchers have shown that perceived equality between friends is correlated with greater relational satisfaction, emotional closeness, liking, and self disclosure.

One of the most robust findings regarding friendship network structure is that they tend to be homogeneous (i.e., friends tend to occupy similar social structural positions). Depending on the age group studied, researchers have examined different aspects of homogeneity. They have shown for example that college students tend to have networks homogeneous in term of nationality and race, adults in terms of occupational status, ethnicity, age, marital status, social class, education, gender, and religion, and older adults in terms of gender, race, and marital status (for recent examples, see Walker 1995; Kalmijin 2003). Although sociologists generally posit a structural explanation for these findings (i.e., people have more opportunities to meet those who are similar to themselves than people who are different from them), preferences resulting from socialization may also contribute to the homogeneity of networks.

In most studies that include measures of friendship structure, the structural characteristics of friendship networks are used to predict outcome variables such as psychological well being, occupational success, or educational achievement. Some studies, however, include examinations of the interplay between the internal structure of friendship networks and dyads and the processes that are exchanged

among participants. For example, the commonly reported interaction among gender, gender homogeneity of friendships, and self disclosure illustrates the effect of the internal structure of friendship on its interactive processes. Gender homogeneity in women's friendships facilitates self disclosure and emotional closeness, whereas gender homogeneity in men's friendships constrains self disclosure. Similarly, it is well documented that equality, as a structural characteristic of friendship dyads, facilitates relational satisfaction across age groups (e.g., Neff & Harter 2003). Because equality is also associated with self disclosure, it is possible to argue that equality facilitates open communication. At the same time, however, friends in egalitarian relationships are likely to *expect* each other to share personal information. In this sense, equality may constrain the way friends communicate with each other (i.e., not being able to keep many secrets).

There are a smaller number of studies about how interactive processes in turn sustain and modify friendship structure. Many researchers seem to take for granted that ongoing friendships are sustained through regular contact, but this assumption is rarely demonstrated in empirical studies. Frequency of contact also has an impact on friendship structure beyond the dyadic level. Frequent contact with friends increases the chance that those friends know *each other*. This finding suggests that frequent contact increases the density of friendship networks over time. Similarly, studies of what interactive processes people use to sustain friendships or which ones predict friendship dissolution also illustrate ways in which friendship process affects friendship structure.

CONTEXTUAL EFFECTS ON FRIENDSHIP

During the last two decades or so, the amount of research placing friendship in context has increased. Researchers have studied friendships in a variety of specific contexts, ranging from immediate social environments to societies, and including historical and international settings. For example, Campbell's (1990) study of a 1939 neighborhood in Bloomington, Indiana, casts doubt on the presumption that past

neighborhood friendship networks were significantly more sociable than contemporary ones. Similarly, Adams and Plaut's (2003) study of friendship in Ghana suggested that friendship is not a universal form, but takes different forms in different cultural worlds. These case studies are important because they challenge assumptions and raise questions about whether findings can be generalized.

In spite of an increase in the number of studies of friendships in non North American contexts and of various subgroups within the US and other western countries, sociologists have not conducted many studies comparing friendships across cultures or across subcultures within a larger context. In lieu of such broad studies, researchers could compare findings across more narrowly focused studies and develop hypotheses about how context might affect friendship. This approach would be problematic, however, because survey researchers often neglect to include detailed discussions of contextual characteristics, and ethnographers and historians do not generally include information on individual participants in the settings they study. It is therefore important that future studies are designed to allow for comparisons of friendships across contexts (e.g., comparative international studies, historical trend analyses).

The lack of systematic evidence about how the broader social context affects friendships has not discouraged sociologists from theorizing about it. In the late nineteenth and early twentieth centuries, for example, German scholars such as Weber and Tönnies argued that the importance of friendship had declined with industrialization and urbanization. Social environments were increasingly diverse; therefore, because friendships are likely to form between people who are similar to each other, they were less conducive to friendship formation. Furthermore, because the newly developing bureaucracies hired people based on their qualifications for jobs rather than on their interpersonal connections, people relocated from their communities of origin to pursue careers, and impersonal economic incentives destroyed the love and trust that had previously existed among co workers.

In a series of articles in the 1960s, Litwak (1985) rejected the notion that close relationships and bureaucratic organizations are

incompatible and argued instead that they perform different, but complementary tasks. He pointed out that families, friends, and neighbors are better than bureaucratic employees at accomplishing simple and unpredictable tasks. Because of their personal commitment to each other, they require less supervision; because of their familiarity, they communicate more effectively. Furthermore, he argued that families are best at handling tasks that require long term commitment, neighbors are most useful when accomplishing tasks requiring immediate or face to face interaction, and friends are well suited to handle tasks where similar experiences and values are important, such as helping someone cope with bereavement or make critical decisions. Therefore, he concluded, friendship has not decreased in importance; its function has merely changed.

More recently, scholars have argued that in the process of industrialization and modernization, the more communal social life of the past has been replaced with a concern for the private world of home and family. Whereas in the past, social lives centered on relationships with co workers and neighbors, now improvements in transportation and communications technologies have reduced the importance of local ties. Some scholars have argued that this has led to increased isolation, but others have argued that people are now free to develop a wider variety of friendships (Wellman 2001).

Although sociologists have tended to study how context shapes friendships, a few have discussed how friendship affects society as well. For example, Oliner (1989) described how friendship upholds the institution of marriage. Similarly, O'Connor (1992) argued that friendship reinforces the class structure. In other words, friends teach people what is expected of them and because friends are similar to each other, the result of this process tends to be the preservation of the status quo, not changes to it. Although these authors, like the classic Greek philosophers, argue that friendship contributes to the stability of society, future research will surely also document ways in which friendship contributes to social change.

friendships of adolescence

Robert Crosnoe

Friendships – intimate, ongoing relationships involving shared disclosure, sustained interaction, and strong feelings of connection – play a significant role in the human life course. The significance of these interpersonal relationships is heightened during adolescence, a period of life in which young people are particularly socially oriented and in which their self concepts are especially sensitive to the judgments of others. Consequently, friendships are a major component of adolescent life, in both positive and negative ways.

Within sociology, theory and research on adolescent friendships has traditionally had a distinctly negative tone. For the most part, it has focused on the role of friends and peers (similar others who may or may not be friends) in problem behavior and school disorder during adolescence. This tradition stands in stark contrast to the other discipline that has historically paid attention to adolescent friendships, developmental psychology, which has focused most often on the salient role of such friendships in normative social, emotional, and cognitive development during the early life course.

In fact, sociologists have virtually introduced the concept of "peer pressure," named and known in various ways, to popular culture. This concept has certainly long been central to key theoretical traditions (e.g., Sutherland's differential association theory) in criminological research on young people. In general, this criminological research has documented that association with deviant friendship groups is the strongest correlate of juvenile delinquency and substance use, through both selection and

socialization mechanisms, and a major explanation for social structural and demographic differences (e.g., race, gender) in both behaviors. Likewise, this power of friends to lead adolescents off conventional developmental and social pathways has also played a prominent role in educational research on secondary school contexts and achievement processes. Two of the more prominent examples in this vein are Coleman's famous study of anti adult peer crowds in American high schools and Ogbu's controversial oppositional culture thesis, which targeted negative anti school messages in minority friendship groups as the foundation of race/ethnic gaps in academic achievement during adolescence. These criminological and educational literatures, disparate but related, have both articulated in convincing fashion the crucial role of adolescent friendships in many of the major social problems that have long fascinated sociologists.

Over the last three decades or so, however, the ways in which sociologists have examined adolescent friendships have slowly evolved into a more multidimensional enterprise. While the peer pressure angle is certainly still an important part of sociology, it is now coupled with other perspectives on adolescent friendships. One perspective concerns the positive developmental significance of adolescent friendships, including how they assist in the meeting and mastering of developmental tasks, influence prosocial behavior, reinforce and strengthen the influences of parents, schools, and other adult groups, and serve as resources that can buffer against hardships in other areas of life. Such research has shown that the power adolescent friends have in each other's lives can be a positive force just as often, even more often, than it is a problematic one.

A good deal of empirical and theoretical attention is now also being paid to the contexts of adolescent friendships, including the important questions of how friendships and friendship groups form and what goes on within them. For example, a wealth of qualitative work by ethnographers like the Adlers and others has generated great insight into peer cultures in childhood and adolescence. Such sociocultural research has illuminated the ways in which young people come together to construct micro contexts of culture, often by reworking

inputs from adult society, and the mechanisms by which such micro contexts shape individual behavior in positive and negative ways. As another example, a good deal of educational research has revealed that one of the most significant influences that schools have on the developmental and behavioral outcomes of their students is their power to organize and shape the friendship associations to which young people are exposed. This phenomenon is clearly delineated in research by Hallinan and colleagues on the effects of tracking and curriculum on friendship formation as well as in investigations of the link between school racial composition and interracial friendships (see Joyner & Kao 2000; Moody 2001). Finally, the study of social networks has long been a major part of sociology and, in recent years, it has been leveraged to vastly improve our understanding of adolescent friendships with in depth investigations of the characteristics of adolescent peer networks, the connection between these network characteristics and larger social contexts (e.g., the school, community), and the developmental significance of location and position in different types of peer networks (see Frank 1998; Haynie 2001).

In these and other forms, the study of adolescent friendships is likely to be a "growth industry" in sociology; as the size of the adolescent population continues to grow, prominent developmental theories (e.g., human ecology) emphasize the connections of friendship groups with other contexts of youth development, nationally representative samples of adolescents (e.g., National Longitudinal Study of Adolescent Health) provide data to the public for investigation of adolescent issues, and adult research increasingly recognizes the importance of adolescent experiences as foundations for the adult life course. These trends will likely spur quantitative and qualitative research that locates adolescent friendships in life course processes – as contexts of adolescent development and experience that link adolescence with other stages of life.

friendships of children

Maureen T. Hallinan

A sociological perspective complements the conceptualization of children's friendships provided by other social science disciplines. Psychologists examine individual level traits that affect a child's friendliness and popularity. Researchers in human development consider the role children's friendships play in the transition from early childhood to adolescence. Anthropologists identify cultural factors that influence and give meaning to children's friendships. In contrast, sociologists examine how social organization and social structure affect children's friendships.

The literature on friendship identifies five bases of interpersonal attraction: proximity, similarity, complementarity, social status, and reciprocity. Characteristics of a child's environment affect the way these factors influence friendship formation and stability. Since children spend much of their time in a school setting, most of the sociological research on children's friendships examines how school characteristics affect children's interpersonal relations.

A major influence on students' friendship choices is the organization of students for instruction. Membership in the same grade and assignment to the same class or ability group create opportunities for students to interact. Proximity enables students to recognize similarities and differences while shared activities create new similarities and complementarities. In addition, working together fosters reciprocity. The level of the ability group to which a student is assigned confers academic status on the student, with higher status associated with higher group levels (Hallinan 1979). These factors promote friendship development within ability groups. Several studies show that students assigned to the same ability group are more likely to become friends than those assigned to different groups (Hallinan & Sorensen 1985).

Membership in co curricular and extracurricular activities similarly influences student friendship choices. Participation in the same group allows students to interact, share interests, and work toward a common goal. These shared experiences foster friendship. Ethnographic studies show that there are more friendships within these groups than among students not belonging to the same groups. The studies also show that many of these friendships dissolve when students no longer participate in the same clubs and activities (Hallinan & Williams 1987; Adler et al. 1992).

Membership in the same group has a positive effect on interracial as well as same race friendships (Hallinan & Teixeira 1987). However, status differences complicate interpersonal attraction between students of different racial backgrounds. Research shows that when black and white students belong to the same ability group, white students are more likely than black students to make a cross race friendship

choice. While students in the same ability group have similar academic status, social status differences may act as a barrier to interracial friendship. Participation in non academic groups is more likely to foster interracial friendships since both black and white students tend to excel in these activities. Success enhances social status, making them attractive as friends.

Male-female friendships are rare among children (Adler et al. 1992). Researchers view friendships between boys and girls as a stage in a developmental process that progresses from indifference to hostility to interest and, finally, to friendship or romantic attraction. The same organizational factors that promote same sex and interracial friendships also influence cross gender friendships.

In addition to organizational factors, properties of networks influence the formation and duration of children's friendships. Sociologists have identified asymmetry and intransitivity as major determinants of friendship choice. Studies show that in a dyad, asymmetric friendship choices (A chooses B but B does not choose A) are unstable and tend either to be withdrawn over time or to be reciprocated. Dyads are embedded in triads. Intransitive triads (A chooses B, B chooses C, but A does not choose C) are unstable and members are likely to add or delete a friendship tie to restore balance. Thus asymmetry and intransitivity are sources of change in friendship networks (Hallinan & McFarland 1975). A change in a single relationship has implications for relationships in the larger group. When imbalance in a dyad or triad is removed by the deletion of a friendship tie, the larger social network becomes less cohesive. Adding a friendship choice to remove imbalance increases group cohesion. Since the evolution of a group toward greater cohesion requires a period of asymmetry and intransitivity, these structural forces are critical to the development of cohesive networks.

As children grow older, they form friendship cliques. Depending on the size of the student population, a school or a grade may have one or more cliques, and a student may belong to more than one clique. A map of the social structure of a high school typically shows well defined cliques, dyadic and triadic friendships, and social isolates. The network also may contain students who act as links or bridges

between cliques or between a clique and smaller social units. More linking relationships in a social network increases the cohesion of the network. Bridging relationships also facilitate the communication of information and the development and enforcement of social norms.

A clique forms a normative and comparative reference group for a student. Peers pressure clique members to conform to the group's norms and standards and exert autocratic control over their behavior and reputation. Peer pressure plays a significant role in shaping a student's values. Coleman (1961) referred to the set of norms and values that characterize a student friendship group as a subculture. An adolescent subculture can influence a student's academic achievement, educational aspirations, extra curricular activities, leisure time activities, attitudes toward authority, and career decisions. Lack of congruence between the norms and standards defined by school personnel and those that characterize a student subculture can serve as an obstacle to student academic achievement. Efforts by adults to penetrate the friendship cliques of older youth or to utilize them for academic purposes have had little success.

Recently, sociologists began relying on life course theory to provide a more comprehensive understanding of children's friendships (Crosnoe 2000). Life course theorists view an individual's life as a series of age related roles that a person enacts within a particular context and at a particular point in history. Children's friendships are embedded in a wider time frame than childhood. They are consequences of social, cultural, and historical factors and determinants of future relationships. By linking childhood friendships to adolescent and adult relationships, and by taking contextual and historical factors that influence friendships into account, this perspective highlights childhood friendships as the building blocks of an individual's maturation and adult social behavior.

friendships of gay, lesbian, and bisexual people

Koji Ueno

Many gay, lesbian, and bisexual individuals first become aware of their orientations in adolescence and are forced to decide who should be told and who should not. Many people make their first disclosures to friends, instead of to parents or other family members (Herdt & Boxer 1993). In this sense, friendships play a critical role in the development of their sexual identities. Friends' reactions are mixed; some friendships dissolve while others increase in emotional intimacy (Herdt & Boxer 1993).

Therefore, coming out may create drastic changes in the composition of friendship networks as well as in the quality of friendship dyads.

In general, friendships tend to develop among people who share sociodemographic backgrounds (race, gender, and socioeconomic status), and this tendency already exists in adolescence. Previous studies, however, have produced mixed findings regarding whether adolescent friendships are homogeneous in terms of sexual orientation. Some studies have indicated that gay, lesbian, and bisexual adolescents are well connected with each other, but these studies tended to be based on adolescents who belong to community organizations that specifically serve the needs of these adolescents (e.g., Savin Williams 1990; Herdt & Boxer 1993). In contrast, in the analysis of school-based data across the United States, Ueno (2005) found that a majority of gay, lesbian, and bisexual adolescents do not have school friends who share their sexual orientation and that they are no more likely than straight students to have such friends. Many gay, lesbian, and bisexual adolescents remain closeted to avoid violence and other forms of discrimination. Consequently, they are invisible to each other at school (Smith & Smith 1998). These factors may explain the sparse friendship networks among these adolescents at school.

Friendships among gay, lesbian, and bisexual people seem to be fairly common in adulthood (Ryan & Bradford 1993; Nardi & Sherrod 1994). These dense friendship networks may reflect these men's and women's desire to share unique interests and exchange support with each other, as well as their opportunities to meet each other at community organizations, bars, and social events. These existing friendship networks may also provide opportunities to meet other members of the gay, lesbian, and bisexual community.

Certain gay, lesbian, and bisexual adults are not well connected to these friendship networks, however. For example, Kirkey and Forsyth (2001) documented that gay men's friendship networks are sparse in suburban areas, where gay residents engage in social activities at home and are more integrated into the larger community than they are into the gay community. Also, gay men in prestigious

occupations tend to have fewer gay friends (Weinberg & Williams 1974). The gay, lesbian, and bisexual community is sometimes portrayed as one cohesive group, but there are some subgroups within the community in which members share specific attributes and interests (e.g., leather, ethnic groups) (Peacock et al. 2001). Structural patterns of friendships most likely reflect the presence of these subgroups and indicate clusters within the community.

Behavioral processes (e.g., shared activities and conversations), affective processes (e.g., relational satisfaction), and cognitive processes (e.g., knowledge about friends) are popular topics in the general friendship literature. Although a limited number of studies focus on these processes in friendships among gay, lesbian, and bisexual people, there is some indication that their friendships are characterized by frequent contact and social support exchange as well as high degrees of emotional intimacy (Ryan & Bradford 1993; Nardi & Sherrod 1994).

Sexual activity is an important topic in the literature on straight people's cross sex friendships. It is also a central issue for gay, lesbian, and bisexual people, whose potential pools of friends and romantic partners overlap considerably. Nardi and Sherrod (1994) documented that sexual activity is relevant to both gays and lesbians but in different ways. Gay men tend to engage in sex in the developing phase of friendships, but many discontinue sexual activities in order to create a boundary between friendships and romantic relations. On the other hand, sex with friends is not as common among lesbians, but they tend to maintain close friendships with their previous lovers.

Systematic investigations are necessary to identify unique characteristics of friendships among gay, lesbian, and bisexual people and directly compare their friendships to those of straight people. Previous studies have mostly focused on educated white gay men who are active in the gay community, but future research should include the remaining parts of this population. In addition, previous studies have focused on gay, lesbian, and bisexual people's friendships with each other, but friendships between them and straight people deserve more attention, as they are likely to be distinct from friendships within each group (Fee 2000).

Fromm, Erich (1900–80)

Neil McLaughlin

Although best known as a Freudian revisionist, global public intellectual, and social critic, German born scholar Erich Fromm made important and lasting contributions to twentieth century sociology. Fromm was trained in

sociology at Heidelberg University, receiving his PhD in 1922 under the direction of Alfred Weber, Max Weber's younger brother (Burston 1991). Fromm then joined the psychoanalytic profession, training and entering into therapeutic practice in Berlin and then Frankfurt. He became a core member of the early Frankfurt School network of "critical theorists" in the late 1920s and early 1930s, an influential network of neo Marxist social theorists formed under Max Horkheimer's direction. Moving to the United States in the wake of Nazism, Fromm worked with the critical theorists, as well as the sociological methodologist Paul Lazarsfeld, at Columbia University. The Frankfurt School scholars Max Horkheimer, Theodor Adorno, Herbert Marcuse, and Leo Lowenthal, in particular, created a range of influential ideas in their time in America; they found refuge from political events in Germany with the help of a large amount of money given them by a rich German benefactor and the sponsorship of Columbia University.

After his contentious break with Horkheimer and Adorno in the late 1930s over disagreements concerning issues of psychoanalytic theory, money, intellectual style, and radical politics, Fromm went on to write a number of influential sociological works from the early 1940s until his death in 1980. Although he is not often identified as a sociologist, three major contributions Fromm made to the discipline will be discussed: his analysis of Nazism, his role as an empirical critical theorist, and his contributions as a public sociologist.

THE SOCIOLOGY OF NAZISM

If Fromm had never written another word in his life, the publication of his classic *Escape from Freedom* (1941) would still have assured him a place in the history of sociology. Written before the United States had joined the war against Hitler, *Escape from Freedom* drew on Weberian and Marxist sociological theories in order to develop an explanation of the Nazi movement. Fromm's revision of psychoanalytic theory stressed existentialist insights into the passionate and often destructive search for meaning that motivates human beings. He rejected both a Marxist determinism that suggested Nazism

was a creation of authoritarian German capitalists and a psychological reductionism that put the emphasis on Hitler's psychology and the pathology of a seemingly "mad" political movement.

Fromm's sociological explanation of Nazism was provocative (McLaughlin 1996). The modern world had created both new freedoms and increased anxieties, and the stage had been set for Nazism by both the breakdown of the security provided by feudalism and the political crisis of the 1930s. In Germany, defeat in war and economic depression had destroyed the legitimacy of democratic institutions. Hitler's "evangelism of self annihilation had shown millions of Germans the way out of cultural and economic collapse" (Fromm 1969 [1941]: 259). The Nazi Party's racism, nationalism, militarism, and "spirit of blind obedience to a leader" were an "escape from freedom" (p. 235). The American sociological theorist Robert K. Merton introduced young scholars to *Escape from Freedom* in graduate seminars at Columbia University and the best selling book had wide spread influence throughout the social sciences.

Fromm's book was not without its flaws and limitations. The argument in *Escape from Freedom*, it is clear now, relied far too much on the questionable assumption that the Nazi movement was a lower middle class phenomenon. More generally, subsequent historical comparative research on genocide and far right wing movements has consigned *Escape from Freedom* to its status today as an inspirational if flawed early example of the sociological imagination.

The book, however, helped put the issue of totalitarianism on the scholarly agenda. *Escape from Freedom* had its origins in Fromm's research on the working class in Weimar Germany with the Frankfurt School network, work that was also instrumental in the creation of the theoretical foundation for Adorno et al.'s *The Authoritarian Personality* (1950) (Brunner 1994). This book, written by Fromm's former critical theory colleagues with the help of Berkeley social psychologists, was one of the most influential works of social psychology in the twentieth century. Developed out of an interest in explaining the psychological roots of anti democratic political behavior and anti-Semitism, the authoritarian personality tradition helped social scientists combine theories of the

psychological mechanism that explains the origins of scapegoats in political life with an empirical measure of authoritarianism called the “F” scale. Individuals whose answers to questionnaires score high on the scale developed in *The Authoritarian Personality* tend to express attitudes of reverence and blind obedience to those above them in the social hierarchy, while viewing those below them with contempt and irrational hatred. Fromm’s role in developing the famous if controversial “F” scale was not well known until the publication of the manuscript *The Working Class in Weimar Germany* (1984), a piece of empirical research from the 1920s and 1930s that Fromm had worked on with Paul Lazarsfeld as his assistant (Bonss 1984).

FROMM AS AN EMPIRICAL CRITICAL THEORIST

Although Fromm’s role as an early member of the Horkheimer critical theorists has often been forgotten in the “origin myths” created by the school’s contemporary proponents, Fromm was the most empirical and sociological of all the major “critical theorists” including Marcuse, Adorno, and even Habermas (Jay 1973; Wiggershaus 1986; McLaughlin 1999). Fromm’s *The Sane Society* (1955), in particular, laid out the basic critical theory critique of modern society and had an enormous influence on the new left generation before even Marcuse was widely known among North American activists and radical intellectuals (Bronner 1994). A key part of this story is a contentious debate between Marcuse and Fromm in the radical journal *Dissent* in 1955 and 1956 on the issue of Freudian theory and utopian possibilities within contemporary capitalism (Richert 1986). Marcuse argued that Fromm’s critique of orthodox Freudian theory created a “neo-Freudian” perspective that was intellectually conformist and insufficiently radical since it suggested that some kind of psychological adjustment was possible under what Marcuse saw as the “total alienation” of modern capitalist conditions. Those sympathetic to Fromm’s side of the exchange argue that Marcuse’s radicalism was unrealistic and would not lead to

positive social change. This debate helped make Marcuse’s name at the expense of Fromm on the eve of the publication of *Eros and Civilization* and nearly a decade before *One Dimensional Man* (1964) made Marcuse a guru for the new left generation of the 1960s.

The Fromm–Marcuse debate helps explain why Fromm is seldom linked to the critical theory sociological tradition in our disciplinary histories and theory textbooks despite the historical facts. The orthodoxy within the Frankfurt School tradition has tended to present Fromm as a “conformist” thinker, often uncritically taking Marcuse’s position on this contentious debate (Richert 1986; Bronner 1994). Fromm, however, was probably correct on the major issues at stake in his argument with Marcuse and Adorno regarding Freudian theory, as the recent work of Nancy Chodorow, Jessica Benjamin, and the larger schools of self psychology and object relations suggests. As sociologist Neil Smelser sums up the contemporary consensus, “many elements of Freud’s psychoanalytic theories have been discredited: eros and thanatos, universal dream language, the psychosexual stages of development, the primal horde.” The discredited aspects of Freud’s theory were, it is worth remembering, *precisely* the elements of psychoanalysis that Marcuse was defending and Fromm was criticizing based on his extensive revisionist Freudian training and writing (Roazen 1996). In addition, Fromm’s critical sociology was backed up by far more empirical sociological research than anything else undertaken by the major Frankfurt School scholars, particularly in *Social Character in a Mexican Village* (1970) and the interdisciplinary *The Anatomy of Human Destructiveness* (1973). Nonetheless, by the time the social protest movements of the 1960s were in full gear, Fromm had become settled in his new home of Mexico City and did not have the direct influence on North American political events and intellectual discussions that he had during the 1940s and 1950s. While he remained active in social movements such as the anti nuclear organization SANE (which was named after his book *The Sane Society*), the American socialist party, and American electoral politics, his association with critical theory was, over the years, lost to the collective memory of both the larger society and critical sociologists.

GLOBAL PUBLIC INTELLECTUALS AND PUBLIC SOCIOLOGIES

In addition to his scholarly contributions, Fromm was also an early example of a global public intellectual who did the kind of public sociology that former American Sociological Association president Michael Burawoy argued for in his influential address “For Public Sociology” (2004). Like the young C. Wright Mills whom he influenced through his popular new left oriented books written in the 1940s and 1950s, Fromm wrote clearly for a general audience without the jargon ridden prose that consigns far too much sociology to narrow professional discourse. Essential reading for young radicals for decades in North America as well as throughout Latin America and Western and Eastern Europe, Fromm was a global public intellectual who spread the sociological imagination far beyond traditional scholarly outlets. Although he had once published in the *American Sociological Review*, and a number of his books were reviewed in the leading sociology journals, Fromm was primarily a writer of commercial press books. Fromm’s flair for expressing complex ideas in compelling prose flourished in such books as *The Sane Society* (1955), *The Art of Loving* (1956), and *To Have or To Be* (1976).

Fromm’s influence on what we now call public sociology is also evident when one looks at the ideas and the career of American sociologist David Riesman. The author of *The Lonely Crowd* (1950), the best selling sociology book of all time, Riesman was first a lawyer and then a sociology teacher at the University of Chicago and Harvard University. Fromm had been Riesman’s analyst, and then mentor and friend; the influence of Fromm’s *Escape from Freedom* and *Man for Himself* (1947) can be seen directly in the analysis of “inner” and “other” directed social characters outlined in Riesman’s sociological classic (McLaughlin 2001).

Riesman himself is probably better remembered for his model as a public sociologist than for his professional sociology. But the Fromm–Riesman collaboration has many lessons to offer in thinking about how to combine Burawoy’s professional, policy, public, and critical sociologies in ways that move the discipline forward. If Fromm provides an example

of public sociology with a critical edge, along side C. Wright Mills, Alvin Gouldner, and France Fox Piven, Riesman provides a useful political balance and a scholarly style and liberal philosophical commitment that avoids some of the excessively prophetic tone of some of Fromm’s writings (Maccoby 1995). With this caveat in mind, Erich Fromm remains an important representative of twentieth century public sociology.

FROMM’S SOCIOLOGICAL IMAGINATION

Erich Fromm was not without his critics, of course. His Frankfurt School former colleagues saw him as a simplistic popularizer, and a conformist cultural conservative. Berkeley liberal political theorist John Schaar viewed Fromm as an unrealistic utopian proponent of an “escape from authority” (Schaar 1961). Fromm was also widely attacked by neoconservatives for his opposition to the Vietnam War, American led “modernization,” and the nuclear arms race, and for his radical democratic ideas on education. Allan Bloom’s best selling book *The Closing of the American Mind* (1987) famously made Fromm a key villain in the importation of European ideas that had led to the “Nietzscheanization of the American Left.” Contemporary empirical sociologists will find much in his research and theorizing that does not come up to the high standards the professionalized discipline had developed by the first decade of the twenty first century.

Erich Fromm’s place in the history of sociology, however, seems relatively secure on the creative margins of the discipline. *Escape from Freedom* is likely to be read as an exemplifier of the sociological imagination in the years to come by undergraduates and the general public alike. Critical theory also has a rich if contested future in sociology and Fromm remains an important part of the Frankfurt School tradition despite their nasty squabbles and intellectual differences. Fromm contributed to and shared the basic Frankfurt School critique of the cultural industries, the focus on alienation and subjectivity that the tradition pioneered, and the refusal to accept the normative limits of the instrumental rationality that dominates

purely professional and policy oriented social science. Erich Fromm wrote his works of the sociological imagination in accessible and clearly written prose, an example of the best kind of critical public sociology. Sociology does not “own” Erich Fromm, to be sure, given his important contributions to psychoanalysis and psychology, and his very clear interdisciplinary commitments. Nonetheless, Fromm was an important figure in the history of sociology, and his work continues to be of relevance to the discipline.

function

Robin Stryker

Function has been an important idea within specific sociological paradigms and in sociology more generally. Analyzing the function(s) of social practices has been central ever since Émile Durkheim, in *Division of Labor in Society* (1893), defined function as consequence, and exhorted sociologists to distinguish functions of social phenomena from their causes while examining both. Arguing that the division of labor functions to create social solidarity, Durkheim likened the “organic solidarity” associated with a complex division of labor to functional interdependence among differently specialized organs in the human body.

Examining functions of social practices need not imply viewing society as an interdependent set of differentiated structures functioning together to promote societal maintenance and well being. However, these two ideas intertwined in the post World War II American structural functionalist paradigm. Like Durkheim, structural functionalists examined how social order is maintained and reproduced. More recently, a metatheoretical movement called neofunctionalism tried to retain structural functionalism's core while extending it to address issues of social change and microfoundations (see Ritzer 1992).

Structural functionalism dominated American sociology in the period after World War II. Kingsley Davis, in his 1959 Presidential

address to the American Sociological Association, went so far as to argue that structural functionalism was neither a special theory nor a special method, but synonymous with *all* sociology. Today, Davis's essay remains helpful for understanding structural functionalism's roots in Durkheim, its debts to anthropological functionalists including Radcliffe Brown and Malinowski, and the intellectual and political institutional issues that concerned its proponents and critics.

Ritzer (1992) asserts that Talcott Parsons was the most important structural functionalist theorist and Robert Merton the paradigm's most important explicator. Both proponent and constructive critic, Merton (1968) characterized functionalism as interpreting data about social practices by establishing the consequences of those practices for the larger social structures in which the practices are incorporated. A social practice is any social phenomenon that is "patterned and repetitive," including social roles, norms, structures, and institutions (p. 104). For example, in a still admired analysis, Durkheim (1893) argued that crime has positive functions for society, not because punishment deters crime, but because punishment reaffirms societal norms, reinforcing both solidarity and boundaries of acceptable behavior. For Parsons, all systems, including biological, psychological, social, and cultural, must perform four functions to meet systemic needs. These functions are adaptation (adjusting to the environment), goal attainment (defining and achieving objectives), integration (coordinating and regulating interrelationships among parts), and pattern maintenance or latency (providing or maintaining motivation or cultural patterns sustaining motivation). In social systems, adaptation is primarily associated with the economy, goal attainment with the polity, integration with law and custom, and pattern maintenance with schools, families, and churches.

Although structural functionalists dealt with social change, they were limited to doing so in a particular way. Change is a process of increasingly adaptive evolution in which distinct societal institutions such as occupations, churches, schools, families, legislatures, police, prisons, and courts proliferate and become increasingly differentiated, but also integrated into an orderly whole through common norms.

Neofunctionalists tried to expand this characteristic treatment of social dynamics.

Like Durkheim, Merton reminded sociologists that function is not equivalent to cause, motivation, intent, or purpose. He criticized assumptions of functional unity, universality, and indispensability, made explicitly or implicitly by many structural functionalists. In place of society as a consensual, unified whole, Merton noted that social practices could be functional for some organizations and groups, and dysfunctional for others. Instead of presuming that a social practice with a particular function in one setting was universally associated with that function and thus indispensable, Merton argued that there could be functional alternatives. Even if some function were required for system survival, there likely would be alternative practices that could fulfill this function. Finally, Merton highlighted unintended consequences of social practices. Intended versus unintended consequence is one dimension of Merton's (1968) famous contrast between manifest and latent functions.

Assumptions that Merton criticized figure prominently in Davis and Moore's (1945) well known functional analysis of inequality in occupational rewards. Whereas this essay highlights pitfalls in functional analysis, Stinchcombe's (1985) functional analysis of contributory social insurance exemplifies possibilities of a functionalist approach. Notwithstanding the sensible caution against equating cause and function/consequence, Stinchcombe purposely makes the idea of function key to his causal analysis of how and why government welfare programs developed. Such a functional *causal* explanation is one in which a practice's consequences are essential elements of its cause. Key steps in considering whether it makes sense to hypothesize and test this form of explanation are: (1) finding a social practice with a consequence/function that is maintained in equilibrium notwithstanding specified tension(s) tending to upset the equilibrium; (2) finding that as these tensions rise, the social practice tends to be created or enhanced; and (3) specifying precisely *how* the function/consequence feeds back to create or enhance the social practice (Stinchcombe 1987).

Lewis Coser synthesized functionalism with conflict theory to specify the functions of social

conflict. Similarly, post war neo Marxists from Louis Althusser to Nicos Poulantzas to James O'Connor specified how democratic governments perform accumulation, legitimation, and class organization and disorganization functions that help maintain capitalism (see, e.g., Ritzer 1992). As Stinchcombe (1987) illustrates, Marx's theory can be recast in functional terms, with the key modification that functions and dysfunctions play out in the context of unequal power relations and conflicting interests among classes. In short, even many ardent critics of structural functionalism embrace the analytic utility of the concept of function, highlighting its centrality to sociology.

functionalism/ neofunctionalism

Donald A. Nielsen

Functionalism is a theoretical perspective in sociology, and the social sciences generally, which emphasizes the positive contributions made by any given social arrangement (e.g.,

institutions, cultural values, norms, rites, and so forth) to the current operation and continued reproduction of society and its cultural pattern. It has rested heavily as a theory on a broad analogy between societies and biological organisms, a tendency especially noted in the work of early functionalists such as Spencer and Durkheim. However, reliance on the organic analogy is already less evident in the work of social anthropologists such as Radcliffe Brown and Malinowski, who drew selectively on Durkheim's work, and has become muted in more recent forms of functionalism, which draw more frequently on general systems theory and not merely on the analogy with organisms. Functionalists also regularly couple the use of analogical reasoning with a claim to the objective analysis of society through the use of scientific methods and have linked their theorizing to one or another form of positivism in philosophy.

The work of Durkheim forms the most influential predecessor of most contemporary variants of functionalism. He used a functionalist method in a variety of his studies. For example, Durkheim (1964) analyzed the division of labor in modern society and found that it functioned under normal conditions to promote the formation of a new type of social solidarity, which he called organic solidarity. His discussion of the division of labor had a strong influence on the development of Radcliffe Brown's variant of structural functional analysis. In a similar vein, Durkheim analyzed the social functions of deviant behavior which, in his view, provided opportunities for the clarification and expression of the collective moral consciousness of society through the execution of rituals of punishment of deviant individuals. Finally, Durkheim (1995) argued that religion represented a system of beliefs and practices concerning the sacred and that its primary function was to integrate the members of society into a single moral community. This image of the integrative function of religion, and common values generally, was to have a strong influence on Parsons's functionalist theorizing.

These early functional perspectives were refined during the period after World War II and in the process often significantly modified by later thinkers such as Talcott Parsons and Robert K. Merton. Both figures created schools

of thought (Parsons at Harvard and Merton at Columbia) where each trained a new generation of sociologists. Each, in differing ways, emphasized one or another form of functionalism. As a result of their work and that of their students, functionalism became the dominant theoretical perspective in the post war period and, despite challenges from other theoretical perspectives, remained a leading trend of thought up through the mid 1960s. In such works as *The Social System* (1951), Parsons developed a grand systematic theory of society which focused on the four functional problems of all social systems: adaptation to their environment, goal attainment, integration, and cultural pattern maintenance. Parsons's systematic theory emphasized the exchanges of social performances which took place among institutions fulfilling these functions (e.g., the economy, government, law, education, religion, the family, and so forth) and the equilibrium established among them, while at the same time linking this outlook, if rather uncomfortably, to the theory of social action which he had begun to develop in his earlier work, *The Structure of Social Action* (1937). In his view, disequilibrium between and among the various institutions performing key social functions was a major way of explaining social change. Parsons also emphasized the relations between culture and society and the integrative role of common values in creating social consensus. These emphases led to a theory of social evolution which focused on increasing social differentiation and the historical development of more abstract and universalistic cultural values in modern societies. This brand of macro functionalism was adopted by Parsons's followers such as Marion Levy, Robert N. Bellah, and Neil Smelser and its analytical scheme was applied to the comparative study of societies and cultures such as China and Japan. Others, such as Kingsley Davis and Wilbert Moore, employed functionalism in the study of particular problems such as social stratification and argued that the functionalist method was largely identical with sociological analysis itself.

On the other hand, in his influential work, *Social Theory and Social Structure* (1949), Merton worked toward a more flexible "paradigm" of functional analysis with strong empirical applications. Merton argued strongly

against the idea of the universal functionality of particular social arrangements, such as religion or the family. Instead, he argued for the idea of functional equivalence, in which differing concrete social arrangements could satisfy any necessary social function. In this way, he was also more successful than Parsons in uncoupling functional analysis from its potentially conservative implications. Thus, no particular way of arranging for society's needs was privileged and new social arrangements were possible. In this same spirit, Merton also emphasized both the positive functions as well as negative dysfunctions of given social arrangements. Social institutions might have both positive and negative consequences for a society or some segment of it. He also emphasized the "latent" character of many social functions and dysfunctions, that is, their largely unrecognized and unintended quality, and linked this problem to his earlier interest in the unanticipated consequences attendant upon all purposive social action. Merton's brand of functionalism was linked to a strategy of theory and research which he entitled "middle range" analysis, one which avoided both Parsons's effort to create grand theoretical systems as well as the minutiae of empirical research devoid of any theoretical orientation. Merton's more flexible emphasis on latent functions and dysfunctions allowed him and his students to engage in theoretically driven research about such topics as bureaucracy, deviance, reference groups, public opinion, propaganda, and a host of others. As a result, Merton was a less central target for those who were increasingly critical of functionalist modes of analysis.

In addition to its importance as a source of influential schools of twentieth century social theory, especially in America, functionalism, particularly its Parsonian variety, has been a major reference point for widespread criticism by conflict theorists, symbolic interactionists, and others less persuaded by functionalists' claims. In the eyes of conflict theorists such as Ralf Dahrendorf, C. Wright Mills, Barrington Moore, and others, who often drew more heavily than Parsons on the Marxian theoretical legacy as well as Weber's theory of bureaucracy and political domination, Parsonian structural functionalism seemed to neglect the problems of power and political conflict, as well as other

forms of intergroup struggle (e.g., between social classes and racial and ethnic groups). In their view, functionalism was not only unable or unwilling to focus on or explain such persistent social realities, but also had decidedly conservative political implications. In the 1960s, movements of national liberation in the former colonies, intergenerational conflicts spearheaded by youth, the Civil Rights Movement, black nationalist currents among African Americans, the women's movement and, not least, the Vietnam War, put the problems of power, inequality, and conflict decisively back in public view. These changes made the functionalist emphases on the role of common values in integrating society and the use of the concept of disequilibrium to analyze change seem out of touch with currently explosive social realities. Parsons attempted to address anew the problems of political power from a functionalist, systems theory standpoint, by treating it (along with money) as one generalized medium of communication in society. In a related response to critiques and current changes, Neil Smelser, one of Parsons's followers, developed his *Theory of Collective Behavior* (1962), while Merton's student Lewis Coser, in his work on *The Functions of Social Conflict* (1956), had already taken up the analysis of conflict itself from a functionalist perspective by drawing on the ideas of Georg Simmel. Despite these and other efforts, after the 1960s, functionalist theorizing never fully recovered its place as the leading theoretical perspective in sociology.

Symbolic interactionists like Herbert Blumer had long been critical of functionalism for other reasons and his critique was increasingly supplemented by critical perspectives emerging from such authors as Erving Goffman, representing newer forms of analysis such as social dramaturgy and social constructionism. These microsociologists viewed the functionalist image of society, its functional problems, its emphasis on macrostructures and institutions, and its focus on common values and culture, more generally, as an egregious reification of what is essentially a complex process of social interaction among human actors whose mutually oriented actions create and sustain what the functionalists designate as "society" and "culture." Other critics of functionalism, working

from several different theoretical orientations, have generally agreed with the symbolic interactionists, even while they have also viewed the interactionist critique as insufficiently broad and systematic to meet the challenges posed by functionalist theory. For example, George Homans, in his 1964 Presidential Address to the American Sociological Association, made a plea for "bringing men back in" and in his book, *Social Behavior: Its Elementary Forms* (1961), developed an empirically based social theory rooted in a variant of social behaviorism, one which aimed at the creation of general propositions and even explanatory laws of social behavior by building the analysis of larger social structures on a foundation of individual behavioral psychology. Others, such as Peter Berger and Thomas Luckmann, sought to outflank Parsons's structural functionalism by offering, in *The Social Construction of Reality* (1966), an alternative systematic theory which combined macro and micro analyses of social action, interaction, and structures in a treatment of social reality as a socially constructed phenomenon. Their merger of ideas drawn from Marx, Durkheim, Weber, phenomenology, and symbolic interaction theory attacked functionalism on its own ground by offering what appeared to be a comprehensive theory of society and culture. In general, theorists who have emphasized the ongoing social construction of society have argued that functionalists omit any meaningful reference to the intentions of individuals and that all so called social functions can be best understood by reducing them to the combined actions and constructions of social actors.

In the last several decades new efforts have been made to revive functionalism by a new wave of "neofunctionalists" such as Jeffrey Alexander, Niklas Luhmann, Jürgen Habermas, and several others who have injected powerful doses of conflict theory, systems theory, an evolutionary emphasis on social change, and a greater emphasis on the role of political power in society into the moribund body of functional analysis. Alexander wedded his neofunctionalism to the broader agenda of developing a multidimensional theory of society, one which would find room for both conflict and consensus, yet also retain the earlier functionalist emphasis on major historical processes such as social differentiation. Luhmann moved

instead toward the merger of functionalism with systems theory and evolutionary perspectives and, in the process, emphasized the role of power as well as trust in society. While Habermas is not always grouped with the neofunctionalists, his dual emphasis on system functioning and lifeworld, as well as his evolutionary theory of social communication with its utopian intent of achieving unconstrained consensus in society, has much in common with Parsons. It represents an attempt to merge aspects of the Parsonian legacy with perspectives from linguistic analysis, phenomenological sociology, and political theory. It is of interest that all the above neofunctionalists draw on one or another element of Parsons's mature structural functional theory (e.g., social systems theory, evolutionary analysis, multidimensional grand theorizing, the role of power as generalized medium, the role of common values in society). It has provided them with decisive impetus, despite their considerable modification and supplementation of his ideas.

fundamentalism

Enzo Pace

Roughly speaking, fundamentalism is a label that refers to the modern tendency – a habit of the heart and mind (Marty & Appleby 1991, 1993a, 1993b, 1994, 1995) – to claim the unerring nature of a sacred text and to deduce from that a rational strategy for instrumental social action. The final goal is to achieve the utopia of a regime of the truth (Pace 1998), gain political power, and rebuild organic solidarity, in jeopardy because of relativism, secularism, and weakness due to the eclipse of religion's social function of integration. This tendency has arisen in various socioreligious contexts: in Protestantism and Catholicism, Islam and the Jewish communities (both in Diaspora and in Israel after the 1967 Six Day War), in contemporary Hinduism and Buddhism, and, to some extent, even in a particular faction of Sikhism (the Khalsa, the religious order of warriors, defenders of the truth and the sacred boundaries of the Punjab). Fundamentalism made its appearance in contemporary times with such manifestations as the first march of the Moral Majority in the United States and the Iranian revolution (1979); the intensification in Sri Lanka of the tension between the Sinhalese Buddhists and the Tamil Hindu from 1977 to 1983; the appearance in Israel of many nationalist religious movements whose aim was to regain and defend the biblical boundaries of the people of Israel (*Eretz Israel*) from 1977 to 1980; and, in the Punjab, from 1984 to 1988 there was an acute crisis in relations between the Sikhs and the Indian government, culminating in an attack by the Indian army on the

Golden Temple in Amritsar and the subsequent assassination of Mrs. Indira Gandhi by a Sikh.

In light of these events, many scholars hold the view that fundamentalism is a modern global phenomenon involving the historic religions, for the most part. One of the most impressive attempts at a comparative analysis was the "Fundamentalism Project," carried out by a team of researchers coordinated by Marty and Appleby and sponsored by the American Academy, which was published in five volumes. In summing up the authors' analysis, five common features characterizing fundamentalist movements can be identified.

First, fundamentalism is characterized by the type of social action dominated by the attitude of *fighting back*. This means, on the one hand, that the social actors claim to be restoring a mythical and sacred order of the past, but, on the other hand, they act with great innovative power of mobilization. The sacred becomes the means for gaining political power. Without this close relation between religious narrative and political rhetoric, with constant mutual contamination between the two, it is impossible to distinguish between the manner of fundamentalist movements and that of traditionalist or conservative ones. The former aim to assume the absolute and unerring truth of the sacred text to legitimate a new social order, the order of an immanent god (the law), pure and integral, to affirm and preserve a pure collective identity. Retracing its collective memory, fundamentalism comes up with a sacred language that inspires the discipline of the body and the mind; through this, it implants common habits in the hearts of the people, an image of solidarity. In contrast to the modern idea of "atomized" individuals in a fragmented society, this solidarity creates a mystical community of Brothers.

The second element highlighted by the authors of the "Fundamentalism Project" – *fighting for* – is implicit in the foregoing: the ultimate goal of the movement is political, despite the furious and intense religious motivations. For instance, at the beginning of the changes in Iran in 1977–8, Islam was perceived as a set of instruments promoting liberation from dictatorship and the modernization of the country run by the Pahlavi dynasty. There was an Islamic liberation theology that later

became, when the Ayatollah Khomeini gained power, a political project to create an integral Islamic state, a process which moved away from the centralized power of the state, shifting the traditional role of the Shiite clerical institution. Up to the time of the revolution, the Shiites were the interpreters of the sacred text without any claim to impose a single model of society or political order. Yet, after coming to power, the ayatollah began to offer a sort of state hermeneutics of the sacred text. In spite of the traditional pluralism within the Shia in the matter of interpretation of canon law, the Khomeini regime imposed a uniform, and unbearable, straitjacket on a society with some degree of social differentiation, accustomed to perceiving the difference between religion and politics.

The third feature – *fight with* – refers to a specific repository of symbolic resources of use in the crusade for restoring identity and gaining political power. As a rule, fundamentalists move toward a mythical past contained in a sacred text, the shrine of the secret of the social order. Thus, they distill – drop by drop – the functional language of social action, the socio-logos of the society in question. In this sense, the fundamentalist approach to both the sacred text and social action is selective: fundamentalists actually interpret the text, whilst pretending to claim its inerrancy, its ahistoricity, and generally its structural refractoriness to any rational (historical and critical) hermeneutics.

The fourth element is the *fight against*. If fundamentalism were a label that could be applied to any kind of (religious) politics of identity (in which case, for instance, the former President Milosevic of Serbia acted as a fundamentalist when he tried to combine nationalist rhetoric with a discourse on the Orthodox origins of the Serbian nation), it would be very easy to demonstrate the link between the fundamentalist mentality and the need for an enemy. Being a fundamentalist assumes the idea and feeling of being threatened by an enemy (real or imagined) as regards one's identity, territory, and survival. When he assassinated Israeli President Rabin in 1995, Yigal Amir believed he was doing what was best, since Rabin, by making peace with Arafat, was yielding to the Palestinians territories that, according to extremist movements, belonged to the promised land given by God to his people.

Finally, the fifth feature of fundamentalism – *fight under God* – represents a simple corollary of the previous assumptions. It refers to the intensity of the militants' conviction that they are "on the right path." They are certain they are called directly by a god to carry on with radical determination the struggle against the enemy. Thus, symbolic and physical violence are legitimized. Sacred violence becomes a logical consequence of the missionary function the fundamentalist feels he has received from God. The fundamentalist believes he carries out the function of defender of the rights of God and executor of his will on earth.

The term fundamentalism has given rise to heated controversy among scholars, the most significant objection being that it has been used to classify different phenomena present in very diverse socioreligious contexts. In other words, we should guard against reducing every radical conservative religious viewpoint to a manifestation of fundamentalism. Other scholars point out the difficulty of comparing different religions under the same label, fundamentalism: religions which are monotheistic with those of a non theistic or polytheistic nature, or religions entailing the crucial importance of a sacred text (the Bible, Koran, Adi Granth) with others that do not.

Apart from these objections, those social scientists who accept the concept and assume a comparative and global approach to studying fundamentalism are divided on another issue: whether the phenomenon should be interpreted as an expression (or the quintessence) of modernity or as a simple reaction to modernity. The contrast refers to a broader debate within social theory about the classic dichotomy between tradition and modernity, postmodernity, and globalization.

To sum up, four main points of view emerge. In the first approach, fundamentalism is a clear reaction to modernity, a defensive protection against the individualization of belief and socio-religious identity (Meyer 1989). The second orientation is well represented, among others, by both Lawrence (1989) and Eisenstadt (1999); they hold that fundamentalism is a modern phenomenon, a direct consequence of modernity, characterized by the rejection of modernism. Using the advantages of modernity (the techniques of propaganda, the logic of social

mobilization, lobbying in the public and political arena, and so on), fundamentalism, according to Eisenstadt, is urged on by a modern Jacobin utopia in antithesis with modernity. Lawrence believes, on the other hand, that the disjunction between modernity and modernism enables fundamentalism to become a transnational movement claiming to give a new and absolute basis for social action and human knowledge, to the social order and the source of political power. The third approach stresses the relationship between fundamentalism and secularization (Kepel 1991), fundamentalism being a countertendency to the gradual eclipse of the sacred many scholars had predicted two decades ago.

The last point of view underlines the importance of the political objectives of the fundamentalist movements' social and religious action (Greilsammer 1991; Van der Veer 2000): their struggle tends to focus all religious energy on the public arena and consequently on political action, according to the crucial hypothesis that only through political power will it be possible to reestablish the divine law and safeguard one's identity (Hindu, Muslim, Christian, Buddhist, Sikh, Jewish, and so on). The way the fundamentalist mentality bridges the gap between religion and politics is characterized by a double abstraction used in the hermeneutics of the sacred text, as pointed out by Bhikku Parekh (1992): by abstracting from the tradition (sometimes in contrast to the traditional authority or a consolidated school of juridical thought and theological doctrine) and inventing a set of religious narratives and a political rhetoric of identity abstracted from a literal interpretation of the text itself. In this sense, fundamentalism is able to invent a tradition by reifying a sacred text and drawing from it paradigms of social action, sometimes without any substantial relation to the historical and theological context in which the sacred text was written. Even when a religious tradition does not refer to a single revealed sacred text – such as Buddhism or Hinduism – one of the most striking phenomena we have seen is the selection of one, among many other sacred texts, and the consequent construction of a sociological and cognitive map; the idea being that in the text we find the roots of our collective memory and identity, the sacred boundaries of

the territory we inhabit, and the source of political authority. When such a discourse is produced by an elite of Buddhist monks in Sri Lanka during the process of nation building (which has been going on since 1955), or by a network of neo Hindu groups and political parties (in India since 1979), which has gradually managed to gain power (with the Bharata Janata Party), there is no doubt that the habits of the heart and the attitudes of the mind are fundamentalist oriented.

gambling as a social problem

Lucia Schmidt

Gambling refers to wagering money or other belongings on chance activities or events with random or uncertain outcomes (Devereux 1979). Gambling opportunities are now widely available throughout the world and playing with and for money is socially accepted as a source of entertainment and recreation. However, a growing tendency to highlight problematic aspects is also to be noticed.

By its very nature, gambling involves a voluntary, deliberate assumption of risk, often with a negative expectable value. Traditionally, heavy gamblers who sustained repeated losses and other adverse consequences were considered derelict, immoral, or criminal. For much of the twentieth century, the prevailing view of excessive gambling continued to define that behavior as morally and legally reprehensible. Only a few decades ago, a new perspective on the problem came up in which the behavior in question is seen as a pathological one – as a form of addictive behavior in need of therapeutic treatment. The disease concept (at least partly) replaced former deviance definitions as a kind of willful norm violation, and excessive gambling increasingly is considered to be an expression of a mental disorder resembling the substance related addictions. This change in perception has been strongly stimulated by – and reflected in – the evolving clinical classification and description of pathological gambling in the various editions (between 1980 and 2000) of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM) published by the American Psychiatric Association.

The medicalization process was initiated in the US by a self help group named Gamblers Anonymous (founded in 1957). Soon, GA formed alliances with medical experts. A small circle of problem gamblers and professional claims makers started to bring public attention to the problem. The National Council on Compulsive Gambling (founded in 1972 and renamed the National Council on Problem Gambling in 1989) served as a model for similar organizations in other countries, all of which have become influential actors in the social construction of the new disease.

The medical conception was developed with strong references to the already established disease model of alcoholism and it highlights loss of control as a basic origin of excessive gambling. The psychiatrist Robert L. Custer was the first expert on pathological gambling who participated in one of the specialized DSM advisory committees. For the 1980 edition of DSM III, where the disease was codified for the first time, he was the *only* one. As Custer puts it in one of his classic works, “compulsive gambling is an addictive illness in which the subject is driven by an overwhelming, uncontrollable impulse to gamble. Accordingly, the afflicted gambler is controlled by his devastating disease. Rhetorical devices like this build up the image of persons as helpless, hapless victims” (Conrad & Schneider 1980).

There are remarkable regional differences in gambling opportunities that are supposed to be inherently problematic (e.g., to bear an increased addictive potential). For example, the discussion about “gambling addiction” in Germany was for years almost entirely restricted to a special kind of slot machine, while classical forms like casino games, lotteries, and sports betting were highly uncommon. Yet this type of slot machine was once described by Robert Custer as a harmless, not very exciting toy.

According to the National Research Council, much of the available research on all aspects of pathological gambling is of limited scientific value and reliable estimates for the national and regional prevalence of pathological gambling are hard to find (NRC 1999). However, the Research Council estimates that approximately 0.9 percent of adults in the US meet specific criteria as pathological gamblers on the basis of their gambling activities in the past year and that the current prevalence rate for pathological gambling among adolescents is considerably higher (NRC 1999: 98ff). The American Psychiatric Association states there are 1–6 percent of young people in the US and Canada who may satisfy diagnostic criteria for pathological gambling, with the rate of gambling problems rising among young people. From a sociological point of view, assertions about the extent of the problem serve as the rhetorical basis on which the discussion proceeds. Within the last few years, youth gambling has become a newly favored topic of research and political discussion. As illustrated by the title of an interdisciplinary reader on this subject – *Futures at Stake: Youth, Gambling and Society* (Shaffer et al. 2003) – rhetorical devices and drama make up an essential part of the ongoing problem discourse on gambling.

gambling and sport

Ellis Cashmore

There are two likely sources for the word gambling: the Old Saxon *gamene*, which became abbreviated to the contemporary "game"; or the Italian *gambetto*, source of "gambit," a practice of sacrificing something minor in order to secure a larger advantage. Gambling now refers to playing games of luck or skill, using a stake, usually a sum of money, in anticipation of winning a larger sum.

While gambling on sports is obviously a product of the growth of organized sports from the mid nineteenth century, playing games of chance for money or staking wagers on the outcome of events probably dates back to antiquity.

Modern forms of gambling emerged in connection with changing ideas about time and nature. As pre Enlightenment thinkers advanced the notion that reason and rationality lay behind all earthly affairs, the roles of chance, happenstance or pure randomness were seen as increasingly problematic. In an ordered universe, ignorance of affairs was merely imperfect knowledge because everything was potentially knowable. August Comte's positivism was perhaps the epitome of this, recognizing only observable phenomena and rejecting metaphysics, theism, and anything else that lay beyond human perception. The emerging emphasis on science led to the conclusion that given greater knowledge, the seeming vagaries of nature could be comprehended and subordinated to the rational, calculating mind.

Gambling is guided by such reasoning: admittedly, the conscious thought that lies behind rolling dice or drawing lots is hardly likely to resemble any kind of calculation; these are games of chance, played with the intention of winning money. But the motive behind gambling on sports is influenced by a more rational

style of thinking: that it is possible to predict the outcome of an event by the employment of a calculus of probability. No one wagers money on a sporting event without at least the suspicion that they are privy to a special knowledge about a competitive outcome. A hunch, a taste, a fancy, a “feel” – all these add to the calculus at work in the mind of even the most casual gambler when he or she stakes money on a competition.

Orientations of gamblers differ widely: some always feel a frisson whether it is in watching a horse romp home or some dice roll; others observe from a position of detachment, their interest resting on only the result. The sports gambler bets with head as well as heart; the reward is both in the winnings and in the satisfaction that he or she has divined a correct result from the unmanageable flux of a competitive event.

In his *Luck: The Brilliant Randomness of Everyday Life* (1995), Nicholas Rescher identifies a surge in popularity in wagering on contests of skill and chance during the English Civil War (1641–5) and the Thirty Years’ War in continental Europe (1618–48). Starved of entertainment, soldiers and sailors killed time by wagering on virtually any activity. Returning to civilian society, the militia brought with them their habits, and the enthusiasm for gambling spread, aligning itself with the games of skill that were growing in popularity in England.

The 1665 Gaming Act was the first piece of legislation designed to outlaw gambling, principally to restrict the debts that were being incurred as a result of the growing stakes. Some activities had attracted gambling for decades, perhaps centuries. Swordplay, for example, was a pursuit that was viscerally thrilling to watch and stimulated the human passion for prediction. As the military use of swords declined, so the contests continued simply for recreation and entertainment. Dueling was perfect for gamblers. Engaging in competitive contests simply for the satisfaction they afforded the competitor and observer was exactly the kind of wasteful and sinful behavior despised by the party of English Protestants and Puritans.

Blood sports were popular in nineteenth century England and North America. Their attraction, in part, was due to their amenability

to betting. Even as the civilizing process altered the threshold of repugnance and made such grim and cruel pursuits less tolerable, cock fighting, bear baiting and other blood sports remained, principally because of gambling. Pugilism was another combat sport that attracted what was known as a “fancy” or following of ardent spectators who would pit their forecasting skills against each other. Sponsors of pugilists were often extravagant backers of their charges. The influence of gambling on prize fighting became injurious and corruption was rife.

Boxing and gambling have gone hand in hand ever since, though there were other less probable sports that attracted bettors. Cricket, for example, in the early nineteenth century, had its hardcore spectators who were prone not only to gambling but also to drinking and rowdiness. Gambling regulations remained in the laws of the game until the 1880s and betting was still very much part of the sport until at least mid century. Lords, the home stadium of cricket’s governing federation, banned gambling in the 1820s and, according to Dennis Brailsford, in his *British Sport: A Social History* one player was banned for allegedly throwing a match.”

Brailsford estimates that the money staked on boxing was rivaled “and sometimes exceeded” by that involved in pedestrianism, the period’s equivalent of track. Pedestrianism defined a variety of races and events, sometimes head to head, or against the clock, often involving both men and women. There were wheelbarrow races and hopping contests, as well as such unusual challenges as picking up potatoes. The appeal of pedestrianism was that it was possible to wager on practically anything. Opposition to working class gambling on sports bore fruit in the form of two pieces of legislation in 1853 and 1906, which were ostensibly framed to forbid off course betting.

In the US, where gambling was – and still is in many states – illegal, baseball nevertheless attracted gamblers. Perhaps the best known instance of corruption had its source in gambling. The Black Sox Scandal of 1919 involved several Chicago White Sox players who were bribed by a gambling syndicate to throw a World Series against underdogs Cincinnati Reds. Money was at the root of this instance

of corruption, which was chronicled by John Sayles in his movie *Eight Men Out*. The players were poorly paid and exploited by Major League Baseball long before the advent of free agency. The film and the Elliot Asinof book (of the same title) on which it is based depicts the players sympathetically, in some senses cheated by their employers.

Animal racing, from its outset, was fair game for gaming. In their modern forms, horse racing and dog racing proved the most attractive to gamblers. Dog racing has its origins in eighteenth century coursing, and involved highly bred and trained dogs, which chased and usually killed a fleeing hare. One of the attractions of meetings was the opportunity to wager and drink convivially. Hoteliers and publicans would promote coursing meets. It became an organized sport, complete with its own organization in 1858, when a National Coursing Club was established.

As opposition to what was obviously one of a number of blood sports prevalent at the time, coursing dispensed with living hares and substituted a mechanical equivalent. The first electric hare was used in 1919 and came into popular use at the end of the 1920s. In the US, the betting norm became *pari mutuel*, from the French, meaning mutual stake. (This type of betting was introduced in New Zealand as far back as 1880.) In the 1930s, this also took off in on course British horse racing (known as the *totalizer*).

A new form of gambling on soccer posed threats to both greyhound and horse racing. Known as the pools, it came to life in the early 1930s and captured the British public's imagination almost immediately. Newspapers had been publishing their own versions of pools for many years, but the practice was declared illegal in 1928. Brailsford notes how the £20 million staked in the 1934/35 season doubled within two years. The outlay was usually no more than a few pence and the bets were typically collected from one's home. The aim of pools was to select a requisite number of drawn games, so it was not classified as a game of chance, but one of skill, thus escaping the regulation of gaming legislation. By the outbreak of war, there were 10 million gamblers on the pools. The popularity the pools enjoyed with working class bettors stayed intact until the

introduction of the national lottery (modeled on the US state lotteries) in the early 1990s.

In the 1990s, betting on the spread became one of the most popular gambling forms. The bettor could wager not only on the result of a contest but on any facet of it. Spread betting was popularized in the US, then became the norm in Britain, especially in soccer.

Sports betting, while nominally illegal in most parts of the US, remains popular because gamblers typically have access to a Las Vegas bookmaker. The Internet has facilitated online betting, which effectively circumvents legal restrictions on gambling. A valid credit card and Internet access is all that is needed to gamble on practically any sports event, any where in the world.

Sociological research on gambling in sports has been rare because it is difficult to collect valid and reliable data. Therefore, we are left with case histories of gamblers and the athletes and teams that altered competitive outcomes or shaved points from their scores to enable gamblers, sometimes themselves, to win bets (Ginsburg 2003). Basketball presents a prime example. As Alan Wykes (1964) points out: "American basketball has been more notorious than football for its fixing scandals of the 1950s when college stars or whole teams were being bribed to throw games." Like any other competitive sport, basketball is a natural, if unwitting, ally to gambling. And history suggests that, where gambling is present, corruption is rarely far away.

Former Arizona State star Stevin Hedake Smith admitted helping a gambling ring by shaving points during his senior year as a way of relieving his own gambling debts. In one 1994 game, the Sun Devils were favored by a 14 point lead, so Smith and his accomplices had to make sure their team won by six points because the bookie wanted a cushion. Late in the game Arizona State led 40-27, but Smith began to allow more space to the shooters he was meant to be guarding and the score narrowed to finish 88-82. Smith revealed to *Sports Illustrated* (Yaeger 1998) how he could adjust his game to accommodate the various spreads, usually by easing off. By holding a victory margin to a certain number of points, players could earn \$20,000. Players sometimes bet on their own games.

Gambling's association with sports continues. Some sports' enduring popularity is directly attributable to betting. In both Europe and the US, horse and dog racing thrive on a betting levy (a fixed proportion of bookmakers' revenues). Interest in jai alai revolves around betting. The movement of major boxing contests to Las Vegas is no accident: boxing's historical connection with gambling is a sturdy one and gamblers flock to Las Vegas as much to bet as to enjoy the bouts.

Any activity, whether shopping, eating chocolate or watching television, has the potential to induce dependency. Gambling also, though "compulsive gamblers" are typically drawn to games of chance rather than gambling on sports events, where elements of choice, discretion, judgment and prescience are allied to luck.

game stage

D. Angus Vail

The game stage is one of three central components of George Herbert Mead's seminal discussion of the social foundation and development of the self. According to Mead, the self has a social genesis which becomes evident if one examines the ways that people develop a sense of their own being as something separate from, but also interdependent with, other people. In essence, the self is situated in the

individual's capacity to take account of themselves. By examining children's styles of play, followed by the games they play, one can see how they develop a capacity to take into account not just the role of a singular other person, but also eventually the roles of many people simultaneously. It is only once a person has reached this stage of development that she or he is said to have developed a complete self. Mead (1962: 151–4) called the second stage the game stage.

The fundamental difference between the game stage and its antecedent play stage lies in the child's ability to take the roles of multiple people at the same time. In order successfully to play an organized game or sport, the child has to be able to take account not only of his or her own actions, but also, and simultaneously, the actions of every other player involved in the game. Little league soccer makes a fine example of the distinction. At a certain age, children playing soccer stop playing swarm ball where every child on the field swarms around the ball, and they develop the capacity to play positions that require taking account of themselves, where the ball is, what their team mates are doing, and what their opponents are doing. Thus, they learn how to play the game of soccer rather than playing at being a soccer player.

If a person is to achieve success in a game she or he has to understand the rules that govern that game. Rules organize both the players' responses to each other and the attitudes that their actions are likely to induce in others who are also playing the game. Thus, while children in the play stage will swarm around a soccer ball, children in the game stage are capable of understanding the rules that govern zone offense or defense where the team acts together.

Of course, the game is a metaphor for the ways that children and adults take account of the diverse, malleable, and emergent roles that other people play, often simultaneously, in social settings. Thus, once a person enters the game stage of development, she or he demonstrates a capacity to take account of others' actions, her or his own actions, and the often quite informal rules (collectively known as the generalized other) that govern the social situation in which they all find themselves together. Mead contends that this capacity is the true mark of development of a complete self.

game theory

Michael W. Macy and Arnout van de Rijt

Game theory is a powerful mathematical tool for modeling conflict and cooperation that originated with von Neumann and Morgenstern's (1944) seminal work. A game consists of two or more *players*, each with a set of *strategies* and a *utility function* that assigns an individual *payoff* to each combination of strategies, such that payoffs for a given strategy depend in part on the strategies of other players. This *strategic interdependence* can be represented in several ways: as a payoff matrix (the "normal form," where players act simultaneously), a decision tree (the "extensive form" for sequential moves), or as a production function (for *n* person games). Strategic interdependence allows two types of games. In *zero sum games*, a gain for one player is always a loss for the other, which precludes the possibility of cooperation for mutual gain. In *positive sum games*, everyone can gain through *Pareto efficient* cooperation, where some are better off and none are worse off, compared to other outcomes.

If cooperation is Pareto efficient and both players are rational, why would cooperation ever fail? There are two reasons: the fear of being "suckered" by the partner and the temptation to cheat. These failures can be avoided through enforceable contracts that preclude "cheating" ("cooperative games") or through collusion (in "non cooperative games").

In cooperative games, non cooperation is contractually precluded. The problem is to negotiate the distribution of resources among a coalition of players. Sociologists use cooperative game theory to study the effects of network structure on power inequality in social exchange (Willer 1999).

Non cooperative games have no enforceable contract. These games are generally more interesting to sociologists because they can be used to model *social dilemmas* which arise when players attempting to maximize their individual well being arrive at a socially undesirable outcome. More precisely, a social dilemma is a game in which there is at least one Pareto deficient Nash equilibrium (NE). An NE obtains when every strategy is a "best reply" to the other strategies played; hence, no player has an incentive to unilaterally change strategy. The equilibrium is Pareto deficient when the outcome is preferred by no one while one or more individuals prefer some other outcome.

The simplest version of a social dilemma confronts two players with a binary choice: whether to "cooperate" or "defect." These two choices intersect at four possible outcomes, each with an associated payoff: *R* rewards mutual cooperation, *S* is the sucker payoff for unilateral cooperation, *P* punishes mutual defection and *T* is the temptation to unilaterally defect. In a social dilemma, mutual cooperation is Pareto efficient yet may be undermined by the temptation to cheat (if $T > R$) or by the fear of being cheated (if $P > S$) or by both. In the game of "Stag Hunt" the problem is "fear" but not "greed" ($R > T > P > S$), and in the game of "Chicken" the problem is "greed" but not "fear" ($T > R > S > P$). The problem is most challenging when both fear and greed are present, that is, when $T > R$ and $P > S$. Given the assumption that $R > P$, there is only one way this can happen, if $T > R > P > S$, the celebrated game of "Prisoner's Dilemma" (PD). In this game, defection is the dominant strategy, that

is, it makes no difference whether a player knows what the partner has chosen. In other social dilemmas, the second mover should do the same as the partner (e.g., Stag Hunt) or the opposite (e.g., Chicken).

An interesting variant is called the “trust game.” The first mover chooses whether to invest resources in a “trustee” and if so, the second mover chooses whether to betray or reward trust. More complex variations allow for N players and continuous choices, whether to “give some” or to “take some” from other players. These games are used to study the *free rider* problem in *collective action*.

Although the games vary widely, the Nash equilibrium is a solution concept that can be universally applied. John Nash (1950) showed that every game contains at least one NE. NE predicts mutual defection in PD, unilateral defection in Chicken, and either mutual cooperation or mutual defection in Stag Hunt. NE also identifies a Pareto deficient mixed strategy equilibrium in Chicken and Stag Hunt. (A mixed strategy cooperates with a positive probability that is less than one.)

NE in non cooperative games is self enforcing – no contract is necessary to guarantee compliance. This allows for the possibility that social order can self organize, even in the absence of a Leviathan. Although this result is clearly of enormous significance across all the social sciences, there are important limitations that have spurred the search for more powerful theoretical extensions. Nash equilibrium analysis tells us if there are any strategic configurations that are stable, and if so, how they are characterized. Knowing that a configuration is an NE means that if this state should obtain, the system will remain there forever, even in the absence of an enforceable contract. However, even when there is a unique NE, this does not tell us whether this state will ever be reached, or with what probability, or what will happen if the equilibrium should be perturbed. Nor does NE explain social stability among interacting agents who are changing strategies individually, yet the population distribution remains constant, as in a homeostatic equilibrium. Put differently, NE explains social stability as the absence of individual change, not as a dynamic balance in a self correcting distribution of evanescent individual strategies,

each of which influences others in response to the influence that it receives.

Moreover, in most games, NE cannot identify a unique solution. Both Chicken and Stag Hunt have three equilibria (including mixed strategy). Worse yet, if these games are repeated by players who care about future pay offs in an ongoing relation, the number of NE becomes indefinitely large (even in PD, which has a unique equilibrium in one shot play). When games have multiple equilibria, NE can not tell us which will obtain or with what relative probability. Nor can it tell us much about the dynamics by which a population of players can move from one equilibrium to another.

Game theorists have responded to the problem of equilibrium selection by proposing procedures that can winnow the set of possible solutions. These include identifying equilibria that are risk dominant (every player follows a conservative strategy that earns the best payoff she can guarantee for herself), payoff dominant (no other equilibrium has a higher aggregate payoff over all players), Pareto dominant (every other equilibrium is less preferred by at least one player), and subgame perfect (all nodes along the equilibrium path can be reached in the extensive form). However, these equilibrium selection methods are theoretically arbitrary (e.g., there is no a priori basis for payoff dominant or risk dominant behavior) and they often disagree about which equilibrium should be selected (e.g., in Stag Hunt, payoff dominance and subgame perfection identify mutual cooperation while risk dominance points to mutual defection).

Another limitation is the analytical simplification that players have unlimited cognitive capacity with which to calculate the best response to any potential combination of strategies by other players. This allows equilibria to be identified by finding the minima of a function that describes the expected utility for any member of a homogeneous population. However, laboratory research on human behavior in experimental games reveals widespread and consistent deviations from equilibrium predictions (Kagel & Alvin 1995).

These limitations, including concerns about the cognitive demands of forward looking rationality, have led game theorists to explore

backward looking alternatives based on evolution and learning. This development has revolutionized game theory by relaxing what had heretofore been regarded as a canonical assumption – the cognitive capacity of rational actors to accurately predict the payoffs for alternative choices. *Rational expectations* were regarded as essential for game theory because of the *consequentialist* logic by which strategic choices are explained by the associated payoffs. Consequentialist explanations defy temporal ordering by attributing the causes of past events to their future outcomes. In *analytical* game theory the calculus of rational expectations provides the necessary link to the future.

Evolution and learning provide a radically different mechanism for consequentialist explanation. Repeated experience, not rational expectations, is the link to the future. In *evolutionary* game theory, prior exposure to a recurrent decision allows strategic outcomes to explain the choices that produce them through a process of iterative search. Thus, the outcomes that matter are those that have already occurred, not those that an analytical actor might expect to obtain in the future. This relaxes the highly restrictive cognitive assumptions in analytical game theory and allows for the possibility that players rely on cognitive shortcuts such as imitation, heuristic decision, stochastic learning, Bayesian updating, best reply with finite memory, and local optimization, thereby extending applications to games played by highly routinized players, such as bureaucratic organizations or boundedly rational individuals whose behavior is based on heuristics, habits, or norms.

Evolutionary game theory models the ability of conditionally cooperative strategies to survive and reproduce in competition with predators (Maynard Smith 1982). Biological models have also been extended to military and economic games in which losers are physically eliminated or bankrupted and to cultural games in which winners are more likely to be imitated (Axelrod 1984).

Critics charge that genetic learning may be a misleading template for models of adaptation at the cognitive level. The need for a cognitive alternative to evolutionary game theory is reflected in a growing number of formal learning theoretic models of cooperative behavior.

In learning, positive outcomes increase the probability that the associated behavior will be repeated, while negative outcomes reduce it. The process closely parallels evolutionary selection, in which positive outcomes increase a strategy's chances for survival and reproduction, while negative outcomes reduce it. However, this isomorphism need not imply that adaptive actors will learn the strategies favored by evolutionary selection pressures. In evolution, strategies compete *between* the individuals that carry them, not *within*. That is, evolutionary models explore changes in the global frequency distribution of strategies across a population, while learning operates on the local probability distribution of strategies within the repertoire of each individual member.

Sociology has lagged behind other social sciences in embracing game theory, in part because of skepticism about the heroic behavioral assumptions in the analytical approach. However, these backward looking alternatives show that the key assumption in game theory is not rationality; it is instead what ought to be most compelling to sociology, the *interdependence of the actors*. The game paradigm obtains its theoretical leverage by modeling the social fabric as a matrix of interconnected agents guided by outcomes of their interaction with others, where the actions of each depend on, as well as shape, the behavior of those with whom they are linked. Viewed with that lens, game theory appears most relevant to the social science that has been most reluctant to embrace it.

gangs, delinquent

Rod K. Brunson

Discussions of gangs in the twenty first century stereotypically conjure up images of young minority males, outfitted in hip hop clothing, hanging out on street corners in impoverished urban communities, and engaging in unlawful acts. Using shorthand to identify gang members may seem logical to citizens, police officers, the media, and social service workers. It fails to recognize, however, the variation that exists among gangs and gang members. This begs the question whether the focus should be on gang members or on examining the conditions and processes involved in gang formation. Both approaches require their own orientation and have specific policy implications for addressing gang membership. At the center of these issues is the lack of consistency regarding how gangs are defined.

DEFINITIONAL ISSUES

One of the most difficult tasks for social scientists interested in the study of gangs is establishing the parameters of their area of interest: in other words, what constitutes a gang. Scholars have been interested in gang definition issues for decades. One key issue is whether delinquency should be regarded as an intrinsic feature of gang involvement. Thrasher (1927) and Klein's (1971) definitions characterize two sides of the debate and have been without question among the most influential. Thrasher emphasizes the spontaneous nature of gang formation, with delinquent activities of gang members regarded as a potential outcome to be examined independently. Klein, on the other

hand, maintains that the delinquent orientation of the group is a central feature of any definition of gang.

Scholars are polarized concerning whether or not delinquency should be considered an inherent trait of gang involvement. Definitions that omit delinquency are sometimes criticized or rejected because they would cause some social groups (e.g., Greek letter organizations, athletic teams, fraternal lodges) to be designated as gangs. Bursik and Grasmick (1993) urge caution, however, regarding the inclusion of the delinquent activities component because they fear it results in a tautology. Specifically, delinquency simultaneously serves as a possible outcome of gang involvement and a key component of the definition. On the other hand, several gang studies have excluded various groups *despite* their involvement in delinquency (i.e., hate groups, motorcycle clubs, prison gangs, and adolescent peer groups). These observations extend the focus beyond delinquency status and draw attention to the possible relevance of additional variables that may increase the odds of groups being labeled gangs (e.g., forms/seriousness of delinquency, characteristics of group members, and contexts where groups function).

Hagedorn (1988) has been particularly critical of gang scholars' acceptance of delinquency based definitions and maintains that the focus on delinquency has caused much contemporary gang research to focus primarily on trying to understand gang member delinquency and its consequences, rather than examining the context in which gangs develop and how they operate within their communities. The latter approach permits analyses of the function, for formation, and disbanding of gangs and thereby recognizes the fluidity of gang involvement. Hagedorn's criticism may be misplaced in that researchers who have accepted the delinquent component of gang definition have documented that gang membership is not a stable phenomenon. Specifically, youths transition in and out of gangs quite readily. Longitudinal studies have found that the typical gang member is in the gang for less than a year. Other literature does not preclude this either and acknowledges that playgroups may at times evolve into gangs and gangs may devolve into non gang like structures.

The lack of a standard definition regarding what constitutes a gang is problematic and yet holds promise for future research in this area. Bursik and Grasmick (1993) observe that, absent such, it is not possible to put forth definitive statements about the current state of gang involvement or make inferences about purported changes that have taken place over time. Horowitz (1990) notes, nonetheless, that consensus is unlikely and discord concerning definitions may in fact serve as a catalyst for future research in previously unexamined areas. This is an important opportunity for expanding gang research to gang like groups that might otherwise be excluded from study, or might inadvertently be classified as gangs.

GROUP STRUCTURES AND GANG TYPOLOGIES

The importance of group structure has generated interest among researchers concerned with distinguishing between particular gang types. Specifically, Maxson and Klein (1995) identified five classifications of gangs (traditional, neotraditional, compressed, collective, and specialty) characterized by age range, duration, size, the claiming of territory, the existence of subgroups, and whether offending patterns were specialized or varied. Such typologies are important beyond being extensions of gang definitions, as they clearly demonstrate the diversity of gangs. Recent scholarship on gangs demonstrates the relevance of this issue and recognizes that there is also variation among individual gang members.

Though scholars agree that gang involvement exists on a continuum rather than as an either/or status, most research on gang youth continues to sort these youths into gang versus non gang categories. Curry et al. (2002) point out that such an approach may fail to acknowledge that there are appreciable differences regarding levels of gang involvement. For instance, scholars have found that most youth, even those who reside in distressed communities with gangs, do not report gang membership. Curry et al. (2002: 283) note that many of these youths, however, acknowledge having "some level of gang involvement," suggesting an intermediary gang status. Because of difficulties

such as this, gang scholars have recently begun to use different methods to determine whether research subjects belonged to gangs.

The variation in approaches to studying gangs has made the pursuit of a unified definition for gang membership less likely. For example, some studies rely upon self nomination and others utilize official data to determine gang membership. This has important implications for the ability to understand the nature and extent of gang involvement as well as the characteristics of gang members, their behaviors, and where they are more likely to be geographically located.

FEMALE GANG INVOLVEMENT

For much of the history of gang research, gang involvement in most major metropolitan areas was considered a male phenomenon. In fact, scholars have been studying male involvement in gangs since the early 1900s. As recently as a decade ago, however, we had little more than cursory information about females' gang involvement, with few studies offering conclusions that were based on information from young women themselves. Historically, researchers have either stereotyped or simply dismissed as inconsequential young women's involvement in gangs. This is not the case today. The recent expanded focus concerning women's gang involvement brings to light that they are more involved in gangs than was previously thought and that their experiences within the gang are, in fact, rather varied.

Within the past two decades there has been unprecedented interest in the purported growth in the number of gangs across the nation. There has likewise been considerable attention paid to the role of females in that increase. Anne Campbell's (1984) innovative book on New York gang members, *The Girls in the Gang*, along with Joan Moore's (1991) study of Los Angeles gangs, *Going Down to the Barrio*, continue to influence gang scholars' examinations of the lives of gang involved young women. Contemporary research has also advanced our understanding of young women's lives in the context of their gang membership. It is no mystery that gang involved youth have garnered the attention of many criminologists

who have found that these youths engage in more delinquency than their non gang peers. In fact, research has demonstrated that gang involved female youth have higher rates of delinquency than their non gang peers of either gender.

FUTURE DIRECTIONS IN GANG RESEARCH

Gang members are responsible for a disproportionate amount of crime. Violent and other serious offenses, however, are more likely to come to the attention of the public and result in the misperception that these events are common in the context of gang membership. Involvement in crime accounts for a small portion of gang members' activities. In fact, the majority of their time is spent engaged in activities usually associated with adolescents (i.e., hanging out with friends, playing sports, watching television, and shopping).

It is important for social scientists to expand studies of delinquent youth groups beyond that of the standard gang/non gang dichotomy, especially since gangs (depending upon how they are defined) account for only a small percentage of delinquent groups. Specifically, there are other delinquent peer groups that are not gangs but also have relevance even in neighborhoods with gangs. These groups also impact adolescent development and should therefore be examined as well.

It is unrealistic to expect that youth in particular types of communities will not have gang involved family members, neighbors, or peers who they interact with at least minimally. The difficulty of discerning membership in gangs or other delinquent peer groups has implications for those who seek to intervene in the lives of youth. This is particularly important if membership in other groups is a precursor to more serious forms of delinquency or gang membership. If it is difficult for parents, school officials, and even other youth to distinguish between various peer groups and gangs, it must also be troublesome for law enforcement personnel. In fact, young people in certain neighborhood contexts comment frequently regarding their being mistaken by police as gang members.

The responses of law enforcement agents, however, have particular implications for young people. For example, external threats to non gang peer groups by law enforcement may serve to increase cohesion among members as it has been found to do among gangs. This is important given that suppression efforts have been problematic in addressing gangs that have loose organizational structures. It is likely that this approach would also be troublesome given that other delinquent peer groups are generally less organized than gangs.

Incorrectly responding to non gang groups of youths as though they were gangs might cause members to be increasingly socially isolated from conventional institutions that could be otherwise beneficial to them. The role of gang membership in the alienation of gang involved youths from prosocial groups has been observed in the literature. On the other hand, simply ignoring delinquent peer groups who are not gangs is also a strategy fraught with problems.

gay bashing

Michael Smyth and Valerie Jenness

Often subsumed under the contemporary rubric of "hate crime," "gay bashing" denotes the perpetration of violence aimed at people identified as, or assumed to be, homosexual, including gay men, lesbians, bisexuals, and transgendered individuals. Although examples of this type of bias motivated behavior range from acts of symbolic and rhetorical violence to physical assaults and homicide, selection of the victim based on his or her perceived non normative sexuality is common to gay bashing in all of its manifestations. The targeting of victims based on perceived sexuality may be seen as a function of perpetrators' hatred for individuals thought to be members of a despised sexual minority. Indeed, gay bashing constitutes a form of victimization and intimidation aimed not only at a primary target, but at the entire group to which that individual is thought to belong.

Violence against people presumed to be homosexual has been documented for as long as the lives of gay men and lesbians have been documented. Boswell (1980), for example, documented violence against gay men and lesbians in Western Europe from the beginning of the Christian era to the fourteenth century. In *Gay American History*, which covers a period of over 400 years, Jack Katz (1976) documented a history of violence directed at individuals because of their sexual orientation, identity, or same sex behavior. Although recent research indicates that young, otherwise relatively

powerless white males, acting most often in pairs or groups, are the most common perpetrators of physical violence against individuals thought to be homosexual, a variety of individuals, groups, and institutions, ranging from victims' intimates (Island & Lettellier 1991; Renzetti 1992), to strangers (Herek & Berrill 1992), to the state (Fout 1990), religion (Boswell 1980), education (Fone 2000), and medicine (Katz 1976), have been implicated in the perpetration of gay bashing.

In the twenty first century the incidence of various types of violence against homosexuals occurs globally, across regional and national boundaries, and across cultures and ethnicities. In many countries around the world, particularly in Africa, the Middle East, and Asia, non normative sexuality is outlawed and those suspected of not being entirely heterosexual are often arrested, imprisoned, and subjected to torture. In addition, many "homosexual" people are beaten, banished, and/or killed by non official individuals or groups in their own communities, often by their own families or kin. Traditional Islamic law, for example, calls for those committing homosexual acts to be stoned to death or, alternatively, they may be killed by their families as a matter of honor. Commonly, even in countries where the government does not actively participate in, or openly condone, violence against "homosexuals," a climate of homophobia pervades the culture to the extent that, when incidents of gay bashing occur, police and other officials look the other way.

Due in large part to their extreme brutality and ultimately fatal consequences, certain incidents of gay bashing have received widespread public attention. The murder of Matthew Shepard in 1998, for example, garnered unprecedented media coverage in the US after the 21 year old gay college student was pistol whipped, tied to a fence, and left to die. His two confessed killers were convicted of murder with aggravating circumstances after separate prosecutors successfully argued that the killing had been motivated by homophobia. Six months later, in 1999, a nail bomb exploded outside the Admiral Duncan, a gay pub in central London. Three pub patrons were killed outright and approximately 80 others injured, some suffering traumatic loss of limbs. Two separate, right wing splinter groups called the

BBC, claiming responsibility for the attack. Also in 1999, the press reported how the body of Billy Jack Gaither, a 39 year old textile worker in the US, was burned atop two old tires doused with kerosene after he was beaten to death by two men, who alleged that the openly gay victim had made an unwanted sexual advance toward them. Two years after Gaither's killing, the press began extensive coverage of the events surrounding the murder of Eddie "Gwen" Araujo, a transgender California teenager. After the victim's biological gender was revealed to them, Araujo was initially strangled and subsequently beaten to death by a trio of young men, with whom she/he previously had sexual relations. Ironically, in April 2004, David Morley, former manager of the Admiral Duncan pub, who survived the nail bomb attack in 1999, was beaten to death in London by a group of four teenagers in the fourth fatal incident of gay bashing in that city in as many months.

Notwithstanding their notoriety, fatal examples such as these are not characteristic of the majority of gay bashings. More commonly, victims of gay bashing report being the object of verbal assaults or having objects thrown at them, as well as being chased, kicked, punched, and beaten. A number of self report studies suggest that the perpetration of these types of non fatal gay bashing are widespread – a majority of gay men and lesbians indicating that they have experienced either actual or threatened violence because of their sexuality – and that these types of incidents are on the rise (National Gay and Lesbian Task Force 1991; von Schulthess 1992). In addition, the entire population of gay men and lesbians has experienced the sting of rhetorical violence perpetrated by anti homosexual politicians, religious conservatives, and others voicing a message of intolerance for sexual diversity.

In one of the first government sponsored efforts to assess the scope of anti "homosexual" violence perpetrated by individuals or groups (as opposed to institutional or state endorsed violence), the US Department of Justice commissioned a report on bias motivated violence in 1987. That report found that "homosexuals are probably the most frequent victims" of bias motivated violence (cited in Vaid 1995: 11). Shortly after the release of this groundbreaking report, the Federal Bureau of Investigation

(FBI) began to collect data on crimes committed because of bias against homosexuals as part of its larger effort to track bias crime in the US. Beginning in the early 1990s, the Uniform Crime Report (UCR) documents a consistent pattern of violence directed toward both male and female homosexuals. According to the UCR, although race based violence is the most frequently reported type of bias crime in the US, violence based on sexual orientation is a close second. Finally, according to the UCR, reported violence against gay men is more common than violence directed toward lesbians. More recently, analyses of these official data reveal that if one adjusts for population size, homosexuals are the most frequent victims of bias crime in the US.

In light of its historically ubiquitous and socially pervasive nature, recent research suggests that the portrayal of violence against "homosexuals" solely as a byproduct of hatred may discount the complexity of the phenomenon. Tomsen (2002), for example, found that many perpetrators view anti homosexual violence not simply as an expression of hatred, but as a means of policing the boundaries of acceptable male sexuality and attaining heightened male status for themselves. In his study of the motives underlying anti homosexual violence, Tomsen advances the notion that, if we are to accept homophobia as the motive for gay bashing, then our definition of the term must be more broadly conceived "to advance an understanding of the links that such acts of violence ... have to commonplace forms of male identity" as they are construed within an overwhelmingly heteronormative society. In short, to understand gay bashing requires understanding the complexities of a larger sex/gender system in which they are inspired and manifest.

gay gene

Edward Stein

The idea that a gene or set of genes makes some people sexually attracted to people of the same sex has become widely accepted over the past few decades. However, scientific evidence supporting the existence of a gay gene is inconclusive and the political and legal rationale some scientists have for the "search for the gay gene" (Hamer & Copeland 1994) is dubious.

Early in the twentieth century, geneticist Richard Goldschmidt (1916) suggested that the bodies of homosexuals did not "match" their sex chromosomes. According to this hypothesis, which was accepted by many people, gay men have female typical sex chromosomes and lesbians have male typical sex chromosomes.

This hypothesis was shown to be false about 40 years after Goldschmidt proposed it (Pare 1956) and it is not accepted even by those who believe in the existence of a gay gene.

Today, some scientists continue to look for genes that account for differences in sexual orientations. The search for the gay gene is at least initially plausible for various reasons, in particular, in light of several recent scientific studies that purport to show that sexual orientations are biologically based and that this biological basis is inborn or determined at an early age (LeVay 1996; Stein 1999: ch. 5). The most prominent study in the search for the gay gene was done by Hamer and colleagues (1993) and it is supposed to support the conclusion that a region of the X chromosome codes for male homosexuality.

Inside of each person's cells is an elaborate chain of DNA that is like a recipe for how to make that person's body. Isolating the role that a portion of genetic material plays in the development of a human is complicated, although the Human Genome Project has recently succeeded in doing just that. Identifying the specific genetic material that leads to complex psychological traits like a person's sexual dispositions is, however, much more difficult. There are, however, less direct ways to get evidence concerning the genetic basis of a trait besides isolating specific genetic material. One way to determine whether a trait is genetic is to study different types of twins. Identical twins have the exact same genes. Fraternal twins, though like identical twins in that they are born at the same time, are only as closely related as two non twin biological siblings are. Because identical twins are genetically identical, differences in characteristics between them must be due to differences in their pre or post natal environment, *not* their genes. This inference does not work in the other direction. If identical twins have the same trait, one cannot infer that this trait is genetic. If identical twins share a trait, it might be because they were raised in the same environment. For example, if both members of most pairs of identical twins know the Ten Commandments, this does not show that knowing the Ten Commandments is genetic. Applying these observations to sexual orientation, several studies suggest that sexual orientation runs in families (Pillard & Weinrich

1986; Pillard 1990). These studies indicate, for example, that the brother of a gay man is more likely to be gay than the brother of a straight man. These studies do not, however, establish that sexual orientation is genetic because most siblings, in addition to sharing about 50 percent of their genes, typically share many environmental variables.

To quantify the extent to which a trait is inherited, scientists have developed the concept of heritability, which represents the extent to which a trait was caused by genetic factors. Heritability is the ratio of genetically caused variation to the total variation among individuals with the trait. Heritability concerns the extent to which differences among people regarding a characteristic are caused by genetic differences. The heritability of a trait is importantly different from whether a trait is genetically determined; it captures some, but not all, aspects of our intuitive sense of genetic causation.

Consider one example. Having 10 fingers is a paradigmatic example of a trait that is genetically determined. The heritability of number of fingers is, however, quite low because having fewer than 10 fingers is typically due to environmental factors not correlated with genetic factors. Most cases of not having 10 fingers (though not all) are due to problems in fetal development (e.g., caused by the sleeping pill thalidomide) or to accidents (e.g., caused while cutting a bagel). The heritability of having fewer than 10 fingers is calculated by dividing the number of people who have fewer than 10 fingers due to genetic factors by the total number of people with fewer than 10 fingers. Since far more people have fewer than 10 fingers because of non genetic causes, the heritability of this trait will be low, despite the fact that having 10 fingers seems like a paradigmatic example of a trait that is genetically determined. The heritability of a trait is contingent on features of the environment. In an environment in which no one took thalidomide or cut off a finger accidentally, the heritability of having less than 10 fingers would be much higher. This highlights the difference between showing that a trait is heritable and showing that a trait is genetically determined (Stein 1999: 140–4).

Sophisticated heritability studies have been done to assess sexual orientation in same sex identical twins, same sex fraternal twins,

same sex non twin biological siblings, and similarly aged unrelated adopted siblings (Bailey & Pillard 1991; Bailey et al. 1993). The idea behind these studies is that if sexual orientation is genetic, then identical twins should have the same sexual orientation and the rate of homosexuality among the adopted siblings should be equal to the rate of homosexuality in the general population. If, on the other hand, identical twins are as likely to have the same sexual orientation as adopted siblings, then genetic factors make very little contribution to sexual orientation. In these studies, subjects were recruited through ads placed in gay publications that asked for gay or bisexual volunteers with twin or adoptive siblings of the same sex. Subjects were asked to rate their own sexual orientation, the sexual orientation of their relatives, and for permission to contact their siblings. In both heritability studies the concordance rates for identical twins were substantially higher than for fraternal twins. For example, 48 percent of the identical twins of lesbians were themselves lesbians, as were 16 percent of the fraternal twins, 14 percent of the non twin biological sisters, and 6 percent of the adoptive sisters (Bailey et al. 1993).

While these results are consistent with a genetic effect, there are various problems with these studies (Byne & Parson 1993; Stein 1999: 148–53), including biases in the sample populations. For, example the twin studies would lose their significance if gay men with gay identical twins are more likely to volunteer for such studies than are gay men with gay fraternal twins (Stein 1999: 191–5).

Building on the twin studies, Hamer and colleagues (1993) endeavored to isolate the portion of the human genome responsible for sexual orientation. Starting with the idea that homosexuality runs in families and is heritable, he recruited gay men using the same methods as the twin studies. Hamer's survey of this population pointed to a distinctive distribution of male homosexuality in his subjects' families: men on the mother's side of gay men's families were more likely to also be gay than men on the father's side. This pattern among gay men's families suggested to Hamer that male homosexuality, like, for example, color blindness, is inherited from one's mother in virtue of being carried on the X chromosome.

To test the hypothesis that there is a gene for homosexuality on the X chromosome, Hamer created a pool of subjects apparently enriched for the gene he was looking for and obtained DNA samples from two gay brothers in each of these families. These samples were then analyzed using linkage analysis to determine how frequently the brothers had matching genetic material in the X chromosome. Linkage analysis is a technique for narrowing the location of a gene using DNA "markers," which act like signposts scattered throughout the human genome. This technique enables scientists to determine the likelihood that two people share genetic material in a stretch of DNA. Hamer found a higher than expected percentage of the pairs of gay brothers had matching genetic sequences in a portion of the q28 region of the X chromosome (82 percent rather than 50 percent). While Hamer did not identify a particular genetic sequence associated with homosexuality, he did find that many of the pairs of homosexual brothers had matching genetic sequences in a region of the X chromosome.

There are several problems with Hamer's study. First, two independent research teams have failed to replicate his results (Bailey et al. 1993; Rice et al. 1999). The only replication was by Hamer's own group (Hu et al. 1995). Second, Hamer's study suffers from the same sort of sampling problems as the twin studies. Third, several commentators have expressed concerns about the most significant result of Hamer's research, namely, the increased rate of homosexuality on the mother's side of the gay men's families. Some have said that the different rate of homosexuality among maternal and paternal relatives is not statistically significant (Risch et al. 1993; McGuire 1995). Further, geneticist Neil Risch has suggested that the increased rate of homosexuality on the maternal side of gay men's families could be due to the fact that gay men are less likely to have offspring than men who are not gay. To see this, suppose that there is a gene that, in certain environments, tends to cause men to be gay and suppose that it is *not* carried on the X chromosome. Even so, in such environments, people would be less likely to inherit such a gene from their fathers because the gene, by hypothesis, tends to cause men to be gay, and gay men are less likely to have offspring than

other men. Thus, a gene linked to male homosexuality would appear maternally linked even if such a gene was not on the X chromosome.

More generally, linkage analysis is best suited for discovering the genetic basis of traits controlled in a genetically simple manner rather than traits that are controlled by several genes working in concert. This technique has mistakenly indicated that a specific genetic sequence plays a role in the development of a particular trait (Bailey 1995). Such mistakes are especially likely in the case of genetically complex traits, cognitively mediated psychological/behavioral traits, or those strongly affected by environmental factors. For these general reasons linkage analysis does not seem a promising technique for the study of sexual orientation.

These concerns aside, Hamer's study simply does not justify talk about gay genes. Genes in themselves cannot directly cause a behavior or a psychological phenomenon. Genes direct RNA synthesis that in turn leads to the production of a protein that in turn may influence the development of psychological dispositions and particular behaviors. There are many intervening pathways between a gene and a behavior or a behavioral disposition, and even more intervening variables between a gene and a cognitively mediated behavior. The concept "gay gene" has no meaning unless one proposes that a particular gene, perhaps through a hormonal mechanism, organizes the brain specifically to support the desire to have sex with people of the same sex (Byne 1996). No one has presented evidence in support of such a simple and direct link between genes and sexual orientation (Allen 1997; Byne 1996; Stein 1999: ch. 7).

In light of this, why are so many people interested in finding the gay gene? For many, including some scientists, the motivation is the legal/ethical/political intuition that proof of a gay gene would establish the wrongness of discrimination against lesbians, gay men, and bisexuals and the wrongness of withholding from them legal and social benefits that heterosexuals take for granted (LeVay 1996). There are several problems with this intuition (Hamer & Copeland 1994: ch. 13; Allen 1997; Stein 1999: chs. 10–12). First, even if there is a gay gene, a person's public identity, sexual activities, romantic relationships, and involvement in childrearing are all not determined by

genes even according to those who believe in a gay gene. Even if there is a gay gene, society could enforce extreme legal and social sanctions against lesbians, gay men, and bisexuals for their behaviors, identifications, and public expressions. Many human characteristics believed to be genetic – like dispositions toward disease, mental illness, or alcoholism – are highly stigmatized and people go to great lengths to avoid them. Even if there was a gay gene, homosexuality might still be deemed a disease or a socially undesirable characteristic, which might result in pressure to “cure” or prevent the birth of homosexuals. The search for the gay gene is thus not only scientifically unproven, but the legal and political motivations for this research are questionable and the social implications of this research are uncertain.

gay and lesbian movement

Stephen Valocchi

The gay and lesbian movement refers to the manifold collective efforts to benefit people with same sex desire. Although an organized movement first appeared in Germany in the late nineteenth century, this effort was

shortlived. The first sustained activities, organizations, and network building for the positive recognition of lesbians and gays and the improvement of their social and political conditions appeared in the United States in the 1940s and 1950s with the establishment of three organizations: the Mattachine Society, an organization for men which devoted itself mainly to social support in a climate of profound public hostility; the Daughters of Bilitis, an organization that concerned itself with the unique challenges of women with same sex desire at a time when women were supposed to be dependent on men for economic and social support; and *One Inc.*, which existed only as a monthly magazine and promoted the view that gay people, rather than psychiatrists or lawyers, are the most qualified to speak for themselves. With the exception of *One Inc.*, these organizations stressed respectability and the desire to be accepted into mainstream society.

In the 1960s, the gay and lesbian movement entered a new phase as social movements created a more militant climate for disenfranchised groups in the United States and forced the movement to shift its focus, strategy, and goals. Following the Stonewall Riots of 1969 sparked by a routine police raid on a gay bar in Greenwich Village in New York City, the movement devoted itself to two somewhat conflicting goals: the pursuit of a variety of civil rights reforms, from the passage of anti discrimination legislation to the elimination of sodomy laws, and the pursuit of fundamental social change aimed at eradicating homophobia, heterosexism, and sexual repression. The Gay Activists Alliance was most closely associated with the former pursuit, the Gay Liberation Front with the latter. By the end of the 1970s, the liberationist impulse had dissipated but the rights based approach proved somewhat successful. At both the local and state levels, people joined organizations and promoted initiatives to combat discrimination against gays and lesbians. The strategy of "coming out of the closet," making public one's identity as gay or lesbian, contributed to this rights based focus since it helped build a group identity, thus giving gays and lesbians access to similar language of pride and positive strategies used by other minoritized groups.

The development of the movement during this time cannot be told without reference to the tensions between men and women in the movement and to their subsequently different trajectories of community building. Post Stonewall collaboration between men and women was sporadic as women experienced homophobia in women's liberation groups and sexism in men led gay groups. Nonetheless, the profound influence of the women's movement led many women to build lesbian feminist organizations identified more by women's resistance to patriarchy than by women's sexual desire for other women. This tendency led in the 1980s to the development of women identified institutions, from bookstores and cafés to sexual assault and rape crisis centers. During this same time gay men were building their own networks of community institutions, but these were of a more commercialized nature in the form of bars, nightclubs, neighborhoods, and sex clubs.

Given the association of gay men with a liberalized sexual culture and lesbians with feminism, it is not surprising that the visibility of the gay and lesbian movement in the late 1970s and 1980s led to the rise of a significant countermovement in the form of the religious right. Their many campaigns directed at state and local gay civil rights ordinances were successful not only in reversing some of these gains, but also, perhaps more importantly, in reviving the rhetoric of immorality from the earlier pre Stonewall era. This countermovement and the election of a conservative Republican administration in 1980 left the movement vulnerable and the community without political support when AIDS starting killing thousands of gay men.

The AIDS epidemic had several consequences for the movement. First, issues of treatment, care, and funding came to dominate the agenda of the movement in the 1980s and early 1990s. Second, it led to the establishment of a dense network of AIDS service, advocacy, and treatment organizations that emerged fairly rapidly due to the already established community and health based resources of the gay and lesbian community. Third, its widespread impact brought many more people into the movement and propelled the movement into a period of heightened mobilization. Fourth, because of the involvement of many lesbians in

this new mobilization and in those care giving organizations, it led to a closer association between men and women in movement initiatives than had been the case since the 1970s.

The epidemic was also partly responsible for a brief but notable shift in focus for some segments of the movement in the 1990s. Dissatisfied with its narrowly rights focused, assimilation based goals, a new militancy invigorated the movement, first in the form of ACTUP (AIDS Coalition to Unleash Power), then with organizations such as Queer Nation and the Lesbian Avengers. These organizations rejected the standard definitions of gay, claimed the more non normative moniker of "queer," and embraced direct action strategies that were directed both at social institutions like the government and the medical establishment and at the general culture, seen by these activists as homophobic, sexist, and anti pleasure.

Various internal challenges also characterized the movement at this time, all of which signaled a loosening of the dominant identity categories of gay and lesbian. Women and men of color, bisexuals, and transgendered activists challenged the white middle class nature of the movement and its notion of a fixed salient identity defined by sex of object choice and insisted the movement take their concerns seriously. Many women in the 1990s also rebelled against the rigid definitions of lesbian feminism by rejecting the androgynous styles and sex negative attitudes of some segments of this community, embracing leather and sadomasochist sexual repertoires and reviving and re eroticizing butch-femme modes of style and embodiment.

The most recent developments in the lesbian and gay movement can be understood against the backdrop of the somewhat more favorable political climate of the 1990s, the heightened cultural visibility of gays and lesbians in the media, and the growth of centralized advocacy organizations. Taken together, these developments led the movement to pursue several top down policy initiatives with more resources and with a wider set of strategies than ever before. The issue of gays in the military consumed much of the movement's attention throughout this period: first in organizing to push President Clinton to make good on his

campaign promise to end discrimination against gays and lesbians; then in trying to undo the damage done by Clinton's "don't ask, don't tell" policy, which had the effect of expelling from the military men and women who expressed any statement of same sex desire. Most recently, the movement and the nation have been captivated by the push to legalize same sex marriages in the United States. Partly in response to court challenges in Hawaii and Massachusetts, the movement has marshaled tremendous resources to support these lawsuits, to prevent anti same sex marriage bills from being introduced into state legislatures and in Congress, and to push for civil unions, domestic partnerships, and bona fide marriage. Both of these policy initiatives – gays in the military and same sex marriage – signal a decided return to a rights based, assimilation focused orientation to the gay and lesbian movement.

As is the case with any number of social movements, the gay and lesbian movement presents sociologists with opportunities to study the dynamics of collective action: the conditions that led to its emergence, the internal development of resources, community, and consciousness, the framing strategies the movement uses, the relationship between the collective identity and the goals the movement seeks, and the factors affecting success and failure.

Until the late 1980s, with a couple of exceptions (Adam 1978; Altman 1971), the gay and lesbian movement was not systematically studied by sociologists. Until that time homosexuality was mainly studied in the context of deviance, subcultural formations, and the formation of a homosexual identity via symbolic interaction. It was mainly the impact of the social movements of the 1960s that transformed sociology's understanding of homosexuality from a deviance perspective to the study of a minority group. It was also due to the development of theoretical frameworks that viewed collective action not as a consequence of collective alienation but as politics by other means. Resource mobilization and political process approaches called attention to the structure of opportunities in the political environment and the quantity and quality of resources of the constituency which in turn affect the emergence and success of social movements directed mainly

at the state. New social movement approaches emphasize a wide array of post scarcity movements, sometimes organized on the basis of social identities and directed not primarily to the state but to challenge "stigmatizing public discourses and representations" (Seidman 1993: 108) of different social groups. Both frameworks informed sociologists' study of the gay and lesbian movement.

Since the 1980s sociologists who have studied the movement have focused on five sets of issues. The first set involves research on the structural conditions that led to the emergence of an organized movement. This research has stressed the importance of the rise of industrial capitalism, changes in the nature of the family accompanying capitalism, the impact of bureaucracy on intimacy among men, and the rise of medical science. These factors taken together had contradictory consequences: on the one hand, they created the contexts whereby individuals with same sex eroticism could turn that practice into an identity and find others in urban areas who did the same. On the other hand, these same factors named the identity as pathological, established a medical and regulatory apparatus to police the identity, and created the (homo)phobia regarding expressions of same sex emotional intimacy or sexual expression. These conditions generated the political opportunities, resources, and grievances that led to mobilization on the basis of a sexual identity defined by sex of object choice.

A second set of issues involves research on the goals of the movement. The initial impulse of the movement had been the desire to change the way the culture views homosexuality: the movement emerged in a society that saw homosexuality as sin, sickness, or crime. Later, the movement shifted to working for civil rights through the state and other social institutions. This dual emphasis of the movement on changing culture and changing laws and policies makes it an interesting case study for sociologists since it allows them to engage issues of reform versus structural change, assimilation versus transformation. Work on this issue has focused on specifying the historically variable conditions that influence whether movement actors will focus on politics, culture, or some combination of the two. This research strategy brings together the concerns of political process

and resource mobilization approaches with political climate, resources, and networks and the concerns of new social movements' perspectives on changing norms and belief systems and with building a collective identity.

The third set of research issues involves the ways that the movement constructs and reconstructs collective identity. Collective identity refers to the shared definition of a group that derives from members' common interests, experiences, and solidarity. Another unique feature of the gay and lesbian movement derived from the socially constructed nature of sexuality is its concern with defining the constituency: who is the "we" that the movement represents? This feature has proven more pressing as conflicts between men and women, and battles over the inclusion of bisexual, transgendered, and intersexed persons have taken place. These battles are about the collective identity of the movement. Research on this issue seeks to explain how the boundaries are established and who gets to police them. It focuses on the material, organizational, and symbolic factors such as the class interests supporting the collective identity, the organizational structure that prevents other competing definitions from taking shape, and the symbolic messages embedded in the collective identity about "respectability" that is then communicated to the larger culture.

Related to this set of issues is a fourth focus on framing. Framing refers to "an interpretive schemata" (Snow & Benford 1992: 137) that distills the message or messages of the movement for several purposes: to recruit a constituency, create a collective identity, craft strategy, and gain outside support. Framing is fraught with dilemmas for all social movements since frames try to satisfy a number of potentially conflicting agendas. For the gay and lesbian movement, this is particularly significant given its framing as both a political and a cultural movement, the fractious nature of the collective identity, and the strength of the countermovement. Research on this issue has typically demonstrated the tensions occurring between a civil rights framing strategy – a dominant frame of many social movements – and other strategies derived from the varied nature of the movement. Frames such as sexual liberation or institutional heterosexism have competed with the civil rights frame, and these competing

frames rise and fall in tandem with internal struggles around collective identity and the external opportunity structure.

A fifth focus is the impact of queer theory and politics on the study of the gay and lesbian movement. Queer theory has called attention to the instability of sex and gender categories and stresses the performative nature of identities thought to be rooted in anatomy or culture. Queer politics extends this deconstructive analysis and critiques the gay and lesbian movement for its essentialist definition of sexual identity, its construction of exclusionary boundaries, and its stabilization of the identities of gay and lesbian. According to this critique, identity based strategies for social change deny the fluidity inherent in sexuality and invalidate the experiences of others with non normative sexuality who may not easily fit the class and race or western inflected definition of the identity. In addition, identity based strategies reinforce the boundaries between gay and straight, man and woman, and thus reproduce the hierarchical relationship between the dominant and the subordinate terms of the sex/gender system. This challenge to the essentialist model of sexual identity of the traditional gay and lesbian movement was first made by ACTUP with its boundary crossing and label disrupting tactics and by bisexual and transgendered people who exemplify the kind of boundary crossing embraced by queer politics.

Research on the movement that has used queer insights has focused on the internal and external pressures that affect when identity stabilizing and identity deconstructing frames and strategies will be used, noting both the concrete gains made through interest group politics and the cultural challenges made through identity blurring queer politics. A queer inflected understanding of social movements has also broadened the repertoire of collective action to include strategies such as political theater, performance art, and drag. This broadening dovetails with the cultural concerns of the movement as well as with the deconstruction of sexual and gender identities that now informs some segments of the contemporary movement. The challenge for sociologists in our future work is to extend, refocus, or alter our theoretical models of emergence, development, and impact to explain collective

action repertoires as diverse as the sit down strikes of the 1930s and the drag shows of the twenty first century.

Gellner, Ernst (1925–95)

Rodanthi Tzanelli

Perhaps one of the most prolific scholars of the twentieth century, Ernst Gellner remains a highly influential figure across many disciplines (sociology, history, anthropology, and philosophy). He was born in Paris, but was of Czech Jewish parentage and he grew up in Czechoslovakia. In 1939, with the resurgence of anti-Semitism in Central Europe, he moved to England, where he spent most of his life. During World War II he served in the Czechoslovakian Armored Brigade (1944–5), and later

he returned to Oxford, where he received a degree in politics, philosophy, and economics. From 1949 until 1984 he was in the department of sociology at the London School of Economics (LSE), where he completed his doctorate in social anthropology (1961) and became professor of philosophy (1962–84). He was, among other things, Visiting Fellow at Harvard (1952–3), the University of California, Berkeley (1968), and the Centre de Recherches et d'Études sur les Sociétés Méditerranéennes (1978–9), member of the Social Science Research Council (1980–6), and Chairman of the International Activities Committee (1982–4). Between 1993 and 1995 he was Director of the Centre for the Study of Nationalism at the Central European University in Prague, where he died in 1995.

Gellner's initial philosophical inquiry involved a critique of linguistic philosophy as conservative, parochial, and restrictive. His *Words and Things* (1959) suggested a sociohistorical approach to theory, which contextualizes schools of thought and questions the ideological subtext of their theses. His critical approach to intellectual production and its sociopolitical origins, which was exemplified in his critique of Oxford philosophical parochialism, earned him many friends and enemies in the social sciences. The same critical spirit guided his pen later, when he reconsidered other hegemonic systems of thought, such as Islamism, psychoanalysis, relativism, and hermeneutics. An early application of this formula can be seen in *Thought and Change* (1964), where Gellner suggested that nationalism legitimates social order, especially in countries in which modernization led to social fragmentation. This Marxist conception of nationalism as a hegemonic product was reconsidered and modified by Gellner himself in his later work, but was never wholly abandoned.

Gellner's anthropological explorations began with *The Saints of Atlas* (1969), a study of Moroccan Berbers and their system of thought. In this study, Gellner defended the value of Berber conceptual frameworks of the world that contest institutional structures derived from the centralized Moroccan state model but enable an organization of social life based on indigenous beliefs. The same themes of local knowledge and hegemonic thought, particularity and

fabricated universality occupied Gellner in *Patrons and Clients* (1977) and *Muslim Society* (1981). Likewise, he developed an interest in Soviet anthropology and its theoretical subtleties that were depreciated by western Marxists. His edited volume *Soviet and Western Anthropology* (1980) marks an attempt to bring together different ways of implementing Marxism in the social sciences. His interest in Soviet politics and society found renewed expression in *Conditions of Liberty: Civil Society and its Rivals* (1994), in which he offered a brilliant reassessment of Marxism through an investigation of the conditions of modernity. *Conditions of Liberty* is deemed to be one of the most scholarly contributions in the study of civil society and its future in a post communist Russia overtaken by market values.

Gellner had a longstanding interest in the phenomenon of nationalism and its different manifestations in Western, Central, Southern European and other, non European, societies. In *Nations and Nationalism* (1983) and *Nationalism* (1997) he examined the rise of nationalism as an ideal that advocates the dominance of a uniform culture. Revising or revisiting some of the ideas he introduced in the 1950s, he argued that nations emerge when local cultures are replaced by the culture of the “nation,” which assimilates or eradicates deviating ways of living. Often, but not always, identifying the nation with the nation state, Gellner located the emergence of national culture in the modern conditions that prevailed with the extinction of close knit, agrarian communities and the advance of industrialization that resulted in social mobility and alienation. In this context, citizenship became the primary loyalty of the nation’s participants. A homogeneous educational system that promotes common traditions, beliefs, and language is sustained by the ruling elites, so that the nation’s members, equally educated, can move flexibly between places and roles without compromising the nation’s solidarity. At times Gellner replaces the industrialization model with the advent of Enlightenment rationality; a modernist at heart, he located the emergence of national identity in the post Enlightenment era. Gellner’s theory was criticized by Anthony Smith, one of his students and a defender of the ethnic, historical origins of nations (an argument encapsulated in

Smith’s concept of *ethnie*). In October 1995 an open debate was held at the University of Warwick between Gellner and Smith, in which Gellner defended the civic model of nationalism in opposition to Smith’s ethnic model. The Gellner–Smith dialogue was published in *Nations and Nationalism* (1996), the journal of the Association for the Study of Ethnicity and Nationalism based at the LSE and chaired by Smith, in 1996. Gellner was invited to continue this debate at the LSE, but he died a few months before the event.

For some, Gellner’s research trajectory appears to be fragmented and lacking a coherent agenda. This is partially because his interests spanned many disciplines and subject areas. Often, Gellner changed his views on phenomena he analyzed, or developed ideas that initially appeared in the form of essays, rather than extensive monographs. His work, however, has been influential in sociology and social anthropology, and still informs the study of culture, nationalism, and modern identity.

gender, aging and

Tomi Calasanti

Interest and research in gender and aging have progressed through a variety of different phases, each spurred by developments in both feminist scholarship and aging studies. While each stage has emerged from the previous, all can be found in contemporary theory and research.

The first stage, which can be further subdivided into two approaches, involved a focus on women. Spurred by the 1970s women's movement, in the early 1980s some scholars of aging began to question the lack of explicit attention paid to aging women. This was obvious in such topic areas as retirement, where women were routinely excluded from research. Even national, large scale data sets, such as the longitudinal retirement study undertaken by the Social Security Administration in the 1970s, only included women as primary respondents after their husbands had died. The presumed split between private and public spheres fostered a belief that paid labor was central only to men's identities and that, for women, retirement was either irrelevant or unimportant.

Two attempts to address the neglect of women in aging research ensued, each representing a somewhat different approach. The first simply added women to research. Similar to what had occurred in other areas of sociology, scholars began to include women in studies or investigate them on their own. However, this "add women and stir" tactic simply placed women into models and theories that derived from men's experiences. Conceptually, gender remained an individual attribute, a demographic characteristic with no structural properties. For example, noting differences between men and women's labor force participation histories led to the conclusion that women's intermittent work histories result in lower retirement benefits. Why and how women's work histories

differed, or why policies such as Social Security or defined benefit plans rewarded stable labor force participation were neither questioned nor explored. Similarly, the equation of workforce participation with adequate retirement finances assumed a gender neutral workplace in which women and men reap similar rewards.

As important as this movement toward inclusion was, using men as the explicit or implicit reference group ultimately rendered women deviant. Results and subsequent theorizing viewed women in terms of how closely they did or did not approximate male models, but revealed little about women themselves. In addition, the ways in which subsequent "differences" could be interpreted and used were problematic. Gibson (1996) pointed to the bias in the ways scholars typically discuss gender differences in old age, noting that men are used as the implicit standard and women are described as deviating from it. This has critical implications for future theory, research, and policies.

The realization that simply adding women into preexisting studies and theories rendered them as the "other" spawned a movement to examine women on their own terms. Spurred by developments in feminist scholarship, scholars undertook a second response to the neglect of women, that of centering on women's experiences from their own standpoint. More common in the 1990s, research that has centered on women has allowed for a reformulation of methods and theories that incorporate women's experiences as well as men's.

For example, in contrast to the model intended to discern if women were more or less satisfied with retirement than men, research beginning with women's experiences revealed that, for most women, leaving the labor force meant leaving only one job, a paid job. For the most part, women retained their domestic labor responsibilities. This does not necessarily diminish their satisfaction with retirement, but certainly shapes their experiences of this time of life in a different way from men's. Indeed, the notion of being "free" in retirement does not mean the cessation of work for women, but instead a reduced work load (for which they may well be grateful). The heightened focus on unpaid labor that resulted from centering on retired women also refocused attention on the productive activities of old people, both

men and women. While unpaid, the varieties of domestic and volunteer activities (to use just two examples) in which old people engage are vital to the economy. In particular, their unpaid labor is called upon to compensate for the increasing retraction of the state from social reproduction, and the formation of policies that continue to leave such activities as caregiving, for young and old, to "families" (i.e., women). The lack of state help and inadequate policies mean that, for instance, grandparents (particularly grandmothers) play an increasingly important role in child rearing, not only in a custodial role but also as day care providers for children who work. Without this important labor, state coffers would be strained and the economic activities of younger generations would be constrained. Thus, the focus on women in this instance has led to transformations in concepts about work, productivity, and retirement.

Continued evolution of the feminist approach in sociology and in aging studies has led to a movement away from a focus on women and aging to the second stage, with its focus on gender and aging. This implies not so much a movement away from examining women as a refinement of the theoretical lens. Centering on women's experiences leads to more explicit theories regarding power in gender relations. Further, it recognizes explicitly that both women and men have gender: "gender and aging" refers to everyone, and not just to women. From this standpoint, gender is taken to be characteristic of both social organizations and identities, embedded in social relationships at all levels, from individual interactions to institutional processes. Men and women gain identities and power in relation to one another with important ramifications for life chances (Hess 1992). As a power relation, gender describes a hierarchical system wherein men's privileges are intimately tied to women's disadvantages. This relational quality means that the situation of one gender cannot be understood without at least implicit reference to the position of the other. As a social organizing principle, then, gender shapes individual interactions as well as policy formation.

The theoretical shift toward viewing gender relations can be seen in many areas of aging research. Depicting both work and family as playing roles in both men's and women's lives

in old age is but one example. To push our example of retirement further still, a focus on gender relations over the life course sees women's and men's experiences of retirement as an outcome of the ways in which each is advantaged or disadvantaged in relation to one another in paid labor, unpaid (domestic) labor, and retirement. The presence and absence of family ties, or domestic labor, paid labor, and the like, are expressions of gender relations. It is not simply that women are constrained by families when they work for pay, or that this domestic labor shapes their retirement by lowering pensions and maintaining their burdens of housework. Both domestic and paid labor realms also influence men's *higher* retirement finances and relative freedom. That is, husbands' abilities to have successful careers rest on the unpaid work of their wives just as surely as this domestic responsibility constrains women's paid labor. Similarly, women's continued responsibility for domestic labor in later life underlies (some) men's ability to be "free" in retirement.

A newer, more sophisticated reformulation of theory results from the greater emphasis on gender relations. Attending to women and men in relation to one another also stimulates greater research interest in masculinity and men. Understanding the processes by which disadvantage occurs necessitates a similar comprehension of privileging processes and struggles. Implicit when we acknowledge that men's freedom in retirement links to women's unpaid labor, this becomes explicit in the next step when we explore the processes that privilege men in the workplace and home. Similarly, we would also investigate the relationship between privilege and widowers' risk for institutionalization or loneliness in later life. In this instance, husbands' more dominant household position also means that women are generally the ones to do the work of daily life and maintain networks. Viewing gender relations in relation to aging thus requires seeing privilege (just as we would disadvantage) as a dynamic, one that must be constantly reasserted and that this in itself has consequences for aging as well. Similarly, some of the same aspects of gender relations that are part and parcel of women's disadvantage may also emerge as sources of strength in later life.

The focus on power relations, and greater recognition of the dynamics of oppression and privilege, have led many to an emerging third stage, which emphasizes intersections of inequalities. Just as gender shapes aging, so other social hierarchies, such as those based on race, ethnicity, class, and sexuality, influence both gender and aging. From this vantage point, to speak of "gender and aging" becomes less apt. Old men and women do not exist outside their racial, sexual, and class based locations. For example, when we look only at old men and women, we see a much higher incidence of poverty among the latter. But when we look at race, for example, we find that, as a group, black men have lower Social Security incomes than do white women. Similarly, black women who live alone have a much higher incidence of poverty than their male or white counterparts despite longer labor force histories. How then can we discuss gender and poverty in old age? As a result, scholars working in this nuanced area increasingly focus on diversity and intersecting hierarchies, and not simply on gender.

As the example of retirement shows, the focus on gender and aging – in all three phases – has led to many insights that have advanced, and often redirected, scholarship. One of the first insights was the existence of a "double standard of aging" that not only devalues women at an earlier age than men, but also leads to age discrimination in the workforce earlier in women's lives. Since then, scholars of gender and aging have continued transforming a wide array of research areas. In relation to health, for instance, researchers go beyond noting gender differences in life expectancies and health conditions to ask *why* these variations prevail, and how they relate to power relations. They point to such things as how men's attempts to achieve dominant ideals of masculinity lead them to take physical risks that women do not take; they also seek out and follow doctors' advice less frequently, actions that will adversely influence their health in later life. Similarly, scholars seek to understand how women's social location makes them more vulnerable to particular health conditions and forms a context in which such ailments will play out in old age. Thus, among other issues, analysts might point to the gender bias in Medicare that provides coverage for acute illnesses, to which men are more

prone, rather than chronic conditions, which more frequently plague women, and the ramifications this might have for such things as nursing home utilization. Going further still, the diversity approach explores racial and ethnic disparities in health over the life course as this relates to occupational conditions, access to health care, and a greater reliance on Medicaid to fund nursing home placement.

Looking at other areas of research, we see that the kinds of grandparenting roles undertaken are closely related to race, ethnicity, class, and gender; those with full time care of grandchildren are more likely to be black or Hispanic women with lower incomes. We cannot simply speak of the ways that aging influences sexuality in later life, or even women's relationships with their bodies, as it appears that old black women, for instance, are far more accepting of diverse body types and also more likely to see themselves in sexual terms than are their white counterparts. Finally, the particular historical and economic conditions under which many contemporary, working class black men have labored means that along with dissolution of first marriages, earlier family ties often become strained as well. As a result, they are especially vulnerable to isolation and institutionalization should they become widowed or divorced in later life. The importance of these and similar findings lies in terms of the recognition that practice and policy interventions, for example, must take into account the differences among the concerns and issues of various old people.

The gender and aging scholarship has advanced tremendously, especially in recent years. However, it is still a one way relationship, with gender scholars often influencing aging research but not vice versa. Still to come, then, is gender scholars' recognition of age relations and the ways in which they intersect and influence gender. The limited discussion of how gender might change over the life course among some aging scholars is not the same as viewing age itself as a power relation that shapes people's interactions, resources, and life chances. Recognition of age relations suggests an array of promising directions for future studies. We should ask how men, even those with the most privilege, lose status with age and struggle with younger men for power, and how this might shape their aging. Greater attention to age

inequality will, in turn, allow researchers and practitioners more fully to view people in a life course context. Recognizing that ageism permeates the lives of all old people, regardless of their level of privilege in earlier life, also has tremendous emancipatory potential. The realization that ageism is the one oppression all will face could provide a bridge across many groups defined by power relations, and spur those with greater privilege to think about and understand disadvantage.

gender bias

Jennifer Rothchild

Gender bias is behavior that shows favoritism toward one gender over another. Most often, gender bias is the act of favoring men and/or boys over women and/or girls. However, this is not always the case. In order to define gender bias completely, we first must make a distinction between the terms gender and sex. When we use the term *gender*, we mean socially constructed expectations and roles for women and men, for girls and boys. Specifically, girls and women are expected to demonstrate feminine behavior, and boys and men are expected to act masculine. By *sex*, we mean biological differences assigned to females and males in order to distinguish between the two. The biological characteristics assigned to females and males often consist of primary or secondary sex characteristics.

The term gender bias is often (wrongly) used interchangeably with the term sexism. *Sexism* is typically defined as the subordination of one sex, usually female, based on the assumed superiority of the other sex (Kendall 2005) or an ideology that defines females as different from and inferior to males (Andersen & Taylor 2005). Sex is the basis for the prejudice and presumed inferiority implicit in the term sexism. The term *gender bias* is more inclusive than the term sexism, as it includes both prejudice (attitudes) and discrimination (behavior) in its definition. Studies of gender bias also focus on gender, rather than on sex. Furthermore, the term gender bias could include instances of bias against boys and men in addition to bias against girls and women. This raises an important question: Are boys and men harmed by gender bias? While individual boys and men may suffer at the hands of gender bias, boys and men as groups benefit from gender bias embedded in our social institutions. The narrow benefits of gender bias for some are outweighed by much broader losses for all (Neubeck & Glasberg 2005). And if gender roles and expectations constrain both girls and boys and both women and men, it can be said that gender bias limits the overall development of contemporary societies.

GENDER BIAS: PERVASIVE INFLUENCE

Gender bias is part of almost every aspect of life. The most common areas of gender bias are found in the social institutions of families, education, the economy, and health.

Within the Household

At the household level, there is documented evidence of gender bias in the allocation of resources. Patriarchal households are maintained through power and control in the hands of men, particularly fathers, as the heads of households. Specifically, gendered roles assigned as “breadwinner husband” and “homemaker wife” lead to unequal distributions of power within the household. However, the numbers of dual income families and female headed households are growing rapidly in the US. Consequently, women’s and men’s attitudes towards sharing work in the household have changed over the years. Both women and men often face conflict between work and family. The juggling of work and family is complicated by the power differences between women and men in families, and these power differences often confirm gender roles, with women typically desiring more change than men (Andersen 2003). Along these lines of power differentials, gender bias within families can come in the form of violence as well. While it is certainly not the case in every family, women are significantly more likely than men to be physically abused and injured by their intimate partners (Renzetti & Curran 2003).

In Education

Gender bias is embedded in education from pre kindergarten through graduate school. Teachers provide important messages about gender through both the formal content of their instruction and materials utilized, as well as informal interactions with students (which is commonly referred to as the hidden curriculum). Gender related messages from teachers and other students often reinforce gender roles first taught at home (Kendall 2005).

Researchers have consistently found that teachers give more time, effort, and attention to

boys than to girls (Sadker & Sadker 1994). Gender bias exists in textbooks and instructional materials as well. Women are often under represented in course materials and/or are presented in stereotypical roles. Over time, gender bias in education undermines girls’ and women’s self esteem and discourages them from taking courses such as math, science, and engineering (Raffalli 1994).

In the Economy

While it is estimated that 60 percent of all women work in the paid labor force (US Bureau of Labor Statistics 2003), women, on average, make up a weaker position in the labor market than men. Specifically, they are more likely to be unemployed, employed in temporary jobs, or employed part time. Because of gender bias embedded in the labor market, women in the US are paid, on average, 76 cents to every dollar in wages that men are paid. Rates for women of color are even lower: 66 cents for African American women and 54 cents for Latinas. More than one million women work in jobs that pay less than the federal minimum wage (Neubeck & Glasberg 2005). Sociologists have argued that this is not a reflection of educational differences between women and men; rather, it is a product of gender bias in employment, promotion, and pay. The gender biased economic system encourages women to go into traditional “women’s jobs,” and this serves employers well: they are able to pay women lower salaries for traditional “women’s jobs” than for traditional “men’s jobs.”

In Health

The US health care system has long been dominated by men – from doctors to researchers to administrators. While more and more women are entering medical school and medical related fields, gender bias is still embedded in the system. As discussed above, women, on average, make up a weaker position in the labor market than men. Thus, they are less likely to occupy positions that offer adequate health care insurance, even when they work full time (Neubeck & Glasberg 2005). Female headed households are affected by this most strongly,

as they are more likely to be poor than male headed or dual headed households.

Biases and shortcomings in the health care system's treatment of women contribute to the problems women face in getting adequate medical care (Ratcliff 2002). Specifically, gender bias embedded in the US health care system contributes to very little research done on health problems pertaining to women. For example, women have been largely excluded as research subjects in studies sponsored by the federal National Institutes of Health (NIH).

CONCLUSION

In addition to the social institutions reviewed here, gender bias is embedded in the media, sports, the state/government, and other social institutions. Gender is so pervasive in contemporary society that we often do not notice gender bias in our everyday lives. However, gender itself is not a variable that stands alone. Our race, ethnicity, social class, sexual orientation, and other social positions affect our everyday gendered experiences. Therefore, gender bias regularly intersects with other forms of bias such as ethnocentrism, racism, classism, and homophobia.

While it may appear gender bias disadvantages girls and women the most, gender bias, as well as other forms of bias, shortchanges all of us.

gender, the body and

Cynthia Fabrizio Pelak

Feminist thinkers have long focused on the body as an expression of power and a site of social control. As early as 1792, Mary Wollstonecraft proclaimed that "genteel women are slaves to their bodies" and that "beauty is woman's scepter" (Wollstonecraft 1988). Sixty years later, Sojourner Truth drew attention to how bodies are not only gendered but also racialized in her *Ain't I a Woman* speech of 1851. And, since the emergence of the second wave of women's movements in the US, feminists have been transforming our thinking on gender and bodies through their writings on rape, sexual assault, domestic violence, reproductive rights, beauty contests, eating disorders, sports, disabilities, cosmetic surgery, and more. Despite the recurrent focus on gender and the body, scholars have asked diverse sets of questions from various disciplinary and theoretical perspectives that have changed over time. This entry reviews some of the major questions that have been raised about gender and the body and discusses the shifting theoretical approaches that have developed in the literature.

A constant thread in contemporary feminist theory is questioning the source of sex differences. Are sex differences "naturally" produced or are they a result of social cultural production (i.e., nurture)? If sex differences are "natural," it is thought that they cannot be altered. However, if they are socially constructed, then sex differences could be altered and possibly eliminated. The emergence of the "nature versus

nurture” question within feminist theory is directly linked to dominant gender ideologies that posit gender differences as biologically determined and women’s subordination and men’s dominance as natural. Such gender ideologies have a long history in western societies and affect virtual every aspect of women’s and men’s lives in contemporary society. As discussed below, recent feminist scholarship on gender and the body critiques the terms of the nature versus nurture debate and offers a new paradigm that recognizes the inherent interaction of biological and social systems.

Perceptions and experiences of gender and the body in western societies have been grounded in dualistic thinking (Bordo 1993; Fausto Sterling 2000). According to influential male philosophers and theologians within Greco-Christian traditions, two opposing entities constitute human existence: the mind and the body. Within this framework, the mind is understood as being superior to the body, and the body, which is associated with wanton desires, is seen as something to be overcome and controlled. Western discourses on the mind/body split developed along with other dualisms such as male/female and culture/nature. On one axis, the mind, culture, and the masculine have been located and on an opposing axis the body, nature, and the feminine are positioned. Moreover, the male body has been assumed to be the standard and the female body an inadequate deviation from the norm.

Sexist ideas about women’s bodies advanced by philosophers and theologians were strengthened by medical and scientific discourses of the industrial and post industrial eras. With the professionalization of medicine, male medical doctors became “experts” on women’s bodies. Based more on ideology than empirical evidence, physicians espoused sexist beliefs about women’s embodied physical fragility, intellectual inferiority, and emotional instability. In her book *The Eternally Wounded Woman* (1990), Patricia Vertinsky shows how the dominant medical discourse of the nineteenth century led to the notion that physical exercise was dangerous to women’s reproductive function. Not surprisingly, the “misinformation” was meant for privileged women who were pushing for more access to the public arena and not poor, immigrant, and enslaved women who

regularly performed physically demanding labor and supposedly reproduced too much.

Since the mid twentieth century, psychologists, sexologists, biologists, and other researchers have battled over theories of the origins of sex differences, gender identities, and gender roles (Fausto Sterling 2000). Corresponding with the development of new technologies, the basis of “scientific” theories about bodily and behavioral differences between females and males moved from genitals to gonads to chromosomes to hormones to brains. As societal views around gender started shifting during the 1970s, feminist theories, which highlighted the importance of gender socialization and other environmental “nurture” factors, entered the debate. The infamous case of the male child who was “successfully” socialized as a girl after his penis was mutilated during a circumcision procedure was offered as proof for the social construction of gender. This evidence, however, was weakened when the socialized girl became a teenager and wanted to become a boy.

Feminist biologist Anne Fausto Sterling (2000) argues much of this debate is deeply limited by dualistic thinking and a devotion to the notion that there are two, and only two, mutually exclusive sexes. Fausto Sterling’s work suggests that sex is more of a continuum and that the body is changeable over the life course rather than fixed at birth. She rejects the framework that views the body and the circumstances in which it reproduces as separable. Instead, she and other scholars theorize an interactive biosocial model in which internal reproductive structures and external social, historical, and environmental factors are inseparable – interacting over time and circumstance. Grosz (1994) uses the metaphor of a Möbius strip to illustrate how social meanings external to the body are incorporated into its physiological expression, as well as unconscious and conscious behavior.

Nowhere are the politics of the debate about sex and gender differences clearer than in the debates over bodies that exhibit sexual ambiguity (Kessler 1998). Although intersexuality is a fairly common phenomenon, intersexuals disappear from our view because doctors quickly “correct” them with surgery. Kessler shows how the medical management of intersexuality (repeated surgeries and hormone treatments)

contributes to the construction of dichotomized, idealized genitals and normalizing beliefs about gender and sexuality. She argues that acceptance of genital and gender variability will mean the subversion of the equation that genitals equal gender.

As mentioned above, the emergence of the second wave women's movement sparked a wealth of new research on gender and the body. Much of the earlier work focused on how women's bodies were regulated, controlled, or violated. The body at this stage was viewed as a site through which masculine power operated rather than as an object of study in and of itself. The desire to counter theories of biological determinism and promote theories of social constructionism led feminists to sidestep theorizing the body. Likewise, the conceptual distinction between sex and gender, which posits sex as the biological/physiological and gender as the social/cultural, may have falsely constructed disciplinary boundaries that led feminist scholars to focus on the social (i.e., gender) and ignore the biological (i.e., sex).

The recent "discursive turn" in feminist theory and the development of poststructural challenges to binary constructs and dualistic thinking have encouraged new theorizing on gender and the body (Conboy et al. 1997). Drawing on the work of Michel Foucault, some feminist scholars are viewing bodies as texts which can be read as a statement of gender relations. Working within this framework, Judith Butler (1992) has tried to build a non-dualistic account of the body and reclaim the material body for feminist thought. Butler conceptualizes the body as a system that simultaneously produces and is produced by social meaning and shows how transgressive body politics can challenge the discursive limits of "sex."

While drawing on poststructuralist thought and insights from recent scholarship on gender and the body, Bordo (1993) cautions feminist scholars not to overemphasize women's embodied resistance at the expense of examining how domination is enacted upon and through female bodies. In her analyses of eating disorders, plastic surgery, media images, and the slender body, Bordo acknowledges the possibility of women's resistance, but also draws attention to the overwhelming power of

disciplinary and normalizing processes surrounding women's bodies in our postmodern world. The emergent field of feminist disability studies also interrogates normalizing discourses and practices of gendered bodies, but draws attention to bodies that are culturally identified as sick, impaired, ugly, deformed, or malfunctioning (Thomson 2002). Feminist disability scholars critique research on bodies, embodiment, and gender that ignores how the hierarchical ability/disability system intersects with other systems of power in shaping gendered experiences of women and men.

One of the most symbolically important social institutions for the naturalization of gender differences in contemporary societies is that of competitive sports. The sociology of sport, in particular, has contributed greatly to our collective understanding of gender and the body by examining the relationships between the symbolic representations of the body and embodied experiences within concrete sociohistorical contexts. The literature on gender and sport, which includes the theoretical tensions and turns outlined above, has contributed valuable insights on femininities, masculinities, and the body (Hall 1996; McKay et al. 2000). The scholarship of Jennifer Hargreaves (1994, 2000) is exemplary in its examination of women's historical exclusion in competitive sport and the seemingly irreconcilable tension between femininity and athleticism. Her work illuminates how competitive sport, throughout history and around the world, has been a site for both maintaining and challenging dominant notions of gendered bodies.

In addressing questions about gender and the body, the history of sex testing or gender verification within the Olympic Games movement provides an ideal case study of the shifting discourses and "science" around gendered/sexed bodies. Sparked by the growing political anxieties of the Cold War, in 1968 the International Olympic Committee instituted sex testing of female athletes, first through visual examinations and then by "scientific" chromosomal testing. Over the years, it was shown that fitting bodies into two mutually exclusive categories of female and male is not so simple. The suspension of gender testing in 2000 serves as an acknowledgment of the complexities of a body's sex and a recognition, at least at some level, that

labeling someone a woman or a man is a social decision (Fausto Sterling 2000).

Recent feminist theorizing on the body and embodiment has encouraged social movement scholars to focus attention on the role of the body in collective social action. Using the body as a site of resistance has long been a strategy of collective protest against gender oppression. Suffragists in the US and England at the turn of the twentieth century adopted the tactic of hunger strikes to draw attention to their cause. Parkins (2000) argues that the daring acts of protest by suffragists challenged dominant ideas about women's bodily comportment and physical capabilities, as well as embodied notions of citizenship. The more recent history of silent vigils of the Women in Black movement, which first emerged in Jerusalem in 1988 to protest the Israeli occupation of Palestine, illustrates how the body still serves as an agent of social and political change (Sasson Levy & Rapoport 2003). The recent theorizing in the social movements literature on the role of emotions and passion in political struggle has also led to new insights on gender and the body (see Goodwin & Jasper 2004). As the diverse and lengthy history of embodied social protest suggests and the various theoretical frameworks and empirical research on gender and the body illustrate, the body has been and seems will remain a central nexus to our understanding of gendered experiences, ideologies, and practices.

gender, consumption and

Christine Williams and Laura Saucedo

The history of consumerism has been shaped by gender inequality. During the colonial period, when families produced most of what they consumed, a gender division of labor prevailed in which men supplied the raw materials (e.g., wheat, flax, animals) and women transformed them into commodities for consumption (e.g., bread, cloth, meals). During industrialization,

the period characterized by historians as bringing about the "separation of spheres," productive activity moved outside the household and eventually became seen as an appropriately masculine endeavor. Consumption became privatized, a range of activities under the purview of women consigned to the domestic arena. Although the separation of spheres was more cultural ideal than historical practice for many marginalized social groups (African Americans, the poor, immigrants), the association of women with consumption, and men with production, prevails today and shapes research and theory on consumerism.

Four major themes characterize research on gender and consumption. The first theme analyzes women's consumer practices as an extension of their primary domestic responsibilities. Sometimes referred to in the literature as "housework" or more recently "carework," this consumer activity centers on shopping as a means to acquire the goods to sustain members of a household (e.g., to cook meals, clean the house, organize family get togethers and other social events, and care for children and elderly parents). Marjorie DeVault's book, *Feeding the Family* (1991), was one of the first to carefully document the extensive effort involved in women's consumer activity on behalf of their families. Feminists argue that this work lacks pay and social recognition, yet it is essential for sustaining the quality of family life.

As many women have joined the paid labor force in the past decades, women's involvement in consumption has changed and in many ways increased. A current thread of research focuses on employed women who subcontract services to perform the domestic labor still expected of them as wives and mothers. Thus, we have witnessed the rise of domestic cleaning services, the proliferation of fast food restaurants, and the increase in private childcare centers. These industries cater to women forced to juggle the demands of paid work and family care. Referred to by Arlie Hochschild (2003) as the "commercialization of intimate life," these service industries are replacing the work that in previous generations women performed in their private homes without pay. The work involved in subcontracting and managing domestic labor is still mostly done by women, a vestige of the separate spheres ideology that remains deeply

embedded in current gender arrangements. The subcontracted work is also performed mostly by women, typically by non white and immigrant workers.

A second major theme in the literature on gender and consumption examines how the advertising industry has shaped cultural ideals of masculinity and femininity. Advertisers exploited the cult of domesticity in the first half of the twentieth century by encouraging women to associate the purchase of certain household products with being a good wife and mother. Although this trend continues through the twenty first century, the focus of advertising has become more personal, centered on how commodities can enable the individual to achieve prevailing gender ideals. In other words, consumption of certain products is presented as central to femininity and masculinity.

Feminist scholars first picked up on this trend in the 1970s. Early critiques emphasized the ideological content of advertisements directed to women that seemed to undermine self esteem while simultaneously promising relief through the purchase of their products. These products were not limited to beauty and fashion accessories, but included a full range of goods, from kitchen appliances to cars to food products, all promising to transform the body and the self to achieve ideal femininity. Early feminist studies of advertising urged resistance through consumer refusal. Thus, when *Ms. Magazine* debuted in 1972, it was free of advertisements, reflecting the feminist critique of the industry's deleterious impact on women's self image, and its central role in perpetuating stereotypical roles for women.

In the mid twentieth century, advertisements also began targeting men with the promise that products could enhance their masculinity. Although early ads were less focused on appearance than those targeting women, they suggested that heterosexual attractiveness could be enhanced with the purchase of expensive cars, stereo equipment, and vacations. *Playboy* magazine, which debuted in the late 1950s, is often credited with establishing the link between masculinity and consumerism, and thus challenging the conventional association of shopping with women (Ehrenreich, *Hearts of Men*, 1983). Unlike the feminist movement, political opposition from men's groups did not materialize,

except from the health community, which challenged ads that equated the consumption of especially unhealthy commodities, such as alcohol and cigarettes, to expressions of masculinity.

Gender scholars have developed increasingly sophisticated understandings of how advertisements shape social ideals of masculinity and femininity. Jean Kilbourne produced an influential series of videos on gender advertisements (*Killing Us Softly*) which have been shown to generations of students in college classes all over the country. These videos demonstrate that ads on television and in magazines represent an exceptionally narrow range of acceptable appearance standards for men and women. Wealth, whiteness, and heterosexuality are taken for granted in most advertisements, suggesting that men and women who are poor, non white, or GLBT have little chance to achieve social approval. Philosopher Susan Bordo (1993) draws on theories of post modernism to understand the allure of advertisements that promote unrealistic weight loss and body sculpting regimens. Women are drawn to these images, however damaging and irrational, because of an internalized sense of inadequacy promoted by a sexist culture that devalues femininity. Although her scholarship recognizes the problematic depiction of both men and women, the emphasis remains on how women are especially dehumanized by their portrayal by the advertising industry and vulnerable to its messages.

Analysis of both conformity and resistance represents a third main theme in the gender and consumption scholarship. In what she calls the fashion beauty complex, feminist scholar Sandra Bartky (1990) suggests that production, marketing, retail, and information companies work together to regulate feminine identity. Thus, pressure to conform to gender ideals goes beyond just advertisements. Department stores, for example, are spatially segregated by gender, clearly defining for customers which items should be purchased for men and for women. Genres in novels, television, and film have been gendered such that romantic stories (or so called "chick flicks") are pitched to women while action plots are geared toward a primarily male audience.

According to Bartky, lifestyle magazines targeting teen and adult women play a critical role

in the fashion beauty complex. Teen magazines claim a significant readership among teenage girls, and these publications prime their audience to continue consuming fashion and lifestyle magazines well into adulthood. Young women are highly invested in popular culture, and research demonstrates that their peer groups tend to encourage conformity to the feminine ideal that pervades these texts. The financial success of the beauty industry suggests that women do in fact support the fashion beauty complex. Cosmetics, dieting, and cosmetic surgery bring in billions of dollars a year, and the majority of these consumers are women. Because conformity is such big business, the industry has little impetus to diversify or alter its constructions of femininity in any way.

Despite this evidence of conformity in women's consumerism, the more micro level question of meaning must also be considered. Cultural theorist Stuart Hall argues that dominant cultural messages may be accepted, negotiated, or even subverted. Feminist scholars, for instance, have noted that shopping represents a relatively safe and socially acceptable way for girls and women to participate in the public sphere, an experience they may find liberating. Ethnographies and interview projects have shown that women often read magazines and romance novels or watch soap operas for personal pleasure, and as a means of escape from mundane domestic responsibilities. Many take pleasure in critiquing these media, which are often considered predictable and even ridiculous in content.

An ongoing debate within feminism questions whether or not women's conformity to beauty ideals can be considered resistant. Some argue that women can use their appearance as a form of bodily capital, in a Bourdieuan sense, to exploit male weakness and gain access to resources. Others point out that such practice fails to challenge dominant expectations of idealized femininity, doing little to improve conditions for women in general. Considering the high rates of eating disorders and the dangers of cosmetic surgery, this strategy may even be harmful to women.

Sociologist Lynn Chancer emphasizes that in everyday life, oppression and resistance often occur together. In order to resolve this debate, feminists must challenge the institutional and

cultural oppression of women without placing restrictions on or passing judgment about individual women's actions.

The fourth major theme of the gender and consumption literature considers the interactive dimensions of race and class. Consumer practices vary widely depending on social location. The economic realities of social class and cultural beliefs about race and gender place restrictions on what and how people consume. Education and occupation determine the amount of disposable income one possesses. Poor neighborhoods attract fewer businesses, thereby limiting the purchasing options of these areas' residents. Customers are treated differently based on employees' perceptions about one's race and/or class status.

The intersection of race, class, and gender results in a social hierarchy that privileges some while putting others at a disadvantage. The predominantly white upper class exhibits what Thorstein Veblen calls "conspicuous consumption," which is to say they purchase goods and services that overtly demonstrate their wealth and social status. In buying expensive and/or rare items, they set themselves apart from those without access to such luxuries. In this way, their consumer patterns help create and maintain class divisions.

Racial/ethnic minorities and the working class experience consumption quite differently. African American women, for example, have historically been relegated to lower socioeconomic status, in which consumption revolves around the provision of daily necessities. In the early twentieth century when beliefs about black inferiority prevailed, investing in beauty products such as hair straighteners and skin lightening creams represented a form of resistance. These items allowed black women to more closely adhere to the dominant feminine ideal, thereby undermining negative stereotypes. These black women viewed conformity as a way to make themselves and their race more respectable to dominant society. The investment in the cosmetics industry also resulted in a significant entrepreneurial opportunity for black women, who began producing and selling products specifically for African American consumers.

Race, class, and gender shape how different groups read and interpret cultural texts as well.

African American teenage girls tend to read teen magazines with a more critical eye than their white counterparts. These girls are less likely to identify with dominant beauty standards embodied by the exceptionally thin white women who are the typical models in advertisements. As a result, they read around much of the content focused on appearance, looking instead for articles they think will give them insight into their lived experiences. Life chances associated with social class guide the consumption of cultural texts in a similar way. Privileged groups of girls are highly invested in conforming to idealized femininity, particularly in terms of appearance and behavior. In contrast, working class racial/ethnic minority girls take interest in content addressing dating, marriage, and motherhood. Due to limited educational and career opportunities, these girls anticipate becoming wives and/or mothers earlier in life than the middle and upper class girls. In short, these cases suggest that social location plays a significant role in determining which products, images, and messages women find relevant to their lives. Intersecting forms of privilege and oppression create different needs and interests, which translate into different consumer practices.

Topics for future research on gender and consumption include: (1) analyses of how new shopping media, such as the Internet, promote and/or undermine conventional gender ideals and practices; (2) the gender socialization of ever younger girls and boys through targeted advertisements on television; (3) the gendered features of anti consumerist social movements; and (4) the impact of niche marketing on cultural constructions of gender, including marketing to members of GLBT communities.

gender, development and

Christine E. Bose

Over the last half century there have been different theoretical frameworks used to understand how women are located in global economic processes, and each has had a concomitant strategy to enhance women's position. In the middle of the twentieth century modernization approaches were common, but dependency theorists critiqued these strategies. By the 1970s these male focused arguments were largely supplanted by women in development (WID) ones, and more recently by gender and development (GAD) approaches.

Development refers to changes in a country that are frequently measured using a country's gross domestic product (GDP), as well as its degree of industrialization, urbanization, technological sophistication, export capability, and consumer orientation. Concerns about development are most likely to be expressed by representatives of advanced capitalist core countries of the "global North" or by international agencies when they create initiatives or generate responses to a whole range of critical problems faced by what they categorize as "developing" nations or the peripheral and semi peripheral countries of the "global South."

On the other hand, countries of the global South tend to see development as addressing survival issues like hunger and malnutrition, refugee displacement and homelessness, unemployment and underemployment, health services and disease, the destruction of the environment, and political repression and violence. Since numerous countries in the global South are former colonies of those in the global North, many survival problems result from the cumulative effects of unequal and dependent relationships that were established centuries ago and are recreated in the present using new mechanisms, especially structural adjustment programs and other economic globalization strategies promulgated by international agencies like the International Monetary Fund (IMF) and the World Bank. Indeed, it is frequently argued that development projects, promoted by core countries, have better served their own interests, in the long run, than those of their recipients.

The condition of women in developing/global South countries is integrally tied to gendered power and economic structures that were established in the colonial era. In addition, although early development programs ignored their needs, usage of women's unpaid or underpaid labor has been crucial to many development programs and policies.

Post World War II modernization approaches assumed that developing nations needed to industrialize rapidly in order to gain economic strength, and that political democracy, gender equity, and national prosperity would follow from industrialization – consequences that were assumed to have occurred in core nations when they industrialized slowly over the course of the nineteenth century. Nonetheless, development agencies measured success only by increases in per capita income, literacy rates, life expectancy, and fertility rates, rather than by the disappearance of authoritarian regimes. Indeed, the prevalence of dictatorships in many Latin American and Caribbean countries that had achieved some degree of economic development helped to discredit the assumed connection between development and democracy. And the fact that some global South countries have greater women's political and professional participation than in the global North helps to

discredit the connection between development and gender equity (Burn 2005).

The industrialization and modernization programs created by international development agencies, and formulated from the perspectives of "western" nations, relied on foreign investment and manufacturing for export rather than for local consumption and did not encourage self sufficiency in the global South (Sen & Grown 1987). Frequently, developing nations depended on single commodity export trade, leaving them vulnerable to the fluctuations and perils of world markets. Many developing economies were "denationalized" because for eign industrial capital often interfered with or restricted the autonomy of local governments, as well as the capacity of national industries to compete in the world market (Acosta Belén & Bose 1995).

In the 1960s and 1970s, dependency theorists such as Gunder Frank (1969) argued that discussions of the need for "modernization" hid the fact that industrial nations were exploiting developing ones. Indeed, developing nations usually were former colonial possessions of present day industrialized nations, and had therefore always been integrated into the capitalist system. They also noted that the modernization model was applied across the board, with little attention to specific national needs. At about the same time, other scholars underscored the problem that modernization approaches paid little attention to women's particular needs and assumed they would benefit in a "trickle down" fashion as economies improved.

In 1975 the United Nations proclaimed the first International Women's Year and the decade 1975–85 was known as the Decade for Women. The UN's focus was intended to acknowledge that women had been active participants in the development process from the beginning, and the call to integrate women into development was more of a denunciation of the male oriented biases in development policies and the invisibility to which development agencies had relegated women's participation:

Indeed, the pervasive idea that men were the primary earners often led to the formulation of development policies that excluded or diminished women's productive roles and thus their status; added extra hours to their double burden when they had to replace men (now

engaged in wage labor) in the subsistence activities that were performed collectively before; and often did not even account properly for women's actual participation and contributions. (Acosta-Belén & Bose 1995: 20)

Prior to Boserup's (1970) key publication, most of the development literature ignored women's economic role and contributions. Assuming women were passive dependents, researchers and practitioners relegated them to reproductive rather than productive roles, confining them to an undervalued domestic sphere isolated from the rest of the social structure. Little attention was paid to variations in women and men's economic roles in different global South nations or to women's activities in the informal economy.

One of Boserup's major contributions was to empirically establish the vital role of women in agricultural economies and to recognize that economic development, with its tendency to encourage labor specialization, was actually depriving women of their original productive functions and on the whole deteriorating their status. Acknowledged by many as a path breaker in the field of women and development (Benería 1982; Bolles 1988; Sen & Grown 1987), Boserup is credited with documenting the existence of a gendered division of labor across nations and showing that women's labor had not been reported in official records. (Acosta-Belén & Bose 1995: 22)

Nonetheless, there were shortcomings in Boserup's important work due to her adherence to the then prevalent modernization approach. She paid insufficient attention to women's household labor as a basis for subordination, and to the differential outcomes of capital growth on various groups of women within colonial or former colonial settings (Benería & Sen 1981; Bolles 1988).

In spite of these problems, Boserup's research fostered an understanding of how development policies ideologically denigrate women's economic contributions, while simultaneously relying upon and exploiting women's labor. Since her initial work, numerous studies have documented the impact of development on women at the local, national, and international levels and confirmed that women's segregated labor generates their low wages and status. One result of the conceptual shift from

modernization theory to the study of women in development was the increased attention paid by feminist researchers to previously ignored sectors of working women who are (or were) essential to third world economies, including African enslaved women, domestic workers, tourist sector workers, women traders and street sellers, craft producers, and sex workers, as well as to non husband/wife household formations, especially families headed by women, who are often landless.

With increased globalization, "development" comes in a new form, as core countries make use of "offshore production" or the transfer of assembly plants, primarily in electronics, apparel, and textiles, to global South countries. Many of the hidden aspects of offshore production occur in export processing zones (EPZs), where young women migrate from rural areas to work in their national segment of the "global assembly line" and married women take on factory "outwork," doing piecework at home. Women's transnational migration for work also has increased, and women from developing countries migrate to more developed ones, often to work (legally or undocumented) as domestics or doing other forms of carework.

Burn (2005) notes that development projects based on a WID perspective fall into three categories. The first, and most common in the 1980s, were income generating projects, which tended to focus on traditional women's skills such as sewing and handicrafts. Burn suggests that these projects rarely were successful because of the low marketability and profit in these areas, and because women were not always included in the design of the projects. The second, but less common, type of project was to introduce labor saving devices for women's traditional tasks – unfortunately focusing on a limited range of tools. The third approach, that has grown in international popularity since the 1980s, is to give women access to development resources, especially in the form of small loans for women micro entrepreneurs. These quick revolving loans with reasonable interest rates and low collateral requirements have helped finance many women's small businesses, and are believed to increase women's autonomy and improve the health status of the women's children, as more discretionary income becomes available to women (Blumberg 1995). Such

outcomes show that women are not passive victims of globalization and development processes, but see creative ways to resist subordination and become empowered.

Many development projects fomented under the WID philosophy helped women economically. However, few if any of these projects were intended to change the power relationships between women and men. In response to these limitations, a new approach, Gender and Development (GAD), was discussed by feminists and in women focused NGOs during the 1980s, with the goal of improving women's rights and increasing gender equity. Many have called GAD an "empowerment" approach (Burn 2005; Moser 1989) because its goal is to create development projects based on the needs expressed by grassroots women and not only to provide services, but to challenge women's subordination in households and in societies. One way GAD does this is by recognizing the multiple connections between women's economic roles outside of the home and those inside the family; a second way is by encouraging women's and feminist activism.

Among the urban strategies used in the global South are organizing collective meals, health cooperatives, or neighborhood water rights groups. Rather than privatizing their survival problems, women collectivize them and often place demands on the state for rights related to family survival. Mohanty (1991) suggests that challenging the state is not merely different, but "a crucial context" for global South women's struggles precisely because it is the state that has created laws with gender and race limitations implicit in them.

Urban organizing is not the only form of empowerment. Indigenous and peasant women in rural areas create projects around agricultural issues such as land tenure or plantation working conditions, issues that link community and labor, as well as cultural issues related to ethnic identity and survival of indigenous peoples.

Other GAD related feminist organizing links self determined women's development with the issues of nationality, race, class, and gender. Among examples in the Commonwealth Caribbean are the Women and Development Unit (WAND), which promotes women's activities especially through income generating projects, local technical assistance, and government

advisement; Development Alternatives with Women for a New Era (DAWN), which is a network of activist researchers and policy makers; and the Caribbean Association for Feminist Research and Action (CAFRA), whose projects have included monitoring the Caribbean Basin Initiative effects, exposing worker conditions in Jamaica's export processing zones, and aiding rural women through the Women in Caribbean Agriculture Project (Bolles 1993). A more occupationally focused group is Trinidad and Tobago's National Union of Domestic Employees (NUDE), which utilizes actions taken at UN women's conferences and other international events to mobilize for change at home (Karides 2002).

By the 1990s international development agencies had begun to adopt GAD rhetoric in their mission statements, but GAD was used more as an analytic framework than as a development strategy – possibly because it is easier to discuss empowerment than to implement it (Burn 2005). Indeed, even in supportive circumstances, when women's equality is considered an important goal of the state, as in the revolutionary experiences of Cuba or China, the changes tend to be token reforms rather than major transformations. In the case of international development agencies, they have tended to adopt the European model called "gender mainstreaming," which "requires a gender analysis to make sure that gender equality concerns are taken into account in all development activities" (Burn 2005: 151). As a result, women are actively engaged in the development process, but women's activism for gender equality is not promoted, as GAD suggests it should be.

Nonetheless, many grassroots groups are actively developing transnational linkages that promote a GAD perspective (Naples & Desai 2002) and international feminist conferences are helping to create a transnational feminism that has many commonalities across nations while retaining local forms. This combination of local creativity and the transnational sharing of ideas may well push GAD ideas forward into future tangible gender equity development programs, and/or toward creating a newer women, culture, and development (WCD) perspective of which Bhavnani et al. (2003) are proponents.

gender, deviance and

Gloria Gadsden

Missing from traditional and most contemporary discussions of deviance and crime is the notion of gender. A rather accessible definition of gender can be found in most introductory sociology textbooks. For the purposes of this entry, gender is defined as the social positions, attitudes, traits, and behaviors that a society assigns to females and males (Macdonis 2004). A close examination of theories of deviance reveals an androcentric or male oriented perspective. Early theorists and researchers in particular extrapolated from studies of boys and men when attempting to explain female deviant behavior. So, barring examinations of a few deviant behaviors, most notably shoplifting, violations of sexual norms (e.g., promiscuity, teen pregnancy, prostitution), status offenses (e.g., runaways), and infanticide, there were, and still are, few serious considerations of female deviant behavior.

Feminists, or members of society advocating equality between the sexes, have made a few strides with respect to introducing notions of gender into theories of deviance and crime. While a single comprehensive theory addressing gender and deviance is still missing from the literature, there appear to be four main

schools of thought: (1) the chivalry perspective, (2) patriarchal considerations, (3) the women's liberation hypothesis, and (4) the theory of victimization.

The chivalry perspective attempts to explain why girls and women are not seen as deviants. Why do most people think of boys and men when considering deviant and criminal behavior, specifically violent deviant and criminal behavior? This theory proposes that members of society are socialized not to see girls and women as deviants. Chesney Lind and Sheldon (1998) suggest that almost all members of society talk about delinquency, by which they generally mean male delinquency. More specifically, this argument theorizes that powerful male members of society (e.g., police officers, judges, the male dominated media) "protect" or "save" girls/women from the label of deviance (Felson 2002). Humphries (1999) specifically postulates a chivalry approach with respect to women and cocaine use in the 1980s and 1990s. She determined that in the early media coverage of cocaine use, white middle class women who used cocaine were presented as promiscuous and as "bad" mothers. Still, television networks showed a remarkable degree of tolerance toward these women. And with respect to domestic violence, Girschick (2002) notes that current understandings of rape and battering suggest that women are not perpetrators. More specifically, according to present day social norms and values, women do not rape and women do not batter.

This perspective posits that members of the male dominated criminal justice system will ignore, dismiss, and/or explain away female deviance and crime. For example, some theorists have attempted to explain away girls' accountability for their deviance by stating girls' deviant behavior commonly relates to an abusive home life, whereas boys' deviant behavior reflects their involvement in a delinquent lifestyle (Dembo et al. 1995). Girls and women, therefore, are not seen as deviant because male members of society protect them from the label. Male police officers, prosecutors, and judges have a traditionally chivalrous attitude toward women and treat them with more leniency than men. Regrettably, this theory, regardless of its potential accuracy,

perpetuates the cycle of male centered perspectives, attempting to explain female behavior by examining male attitudes and behaviors.

Patriarchal explanations posit that male dominated social institutions, especially the family, are designed to prevent girls and women from engaging in deviance and crime. Socialization processes within the family control girls more than boys, teaching boys to be risk takers while teaching girls to avoid risk (Hagan 1989). According to Akers (2000), in patriarchal families the father's occupation places him in the "command" position (e.g., manager, supervisor, CEO) and the mother either stays at home or works in a job where she occupies the "obey" position (i.e., taking orders from supervisors). In these families, according to the theory, the behaviors of girls and women are more closely monitored and controlled (Thorne 1994). Girls are expected to adhere to stricter moral standards and face a stronger sense of guilt and disapproval when they break the rules (Chesney Lind & Sheldon 1998).

Unfortunately, much like the previous theory, this is a male oriented perspective. This line of reasoning argues that males control girls and women and, therefore, control female deviance and crime. These androcentric theories do not attempt to understand female deviance in and of itself, explaining female behavior by way of male behavior (Chesney Lind & Pasko 2004). They are flawed and have been, for the most part, discredited.

The remaining two perspectives, the women's liberation hypothesis and the theory of victimization, attempt to explain the deviant behavior of girls and women apart from the attitudes/behavior of males. The women's liberation hypothesis proposes that as the gap between women's and men's social equality decreases, the gap between women's and men's deviant behavior decreases as well. This theoretical explanation suggests that the women's movement has brought about changes in traditional gender roles, greater equality for women, and an increase in the female labor force. An unintended consequence of this "liberation" for women is a greater involvement in deviance and crime. According to Adler (1975), the movement for gender equality has a darker side. Some women are insisting on equal opportunity in

fields of legitimate endeavor while other women are demanding access to the world of crime.

The "liberation" hypothesis, however, has not received much empirical support. Though increasingly represented in the labor force, women continue to be concentrated in traditional "pink collar" work – teaching, clerical and retail sales work, nursing, and other subordinate roles – that reflects a persistence of traditional gender roles (Zaplin 1998). In contrast, contemporary gender differences in quality and quantity of crime continue to parallel closely those of the thirteenth century. Additionally, Chesney Lind and Pasko (2004) state there is no evidence to suggest that as women's labor force participation has increased, girls' deviant behavior has also increased.

Therefore, it has not yet been compellingly demonstrated that female crime rates are significantly correlated with increasing gender equality. In fact, patterns of female deviance have remained relatively consistent over time.

One of the most persuasive theories regarding girls' and women's deviance is predicated on the reality girls and women face as victims. The theory of victimization proposes that women are deviants in part because of their status as victims of male abuse and/or violence. Chesney Lind and Pasko (2004) recognize that girls are much more likely to be the victims of child sexual abuse than are boys. Additionally, girls are much more likely than boys to be assaulted by a family member (often a step father) and women offenders frequently report abuse in their life histories. About half of the women in jail (48 percent) and 57 percent of women in state prisons report experiences of sexual and/or physical abuse in their lives. Chesney Lind and Pasko note that all of the girls in gangs interviewed hail from a more troubled background than boys in gangs. And with respect to spousal homicide, Zaplin (1998) revealed that wives are far more likely to have been victims of domestic violence and turn to murder only when in mortal fear. Husbands who murder wives, however, have rarely been in fear for their lives.

Empirical research does suggest that exposure to abuse and violence, too often a reality girls and women face, could compel girls/women to engage in various types of deviance (e.g.,

running away, truancy) and ultimately crime (e.g., theft, drug abuse, prostitution) (Flowers 2001). In fact, some theorists have highlighted the fact that a potential survival mechanism, running away from home, continues to be the most prevalent offense for female juvenile delinquents (Chesney Lind & Pasko 2004). This theory, although it addresses girls' and women's relationships with boys and men, serves as a building block for theories that consider the unique status of girls and women in society and its contribution to deviant behavior.

In conclusion, contemporary research continually reflects a need to take female deviance and crime much more seriously. While there are currently four major schools of thought, two have been discredited and one has little empirical support. It is evident that studies of women and deviance are lacking, even now. There is an increasing body of research examining girls and women engaged in deviance and crime (e.g., female gang members), but most of the contemporary research continues to examine girls and women engaged in traditional deviant and criminal behaviors (e.g., status offenses, prostitution) and/or limits discussions of women and deviance to women's status as victims.

A partial explanation for this continuing trend hails from Akers (2000), who has suggested that there is little empirically to sustain the criticism that current theories are falsified or inadequate when applied to the criminal behavior of women, or to uphold the conclusion that girl/women specific theories are needed to account for gender ratios in crime and deviance. And yet there are clear indications of differences in female and male deviant and criminal behaviors, arrest rates, and incarceration rates. What can explain these differences if no additional theoretical considerations are needed? Sociologists need to spend more time considering the unique aspects of the lives of girls and women with respect to deviance. Additionally, demographic considerations must be taken into account more systematically. Race, class, age, and many other social characteristics that are commonplace in male oriented research on deviance and crime must be folded into theories examining girls and women. "We've

come a long way baby," but we still have a long way to go.

gender, education and

Jennifer Pearson and Catherine Riegle Crumb

Social scientists and educational researchers paid relatively little attention to issues of gender in education until the 1970s, when questions emerged concerning equity in girls' and women's access to education across the world. Researchers documented a link between increasing rates of female education in developing countries and a subsequent decline in fertility rates (e.g., Boserup 1970). In the context of an emerging global economy, increasing female representation in primary and secondary education was cited as an important factor in promoting national economic development, and therefore seen as a vehicle for social change.

As the feminist movement increased awareness of widespread gender inequality within US society, researchers began to focus on the educational system as a site of and explanation for women's subordinated status. Feminist scholars documented sex discrimination in educational experiences and outcomes, and this early work led to the passage of Title IX in 1972, legislation that prohibited discrimination on the basis of sex in federally funded educational programs.

During the 1970s and 1980s, women gained access to higher education and their share of college degrees climbed steadily. Women now comprise the majority of US college students and have achieved parity with men in number of undergraduate and graduate degrees, though men are over represented in the most prestigious colleges and universities and obtain a greater number of doctoral degrees than women (Jacobs 1996). Despite this greater equality in educational access, women remain significantly behind men in economic and social status. There remains a significant gender gap in pay, while women are also concentrated in low status, sex stereotyped occupations and continue to bear primary responsibility for domestic tasks despite their increased labor force participation. This paradox has led researchers to shift their focus from women's educational access to their academic experiences and outcomes.

While education is seen as an important mechanism of upward mobility in US society,

many sociologists of education have described the educational system as an institution of social and cultural reproduction. Existing patterns of inequality, including those related to gender, are reproduced within schools through formal and informal processes. Knowledge of how the educational system contributes to the status of women requires a look at the institution itself and the processes that occur within schools.

While women's access to education has improved, sex segregation within the educational system persists. Research following Title IX documented a wide gender gap in course taking during high school that led to different educational and occupational paths for men and women. For example, the American Association of University Women revealed in a 1992 report titled *Shortchanging Girls, Shortchanging America* that girls took fewer advanced math and science courses during high school, and these course taking patterns left them unprepared to pursue these fields in higher education. This contrasts with the primary school years, where girls receive better grades in math and are often over represented in high ability math courses, while boys are over represented in low ability courses. Additionally, average math test scores for boys and girls are similar, although there is more variation among boys, leaving them with the highest, but also with the lowest, scores. Girls' attitudes toward and interest in math and science begin to decline during the middle school years (fourth through eighth grade), and gender differences in test scores in these subjects are apparent by high school.

Recent research suggests that the gaps in high school course taking are closing, and girls and boys now take similar numbers of math and science courses. This may be the result of increased educational requirements and fewer choices in course enrollment, as girls continue to score lower on standardized tests and express less interest in these subjects. In addition, girls are now taking advanced courses such as calculus at comparable rates to boys, with the exception of physics. Furthermore, technology and computer courses remain highly gendered: though both boys and girls take computer courses, boys are more likely to take high skills classes, such as those that focus on computer

programming, while girls are over represented in courses featuring word processing and data entry, skills associated with secretarial work (AAUW 1999). Conversely, girls are more highly concentrated in the language arts, including literature, composition, and foreign language courses, and they tend to score higher than boys on verbal skills on standardized tests. This gender gap in favor of girls does not appear to be closing, but it is given relatively little attention in discussions of gender and education.

These high school course taking patterns foreshadow gender differences in higher education, where a high degree of sex segregation remains in terms of degrees and specializations. In the United States, women are concentrated in education, English, nursing, and some social sciences, and they are less likely than men to pursue degrees in science, math, engineering, and technology. As these male dominated fields are highly valued and highly salaried, women's absence from them accounts for a great deal of the gender gap in pay.

Sex typing in education appears to be a worldwide phenomenon, though it varies somewhat in degree and scope between countries. In countries where educational access is limited and reserved for members of the elite, women are often as likely as men to have access to all parts of the curriculum (Bradley 2000; Hanson 1996). However, in countries with more extensive educational systems, women have lower rates of participation in science and technology (Hanson 1996), fields greatly valued because of their link to development and modernity.

Some have used a rational choice approach in explaining the persistence of educational segregation, particularly that of higher education. These scholars suggest that women choose female dominated fields despite their lower status and pay because they will suffer smaller penalties for an absence from the workforce for child rearing; however, women in male dominated fields not only receive higher pay but are also offered more flexibility and autonomy. Others suggest that while individual choices are at play in perpetuating sex segregation, these choices are constrained by cultural beliefs that limit what women (and men) see as possible or appropriate options (Correll 2004). Math, science, and technology are regarded as masculine subjects, especially given their

emphasis on objective knowledge and rational action, and women are seen as ill equipped for these fields. Conversely, subjects such as language arts and nursing are perceived as feminine subjects, and men are largely under represented in these fields. In contrast to the push to include women in male dominated fields, however, the under representation of men in these subject areas goes largely unacknowledged and is often not regarded as problematic, probably due to the low status and low paid jobs associated with these fields.

These beliefs about appropriate interests and talents for men and women are part of a "hidden curriculum" that involves interactions and covert lessons that reinforce relations of gender, as well as those of race and social class, by teaching and preparing students for their appropriate adult roles. Several scholars have examined this hidden curriculum within schools, pointing to ways in which classroom interactions with teachers and between students impart these lessons. Observational studies by Sadker and Sadker (1994) suggest that in the same schools and in the same classes, boys receive more attention than girls. Teachers ask them more questions and offer them more feedback and constructive criticism, all of which are essential to learning. Boys monopolize classroom discussion beginning in the early school years, and girls become quieter over time, participating little in college classrooms. These classroom dynamics reinforce notions of femininity, teaching girls that they should be quiet, passive, and defer to boys, characteristics that disadvantage girls in competitive fields of math and science. Furthermore, an emphasis on social and romantic success can distract young women from their studies and make academic pursuits tangential.

Several feminist scholars have advocated single sex schooling in order to avoid these negative consequences. They argue that girls in all girls' schools have greater achievement, higher educational and career aspirations, attend more selective colleges, take more math courses and express a greater interest in math, and hold less stereotyped notions of female roles. These benefits allegedly result from smaller classes, higher teacher quality and attention, and freedom from social pressures of romance. However, other scholars argue that single sex education itself

does not ensure any particular outcomes because these schools vary greatly in the inspirations, desired outcomes, and sociocultural environments they embody. Indeed, recent research on single sex schools is often inconsistent, and their advantages in comparison to coeducational schools may have decreased after public schools began addressing issues of gender bias. More research is needed on school characteristics that are associated with improved outcomes for girls.

Some educational researchers suggest that concern for girls' education overshadows boys' disadvantages in education, advocating a shift in focus to boys. They argue that though the gender gap in math and science is closing, boys remain behind in language arts course taking and verbal skills. Further, boys are over represented in remedial and special education classes, and they are more likely to fail a course or drop out of school. Others contend that these disadvantages are short term costs of maintaining long term privilege: subjects in which girls outperform boys are devalued, so boys focus their energy elsewhere, such as in sports or math and science, which hold more prestige and will earn greater status and pay in the long run. Moreover, negative outcomes tend to be concentrated among working class boys and boys of color, suggesting that these problems may reflect race and class inequality rather than disadvantages affecting all boys. Regardless, considering boys only as a contrast group to the experiences of girls, rather than examining their position within and experiences of the educational system, will not provide a complete understanding of issues of gender in education. Future research focused on the experiences and behaviors of boys in schools is needed to further this knowledge.

Research on how race and class shape gendered educational experiences and outcomes has been relatively scarce, and only in the past ten years have race and class become focal points in research on gender in education. The advantages granted boys in schools are not equal among all boys: working class boys and boys of color do not demonstrate the same academic success as white, middle class boys. Further, among some groups, girls surpass their male counterparts in math and science course taking and achievement. Ferguson (2000) examines how the hidden curriculum

affects black boys, noting that many school practices disadvantage black boys, leading them to seek achievement and masculinity in ways that are detrimental to their future success. Similarly, perceived cultural differences can penalize girls who do not meet white, middle class standards of femininity: working class girls and girls of color are sometimes seen as troublemakers for being outspoken or assertive. Research on how the intersection of race, class, and gender shapes educational experiences and outcomes is an important direction for the future of the sociology of education.

gender, friendship and

Stacey Olikier

The subject of gender and friendship links two fields of sociological scholarship. Gender was rarely a salient theme in pioneering studies of friendship, communities, and social networks that emerged in anthropology and sociology in the 1960s. By the 1980s, though, burgeoning gender scholarship in the social sciences ignited interest in gender and friendship. For the most part, the sociology of gender and friendship has explored how differences in the meanings, expectations, experiences, and identities that are culturally associated with biological sex create patterns of difference in the friendships of men and women. A second perspective, examining friendship patterns as a force in the constitution of gender difference and inequality, is less prominent in the literature, but it is promising.

Sociologists trace the modern forms of both gender and friendship to the emergence of a market economy, the separation of work and family life, and the cultural changes that cultivated modern individualism. In the nineteenth century public sphere that men entered as workers and citizens, men developed forms of individualism and masculine identity that emphasized autonomy, competitiveness, and the emotional toughness to suppress personal concerns that could contaminate their public roles. In the newly defined private sphere of family that became women's proper domain, women elaborated new private themes of individualism, emphasizing emotional introspection and expressiveness, which supported the new maternal role of attentive and responsive nurturer and moral exemplar. From these gender polarities in culture and experience, men and women developed distinctive versions of the warmer, more individualized friendship patterns of modern society (Olikier 1989).

In the institutions of private life, middle class women forged new patterns of intimate friendship, while masculine intimacy developed more ambivalently – in conflict with public sphere expectations and ideals of masculinity, and in the less private sites of male camaraderie in the streets, clubs, and taverns. Contemporary

patterns of gender and friendship originated in this era, where modern meanings of masculinity and femininity formed, and where institutions of work and family were reconstituted in sturdy forms that carried nineteenth century gender ideas into the present (Olikier 1989; Olikier in Adams and Allan 1998; Walker 1994; Wellman 1992).

Since the 1980s, studies have explored gender differences in communication between friends, friendship over the life course, and network size and composition. The most frequently identified gender difference is in intimacy, that is, the exchange of self disclosure, private experience, and emotional expression. Women talk more about themselves and show their feelings more to friends than men do. Women often bond by intimate talk, men by shared activity over time. Scholars disagree about what gender differences in intimacy mean for understanding friendship and for understanding gender. A "different but equal" position holds that we have misleadingly "feminized" our concept of intimacy: narrowly associating intimacy with expressive, self disclosive exchange and ignoring the bonds created in the familiarities of joint activity and the exchange of instrumental help distorts our understanding of male intimacy in friendship (Wright 1998).

Those who maintain that the concept of self disclosive intimacy is meaningful argue that conceptualizing intimacy in introspective and emotional terms illuminates the personal and social meanings of close friendship. When asked, men and women define intimacy similarly, in terms of self disclosure and emotional warmth, and both sexes assert that this kind of intimacy is the central characteristic of close relationships. Studies of the effects of disclosive intimacy suggest that both men and women feel better off and happier in relationships when this kind of intimacy is present (Reis 1998). Though shared activities may promote emotional intimacy, the settings and tasks of shared activity may discourage the attentiveness and candor required to achieve the bonds both men and women associate with close friendship.

Intimacy, affection, trust, and commitment to friends are not the same qualities, though the literature often elides them. Plausibly, each has different meanings for and influences on individuals, relationships, and even larger institutions,

such as marriage and the family. For example, through self-disclosive intimacy with best friends, women appear to actively reinforce each other's commitments to marriage and evolve strategies of marital bargaining and accommodation. Those who do not talk to close friends about problems in their marriages are unlikely to receive as much communal reinforcement of social norms of marital commitment, tailored to their particular perceptions, and do the kind of collective "marriage work" that stabilizes marriage. Gender differences in self-disclosive intimacy with friends may position men and women differently in the process of sustaining marriage commitments and stable families (Oliker 1989).

Sociologists have used depth psychology (primarily psychoanalysis), role theory, varieties of structural explanation (prominently, network concepts), and interactional approaches to explain how gender shapes friendship. With the exception of psycho-dispositional frameworks, all are deployable for an alternative approach to gender and friendship, which examines how friendship patterns shape gender. For example, studies of social networks and of foci of activity suggest how gendered divisions of labor result in men's looser knit and more work-focused networks that give men better access to information and contacts that advance their careers, while women's denser networks (denser in kin and neighborhood ties) offer women more resources for childrearing but fewer resources for career advancement (Smith-Lovin & McPherson 1993). In these studies, structures of friendship mediate the construction of gender inequality. Interactional frameworks that examine how gender behaviors and identities are produced in friends' interactions can explain persistent gender patterns even among individuals who may not be primed by dispositions, prompted by roles, or prodded by structural constraints. Evidence that men in cross-sex friendships are more disclosive than men in same-sex friendship and that women in cross-sex friendship are less disclosive suggests an analytical move in which gender identities and inequalities emerge in friendship dynamics (Reis 1998).

Enriching the study of gender and friendship will likely involve both analytical and methodological changes. The debate about gender

differences in intimacy shows the advantages of greater conceptual precision. Such precision would also make contradictory research findings easier to sort out. Two decades of qualitative research, most often studying either men or women, posits distinctive gender differences, while quantitative research finds few gender differences and small ones. Though such contradictions are entrenched, to some extent, in contrasting methods, more comparative qualitative studies and more interpretive strategies in quantitative work are likely to produce less discordant knowledge. Conceptual precision might also inspire scholarship on gender and the social, cultural, and psychological capital gains from less intimate "weak ties" of sociability and friendly acquaintance and co-participation. Finally, by shifting the analytical frame held up to gender and friendship, research exploring how friendship shapes gender could enrich the separate areas of friendship and gender, and the subject of relations between them.

gender, health, and mortality

Ulla Larsen

Although life expectancy at birth of women in western societies is significantly longer than that of men (e.g., 80 versus 74 years in the United States), women experience more sickness and non fatal health problems than men (e.g., higher morbidity). Specific biological and behavioral explanations for these gender differences are largely unknown. It remains unclear whether these gender differences in health and mortality are found throughout the world. Here, the term "gender" refers to the way biological differences are socially and culturally constructed and expressed in actions and thoughts, whereas the term "sex" is used to define a biological category based on anatomical and physiological differences between males and females. "Health" is a state of complete physical, mental, and social well being and not merely the absence of disease or infirmity, according to the World Health Organization (WHO). "Mortality" is the rate of death in a population in a specified time period.

In the year 2000, the overall life expectancy at birth ranged from a high of 81.1 years in Japan (84.7 for women and 77.5 for men) to a low of 37.5 years in Malawi (37.8 for women and 37.1 for men), as measured from the 191 Member States of the WHO. At the beginning of the twentieth century female life expectancy exceeded male life expectancy by only 2-3

years in Europe, North America, and Australia, whereas at the beginning of the twenty first century this gender related difference in life expectancy was more than 10 years in some countries. Fewer deaths in childbirth help women today to live longer, accounting in part for the increase in the gap between male and female longevity. Worldwide analysis reveals a few exceptions: male life expectancy is higher than that of women (by less than a year) in a few countries (including Botswana, Namibia, and Nepal). These mortality sex differences prevail at all ages, races, and social conditions.

In 2002, worldwide, the four leading causes of disease burden (premature death and disability) over age 15 included HIV/AIDS, coronary heart disease, cerebrovascular disease, and unipolar depressive disorders. More specifically, HIV/AIDS was the leading disease burden for males and the second leading one for females (7.4 percent and 7.2 percent). The number one disease burden in females was unipolar depressive disorders (8.4 percent), whereas this disease ranked fourth for males (4.8 percent). Thus, of the four major causes of disease burden, unipolar depressive disorders have the greatest gender specific difference. Coronary heart disease and cerebrovascular disease were the second and third most common cause for males (6.8 percent and 5.0 percent), and the third and fourth most common cause for females (5.3 percent and 5.2 percent). In conclusion, unipolar depressive disorders affected women relatively more than men, while coronary heart disease was somewhat more prevalent among men.

Women experience more poor health during their lives than do men. This gender difference in overall health is assessed by determining the number of days confined to bed, the frequency of sick leave from work, rates of yearly doctor and hospital visits, and the number of self reported disease symptoms. For example, in the 1991 US National Health Interview Survey, the total proportion disabled (reporting difficulty with one or more activities of daily living) was nearly twice as high for women as men. However, the finding that women experience more health problems than men is being challenged with recent research documenting a more nuanced picture of gender differences in health, at least within developed western societies. For example, one study found no

consistent gender differences in reported health symptoms for young people in England. An other study, based on men and women working full time for an English bank, found difference by sex in symptoms of malaise (e.g., difficulty sleeping, nerves, and always feeling tired), but not in physical symptoms (e.g., hay fever, constipation, and a bad back) or in minor psychiatric morbidity (a 12 item general health questionnaire). The hypothesis that women are more willing to acknowledge and report poor health has also not been supported consistently in recent studies.

More research is needed to better understand the prevalence and causes of these general health differences between men and women. Future research will benefit from the use of health indices that have been evaluated for their validity and reliability in different research settings in order to ensure that findings between countries and across time are comparable and generalizable. In addition, the accuracy and completeness of health and mortality statistics are crucial in determining sex or gender differences. For example, measured differences might be the result of incomplete coverage of national death statistics, interviewer bias in health survey data, or because hospital and clinical data on disease include only the population attending these institutions, although women and men may be differentially admitted and treated.

Differing life span and quality of health can be due to biological factors, but medical research has not always accounted for sex differences. In 1977, in response to the adverse events following use of thalidomide and diethylstilbestrol in pregnant women, the US Food and Drug Administration (FDA) issued guidelines recommending that women in their childbearing years be excluded from phase 1 clinical trials (safety evaluations of new drugs based on healthy subjects). On scientific grounds it was justified to exclude women as clinical research participants because it was believed that men and women did not differ significantly in response to treatment in most situations, and the inclusion of women would introduce additional noise (from the hormonal variations caused by the menstrual cycle) and increase the heterogeneity of the study population. These faulty assumptions led to a period in which women were under represented

in research subject populations, a trend that may have reduced the effectiveness of new therapeutics for female patients. Thus, in 1985, the US Public Health Service Task Force on Women's Health Issues concluded that health care for women and the quality of health information available to women had been compromised by the historical lack of research on women's health. In 1993, with the National Institutes of Health Revitalization Act, the guidelines for inclusion of women became law and the FDA lifted the 1977 restrictions. In 1998 the FDA issued a rule allowing the agency to refuse new drug applications that did not appropriately analyze safety and efficacy data by sex.

In 2001 the Institute of Medicine formed a Committee on Understanding the Biology of Sex and Gender Differences, which found evidence suggesting that published research frequently did not present findings by sex, even though the data were available. It was noted that research on women's health and the inclusion of women in clinical trials would have limited value unless the actual differences between males and females were systematically studied and reported in published research. This committee noted that a number of sex based differences in health are attributable to sexual genotype (XX in the female and XY in the male on the 23rd chromosome pair) and hormonal or genetic differences between the two sexes. Also, men and women have dissimilar exposures (e.g., work and leisure activities), susceptibilities, and responses to initiating agents. Finally, sex differences in energy storage and metabolism result in variable responses to pharmacological drugs and the development of diseases such as obesity, autoimmune disorders, and coronary heart disease.

Examining the different experience of men and women with a particular disease, such as coronary heart disease, illustrates the complex effects of sex and gender on health, as well as the need for more research. Coronary heart disease begins *in utero*, evolves through childhood and young adulthood, and becomes a serious and often fatal health problem in middle and old age. Plaques of cholesterol and other cellular materials are deposited in the coronary arteries of the heart and over time compromise the flow of blood, causing cell and organ death (myocardial infarction). In general,

men manifest symptoms 10–20 years earlier than women, have higher prevalence of primary risk factors, and die at earlier ages, although women who have had a myocardial infarction are much more likely to die within a year compared to men. Female sex hormones (estrogen) reduce women's risk of coronary heart disease, in part by mitigating negative effects of serum lipids (fats in the bloodstream), while men's higher testosterone levels have unfavorable effects on serum lipids. In many non industrial societies, sex differences in cholesterol levels are minor or absent, largely an effect of diets low in saturated fats. It might also be that sex differences in serum lipid levels are linked to body composition, men having more abdominal fat, whereas women have more hip and thigh fat.

Several longitudinal studies, such as the Framingham Heart Study (US), the Tromsø Heart Study (Norway), and the National Health and Nutrition Examination Survey (US), documented that genetics, age, and environmental and lifestyle factors are associated with onset of coronary heart disease. For example, environmental agents such as smoking, diet high in calories and saturated fat, obesity, a sedentary lifestyle, and psychosocial stress are linked to high blood pressure, high cholesterol, and diabetes. These factors are risk factors for coronary heart disease in both males and females, although susceptibilities and responses vary by sex. However, these studies did not explain why such sex differences exist. Smoking is a strong risk factor for coronary heart disease and the increase in smoking among women relative to men has contributed to narrowing the gap between men and women in mortality from coronary heart disease. There is evidence suggesting that medical care reduces coronary heart disease mortality more for men than for women, at least in the US. Women's complaints about chest pains tend to get cursory attention and women are less likely to get diagnostic evaluations. The data indicate that women get treatment at more advanced disease stages and more often have emergency surgery. Finally, heart conditions often present different symptoms in men and women, but more is known about this disease in men, in part because women often were excluded from clinical trials and epidemiological studies. Results

from research on men have simply been extended and applied to women, although it is now acknowledged that men and women have different exposures to risk factors and respond differently to some of the same risk factors. This underscores the importance of designing studies that address heart disease risk factors, treatment, and prevention in women.

Men and women respond differently to stress (the perception of excessive demands with which an individual is unable to cope), which is a risk factor for coronary heart disease. Lack of control induces stress and evidence suggests that women experience less control than men. In general, women experience more stress from their work because they have relatively lower status jobs with less control, less security, and less financial reward. In addition, women usually take on a greater burden of household chores, including childcare. Women do report more stress than men, but it has been argued that women simply express their distress more than men. Recent research showed that women are not socialized to complain more than men (express more stress), although it is possible that women and men feel differently about expressing emotional problems. Thus, there is accumulating evidence from western societies that women encounter more stress than men in their daily lives. Hence, stress might be a more important risk factor for coronary heart disease for women than men, although the higher levels of estrogen somewhat protect women from the negative effects of stress.

The question is whether the effect of stress on cardiovascular health is different for women and men. Laboratory studies showed that men express greater adrenaline response to stress than women, and it is hypothesized that women are protected against elevation of adrenaline because of higher levels of circulating estrogen. Elevated levels of circulating adrenaline may be bad for cardiovascular health because adrenaline stimulates the release of metabolites that contribute to raising levels of serum cholesterol. In addition, adrenaline is involved with the regulation of blood pressure, and repeated high blood pressure may lead to sustained hypertension. Studies of men and women in a number of non manual occupations showed significantly higher adrenaline levels in men on working days than on weekends, but no

such difference for women. Furthermore, self reported stress experienced on rest and work days was significantly associated with adrenaline response in men, but not in women. This difference in adrenaline response was seen, even though women and men reported (by questionnaire) similar levels of stress on workdays and the weekend and both sexes reported higher stress on workdays. Men and women also reported similar mood states, with the exception that men's anxiety dropped after work, while women's did not change. Thus, differences in subjective experience could not explain differences in adrenaline response to work between men and women, suggesting the influence of biological mechanisms. In summary, sex differences in coronary heart disease and mortality appear to be due to the interaction of multiple biological and behavioral factors.

Despite the importance of understanding why women live as much as 10 years longer than men and why women experience poorer health throughout their lives, so far no behavioral or biological explanation adequately explains this paradox. It is unlikely that biological and acquired risk differences fully explain why women experience poorer health, but live longer, for psychosocial aspects of symptoms and health care seeking (illness behavior) might play an important role.

gender ideology and gender role ideology

Amy Kroska

Both gender ideology and gender role ideology refer to attitudes regarding the appropriate roles, rights, and responsibilities of women and men in society. The concept can reflect these attitudes generally or in a specific domain, such as an economic, familial, legal, political, and/or social domain. Most gender ideology constructs are unidimensional and range from traditional, conservative, or anti feminist to egalitarian, liberal, or feminist. Traditional gender ideologies emphasize the value of distinctive roles for women and men. According to a traditional gender ideology about the family, for example, men fulfill their family roles through instrumental, breadwinning activities and women fulfill their roles through nurturant, homemaker, and parenting activities. Egalitarian ideologies regarding the family, by contrast, endorse and value men's and women's equal and shared breadwinning and nurturant family roles.

Gender ideology also sometimes refers to widespread societal beliefs that legitimate gender inequality. For example, Lorber (1994: 30) defines gender ideology as "the justification of gender statuses, particularly, their differential evaluation. The dominant ideology tends to suppress criticism by making these evaluations seem natural." Used in this way, gender ideology is not a variable that ranges from

conservative to liberal; instead, it refers to specific types of beliefs – those that support gender stratification. Gender ideology in the remainder of this summary refers to the first sense of the concept: attitudes that vary from conservative to liberal.

Sociologists' interest in measuring gender ideology can be traced at least as far back as the 1930s, with the development of instruments such as Kirkpatrick's 1936 Attitudes Toward Feminism scale. Interest continues today, and currently most major national surveys in the US, such as the General Social Survey (GSS) and the National Survey of Families and Households, include gender ideology scales. Two volumes by Carole Beere (1979, 1990) summarize the psychometric properties and past uses of most gender ideology instruments developed through 1988.

The most common technique for measuring gender ideology is a summated rating scale in which respondents are presented with a statement and given three to seven response options that vary from strong agreement to strong disagreement. The following statement from the GSS is illustrative: "It is much better for everyone involved if the man is the achiever outside the home and the woman takes care of the home and family." Other measurement techniques include Guttman scales, Thurstone measures, identity vignettes in which respondents rate their similarity to fictional characters, and intensive, open ended interviews.

Researchers have examined the correlates, causes, and consequences of individuals' gender ideology. Within the US the documented antecedents include gender and birth cohort, with males and earlier cohorts reporting more conservative attitudes than females and later cohorts. Among women, labor force participation and educational attainment decrease conservatism. More generally, conservative gender ideologies are positively related to church attendance, fundamentalism, and literal interpretations of the Bible, and negatively related to education, family income, parents' gender liberalism, and women's labor force participation (whether self, spouse, or mother).

Other correlates and consequences of gender ideological positions have also been studied. Liberalism is positively related to married men's housework and childcare contributions

and negatively related to women's housework contributions. Yet gender ideology is unrelated to the affective meanings (goodness, power, activity) associated with most social roles (e.g., a husband, a wife) and self meanings (e.g., my self as a husband) among individuals of the same sex, suggesting that gender ideology does not affect perceptions of most social roles or self meanings within those roles.

Researchers have also investigated the way that gender ideology shapes spouses' perceptions of their marriage. Liberalism reduces women's perceived marital quality but increases men's. Women's gender ideology also moderates the relationship between housework divisions and perceptions of fairness in housework divisions: as women's gender ideology becomes more liberal, the negative relationship between housework inequities and perceptions of housework fairness becomes stronger. Women's liberalism also increases the positive relationship between perceived fairness in housework and marital stability.

Researchers have recently begun to examine discrepancies between gender ideological positions and self identification with feminism. Schnittker, Freese, and Powell (2003) show a cohort effect in the US such that self identification with feminism is most strongly related to liberal gender ideologies for males and females who were young adults during the second wave of feminism. In addition, Klute et al. (2002) have applied Melvin Kohn's ideas to gender ideology. They found that self direction at work is positively related to values emphasizing self direction rather than conformity, and that spouses who value self direction are also more likely to hold egalitarian attitudes about marital roles. Thus, workplace experiences may have an indirect effect on gender ideologies through the values that they foster.

Cross national research has also shown that gender ideology is also related to women's political representation. Using the *World Values Survey*, which includes individual level information on gender attitudes in 46 countries in 1995, Paxton and Kunovich (2003) showed that a conservative gender ideology is negatively related to the percentage of female members in the national legislature of a country even when controlling for political and social structural factors.

gender mainstreaming

Silke Roth

Gender mainstreaming is a strategy for achieving gender equality. The approach seeks to reorganize and restructure policies, institutions, and social programs by taking women's and men's perspectives, experiences, and needs into

consideration. Gender mainstreaming does not replace, but supplements, specific targeted interventions to address gender inequality such as affirmative action.

Gender mainstreaming was first introduced when UNIFEM (the women's division of the United Nations) was restructured. At the Third UN World Women's Conference in Nairobi in 1985, gender mainstreaming and empowerment were adopted in development policies due to the persistent marginalization of women with respect to access to resources, information, and decision making, replacing the earlier "women in development" (WID) approach. The goal of gender mainstreaming is to support women and to ensure their involvement in decision making processes and agenda setting. UNIFEM conceives gender mainstreaming as a double strategy: gender differentiation and taking into consideration the different living conditions and interests of men and women in all developmental programs and project interventions at the macro economic and macro political level, as well as women specific measures in those instances where gender analyses revealed inequalities with respect to resources.

Ten years later, the systematic incorporation of gender as a factor in policymaking was formally adopted at the Fourth World Conference of Women in Beijing in 1995. Due to extensive lobbying of the European women's lobby, gender mainstreaming was included in the Amsterdam Treaty of the European Union (EU), which was signed in 1997 and ratified in 1999 (Mazey 2001). The treaty declares gender mainstreaming as a core task of the EU and thus requests that member states (and those countries which seek to join the EU) mainstream gender into policies developed in their countries. Thus, the new member states which joined the European Union in May 2004 were required to adopt gender mainstreaming. The EU enlargement process thus provided important policy instruments for increasing equality between men and women. The implementation of gender mainstreamed regulations is monitored by the EU, but has to be carried out by the national governments.

Gender mainstreaming involves analytic tasks, taking into account inequalities in political power within households and in the domestic and unpaid sector, differences in legal status

and entitlements, the gender division of labor in the economy, violence against women, and discriminatory practices. Furthermore, it encompasses policy analysis and policy development: the formulation of the policy outcome to be addressed, the definition of the information needed to assess policy options, the assessment of the implication of different options by gender, the determination of who will be consulted and how, and the formulation of recommendations for policy choices. It is based on research and informs data collection, analysis, and dissemination. Gender mainstreaming in technical assistance draws on national commitments to women's rights and gender equality, ensures that the expert team includes members with gender analysis experience, and includes the consultation of local experts on gender equality (United Nations 2002).

In addition to development, gender mainstreaming was also introduced in other institutional arenas, for example international peacekeeping, education, and medicine. In October 2000 the UN Security Council adopted Resolution 1325, recognizing the urgent need to mainstream gender perspectives into peacekeeping operations, the importance of specialized gender training, and the need to understand the impact of armed conflict on women and girls. This includes the acknowledgment of sexual violence. In local societies, in which women constitute the majority of the population, it is especially beneficial to include a significant number of women in peacekeeping since female peacekeepers more easily establish dialogue with local civilians than their male partners because women may be perceived as less threatening and cultural norms might prohibit women to interact with men who are not family members. Security procedures such as body searches of women are easier if they are carried out by female peacekeepers (Olson & Torunn 2001). Gender mainstreaming of the education sector is based on the assessment of the educational status of girls and women, boys and men and involves the review of policies, laws, regulations, plans, and programs from a gender perspective, the analysis of the impact of educational policies and programs, and recommendations for more effective mainstreaming. Gender mainstreaming in the health sector guarantees that the different needs of men and

women are addressed, rather than extrapolating from male specific findings to women. Strategies include taking full account of diseases and disabilities from which women suffer because of their sex, which are more prevalent in women, which affect women more severely than men, which have more adverse effects on women during pregnancy, and against which women are less able to protect themselves. Men have a higher death rate from acute medical conditions such as cardiovascular or cerebrovascular episodes. Furthermore, men's workplace conditions, as well as gender stereotyping that discourages men from articulating their problems and emotions, need to be taken into consideration.

Gender mainstreaming represents a paradigm shift with respect to equality policies in as far as it declares all policy fields as relevant for women, in contrast to earlier gender policies which focused on women and developed political units (e.g., gender desks or women's ministries). This means that instead of helping women to adapt to structures which benefit men, the goal is to change the gendered structures in order to become more women friendly. Gender mainstreaming is future oriented in that it tries to anticipate gender processes in the planning and decision making stage, while earlier strategies to achieve gender equality retroactively sought to remedy past decisions and social inequalities.

gender oppression

Vrushali Patil

Gender oppression is defined as oppression associated with the gender norms, relations, and stratification of a given society. Modern norms of gender in western societies consist of the dichotomous, mutually exclusive categories of masculinity and femininity. Developing in tandem with industrial capitalism and the nation state, they had particular consequences for women and men. While masculinity was to consist of rationality, autonomy, activity, aggression, and competitiveness (all qualities that made men the ideal participants in the emerging public sphere of economy and polity), femininity was defined in contrast as emotionality, dependency, passivity and nurturance – all qualities that deemed women’s “place” in the private sphere. These naturalized views of gender categories were embedded in burgeoning disciplines such as biology and sociology. However, not only were they premised on a dichotomous conception of sex and gender, they were also premised on heterosexuality, middle class status, and European ethnic origin. As such, the gender oppression embedded therein is associated not only with the category with less power in the binary (femininity), but also with subjects that somehow deviate from either category.

Mainstream sociology initially ignored gender as well as gender oppression, marginalizing feminist sociologists in the early years. The subsequent period of structural functionalism excused and even supported dichotomous gender norms and their oppression, arguing that gender roles and identities served some functions in society. Sociological recognition and theorization of gender oppression thus required the denaturalization of the concept of gender itself within the discipline. A first step occurred in the 1970s, with debates regarding the extent to which “differences between the sexes” were biological. While this exchange enabled a limited discussion of gender oppression, the next set of debates allowed a greater role for the “social” – moving from sex differences to sex roles and socialization (Ferree et al. 2000). This shift was particularly useful for elaborating the gender oppression of those who “fit” or who

were able to comply with gender norms. One of the most important insights gleaned from this perspective was the relationship between the aforementioned gendering of public and private spheres and the fundamental gendering of personhood: that is, the gendering of the two spheres meant that women’s primary access to personhood within society was through the uptake and performance of their roles as wives and mothers within the private sphere, while men’s access to personhood was through participation in various worker and citizen roles in the public sphere (as well as through the status of head of household in the private sphere).

Studies of gender relations in societies around the world have demonstrated that almost everywhere in the modern era, though in culturally specific ways, femininity is associated with a domestic sphere while masculinity is associated with a public sphere. At the macro level, dichotomous and naturalized views of gender are evident in the gendering of economic, political, and other institutions, where especially elite men dominate every major institution in most societies around the world (see Peterson & Runyan 1999). Ultimately, this gendering shapes the experiences of different groups of women globally and is expressed in higher levels of poverty; lower levels of formal political power; trivialization and sexual objectification in media; gender specific health issues such as eating disorders, greater risk of AIDS, inadequate food/health care, and ongoing challenges to reproductive autonomy; greater levels of fear; and greater risk of interpersonal violence, to name a few.

Presently, the sociological approach to gender is even more “socialized,” and gender is now recognized as a thoroughly social entity as well as a central organizing principle in all social systems, including work, politics, family, science, etc. (Ferree et al. 2000). As such, understanding of its complexity and scope has increased as well. Hence, a central area of interest in recent years has been the intersection of gender with other dimensions of experience and oppression, including race, class, culture, sex, and sexuality. Otherwise stated, while the above perspective elaborated the gender oppression of those who “fit” the dichotomous gender categories of masculinity and femininity, this lens is particularly useful for understanding the gender oppression of those who “do not or cannot fit”

these categories. For example, the static and mutually exclusive norms of sex and gender that emerged in modernity denied the existence or personhood of the intersexed and the trans gendered. Premised on heterosexuality, they denied the personhood of gays, lesbians, and bisexuals. Further premised on a masculine public sphere, working class women who necessarily transgressed this space have also been made deviant. Moreover, these norms are fundamentally racialized in that they emerged in the context of the conflict ridden contact between different peoples from the sixteenth century onwards. As European travelers in this period especially encountered racial and cultural “others,” with their varying gender practices, European gender norms became a symbol of civilization, the deviation from which became a sign of racial and cultural inferiority. In this fashion, gender became a central vehicle for constructing racial and cultural hierarchy (Enloe 1990; McClintock 1995).

Additional emerging areas of interest in the field include gender oppression associated with varying masculinities, gender experiences and oppression in a transnational framework, and gender symbolism that may perpetuate inequalities beyond the bodies of men and women (i.e., the denigration of “feminine qualities,” which denigrates not just women but any feminized entity).

gender, social movements and

Nancy Whittier

Social movements are shaped by gender systems and they also are a source of social change in gender. Some social movements directly attempt to change gender relations; these movements, particularly women's movements, have been the focus of considerable scholarship. Increasingly, scholars also recognize the gendered nature of other social movements and the impact of systemic inequalities of gender on the opportunities, constraints, and forms of social movements in general.

Research on gender and social movements has proceeded through several stages. Initial works focused on documenting women's movements, including feminist and non feminist movements, and explaining their emergence and development. A second phase of work began to analyze gender in social movements more broadly, including masculinity, and to analyze the intersections between gender, race, class, and nationality in social movements. Most recently, numerous scholars have begun to examine the ways that movements are gendered in their origins, collective identities, frames and discourses, organizational structures, tactics, and political and cultural opportunities. In doing so, they contribute to a rethinking of the basic concepts of the field of social movements. These phases are similar to those for scholarship on gender more

broadly, which initially focused on documenting women's experiences and remedying male bias, next on gender as an institution and the intersections between gender and other major forms of social inequality, and lastly on reformulating basic sociological knowledge and theory based on a perspective that makes gender central. Sociological work on gender and social movements thus reflects the influence of the feminist movement on the academy.

Many social movements have targeted the social structures, culture, and interactional norms around gender. These include feminist movements, which in many countries focused first on gaining basic political rights such as the vote and the right to own property, and then progressed in later waves to addressing other forms of inequality between women and men ranging from responsibility for child raising and household labor, discrimination in paid employment, sexuality, reproductive rights, health care, stereotyping in the arts and popular culture, election to public office, and so on. Parallel to these movements are anti feminist movements, which tend to emerge in response to feminist movements and also target gender directly in an attempt to forestall or roll back changes.

Other movements have been organized around gender, without taking gender as a central or explicit target. For example, women's temperance and social reform movements in the late 1800s and early 1900s in the United States organized women based on their social responsibilities for morality, childrearing, and the promulgation of religious values. Women have organized in "mothers' movements" to challenge governmental killings and disappearances of their children (such as the *Madres de la Plaza de Mayo* in Argentina), or to fight against environmental degradation or for better public education. Such "maternalist politics" can uphold traditional definitions of women's place while simultaneously expanding those definitions, bringing women into the public sphere and often changing activists' own family relations and identities. Men's movements, such as the mythopoetic movement, also organize men around some traditional definitions of masculinity while simultaneously stretching those definitions by, for example, encouraging men to express emotions more freely (Schwalbe 1996).

Further, movements do not have to be oriented around gender to be shaped by it. Because gender is a central feature of social structure, culture, and daily life, all movements are gendered. The major elements of social movements are their emergence and recruitment, collective identities, frames or discourses, organizations, tactics or actions, and external contexts or political opportunities. Each of these elements is gendered.

First, movements' emergence and processes of recruitment are gendered because the status of women and men shapes their differential ability and willingness to organize on their own behalf. Gendered factors such as family structures and responsibilities, access to higher education, paid employment, and fertility rate all affect recruitment and participation in activism. These factors all vary according to race, class, and nationality as well as gender, and also change over time; such variations account for some of the differences in the level and form of women's mobilization cross culturally and historically. Further, social movements emerge along gendered lines because they emerge from gendered preexisting organizations and networks (Taylor 1999). For example, feminist organizing during the late 1960s in the US emerged partially from the Civil Rights Movement, in which women gained organizing experience and an ideology opposing inequality, but also faced gender barriers to full participation. However, grievances and networks based on race and class cross cut those based on gender. For African American and Latina women during the same era, their connections to mixed sex movements around race mitigated their interest in a mixed race movement around gender. Instead, they advocated for women's interests within mixed sex movements (Roth 2004). Similarly, international women's conferences sponsored by the United Nations have illustrated how women in third world countries define their interests quite differently from those in the highly industrialized global North.

Second, movements' collective identities, or group definitions, are gendered. Some social movements directly try to change the definition associated with their group, as feminist movements, for example, try to change what it means to be a woman. Beyond this, movement participants bring with them a gender consciousness

that affects the collective identities they construct, and they draw on ideas about gender from both dominant and oppositional cultures. For example, environmental or peace activists may define themselves as mothers concerned about the well being of children and future generations, and participants in anti globalization protests may draw on masculinity to define themselves as warriors standing up to the police, or they may draw on feminist and queer politics to define themselves as rejecting the dominant gender order along with capitalism.

Third, social movements construct interpretive frames to explain their grievances and issues, addressing their causes and calling for action. In doing so, they draw on mainstream discourses and also challenge and extend those discourses. Mainstream frames and discourses are built around particular definitions of the nature, roles, and responsibilities of women and men, and social movements include elements of these mainstream frames and discourses and construct alternatives. Often they may do both, as in the case of maternalist movements that draw on women's special place as mothers to argue for a greater influence by women on national affairs.

Fourth, social movements' organizational structures are gendered. For example, the American Civil Rights Movement assigned formal leadership to men while assigning women to more informal leadership roles (Robnett 1997). Recognizing these differences entails not only recognizing discrimination within the movement and bringing to light the previously unacknowledged role of women, but also redefining theories of leadership to include the ways that women exercise influence outside of official leadership positions. Beyond leadership, women and men may take on different tasks within movement organizations, with women taking more responsibility for activities such as providing food for events or monitoring the emotional climate at meetings, and men undertaking more public speaking, drafting of position papers, or providing "peacekeeping" at public demonstrations. Gendered divisions of labor within movements vary considerably across time, space, and among movements, of course. In movements that explicitly challenge the gendered status quo, such differences may be much less marked or even at times inverted;

while in movements that seek to restore traditional gender roles, they may be exaggerated.

Fifth, tactics and strategies are affected by gender. Women and men may draw on established social activities in order to work for change, as in men's use of violent intimidation compared with women's reliance on boycotts and vicious gossip in the US racist movement of the 1920s (Blee 1991). Here, too, incorporating tactics grounded in traditionally feminine activities into social movement theory suggests a broader definition of tactics and strategies that includes actions previously not seen as part of social movements.

Sixth, gendered external social structures and mainstream culture delimit the opportunities and constraints for social movements. Political opportunities are affected by gender because women and men have differential access to the state, both as elected officials and as outside activists. On a more subtle level, the state and other major social institutions operate through gendered structures, procedures, and discourses (sometimes termed gender regimes). When activists target or enter institutions, therefore, they face particular opportunities or barriers depending both on their actual gender and on the way their movement engages with or challenges existing notions of gender. For example, in working to change discourses about gender in the Catholic Church, women were able to draw on the institutional base of female religious orders but were limited by their structural subordination. As a result, they focused on *discursive* rather than structural change (Katzenstein 1998). Mainstream culture affects how movements' claims are received, as well, with activists who challenge accepted notions of gender being more likely to be marginalized. Men who openly display affection toward each other and lobby for an expansion in the definition of masculinity, for example, are the subject of considerable ridicule (Schwalbe 1996), while women who lobbied for restrictions on hunting were viewed as hysterical females treading into waters where they did not belong (Einwohner 1999).

In addition to being shaped by gender, social movements are an important force in changing gender systems. Feminist movements in the US and Western Europe have produced considerable change in cultural beliefs, the

structure of paid employment, women's access to higher education, and basic rights such as the vote, credit, and property ownership. In many countries, women's activism has produced constitutional guarantees for women's minimum representation in elected office. Further, social movements have contributed to changes in the cultural codes and interactional norms that define gender. At the same time, these changes have been contested by anti feminist movements.

Several lines of research are promising. First, more analyses of the gendered dimensions of men's and mixed sex movements will augment the extensive work on women's movements. Second, work on cases outside the US and Western Europe is examining the gender dimensions of a variety of movements. Because gender systems vary comparatively, this work promises to expand theorizing on the topic. Third, efforts to reconceptualize social movement theory based on this work have begun, and promise to produce a richer and more inclusive theoretical model.

gender, sport and

Louise Mansfield

Gender refers to the socially constructed differences between women and men, while the term "sex" is a reference to the biological and physical differences between males and females. Gender draws attention to the socially unequal distinction between femininity and masculinity. Femininity is used to describe characteristic behaviors and emotions of females and masculinity refers to the distinctive actions and feelings of the male sex. In studies of gender and sport, the concept of gender is analytically distinguished from that of sex even though the two are often used synonymously in everyday language and thought. Not all the differences between females and males are biological. But historically, ideas about the implications of biological differences between women and men have served to justify the exclusion or limited inclusion of women in sports. Such views reflect an ideology of biological determinism, where it is claimed that men, and not women, are inherently strong, aggressive, and competitive and, therefore, better suited to sports.

Since the 1970s, gender has become an important category of analysis in the sociology of sport. Research has clearly demonstrated that sports are gendered activities as well as social contexts in which boys and men are more

actively and enthusiastically encouraged to participate, compared with girls and women. Evidence also shows that more males than females participate in organized competitive sports, and that male dominance characterizes the administration and coaching of sports. Sports, it is theorized, operate as a site for the inculcation, perpetuation, and celebration of a type of (heterosexual) masculine identity based on physical dominance, aggression, and competitiveness. Associated with such masculine imagery, sports serve to legitimize a perceived natural superiority of men and reinforce the inferiority of females who are defined with reference to relative weakness, passivity, and grace – the characteristics of femininity. Therefore, sports are often described as a “male preserve.”

Social changes reflecting the condition of women in society have influenced the status of knowledge about the relationships between and within groups of women and men in sports. Starting in the 1970s, a consequence of the feminist movement was to raise public awareness about the need for increased opportunities for girls and women in sports. Since then there has been growing political and public recognition of the importance of health and fitness. Furthermore, emerging knowledge about the health benefits of physical activity provided a foundation for the promotion of physical activity for girls and women. Opportunities for girls and women in sports have improved and participation rates among females have increased. Scholars studying gender and sports indicate that these developments have resulted in ongoing challenges to gender stereotyping, resistance and negotiation of established gender ideology, and the initiation of important legal and political change regarding sex discrimination in sports and society. For example, Title IX of the Education Amendments of the Civil Rights Act (1972) in the US, and the Sex Discrimination Act (1975) in Great Britain were intended to counter public discrimination against women. Such legislation has been used to prevent and remove many barriers to female participation in sports.

There is now over 35 years of scholarship that theorizes gender and sport. One of the most sustained attempts at conceptualizing and theorizing about gender in the sociology of sport is found in feminist scholarship.

The first attempts to analyze women's place in sport were made in the 1960s by physical educators. The result was a corpus of largely atheoretical work on “women in sport” founded upon a liberal feminist consciousness about sport as a “male preserve” characterized by gender inequities. Between 1970 and 1980 psychological models were mainly used to explain female attitudes and motivations in sports. In the 1980s, emerging theoretical diversity and sophistication in feminist approaches led to the development of a clear sociology of women in sport. As political and theoretical feminisms have changed, so too has the focus of feminist research.

Depending on the theoretical and methodological position of the researcher, different questions about and accounts of gender and sport prevail. Debates surrounding the gendered character of sporting practices have changed with increasing awareness of feminist theories and a more sophisticated use of these theories. For example, much of the initial work on gender and sport highlighted inequities but did not explicitly deal with how the prevailing organization of sports privileged the physical experiences of boys and men. Subsequent critical analyses revealed that research focused on differences between males and females generally supported traditional claims about the biological inferiority of females and the legitimacy of efforts to control women's sports participation. Such research, it was argued, did not deal with the underlying structural and cultural sources of gender inequality. More recent scholarship has attempted to resolve the shortcomings of early research and theory by considering difference and diversity between and within groups of women, and by theoretical and methodological approaches that consider women as active agents in the construction and reconstruction of their sporting experiences.

There is no single feminist movement or theory that has informed current scholarly work on gender and sport. Liberal feminist accounts of sport are based on claims that women should have equal rights to those of men in terms of access to resources, opportunities to participate, and decision making positions. Radical feminists are critical of the patriarchal power relations that operate to maintain the dominance of heterosexuality and

construct homophobic attitudes and practices in sport. Socialist feminists have examined the connections between gender, social class, and race and ethnicity under conditions of patriarchy, capitalism, and neocolonialism. Significant theoretical influences in understanding gender and sport have also emerged in cultural studies and in work guided by the writings of Norbert Elias, Pierre Bourdieu, and poststructuralist theorists. Contemporary work in the field reflects the move toward critical analyses of the complex relationships between and within groups of women and men in sport. Current scholarship examines the ways in which gender relations are produced, reproduced, challenged, and transformed in and through sporting practices.

Three key themes have driven debates about gender and sport since the 1970s. First, leading scholars in the sociology of sport have highlighted that throughout history, sporting practices inculcated behaviors and values defined as male, manly, and masculine. Second, issues surrounding the body, physicality, and sexuality have been brought to the fore in understanding gender relations in sport. Third, it is emphasized that both women and men reinforce and challenge dominant gender ideology in sport in various ways. In this regard scholars have eschewed ideas about women and men as homogeneous categories, and have recognized and examined difference and diversity in people's gendered sporting experiences at the level of the subject and in terms of institutional politics and practice. Recent research includes work that examines the production and reproduction of gender in sport in terms of the sporting experiences of women and men from various sociocultural backgrounds.

HISTORICAL DEVELOPMENTS AND THE GENDERING OF SPORT

Sociologists of sport have illustrated that the historical development of modern sports laid the foundations for the gendered character of sporting practices. Over time, sports have been constructed and reconstructed around the assumptions, values, and ideologies of males, maleness, and masculinity. The roots of contemporary sports lie in the Victorian period in

Britain, when sports began to be characterized by organized structures and standardized rules. In terms of gender, late nineteenth century British developments in sports largely centered on the beliefs and values of white middle class males. The prestige, status, and superiority afforded to men in society became marked at this time. In institutions such as public schools, universities, churches, and private clubs, sports came to represent a Victorian version of masculinity based on physical superiority, competitiveness, mental acumen, and a sense of fair play. Established ideals of femininity such as passivity, frailty, emotionality, gentleness, and dependence were in stark opposition to the strenuous task of playing sports. The belief that male and female traits were innate, biological, and somehow fixed prevailed. Women's participation in sports was therefore a subject of debate regarding what type and how much physical activity was appropriate for them. The marginalization of women and the dominance of men in sports is a legacy of Victorian images of female frailty that is also reflected in the making of modern sports in the US.

In both Britain and the US, changes in social life during the late nineteenth and early twentieth centuries impacted on gender relations in sport. British and American society at this time was characterized by social relations that were becoming less violent, there was a decreasing reliance on physical strength in the workplace, and home and educational environments were becoming ones in which young males spent increasing amounts of time with females. Eric Dunning (1999) and Michael Messner (1990) refer to these social transformations as the "feminization" of society. One consequence of these processes was the reconstruction of sporting opportunities and social enclaves (such as the Boy Scouts and the YMCA) for boys and men to reclaim and reassert their masculinity. While opportunities for women in sports also increased in the early part of the twentieth century, participation rates for females remained considerably smaller compared to males. Some sports were acceptable for women so long as they were not as strenuous or competitive as the male version. Women's sports were still the subject of intense debate reflecting and maintaining the Victorian myth of women's physical ineptitude.

SPORT, GENDER, POWER, AND PHYSICALITY

Many scholars have advanced an understanding about gender and sport by recognizing and examining the connections between physicality, power, and the production of gender. It is emphasized that in sport, physicality is predominantly defined in terms of bodily strength, muscularity, and athletic prowess. Connell (1995) explains such characteristics as a "culturally idealized" form of masculinity. Much has been written about the ways that contemporary sports reinforce a male model of (heterosexual) physical superiority and, at the same time, operate to oppress women through the trivialization and objectification of their physicality and sexuality. Several scholars assert that the acquisition of muscular strength and athletic skill is less empowering for women than it is for men. There is a commonsense assumption that muscularity is unfeminine, and that strong and powerful females are not "real" women. An increasing amount of work illustrates that such beliefs are reflected in the proliferation of media images emphasizing female heterosexuality at the expense of athletic prowess. The sexualization of female athletes through media representation is one way in which images of idealized female physicality are reproduced and perpetuated.

There are other mechanisms of control over female physicality in sport. Some writers explain that aerobics and bodybuilding operate to reproduce established gender ideology by feminizing the corporeal practices, rituals, and techniques in which women are involved, as well as objectifying and sexualizing women's bodies. Some consider that sexual harassment and vilification of women by male athletes provides evidence that the use of violence, aggression, and force is a defining feature of masculine identity that is constructed and legitimated in sporting contexts. There is also some scholarship that focuses on the way in which sports perpetuate the denigration of lesbians and gay men. It is argued that sports maintain a culture of homophobia in which homosexuality is feared and deemed to be unacceptable. Lesbians and gay men are discouraged from expressing their sexual identities through threatening homophobic sentiments

and actions. Sports reinforce a culture of heterosexuality and effectively silence homosexual identities.

A central argument in contemporary work on gender, sport, and physicality is the idea that the empowering experience of sport for heterosexual males is not universal, fixed, or unchallenged. Robert Connell illustrates the inherent contradictions in hegemonic masculinity. Strength, power, skill, and mental and physical toughness are not the only defining characteristics of masculinity. Not all sports privilege the values of aggression and physical domination associated with culturally established ideals of masculinity. It is also the case that the dominant image of masculinity, most often represented in sport, is one that can be limiting and restrictive for some men as well as most women. There are fewer opportunities for boys and men to participate, without prejudice, in sports that are not based on strength, power, and domination. There is work that shows that boys and men who are not good at sport, or who do not participate, have their heterosexual masculinity called into question. The sports experience is a negative and disappointing one for such males.

SPORT, GENDER, AND CONTESTED IDEOLOGY

It is increasingly emphasized in studies of sport and gender that dominant ideals of masculinity and femininity exist at the same time as emergent and residual ones. Such work is concerned with the relational character of gender. Michael Messner explains that in terms of gender, sport is a "contested terrain." This means that at any moment in history and in specific sporting contexts, there are competing masculinities and femininities. There are many scholars who now recognize that in sport, as well as in other social settings, some women are more powerful and influential than other women and men, and some women are empowered at the expense of other women and men.

Scholars in the sociology of sport have illustrated that many people are empowered by being involved in sport in spite of traditional gender ideology. Examples show how sport is a

site where established values about gender have been resisted, negotiated, and sometimes transformed. The assumption that homosexuality does not exist in sport is challenged in research about the many gay men competing in sports at recreational and elite levels. There are events such as the Gay Games that allow athletes to compete in a relatively unprejudiced environment where they have less to fear about derogatory and violent responses to their publicized sexual orientation. Several scholars question the assumption that sport is a site for the oppression of women by exploring the ways in which women gain from their sporting achievements. Such research shows that it is possible for women to experience feelings of independence, confidence, and increased self-esteem from their involvement in a variety of sporting practices. Female participation in physical activity can also contribute to broadening and alternative definitions of physicality that are not simply based on traditional ideals about feminine appearance. In the case of professional sports, some women are able to gain considerable financial wealth and worldwide recognition from their sporting achievements.

The extent to which sports are oppressive and liberating for women and men is culturally specific and related to the political and economic conditions in which they live their lives. There is increasing interest in the relationships between sport, gender, race, and ethnicity, and work on this topic emphasizes that questions of femininity and masculinity are inseparable from questions of race and ethnicity. In the main, research on sport, race, and ethnicity has examined issues connected with black sports men. Recent research takes a closer look at the complex relationships between masculinity, blackness, and sport. Critical examinations of the historical development of sport emphasize that sports were constructed in the image of particular ideals about white masculinity. Analyses of the racial significance of sport illustrate that sporting practices can provide black males with (symbolic) opportunities for resistance to racism through the assertion of manly qualities such as athleticism, aggression, and toughness. These writings also illustrate that sport reflects the historically constructed (subordinate) place of black males in (Western) societies. Dominant images of black male athleticism tend to

reinforce stereotypes of black men as powerful, aggressive, and hypersexual.

Scholars concerned with the relationship between sport, ethnicity, and femininity emphasize that sportswomen are not a homogeneous group. Increasingly, there is literature that presents a challenge to dominant universalistic conceptions of women in sport that serve to construct white, western, middle class, able-bodied women's experiences as representative of all sportswomen. Sociologists of sport have argued that the dominant assumption about female sports operates to marginalize or even silence the sporting triumphs and struggles of women who live outside the West and those who represent minority groups of females. A central feature of scholarship in this area is the recognition of difference between and within groups of women in relation to ethnicity, religious affiliation, social class, age, and physical (dis)ability. Jennifer Hargreaves (2000) explains that a sense of difference is characterized by power relations operating simultaneously at the personal and institutional level. In many ways, sport can be empowering for black women, Muslim women, Aboriginal women, lesbians, and disabled women. At the same time, these women are incorporated into the wider social networks of power in which they live out their lives.

gender, work, and family

Elizabeth Thorn

Gender, work, and family is the study of the intersection of work and family, with a focus on how those intersections vary by gender. This research is motivated in large part by the tremendous growth in labor force participation among women in their childbearing years during the second half of the twentieth century. This influx of wives and mothers into the workforce has raised questions about the division of labor in the family and whether state and corporate policies are sufficient to support new family types. Researchers also examine the causes of the divergent outcomes men and women experience in the workplace, as well as the effects labor force participation has on family formation, dissolution, and carework. These questions are most frequently researched quantitatively, but qualitative and theoretical work also contributes to the understanding of gender, work, and family.

THE MYTH OF SEPARATE WORLDS

Rosabeth Moss Kanter's pivotal book *Work and Family in the United States* (1977) laid much of the groundwork for the study of gender, work, and family. Kanter made the case that changing family structures and increasing labor force

participation among women were creating a new and complex set of interactions that were not being sufficiently studied in the traditional domains of the sociology of the family and the sociology of the labor force. Social scientists, Kanter claimed, subscribed to the "myth of separate worlds," a belief that work and family are separate and non overlapping spheres, each of which operates free from the influence of the other and can be studied independently. She locates the origins of this myth in anti nepotism policies and employer claims on worker loyalty, in the increasing geographical separation of home and work, and in American individualism.

Kanter's counterargument is that the structures of work are actually quite crucial in shaping personal lives. Occupations have different levels of absorptiveness; some occupations may require little of the worker outside of the work place, but workers in other occupations, such as foreign service and military officers, clergy, and high level executives, must behave in certain ways even when officially off duty. The time and timing of work is another important consideration. Time that workers spend at work and commuting is time they do not spend with their families, and business travel and non standard work schedules may make spending time with family difficult even when the number of hours in itself is not onerous. Work is associated with rewards and resources, meaning that different workers have very different levels of compensation available to share with their families. Occupational cultures may become part of workers' worldview, shaping their values and especially the way they raise their children. Finally, the emotional climate of the workplace can produce feelings of self confidence or tension in the worker, affecting relationships within the family.

Similarly, family can influence workers' behavior in the workplace. Cultural traditions held by the family may shape workers' decisions about work. Family firms may offer employment to family members, and family connections may open doors to job opportunities. Families of workers in highly absorptive occupations have an impact on the worker's performance in that role; an executive, for example, might be hampered in his career mobility without the expected "corporate wife."

Finally, the emotional climate of the home may affect family members in their roles as workers.

The myth of separate worlds was so strongly gendered that the ways in which men's and women's work and family roles were studied were quite different prior to Kanter's book. Research often lumped all working women together without acknowledgment of the specifics of their work. At the beginning of the twenty first century, societal norms are still such that gender is an important consideration in the study of work and family.

TIME USE

One of the intersections of work and family Kanter identified is the time and timing of work, an area which has been extensively studied by subsequent scholars. Work and family responsibilities are both quite time consuming. As more and more women joined the labor force, researchers became increasingly curious about how families manage to find the time for paid employment, unpaid work in the home, and leisure. Most research has found striking and persistent differences in time allocation by gender.

Arlie Hochschild's (Hochschild with Machung 2003) ethnographic study of dual earner households with children living at home found that mothers were working what amounted to a "second shift" of housework and childcare when they got home from their paid jobs. Their husbands, by comparison, shouldered a much lighter load. There were some variations in the division of labor associated with different gender ideologies, with couples who shared an egalitarian ideology sharing the work of the second shift most equally, but the effects of those ideologies were mediated by the constraints of employment and actual feelings about work and family responsibilities. Hochschild attributed the uneven workload of the second shift to a stalled revolution, in which women had begun participating in the traditionally male domain of the labor force to a much greater extent than men had begun participating in the traditionally female activities of childcare and housework.

Other researchers have found that the imbalance might not be as extreme as the second

shift suggests (Bianchi et al. forthcoming). Time diaries show that across broader samples of American adults, there is less difference in the amount of work – both paid and unpaid – that men and women do. Although women as a group do more of the unpaid work in the home, they also tend to work fewer hours for pay than do men. Historical trends indicate that as women increased their hours in the labor force, they decreased the amount of time they spent on housework. Men have decreased the amount of time they spend in the labor force to some extent, generally by entering at later ages and by retiring earlier, and have increased the amount of housework they do, but not by as much as women have decreased their hours of housework.

An important related question is how much time fathers and mothers spend with their children, and how that has changed since more mothers began participating in the labor force. After all, it is one thing to spend less time on housework than was done in the 1960s and another to spend less time with one's children. However, in the United States, mothers' time with children has remained remarkably constant between 1965 and 1998, and if anything has grown slightly. Married fathers spend much more time with their children than did their counterparts in 1965, and this time is not just in playing with and teaching their children, but also in childcare activities such as dressing, bathing, and putting children to bed.

Another approach is to look at the time use of families, rather than that of men and women as individuals. Family structures have changed considerably since the middle of the twentieth century. Whereas most families with children in the 1950s and 1960s had a dedicated homemaker, today's families are much more likely to have two employed parents or be single parent families. It is in these families in which all adults are employed that work-family conflict – in this case a "time crunch" – is most likely to be felt (Jacobs & Gerson 2004). Dual earner families with children find it particularly difficult to balance the requirements of work and family. At the same time, however, there are also many families whose members are not able to find enough hours of paid work.

In addition to looking at the numbers of hours worked by men and women and different

family types, it is also important to consider *when* those hours are worked (Presser 2003). It is often assumed that paid employment takes place from nine to five, Monday through Friday. However, as of 1997, in a quarter of dual earner married couples, at least one spouse worked something other than that standard schedule. Looking only at married dual earner couples with children, that fraction increases to a third. Those non standard schedules have a number of consequences for the family. Non standard schedules are associated with lower marital quality and marital instability, especially when there are children in the home. Non standard work schedules make childcare arrangements more complex and difficult to manage, particularly in families with young children. One interesting consequence of non standard work schedules is greater participation by men in what are generally considered female household tasks and childcare.

FAMILY ROLES AND THE LABOR FORCE

Family roles and statuses are associated with different outcomes in the labor market. Some roles are linked to increased productivity and income, while others are related to decreased wages. Gender, work, and family researchers examine the relationships between various family positions and labor market outcomes and try to establish the causes of differences. Different positions within the family may actually cause different labor market outcomes through the family's effect on productivity. Alternatively, employers may discriminate based on family roles. A third possibility is one of selection; perhaps the same sort of person is likely to be found in both certain family roles and in certain labor market positions. Conversely, labor force positions may affect family functions, such as propensity towards marriage or divorce.

Much research has demonstrated that married or cohabiting men earn more than their single counterparts. Data from longitudinal studies (Korenman & Neumark 1991) suggest that this is not merely a selection effect – that is, it is not just that men who are likely to do well in the labor force are also likely to get

married. Rather, wage growth is faster for married men than single men, and married men receive higher performance ratings. This lends support to the idea that married men are either more productive or are more desirable to employers than are single men. Men may become more productive in the labor market because their new partner takes on more of the responsibilities in the home, which allows men to develop those skills that are most marketable. Research indicates that although men's earnings go up when they form an intimate union, their overall financial position may not change much, largely because their spouse's labor market activity may be reduced, causing a reduction in family income. For women, on the other hand, marriage does not seem to be associated with significant changes in wages.

Like union formation, the transition to parenthood is another large shift in family roles, and the labor market outcomes associated with becoming a parent vary by gender. Fathers are more likely to be employed and to work more hours than childless men, but the opposite is true for women. Wages are affected as well. Budig and England (2001) found a motherhood wage penalty of 7 percent per child. That is, each child a woman has is associated with an additional 7 percent decrease in wage rate. This wage penalty may be explained in part by new mothers exiting the labor force or reducing their hours, but even after controlling for work experience, Budig and England still find a penalty of 5 percent per child. They attribute this penalty to either a reduction in productivity or discrimination on the part of employers.

Lundberg and Rose (2000) also found that motherhood is associated with reduction in wages – 5 percent in their calculations. Fatherhood, in contrast, is associated with a 9 percent increase in wages. However, they attribute much of this difference to increased specialization on the part of the new parents; mothers' salaries decrease because their new roles divert their attentions and energies from the labor force, which lowers their productivity. When the analysis is restricted to couples in which the new mother is continuously employed, a different pattern emerges. These mothers work fewer hours, but at the same wage. The new fathers, on the other hand, work slightly fewer hours, but at a *higher* wage rate. Women may avoid a

wage penalty if they remain continuously employed upon the transition to parenthood, but men generally see a boost in wages upon becoming fathers, whether they reduce or expand their work time.

Family roles influence labor force outcomes. The reverse is also true: labor force positions can influence family roles. To take one example, the historical changes in women's labor force participation are associated with the increasing importance of women's earnings for marriage formation. Among younger cohorts, women with higher earnings are more likely to marry than women who earn less. Women now contribute significantly to their families' incomes, so women with high incomes are more desirable marriage partners. Men's earnings have long been associated with their chances of marrying. Labor force position can influence union dissolution as well as formation. Because women's labor force participation increased at the same time as divorce rates, it has often been supposed that women's employment leads to divorce. However, as indicators of marital dissatisfaction are much more accurate predictors of divorce than a wife's employment, it is more likely that employment allows women to leave bad marriages than women's employment causes marital disharmony. Occupation may also influence the likelihood of a woman remaining childless. Highly educated women in high level positions in the labor force are much more likely than other women to not have children, either because they always planned to pursue only a career, or because the tradeoffs associated with child rearing were too great.

PUBLIC POLICY AND GENDER, WORK, AND FAMILY

Public policy in the United States and Europe has historically assumed that most families fit the breadwinner/homemaker model. However, as fewer and fewer families match the breadwinner/homemaker model and gender roles in work and family change, policymakers have had to adapt many policies. Examples of changing policy include family leave, welfare reform, and dependent care policy. In some cases, these

new policies play a role in shaping gender norms in work and family.

One of the most striking examples of policy change is in the growth of family leave. In the US, family leave was first enacted at the federal level in 1993 as the Family and Medical Leave Act (FMLA). The FMLA provides certain workers with 12 weeks of job protected, unpaid leave to care for a new child or a sick family member, or in the case of the worker's own serious illness. The implementation of this right displays a recognition that workers are often also responsible for care taking in the home and cannot rely upon the efforts of a non-employed family member. However, use of FMLA leave is gendered along traditional lines; women are more likely to use it than men, and they are more likely than men to use it to care for others. While leave is unpaid under the federal law, in 2004 the state of California began offering leave takers a wage replacement rate of 55 percent, up to a maximum of \$728 per week.

European countries typically offer longer leave, plus wage replacement. Norway and Sweden, exceptional even in Europe, offer new parents a choice between 42 weeks of leave at 100 percent of pay and 52 weeks of leave at 80 percent of pay. The time can be split between the parents as they decide, but a minimum of four weeks is reserved for the father. The "father quota" was established in these countries in the hopes that it would both improve father-child relationships and balance gender roles within the family. There is some evidence that this policy does affect gender roles; men report that the father quota makes it easier to approach employers about taking leave, and researchers have found that new fathers who take leave are more likely to share in housework and childcare tasks. At a minimum, the policy has encouraged more men to use parental leave. Before it was established, only 4 percent of fathers took any leave in Norway, but in 1996, after the father quota went into effect, 80 percent of eligible fathers took leave (Boje & Leira 2000).

The availability of family leave does not necessarily support new gender norms and roles. Some countries in Europe, such as France, Germany, and Finland, have long leaves of two or three years. Leave of this length has a deleterious effect on experience,

training, and opportunity for promotion, and is overwhelmingly used by women, weakening women's labor force attachment. As a result, women's labor force participation rates decline, and the traditional breadwinner/homemaker family model becomes more common again.

Welfare reform in the United States is another example of policy changing to reflect new gender norms in work and family. Aid to Families with Dependent Children (AFDC), the original welfare program, was established to provide for the rare family that lost its breadwinner – usually through death or abandonment – and assumed that women with young children would not be in the labor force. This became increasingly untenable politically as single parent families were more frequently formed through non marital childbirth and as it became normative for married mothers to be employed. State level reforms were initiated during the first half of the 1990s, and on the federal level, AFDC was replaced in 1996 by Temporary Aid for Needy Families (TANF). TANF revised welfare policy by creating work requirements for aid recipients and by imposing lifetime limits on receipt of aid. These measures are in line with new gender norms that support women's participation in breadwinning. It is not only accepted but also expected that single women will provide economic support for their families.

Welfare reform has apparently had an impact. The 1990s saw a dramatic increase in the employment rates of single mothers, and welfare caseloads shrank dramatically. However, welfare reform also had other objectives, including encouraging marriage and discouraging non marital fertility. The most prominent provision to address these concerns was the broadening of eligibility to include two parent families. Theoretically, this would remove the disincentive to marriage that existed under AFDC. Researchers have found that welfare reform has instead led to *fewer* new marriages, but also fewer new divorces (Bitler et al. 2004). Nor has welfare reform led to reduced rates of single mother families (Fitzgerald & Ribar 2004). It is hypothesized that the economic independence fostered by TANF weakens the attractiveness of marriage.

Child and elder care policy in the United States has yet to catch up with new gender

norms in work and family, perhaps reflecting ambivalence about these changes, particularly when young children are involved. While the US has a patchwork of relevant policies – tax deductions for a portion of dependent care expenses, dependent care savings accounts, Head Start and Early Head Start, and childcare assistance to families receiving benefits through TANF – child and elder care costs are high and quality is highly variable. Childcare remains gendered in the family, with mothers reducing paid employment to care for children to a much greater extent than fathers. Similarly, women are much more likely to provide elder care than men. Childcare policy will continue to be an important issue, and with the aging of the population, elder care will become increasingly important.

gendered aspects of war and international violence

Shahin Gerami and Melodye Lehnerer

Research has shown that gender is an integral element of violence (Tiger & Fox 1971; Elshtain & Tobias 1987; Goldstein 2001). Most cases of violence are committed by men against men. While women can be combatants in armed conflicts (Enloe 2000; Goldstein 2001), they are more likely to be victims than organizers and perpetrators of international violence. The intersection of social categories of gender, class, and nationality informs the effects of international violence for groups and individuals. Working class and peasant women pay higher prices, both directly and indirectly, for international violence. In violence between states, women of the South are victimized more often, more harshly, and pay higher costs during and after wartime. In fact, the benefits of peace reach them later and in smaller amounts.

International violence is collectively planned and systematically implemented by a group against another for political and economic goal(s). Four types of international violence are identified here. First, there are empire building,

multinational wars. Second, there are bilateral wars between two nation states most often over territorial disputes. A third type of international violence results from liberation movements when the colonized fight the colonizers for their sovereignty. Revolutions against a tyrannical government fall under this category because they frequently involve foreign players and interests. Lastly, there are civil wars that occur within a nation state. International forces often influence civil wars.

With regard to international violence, World War I marks a point in military history in which systematic and deliberate attacks on civilians became a pronounced strategy of war (Barstow 2000). Moving from the trench campaigns of World War I to the massive aerial bombings of World War II to more contemporary international conflicts of varying sizes, the ratio of combatant to civilian casualties has changed from 8:1 to 1:1 to 1:8 (Barstow 2000: 3). The great majority of these civilian casualties are women and those whom they care for – children and the elderly. This time period is also significant because, beginning with World War I, the “home front and the war front became intimately connected” (Goldstein 2001: 9).

The reach of new technology allowed targeting goals beyond the front line. Large scale street battles in urban areas became possible and a strategy of the war itself, not just for control of cities after the conquest. Unlike earlier periods, in which mass killing of civilians was more a consequence of the war, the reach of new technology allowed civilian targets to be integrated into war planning. Most importantly, the social distinction of public and private that had kept women away from the battlefield and its effects was obscured. Women, children, and the elderly, along with able bodied men, were constructed as the enemy and subject to annihilation. The violent consequences of this change for women were twofold: bodily injury and social role disruption.

VIOLENT ASSAULT: BODILY INJURY AND SOCIAL ROLE DISRUPTION

“Mass rape has long been a deliberate strategy of military leaders. By marking the raped women

as 'polluted,' mass rapes destroy families and weaken communal life" (Barstow 2000: 45). The violence of bodily assault includes physical injury from a weapon, torture, malnourishment, disease, and, most noteworthy, sexual assault. Sexual assaults on women can be an offensive or a defensive strategy. Sexual assaults as offensive strategy are planned and executed to destroy the enemy, his house, and his future offspring. Mass rape as a defensive tactic is carried out with the hope of increasing the invaders' descendants. Murder and maiming of women destroys the home base, demolishes the soldiers' morale, and often cripples the backbone of the war machinery.

When the Germans invaded Belgium in August of 1914, and as they marched through, reports of rape are documented along with villages burned and civilians bayoneted (Brownmiller 1975: 41). A clear cut pattern emerged: rape of women in war is not for sexual pleasure but for control and therefore has propaganda purposes to humiliate and demoralize the enemy. Similarly, the victimized community may exaggerate the atrocities to mobilize the combatants to avenge the dishonoring of women.

What did not get public attention was the huge price that women paid indirectly through social role disruption. It is well documented that French and Belgian families – men, women, and children – lost homes and lives in the first three months of the war. Less well documented are the experiences of Russian women. The Russian women served at the front in Women's Death Battalions, worked the field, served as caretakers at the back of the lines, and lived in destitute conditions during the war, the 1917 Revolution, and the aftermath of these events (Clements et al. 1991). It is this aspect of international violence, disruption of women's roles, which contributes to communal disruption.

Socially, disruption of women's roles as care givers and network organizers destroys the social fabric of the enemy's home base. Planned scarcity, economic blockades, and disruption of basic services harm women physically and mentally, making their tasks harder to perform. Shortage of basic medicine or water sanitation means sick and starving children for distraught women to mind. The social disruption of women's roles has far reaching consequences

for women's and girls' lives. Not only is the impact in the moment, it is also for generations to come.

SEXUAL AND PHYSICAL ASSAULT: THE PRIMARY CONSEQUENCE OF INTERNATIONAL VIOLENCE

In 1993, the UN Commission on Human Rights recognized the systematic rape, forced slavery, forced pregnancy, and forced prostitution of women as war crimes (Barstow 2000: 237). In 1996, this recognition led to the indictment of eight Bosnian Serb military and police officers solely on the charges of raping Bosnian Muslim women (Enloe 2000: 135). Over time, five patterns of sexual assault have been identified, regardless of the ethnicity of the perpetrators or the victims. These patterns were officially identified in the Final Report of the UN Commission of Experts on Serbia (1994). Nevertheless, they hold true for any time period and any type of international conflict. Not all patterns of sexual violence may be used in any one conflict, but often a combination of patterns does apply.

In the first pattern, looting and intimidation accompany sexual assault prior to widespread fighting. Assaults take place in women's homes and in front of family members. In addition, rape may occur in public. The intent is to terrorize local residents in hopes they will flee or passively submit (Final Report 1994). The second pattern of sexual violence occurs during fighting. Once attacking forces have secured a town or village, those men, women, and children who remain are rounded up and then divided by sex and age. Women and girls are raped in their homes or in public. Those who survive are transported to detention facilities. The intent of this practice is to traumatize those detained as well as those who escape. Victims and witnesses are unlikely to return to the scene of such events (Final Report 1994). The third pattern of sexual violence occurs in detention facilities or other sites where refugees are kept. Again, the detainees in these "collection centers" are divided by sex and age. Men of fighting age are tortured, executed, or sent to work camps. The women who remain are raped or sexually assaulted by soldiers,

camp guards, paramilitaries, and civilians. There are two variations to this pattern of assault dependent upon location and visibility. In the first scenario, women are selected and raped at a separate location from the "camp" in which they are housed. Sometimes they are returned; other times they are killed. Alternately, women are raped at the location where they are detained in front of other detainees. On occasion, detainees, both women and men, are forced to assault each other. The obvious goals are multiple: humiliation, demoralization, and/or ultimately death.

A fourth pattern of sexual assault occurs in camps that are specifically identified as rape/death camps. These camps are set up for the purpose of punishing women through sexual assault and other forms of torture (Salzman 2000). In the case of Serbia, these camps were specifically set up to impregnate women with the "conqueror's seed" (Salzman 2000). The intent of this practice is to achieve ethnic cleansing through women's reproductive capabilities. The fifth and last pattern of sexual assault is the establishment of camps as sites of prostitution. Women are held in these camps to "service" soldiers returning from the front lines. In most instances, the women in these camps are eventually killed (Final Report 1994). This is a common practice wherever there are military bases in occupied territories.

SOCIAL ROLE DISRUPTION: A SECONDARY CONSEQUENCE OF INTERNATIONAL VIOLENCE

While the sexual abuse of women by the enemy has received some attention by international tribunals and can possibly be compensated for, the many other categories of harm that are more widespread, more intense, and have more long term effects are rarely documented, defined as war crimes, or accounted for in war reparations. International violence impoverishes masses, and among these masses women carry greater responsibilities and receive fewer opportunities. Such practices as the bombing of residential areas, home invasions, and economic blockades prevent women from carrying out their roles as wives and mothers. When homes are destroyed to disperse men, women's domain

is destroyed and families displaced. When economic blockades lead to planned scarcity of food, water, medicine, or population movements, women refugees, as caregivers, face more hardships than male combatants whose task it is to fight and to survive.

Women's injuries in the war from bombing, landmine explosion, street combat, unexploded ordinance (ammunition), and chemical exposure are of lower priority in the scarcity of health care and rehabilitation of the wounded. The secondary physical and psychological sufferings due to stress and scarcity of the war are not considered in war casualties, while men's shell shocks are documented. As in any period of stress, a side effect of post war trauma is domestic abuse (Amnesty International 2005). Women are told, and they believe, that their suffering is part of their role, and complaining makes them selfish at best and traitors at worst.

CONCLUSION

While the focus here has been on immediate and long term physical and social harms of international violence for women, international violence goes beyond harms to women. Men are forced to fight and, when they refuse, are drafted, kidnapped, and killed more frequently than women. Furthermore, the duality of soldier prostitute, soldier wife, or soldier mother overlooks the multifaceted roles that women perform in international violence. For example, Cynthia Enloe discusses "militarized women" in her book *Maneuvers* (2000). These militarized women include prostitutes, rape victims, mothers, and wives of military personnel, nurses, women in the military, and feminist activists. Simplistic dualities also overlook women's agency as individuals or collectivities (Gerami & Lehnerer 2001). Women suffer, but also gain in international violence in terms of economic independence, individual freedom of actions and mobility, and feminist consciousness. International violence puts social mores in a flux, allowing women to engage in activities not permitted before, expand their public role, and acquire greater responsibility and, with it, greater decision making ability and empowerment.

This deconstruction of the binary mode of gender and international violence also applies to any analytical evaluation of gender and peace. Gender narratives of men/soldiers and women/peacemakers on the one hand ignores the role of men in peace movements, and on the other hand implies gender determinism of violence and peace. As Ruddick (1989) reminds us, even anti militaristic feminism can fall prey to this binary interpretation of war and peace.

gendered enterprise

Gill Kirton

What do we mean when we say that enterprise or organization is gendered? As Acker (2003) argues, "to say that an organization, or any other analytic unit, is gendered means that advantage and disadvantage, exploitation and control, action and emotion, meaning and identity, are patterned through and in terms of a distinction between male and female, masculine and feminine." However, the traditional approach to organizational analysis is criticized by a number of contemporary authors, including Acker, for its neglect, up until the 1980s at least, of women and gender. This neglect occurred firstly because organizational research often focused on senior levels of the hierarchy where men predominate. Secondly, men dominated the academic research process and generally showed little interest in female employees or gender as a unit of analysis. Critics argued that within traditional organizational analysis men's experiences and interpretations of organizational life were taken as universal, producing gender neutral knowledge, which failed to recognize gender as a significant dynamic of organizations and rendered women invisible. Although some of the criticisms remain valid in regard to mainstream organization and management studies, there is now a significant and growing body of gender and organization literature, largely produced by women and often with women as the analytic focus, which sees organizations as important sites in which gendered meanings, identities, practices, and power relations are produced, enacted, and reproduced.

Much of the gender and organization literature is influenced by liberal, socialist, and post modernist/poststructuralist feminist theories. Generally, the literature can be characterized according to one main feminist orientation, while perhaps reflecting insights from others. To summarize, liberal feminism conceives of people as autonomous individuals aspiring to fulfil themselves through a system of individual rights. Women's inequality is rooted in attitudes, customs, and legal constraints standing in the way of their entry to and success in

public life. Socialist feminism conceives of women as an oppressed social group facing a common struggle against male domination and exploitation. Women's inequality is rooted in the capitalist and patriarchal systems of production and reproduction. Postmodernist/poststructuralist feminism conceives of gender as a discursive practice through which femininities and masculinities are produced, sustained, and reproduced. There is less a concern with women's material inequality than with demonstrating the ambiguous, unstable, complex nature of social categories and the subjectivity of identity. Influenced by feminist theories, the gender and organization literature has over time taken various turns producing a number of strands, although the themes and foci often overlap. However, no precise chronology of the emergence of the strands can be proffered, and indeed different strands continue to coexist in the contemporary literature.

One dominant strand of this literature, most strongly influenced by liberal feminism, focuses on women managers and vertical gender segregation. Here it is assumed that individuals aspire to climb the organizational hierarchy and that the fair organization will allow both men and women to realize their capabilities within a merit system. The research concerns include gender differences in leadership, work commitment, motivation and satisfaction, sex stereotypes, and gender biases in recruitment and selection. The conclusion often drawn is that if women became or behaved more like men (i.e., if gender difference were eliminated) then they would defy sex stereotypes and succeed in organizations. Therefore, there is a focus on women's "deficiencies" rather than on any built unfairness within organizations, with policy recommendations such as assertiveness training courses, or "dressing for success" with the general aim for the fair organization conceived as needing to "fix the women" (Kolb et al. 2003). More recently the perceived existence of gender difference is seen less as something in need of correcting than as a potential organizational resource to be celebrated. Critical authors generally regard this strand of the literature as an inadequate and one dimensional way of analyzing gender and organizations.

Kanter's *Men and Women of the Corporation* (1977) is an example of an important turn in the literature in that it set out to show that gender differences in organizational behavior are due to structure rather than to the characteristics of men and women as individuals. Hence, from this perspective, it is organizations that need to change, rather than women, in order to encourage more women to join the race to the top. This perspective remains influential and policy oriented studies examining the gender structure of organizations continue to investigate the ways organizations might accommodate gender difference. For example, the contemporary "women in management" literature explores the problem of the invisible barriers to women's advancement (often referred to as the glass ceiling). These include the lack of senior female role models in organizations, the culture of presenteeism, and the evaluation of individuals according to their ability to separate home and work. Policy recommendations, which are compensatory in nature, are postulated, including the establishment of mentoring for women, women's business/professional networks, and schemes to enable women to reconcile work and family. However, the literature influenced by liberal feminism is uncritical of organizations fundamentally, for example the gendered processes of organizational decision making (e.g., why is it necessary to work excessively long hours?) or the dominant ideal of meritocracy (e.g., how is merit measured and judged?) are rarely questioned.

Another strand of the gender and organization literature is influenced more strongly by socialist feminist theory. This posits that paid work cannot be the sole unit of analysis and that the intersection between the public and private spheres (or work and the home) must be explored in order to understand women's position in the labor market. Analytically, research is often concerned with the macro level of the labor market and the temporally and spatially persistent pattern of vertical and horizontal gender segregation, which is seen to disadvantage women. However, empirical studies are often situated at micro level, although seeking to raise questions and offer arguments and illustrations that are applicable to the wider labor market. Research tries to uncover the social processes and relations involved in

sustaining and reproducing women's inequality and calls for transformation of organization structures and cultures. Generally, organization researchers influenced by this theoretical orientation favor qualitative case study methods that make visible informal gendered processes, relations, and practices.

For example, Collinson et al. (1990), through their detailed case studies of recruitment practices in the banking, mail order, insurance, hi tech, and food manufacturing industries, show that gender divisions of labor at home and in employment are both a routine condition and consequence of organizational recruitment and a common means of legitimizing sex discriminatory practices. Collinson et al. also show how sex discrimination is reproduced in recruitment practices through the agency of management, labor, men, and women to highlight how the perpetuation of job segregation is characterized by a self fulfilling vicious circle incorporating three key recruitment practices of reproduction, rationalization, and resistance. They argue that taken for granted beliefs about the male "breadwinner" and female "homemaker" inform the preference for either men or women in particular jobs so that preconceptions about the domestic responsibilities of both sexes are often perceived to be of central relevance to selection decision making.

The themes of reproduction, rationalization, and resistance are also evident in Cockburn's (1991) case study research situated in retail, local, and central government and trade unions. For example, Cockburn explores the way that powerful men in organizations use cultural means to deter women from aspiring to senior jobs by striving to retain women's loyalty to men and to the status quo. This then discourages women who are successful from identifying with women at the bottom of the organization. Cockburn is also concerned with horizontal segregation, what she calls the "ghetto walls," which keep the majority of women, especially mothers and other women with domestic ties, in low paid, part time work. To bring down the ghetto walls, she argues, it is necessary to institute structural change in organizations by redesigning jobs or retraining staff; reevaluating occupations and restructuring grade systems to reduce differentials

between people at the bottom and people at the top. Cockburn's work is important in that it integrates class analysis with the study of gender in organizations, shifting the focus simply from managerial and professional women to consider the majority of women in low level employment.

Similarly, Bradley's *Gender and Power in the Workplace* (1999) argues for a theoretical integration of gender and class in order to understand change and continuity in the gendered nature of organizations. She also draws attention to the polarization between younger and older women, whereby younger women are grasping the opportunities provided by the feminization of work and organizations and by "woman friendly" policy developments. However, Bradley finds marked patterns of gender segregation in her case study organizations, which are maintained in part, she argues, by a powerful set of gendered images about masculine and feminine attributes and their association with particular jobs and forms of employment. For example, as Cockburn (1991) and Collinson et al. (1990) assert, the jobs of trade union official and insurance sales person are permeated with masculine meaning, while the lower status, less well paid jobs of retail sales assistant and clerical support worker are permeated with feminine meaning. This powerful gender symbolism means that individual women or men who transcend traditional gendered occupational boundaries (e.g., women fire fighters, male nurses) often find themselves in a precarious and isolated position such that both sexes more typically keep to "gender appropriate" jobs. An interest in the gendered rhetorical devices, discourses, and imagery that sustain gender segregation is now a prominent theme in the gender and organization literature.

Arguably, this interest is influenced by post modernist ideas within the social sciences, although authors take these ideas in different directions. For example, Bradley retains an interest in "real" differences "out there" between men and women and their experiences of organizations, while perceiving discursive constructs as significant in constituting the gendered social relations that contribute to producing the differential "real" experiences. Other authors influenced by postmodernism

have less of an interest in material gender inequalities or setting out policy implications and more in the “performance” and “accomplishment” of gender by individual men and women in organizational contexts.

Another research focus in the strand of gender and organization literature influenced by postmodernist/poststructuralist feminist theories is on “femininities” and “masculinities.” These terms point beyond categorized, biological sex differences, treating them more as forms of subjectivities and using them to describe cultural beliefs without any close connection to men and women. In terms of what this means for the study of gender and organization, it is argued that men and masculinity remain taken for granted, hidden, and unexamined in much of the literature, which more typically equates gender with women. In contrast, studying masculinities is regarded as central to understanding the process and structuring of gender relations and discriminatory experiences. In this vein Collinson and Hearn (1994) call for men to be “named as men” in order to expose men’s power, discourses, and practices which underpin the asymmetrical gender relations found in organizations. They identify five discourses and practices of masculinity that remain pervasive and dominant in organizations: authoritarianism, paternalism, entrepreneurialism, informalism, and careerism. The consequence of their reproduction is a perpetuation of women’s inequality arrived at through the exercise and development, particularly by managers, of coercive power, protective practices, competitive approaches to business and performance, informal relationships between men, and aggressive concern with hierarchical advancement.

Some authors note the class differences in masculinities, arguing that although paid work as a source of masculine identity and power transcends class boundaries, class is a variable in terms of how masculinities are practiced in organizations. For example, a number of studies show how male manual workers seek to maintain masculine identities through discourses and practices of identification and differentiation, including heterosexualized humor and sexual harassment. Sexual humor, it is argued, constructs an image of men as assertive,

independent, and powerful and one of women as passive and dependent.

Having evolved over time, the gender and organization literature is now at a crossroads, with some authors arguing for the integration of gender into mainstream organization analysis and others foreseeing dangers in integration, namely the neglect of gender as a unit of analysis once again. It is clear, though, that studying gender will no longer mean studying just women.

gendered organizations/ institutions

Lauren Rauscher

CONCEPTUAL BEGINNINGS

Understanding organizational practices and processes is central to explaining gender inequality. While women remain clustered in secondary labor markets marked by lower wages, uncertainty, short career ladders, and few if any benefits, most men find employment in primary labor markets characterized by greater economic rewards. Occupational and job segregation continue to be an enduring feature within most firms. Additionally, gender differences in income, power, authority, autonomy, and status translate into men, particularly white men, enjoying systematic advantages over women. Despite changing social and economic conditions and legislation prohibiting sex discrimination, these inequalities persist and subsequently inform an impressive body of labor market and workplace analyses.

The study of "gendered organizations" as a distinct area of scholarly inquiry has developed over the last 15 years in an effort to explain such inequality. The concept, coined by Joan Acker, means that "advantage and disadvantage, exploitation and control, action and emotion, meaning and identity, are patterned through and in terms of a distinction between male and female, masculine and feminine" (Acker 1990: 146). Although relatively new, this field has roots in second wave and radical feminist scholarship dating back at least to the 1960s. Scholars began merging gender studies with organizational literature in an effort to render visible women's experiences, place men's experiences in a gendered context (rather than a universal experience shared by all), and identify the ways in which gender inequality is (re)created and maintained over time.

Early work by Heidi Hartmann, Rosabeth Moss Kanter, Catharine MacKinnon, and Kathy Ferguson revealed organizational dynamics that produce gender specific outcomes, which

disadvantage women and advantage men. For example, Kanter's classic study, *Men and Women of the Corporation* (1977), demonstrates how one's structural position within a firm (e.g., the job one holds in the hierarchy) determines one's "success," defined in terms of career mobility, authority, and power. One's job also affects one's personality, behavior, and aspirations, such as women acting timid. Thus, women's disadvantaged location stems from being disproportionately concentrated and "stuck" in positions with limited power and short to non-existent career ladders. One of the primary strengths of Kanter's work lies in the shift from individual level behavior of men and women to a structural explanation of gender inequality. Although Kanter provides mechanisms for how, once in place, gender inequality is maintained through occupational sex segregation, she neglects to explain the *origins* of segregation that leads to an array of unequal work rewards.

Turning to Marxist feminist scholars such as Heidi Hartmann helps find an explication of the origins of gender segregation and its consequences. According to Hartmann, capitalism and patriarchy are separate but interlocking systems that work in concert to structure social organization. (Hartmann defines patriarchy as a set of social relations with a material base, where hierarchical relations between men and solidarity among them enable men to control women.) Specifically, she contends that capitalism and patriarchy operate to subordinate women as individuals and as a collective group through various modes of production, the gendered division of labor, and subsequent sex segregation. Therefore, according to this perspective, patriarchy proceeds yet interacts with capitalism so that women enter the wage labor market at a disadvantage, and men's actions maintain women's subordinate position while protecting their own privileges. Hartmann's theory acknowledges the interconnections between gender and other institutions. She also shows that men's actions matter in maintaining gender inequality in addition to men and women's structural positions, thereby making the link between structure and agency explicit. Since Hartmann's account, feminist scholars have demonstrated the ways in which gender infuses

our lives through all institutions. Because institutions are intertwined and interdependent, we can use gender as a lens through which to describe and understand people's experiences within them.

Joan Acker argues that despite such advances in gender theorizing, conceptions of institutions (other than "the family") remain gender free or gender neutral, when, in fact, gender permeates their ideologies, practices, and symbols. Indeed, many argue that gender constitutes an institution in and of itself, in addition to shaping other forms of social organization. That is, gender is not only an individual attribute but also a major organizing system that structures patterns of interactions and expectations across other major social institutions (Lorber 1994). Thus, gender fundamentally structures family and kinship, the economy, language, education, culture, interpersonal relationships, sexuality, ideology, and personality. Conceiving institutions as genderless, separate entities is problematic because this obscures the fundamental processes of creating and maintaining power inequities between men and women.

According to Acker, the gendering of institutions and organizations occurs through the following processes. First, there is the division of men and women into distinctly different realms, in terms of the type of labor performed, physical work locations, and acceptable behaviors and emotions. Second, symbols and images, such as language and culture, are constructed that reinforce these divisions. Third, gendering processes occur in interpersonal interactions between and among women and men. Individual identities also promote and reinforce gendered outcomes to the extent that people enact and internalize gender specific scripts for behavior. Fourth, gender constitutes one of the fundamental organizing elements of creating organizational structures.

In a pathbreaking article, Acker (1990) uses complex, bureaucratic organizations as an example to detail how organizations reflect specific gendered expectations and relations. More specifically, she shows that jobs, work rules, contracts, evaluation systems, and firm cultures (e.g., organizational logics) are not gender neutral. Rather, she draws on feminists such as Dorothy Smith, Joan Scott, and Sandra

Hardin, who advocate that gender constitutes a meaningful analytic category to argue that a gendered substructure undergirds the entire bureaucratic organizational system. Notably, this substructure is gendered masculine, with the interests of men at its center. Therefore, gender inequality stems from the very organization of bureaucracies rather than being produced solely by the actions of particular gendered individuals enacting gendered scripts for behavior within them.

To illustrate, in organizational terms "jobs" constitute an abstract category, filled by an abstract worker, one with no gender. In this conception, the successful performance of a job requires a worker to focus on a set of tasks commensurate with a certain level of skills, credentials, and remuneration. Also, we expect a worker to be unencumbered by competing obligations that would interfere with job demands. Acker makes clear, however, that real people fill jobs; that is, jobs are embodied. And by examining jobs this way, we can see that the abstraction best reflects men's lives, since men stereotypically assume the majority work in the public sphere while having few competing demands in the private sphere. Instead, women perform reproductive, childrearing, domestic, and care work in the private sphere, which enables men to work outside the home. Thus, Acker shows that a gendered division of labor provides the foundation for the conception of a job.

Procreation, childrearing, and stereotypically feminine emotions upset the successful functioning of jobs within bureaucratic organizations, again making clear that jobs are based on men's lives, men's bodies, and masculinity, while relegating women to the margins. Thus, despite the inroads women have made into traditionally male dominated occupations and the greater number who have entered the ranks of management, gender inequalities between men and women remain remarkably stable. Although Kanter's theory would have predicted more equality as more women changed structural positions within organizations, Acker suggests that such mobility offers a futile attempt at disrupting gender differentials due to the gendered substructure privileging men that operates as a fundamental structuring element of the organization itself.

EMPIRICAL EVIDENCE

Empirical projects examining Acker's theoretical claims can be found in a burgeoning literature bridging multiple academic disciplines. For instance, significant work is devoted to the ways in which *occupations and jobs* are gendered. In her book *Gender Trials* (1995), Jennifer Pierce demonstrates how norms and expectations for lawyers and paralegals in corporate law firms are culturally constructed, symbolized, and reinforced through masculinity and femininity, respectively. For instance, successful lawyers are characterized by their "Rambo" litigating techniques where they obliterate their enemies in fierce competition. Token women lawyers (tokens because they represent a numerical minority in the occupation) must also conform to these ultra masculine behaviors in order to achieve success and not be considered weak and incompetent (or impotent). In contrast, women paralegals must nurture and mother their bosses or suffer consequences of criticism from them. Yet men paralegals do not experience the same set of constraints and experiences.

This work is similar to Williams's (1992) account of how men as librarians, elementary school teachers, and nurses face different experiences than women in the same occupations. Although these occupations are gendered feminine, men are promoted at exceptional speeds, "riding the glass escalator" rather than facing barriers to advancement. Such scholarship varies significantly from Kanter's findings of how women experience tokenism as having little power, needing to prove themselves, and exclusionary. These findings illustrate how a masculine gendered substructure operates to benefit men even where men constitute the numerical minority of workers in a given occupation or firm.

Other scholars have studied *gendered organizational practices and policies* across a broad spectrum of settings ranging from restaurants and prisons to an Anglican parish, Malawi NGOs, and a Latino health organization in Los Angeles. For example, Britton (1997) shows how training materials and examples for prison officers are presented as generic, but in actuality are constructed as though all of the trainees are men. The material neglects

issues and information germane to women's prisons (only men's), and completely ignores sexual harassment of officers from inmates.

The journal *Gender, Work and Organization* was created to advance interdisciplinary theoretical and empirical work on the process and outcomes of gendered organizational structures. Additionally, one can now find scholarship in this area in business journals, which historically have neither published extensively on women's experiences nor analyzed men's positions as gendered beings. *Gender and Society* also devotes considerable space to analyses on gendered processes and outcomes across a variety of institutions and organizations. Although challenges to integrating literature on gender, work, and organizations remain along theoretical, gender, and geographic lines, there is excitement about both the possibilities of "striking out" into new territories and problematizing current work in an effort to enrich this field.

FUTURE DIRECTIONS

Several scholars have responded to Acker's original treatment of gendered organizations, including Acker herself. Consensus exists on at least two of the future directions for work in this field.

First, scholars must seriously consider the specific context in which gendering processes occur to avoid criticisms that arguments of a gender substructure are essentialist and ahistorical. That is, instead of conceiving organizations as stable and rigid structures, Acker and others emphasize the process oriented and contextual nature of gendering. For instance, in "The Epistemology of the Gendered Organization" (2000) Dana Britton notes that one of the major themes in this field claims that bureaucratic organizations are *inherently* gendered masculine. Britton argues that turning a testable proposition into an underlying assumption stifles potential for changing the ways that work places (re)produce gender inequality, short of eradicating complex bureaucracies and replacing them with collectivist organizations. Moreover, such a static conceptualization does not account for the ways in which some formal bureaucratic practices benefit women (see Cook

& Waters 1998) and protect women from sexual harassment.

Additionally, Britton cautions scholars examining the ways in which occupations and jobs are gendered, most of whom rely on the extent to which occupations are male or female dominated. According to Britton, this approach presents the tendency to conflate sex with gender while simultaneously neglecting the complex historical process that leads to occupations being gender typed as feminine or masculine.

Context also remains important as organizational boundaries and contemporary work configurations change, partially fueled by globalization. Patricia Yancey Martin and others call for more systematic analyses of how contemporary practices, such as flattened hierarchies, team based approaches, telecommuting, and e commerce, affect gendered occupations and practices and subsequent inequalities.

Second, a substantial body of literature demonstrates that inequality is patterned along gender, race, and class lines. Moreover, the intersections of these stratification systems translate into white men enjoying systematic advantages over other men as well as all women. In some instances, white women experience privileges that men and women of color do not, depending on the context. Thus, patterns of inequality are far more complex than simply noting gender inequities between all men and all women.

In response, scholars argue to move beyond solely examining the gendering of organizations to account for other axes of inequality, namely race. In *What a Woman Should Be and Do* (1996) Stephanie Shaw provides an exemplary study of how teaching as an occupation is both gendered and raced. Moreover, Collins (2000) draws on work by Barbara Omolade to argue that organizations maintain (white, masculine) power by having professional black women in supervisory positions who "serve white superiors while quieting the natives" (e.g., other women of color).

In addition to her suggestions noted above, Britton calls for greater theoretical clarification and refinement in an effort to create meaningful strategies for social change. Patricia Yancey Martin, Jeffrey Hearn, and colleagues contest

this call for synthesis, finding strength in the "ambiguity, contradiction, paradox, and multiplicity" that accompanies the diverse literature in this field (Martin & Collinson 2002).

genealogy

Steve Fuller

The appeal to genealogy as a general historical method is usually attributed to Michel Foucault, who contrasted it with both teleology and his own preferred “archeology,” which suspends the search for causation altogether in favor of treating socio epistemic structures (or epistèmes) as superimposed space time strata, each of roughly coexistent events. (The palimpsest was thus Foucault’s model for historiography.) Foucault’s foil was Friedrich Nietzsche, whose *Genealogy of Morals* resurrected worries of legitimate lineage that had dominated the reproduction of social life prior to the constitution of the modern nation state. Replacing traditional legal concerns that political succession might be based on fraudulent documents, Nietzsche argued that contemporary morality might rest on forgotten etymologies, whereby “obligations” turn out to be strategies for the weak to inflict a sense of guilt on the strong, simply for being stronger. Here Nietzsche was explicitly siding with the survivalist ethic of Social Darwinists against socialists who argued that the rich “owed” their success to the collaboration of the poor.

A natural question to ask is what led Nietzsche to think that a defunct method for establishing right to rule should provide the basis for a deep understanding of society. Here the appeal to biology is crucial. Ernst Haeckel, Darwin’s staunchest German defender, famously declared “Ontogeny recapitulates phylogeny,” by which he meant the biological development of the individual organism (i.e., the gestation period) repeats the stages undergone in the evolution of all organisms. Nietzsche cleverly reworded Haeckel’s slogan for his own purposes: “Ontology recapitulates philology.” Nietzsche, a prodigy in the study of classical languages, unsurprisingly found Haeckel’s slogan appealing.

Darwin had depicted – and Haeckel popularized – evolution as a “tree of life” founded on a principle of common ancestry of morphologically similar species, ultimately deriving from a unitary “origin of life.” The imagery

remains powerful today as both a principle of biological taxonomy and an account of migration patterns within species or closely related species (e.g., the idea that all humans emerged out of Africa). Both uses are indebted to Darwin’s own inspiration, the comparative linguist August Schleicher, who drew the first “tree of life” (or “cladogram”) to show the interrelatedness of Indo European languages, which together implicated an ultimate ancestor, a pure “Aryan” language probably spoken in Western India. Many of Schleicher’s fellow philologists were inclined to think of this inferred source as the medium in which the biblical deity originally communicated with Adam. However, Darwin and Nietzsche were prepared to take at least one aspect of the tree of life metaphor literally, namely, that language – and life – began arbitrarily at a particular place and time.

The contingency of origins is crucial for the genealogical method. To see this point, consider that history may be considered from two general perspectives: from the past looking forward into the future, and from the present looking back at the past. The former standpoint focuses on “turning points” when the future is open to multiple alternate futures, with the decisions taken at those times generating what economists call “path dependent” outcomes. In contrast to such “underdeterminism,” the latter standpoint tends to presume “overdeterminism,” whereby when and where the origin actually occurs is irrelevant because eventually the outcome will turn out the same. Overdeterminism produces teleology, underdeterminism genealogy. In the latter, the perceived sense of “necessity” in current ways of knowing and being merely reflects the reinforcement of an original moment of decision.

It is worth observing that Nietzsche wrote at a time – the final quarter of the nineteenth century – when the inexorability of human progress was a default position among intellectuals. Thus, the shock value of the genealogical method was stronger then than now, when, under the influence of postmodernism, relatively few intellectuals take seriously Nietzsche’s teleological foil. In Nietzsche’s day, genealogy’s potential to scandalize was perhaps best presented in Henrik Ibsen’s “bourgeois dramas,” whereby some apparently ordinary situation

turns out to betray the traces of a sordid past that persists, albeit in some hidden form that veers between sanctification and mystification. The moral dilemma that repeatedly arises in Ibsen's plays is whether knowledge of that past should be allowed to influence contemporary judgments.

Darwin, Nietzsche, and Ibsen all lived before the incorporation of Mendelian genetics into modern evolutionary theory, which occurred in earnest only in the 1930s. Thus, they operated with a semi coherent sense of hereditary transmission, in which an older Lamarckian view of the inheritance of acquired traits was grafted onto a much less teleological view of offspring simply manifesting a blended version of their parents' family traits. Yet, despite its semi coherence, it was precisely this view that fueled the imagination of Freud, who saw his psychoanalytic practice as a micro application of Nietzsche's genealogical method. Freud replaced the rogue ancestor, whose identity is revealed in the course of the bourgeois drama, with the rogue incident in the patient's past – say, the source of the Oedipus or Electra Complex – that anchored his or her subsequent conduct.

In terms of earlier theories of genealogy and inheritance, Mendelian genetics constitutes a turn toward essentialism that undermines the need for extensive historical investigation. According to Mendel, the traits expressed in an individual's life (i.e., its phenotype) reflect a limited range of possibilities circumscribed by its genetic program (i.e., its genotype). In other words, an individual's inheritance can be ascertained simply through an intensive examination of that individual. A case in point is the increasing use of genetic profile, whereby "susceptibility" to, say, crime or disease is determined by genetic sequences that an individual shares with others who bear no obvious family relation. In this context, Gilles Deleuze's views about the "virtualization" of identity have considerable purchase.

general linear model

Xitao Fan

The social science researcher's repertoire of statistical tools ranges from simple techniques (e.g., *t* test) to sophisticated multivariate analytic techniques (e.g., structural equation modeling). Many of these statistical techniques appear to be different analytic systems designed for different research situations. The distinctions, however, are often superficial. Fundamentally, many techniques are related to each other to such a degree that they can be considered as variations of a more general statistical model. For quantitative researchers in social sciences, understanding the relationship among the seemingly different analytic techniques is important, because such understanding helps researchers make judicious choices of analytic techniques in research.

In the social and behavioral sciences, traditionally, techniques involving categorical independent variables (e.g., *t* test, ANOVA) and those involving continuous variables (e.g., correlation, regression) used to be treated as distinctly different data analysis systems "intended for types of research that differed fundamentally in design, goals, and types of variables" (Cohen et al. 2003: xxv). Despite the superficial differences, these and many other statistical

techniques share one thing in common: they are designed to analyze linear relationships among variables. Cohen (1968) demonstrated that ANOVA type techniques and regression type techniques were statistically equivalent. Because of this, many techniques can be conceptualized as belonging to a general statistical model called the general linear model (GLM).

The GLM underlies most of the statistical techniques used in social science research. In the conventional (and narrower) sense, GLM may be conceptualized as a regression based model. In regression analysis, the independent variable is assumed to be a continuous variable. In ANOVA type methods, the independent variable is a categorical variable representing group membership (either naturally occurring groups such as gender or ethnic groups, or groups based on manipulated variables such as treatment vs. control groups in an experimental design). However, it is easy to extend the regression technique to subsume ANOVA type methods (e.g., *t* test, ANOVA, ANCOVA, MANOVA) by converting the group membership categories to some form of “pseudo” quantitative coding. “Dummy coding” and “effect coding” are the two most popular coding schemes for this purpose, and both are illustrated in a typical regression analysis textbook (e.g., Cohen et al. 2003). This conceptualization of GLM is currently implemented in the major statistical software packages (e.g., SPSS, SAS).

Broadly speaking, the concept of GLM goes beyond the regression model. As discussed more than 30 years ago (Kshirsagar 1972: 281), “most of the practical problems arising in statistics can be translated, in some form or the other, as the problem of measurement of association between two vector variates x and y .” (Here, x and y are vectors each containing multiple variables.) This extension allows for linear combinations of *multiple* dependent variables, thus extending the GLM concept to such multivariate techniques as discriminant function analysis and canonical correlation analysis (Thompson 1991; Fan 1996). The more recent development of the structural equation modeling (SEM) technique further suggests that SEM should be conceptualized as the most general of the general linear models, because it is the most general analytic technique for analyzing linear relationships among variables,

and it subsumes most parametric analytic techniques widely used in social and behavioral sciences (Bagozzi et al. 1981; Bentler 1992; Fan 1996; Jöreskog & Sörbom 2001). So GLM should not only be understood as an analytic model, such as that implemented in statistical software packages like SPSS and SAS, but more importantly, GLM should be viewed as a conceptual framework that subsumes a variety of analytic techniques as its variations or special cases.

The concept of GLM has some important implications for social science researchers. First, the concept of GLM makes it clear that the choice of an analytical technique does not contribute to the validity of any causal inferences that a researcher may make. Some researchers often have the misconception that ANOVA type methods are closely related to experimental design, thus are more suitable for research studies intended for making causal inferences. Even some textbooks on research methods (e.g., Gall et al. 1996) unintentionally contribute to this misconception by linking analysis techniques to research designs (e.g., ANOVA type methods for experimental designs, and correlation/regression for correlation/observation research designs). The GLM concept informs us that the choice of statistical technique has no bearing on the validity of causal inference, and only the research design does.

Another issue is related to the often observed research practice of categorizing an independent continuous variable (e.g., categorizing family income originally measured in dollars into three income levels: high, medium, and low) so that ANOVA type methods can be applied. This is often done because a researcher wants to know if families at different income levels (high, medium, low) differ on the outcome variable of interest. This research practice is ill advised because analytic precision is reduced in the categorization process, and the same question can be more precisely answered by preserving the original measurement scale and applying correlation/regression type analysis.

generalized other

D. Angus Vail

The generalized other is one of George Herbert Mead's central concepts in his seminal discussion of the social genesis of the self. According to Mead, the self resides in the individual's ability to take account of himself or herself as a social being. It thus requires the individual to take the role of the other as well as taking account of how his or her actions might affect the group. *Generalized other* is Mead's (1962: 154-8) term for the collection of roles and attitudes that people use as a reference point for figuring out how to behave in a given situation.

This term is often used in discussions of the play and game stages of development.

According to Mead, selves develop in social contexts as people learn to take the roles of their consociates such that they can with a fair degree of accuracy predict how one set of actions is likely to generate fairly predictable responses. People develop these capacities in the process of interacting with one another, sharing meaningful symbols, and developing and using language to create, refine, and assign meanings to social objects (including themselves). In order for complex social processes such as these to work, people have to develop a sense for the rules, norms, roles, understandings, and so on that make responses predictable. While they learn these sets of rules from concrete others, their aggregate constitutes a generalized other.

Since different social settings are governed by different sets of rules, competent social actors have to be able to take account of different sets of rules as they move from one social setting to another. Each setting, then, is governed by its own generalized other. If one were to invoke Mead's preferred sports metaphor, the athlete has to be able to take account of different sets of rules as she or he moves from sport to sport.

As people develop more complete selves, then, they learn to internalize and recognize a greater diversity of perspectives operating among different communities. As they move among settings and/or communities, they have to take into account the aggregate expectations of the people they are likely to encounter in that setting, the culture that is likely to make that aggregate make sense, and the reasons that aggregate is different from other aggregates. Thus, while children in the play stage take the role of a single other, and children in the game stage learn to take the roles of several others, a person who has developed a sense of a *generalized other* can take the role of abstract sets of attitudes, beliefs, and norms she or he expects *concrete* others to embody.

In a sense, then, the generalized other is the process through which the individual internalizes and takes account of society's expectations. As society is processual, emergent, and contextual, so must be the person's ability to take account of different generalized others that

are likely to govern people's behaviors from setting to setting.

generational change

Martin Kohli

In its most obvious sense, generational change means change occurring along succeeding generations, showing up in differences between them. In a more fundamental sense, it expresses the idea that social change needs to be understood in terms of the sequence of generations, and is to a considerable extent driven by their dynamics.

The concept of generation can be defined with regard to society or to family – two levels which are usually analyzed separately but should be treated in a unified framework (Kohli & Szydlik 2000). At the level of the family, generation refers to position in the lineage. At the societal level, it refers to the aggregate of persons born in a limited period (i.e., a birth cohort according to demographic parlance) who therefore experience historical events at similar ages and move up through the life course in unison.

At both levels, the concept of generation is a key to the analysis of movement across time. In the sequence of generations, families and societies create continuity and change with regard to parents and children, economic resources, political power, and cultural hegemony. In all of these spheres generations are a basic unit of social reproduction *and* social change – in other words, of stability over time as well as renewal (or sometimes revolution).

SOCIAL AND INTELLECTUAL CONTEXT

In some “simple” traditional societies without centralized political power and class based social stratification, age and gender are the basic criteria for social organization. The most obvious type are the societies – to be found mostly in East Africa – based on formal age classes (or age sets, as they are sometimes called). A subtype of particular relevance are those societies in which the basis is not age but generation – that is, position in the family lineage. Here, the sequence of generations in the family directly conditions the position of the individual in the economic, political, and cultural sphere. Family filiation is linked with material security, power, and social status.

In modern societies these features of social organization have been differentiated and are now institutionalized in separate spheres. But they need to be linked at least conceptually, so that shifts in the relative importance of these spheres may be detected. There are indications, for instance, that in the West the main arena of intergenerational conflict has shifted from the political and cultural to the economic sphere. The political and cultural cleavage between generations, so highly visible and outspoken in the “silent revolution” of the 1960s and 1970s (Inglehart 1977), has turned into a distributive cleavage played out around the institutions of the labor market and the welfare state.

Generational dynamics have always been a major engine of social change. In structural as well as symbolic terms, generations define themselves (or are defined) against each other; new generations come into being by setting themselves apart from and competing with existing older ones (Attias Donfut 1988).

Under conditions of modernity, this has taken on a special twist. Each new generation – both at the level of society and of family – is socially expected to come into its own and acquire some measure of autonomy. Adolescence and youth have thus become a period of particular unrest.

This was the situation faced by Mannheim (1928) when he put the problem of generations on the agenda of modern sociology. Mannheim did not invent the concept as such; when he wrote his seminal paper he identified two distinct traditions of thought on the subject that he labeled the French and the German:

The first, born of the spirit of positivism (Auguste Comte), was the search for an objective (external) historical rhythm and thus for a general law of social change. Comte and his followers thought that they had found this rhythm in the regular sequence of human generations.

The second, born of the spirit of hermeneutics (Wilhelm Dilthey), was the search for the inner totality (*Gestalt*) of an historical epoch and thus for what sets it apart from all others. Dilthey and his followers believed that this totality could be found in the specific historical experience of a generation. (Mannheim 1928)

Mannheim took up the “German” tradition, but gave it a sociological turn by combining it with some of the formal analysis characteristic of the “French” one. The problem that Mannheim defined was how experiential generations (as in the hermeneutic tradition) became political generations that created social dynamics (as in the positivist tradition).

Following Comte, Mannheim proposed a simple thought experiment: What would happen to a society if its members lived on indefinitely and no new members were born? In his view the likely consequence would be that change would be stifled. Social innovation – for Comte and Mannheim – is brought about by the onset of new generations. The young are the natural carriers of the new. On the other hand, people have to die in order to allow social renewal to take place. Generations must make room for the next ones at regular intervals. “Creative destruction” – to use Schumpeter’s famous term – depends on the disappearance of the old. It follows that – all things being equal – societies with shorter lives are more dynamic. We should note that modern societies have

institutionalized a functional equivalent for physical death: retirement.

This conception is based on a very strong presupposition: that people acquire their basic worldview and dispositions early in life and then more or less stick (or are stuck) with them. For Mannheim, the formative experiences are those of adolescence when the mind awakens to a reflexive conscience of itself. This argument is in line with his sociology of knowledge (later elaborated upon by phenomenological sociology). The first worldview or structure of knowledge that an individual acquires colors all later additions and corrections, positively or negatively.

A great deal of work has been devoted to assessing the validity of this presupposition; that is, whether there is stability of basic orientations and dispositions over the life course, and as a corollary, whether the elderly are less able and willing to innovate than the young. In developmental psychology there is broad evidence for learning and development throughout the life course; the potential for change thus remains until late in life, but in many dimensions the prevailing empirical pattern is one of continuity, with a possible trend towards less controlling and more accommodating action styles. The evidence in terms of political psychology is discussed by Braungart and Braungart (1993). From a sociological perspective, it can be argued that personal continuity may be less a product of “innate” tendencies or developmental path dependency than of the institutional commitment to stability (or the lack of institutional incentives for change) during adulthood. But as with other “big questions,” the overall answers have so far been rather unsatisfactory in terms of elegance and simplicity. At the most general level what can be asserted on the basis of this large body of research is that stability (or lack of innovation) is the general rule in *some* domains, under *some* conditions, and in *some* periods. In recent years, research activity seems to have slackened even though the basic issues have not really been resolved.

The three basic domains are those of political, economic, and family generations. There have also been studies on cultural generations, such as those in the world of art or of science, but given the close links between, for example, literary and political intellectuals (Wohl 1979),

this will now be discussed as part of the political field.

POLITICAL GENERATIONS

There are additional reasons why generational cleavages have deepened over the course of modernization. The first is the increasing age grading of social organization brought about by the institutionalization of the life course (Kohli 1986). The second is that other cleavages which organized early industrial societies have lost some of their salience, especially those of class.

In the history of most western welfare states, the key “social question” to be solved was the integration of the industrial workers – in other words, the pacification of the class conflict. This was achieved by giving workers some assurance of a stable life course, including retirement as a normal life phase funded to a large extent through public pay as you go contribution systems or general taxes. In the twenty first century, class conflict seems to be defunct and its place taken over by the generational conflict. The new prominence of the latter is due both to the evolved patterns of social security, predicated upon the institutionalized tri partition of the life course (which has turned the elderly into the main clients of the welfare state), and to the demographic challenge of low fertility and increasing longevity. Demographic discontinuity creates unequal life chances among generations (Easterlin 1980).

It remains essential, however, to assess the extent of generational cleavages per se and the extent to which they mask the continued existence of the received cleavages between rich and poor (or capitalists and workers); in other words, the extent to which new *intergenerational* conflicts have really crowded out traditional *intragenerational* ones. There are moreover other intragenerational cleavages that are usually categorized as “new” dimensions of inequality (in distinction to the “old” ones of class), such as those of gender and ethnicity.

There is thus a problem of internal differentiation. An individual does not live in a specific generational space only, but also belongs to a specific class, gender, ethnic group, and so on. By assuming the homogeneity of all those living together in the same stratum of historical time,

and neglecting the dimensions of conflict within this generation, the concept can even become ideologically tainted.

In political survey research, there has been a series of attempts to identify political generations as aggregates with specific orientations and dispositions. The broadest and best known comparative research program in this respect is that of Inglehart, who has made a strong case for a basic generational shift starting in the 1960s from materialism to post materialism. Smith (2005) analyzes the extent of the “generation gap” – the difference between the young and the old – in a wide range of attitudes, values, and behaviors and its change over the 25 years from 1973 to 1997 based on the US General Social Survey. He finds a wide generation gap at the beginning of this period with a narrowing thereafter, in line with the notion that the main cultural transformation occurred in the 1960s and that people who grew up during or after this time can be expected to have more in common with each other than those who were raised before. We may expect that in Eastern Europe the early 1990s would again be a transition with the potential of widening the generation gap.

But this is only the first level in the formation of a political generation. What is at issue here can be expressed analytically as a progression from (1) a common social location and experience to (2) consciousness of this shared reality to (3) getting organized together to form a unified political actor. This framework has obvious parallels to Marx’s distinction between *Klasse an sich* and *Klasse für sich*, which has been put to good use in studies of the historical formation of labor movements and labor organizations, and is now also being applied to gender and ethnicity. Studies of political generations can be set up in similar ways – Mannheim developed his framework as an explicit analogy to Marx’s terms – but appear to face a more difficult task.

In fact, the formation of a generation as a unified political actor seems rather unlikely because it is not based on a membership characteristic that is clearly visible in social life and so cannot be easily shed (such as gender or ethnicity), or refers to well defined resource positions and ways of life (such as class).

Many authors have concluded that, while there may be groups that share certain social

locations, experiences, and dispositions, there are no generations in the sense of population groups that are conscious of sharing them, and even act on this consciousness. Against this skepticism, historical reality has time and again tended to reaffirm the existence of such political generations, and to put forth phenomena which can be understood only within a generational framework. These phenomena have manifested themselves as (often revolutionary) movements at various points in the course of modernization (Roseman 1995). They are often youth movements, and they often occur at major historical watersheds, such as 1914, 1945, 1968, and 1989. They may be focused on literary and intellectual groups (Wohl 1979) or on political groups and elites as such. There may be competing movements within a generation – “generational units” in Mannheim’s terms – such as left wing and right wing ones. An example of the latter was the German National Socialist takeover in 1933 which brought to power a large group of young adults, including a number of top level political functionaries who were about as old as the century – that is, in their early thirties – and after the demise of the Thousand Year Reich, in their mid forties. That social movements tend to be generational in spite of the presumed unlikelihood of generation based mobilization may again be explained by the age graded structure of the modern life course (Kohli 1986). People are typically processed by the institutions of schooling, army, labor market, and welfare in groups of age peers. Such groups have the opportunities to organize as well as the moral resources – because they know each other, they more easily develop the necessary closeness and trust.

ECONOMIC GENERATIONS

In the study of political generations economic opportunities have traditionally entered the picture as a key component of social location, although interest has always focused on their consequences in terms of political action. This is now changing. As mentioned above, the main arena of conflict in western societies has shifted from the political to the economic sphere. The issues of politics (power, hegemony) have given way to the issues of welfare (economic security,

resource allocation). The political conflict between generations has turned into a (potential) distributional conflict.

These issues are often framed as a conflict between young and old, or younger and older generations, and discussed under the label of “generational equity” (Kohli 2005). It refers to the argument that the elderly have got more than their fair share of public resources, and that this comes at the expense of the non aged population, especially children. In generational terms, this means that today’s older generations have profited from the expansion of public old age security without having had to pay full contributions, while the younger generations who now have to bear an increasing contribution load will not get the corresponding benefits any more. The growth of this argument into a full blown political discourse can be dated to the mid 1980s. From the US the discourse has been imported to the UK and to the European continent, where institutionalization has been slower but with more current weight (Attias Donfut & Arber 2000).

The discourse of generational equity has clearly been one of the more effective ones in shaping the public agenda of welfare retrenchment over the last two decades, even though its impact in changing popular attitudes and beliefs has so far been less impressive. The political consequences drawn by the proponents of generational equity go in the direction of reducing public spending for the elderly (e.g., by privatizing parts of old age security, reducing benefits, and increasing the retirement age). Other demands include age based rationing for some types of medical care, and age tests for a range of issues such as driving or even voting. In Europe, the demands are often grouped under the term *sustainability*, which links the long term survival of social security schemes to issues in the domain of ecology.

Against these claims it has been pointed out that the expansion of old age security should be seen as a success that – far from unduly privileging the elderly – has only given them their due share by finally bringing them up to par with the active population. Moreover, improving their well being does not necessarily come at the expense of other population groups; the distribution of resources between young and old is not a zero sum game.

One line of research examines the input side: welfare state spending targeted to different population groups (among them, the young and the old) and how it is brought about by welfare state institutions. This concerns not only the large redistributive programs such as old age income security or health insurance, but also arrangements only partially organized or subsidized by the state, such as long term care. An important extension is that of generational accounting which includes contributions as well as spending, and tries to establish full life time balances of contributions and benefits for each successive cohort.

The result is usually that the older generations, through the expansion of pension and health care programs over the past decades, benefit at the cost of the young and future generations. A direct comparison between spending on the elderly and on children and youth is misleading, however. In modern welfare states, incomes and services for the elderly are to a large extent publicly financed, while those for the young are still mostly borne by their families. The one exception is the educational system, but even this is often not fully accounted for. As Bommier et al. (2005) show, the usual intergenerational picture is turned upside down when public education is included in generational accounts along with pensions and health care. They estimate that in terms of benefits received minus taxes paid, all US generations born 1950 to 2050 will be net gainers, while many of today's old people are net losers. Windfall gains for early generations when Social Security and Medicare started up only partially offset windfall losses through the expansion of public education.

The more straightforward way of validating the claims of the generational equity discourse is to assess the output side: the outcome of market distribution and state redistribution in terms of the economic well being of the young and the old (Kohli 2005). Comparative OECD data show that from the mid 1980s to the mid 1990s children have indeed lost ground, and that their income position is considerably below that of the active population. The income position of the elderly has improved in most countries, but also remains below that of the active population, particularly so in the UK with its "residual" welfare state. Moreover, the position

of those above age 75 is clearly less favorable than that of the "young old." It is obvious from these results that in terms of generational equity families with young children should indeed be the target of supplementary welfare efforts. But the results give no reason to strip the elderly of (part of) their current benefits.

Thus, the potential for distributional conflicts among generations certainly exists and is fueled by the current challenges of public finances and demography. However, the discourse of generational equity overstates the extent and inevitability of such conflicts, and sharpens them at the expense of conflicts along the more traditional cleavages of class. Survey data regularly show that the public generational contract still enjoys high legitimacy among all ages and segments of the population. There are some age and generation effects, but they are much less pronounced than the public discourse would lead us to believe. A critical factor is the institutions – such as parties or unions – that mediate generational conflicts by favoring or disfavoring age integration in the political arena.

FAMILY GENERATIONS

The family is the institution where the concept of generation has its most basic meaning: the creation of offspring. While the generational process within a specific family lineage is highly discontinuous, at the population level it is continuous: births occur more or less regularly. There is thus no immediately available "translation" of family generations into political or economic generations. But there is a link relating the generational succession in the family to that in the polity. It is the claim that political innovation or rebellion is favored by generational conflict between parents and children. This claim has already been put forth as an attempt at explaining the movements of 1968. The shift away from authoritarian towards more egalitarian socialization styles in western families would then be another reason for the weakening of the generational conflict in the political arena.

Another link pertains to the reasons why age and generation effects in attitudes towards redistribution through the welfare state even

today are so relatively modest. For the young, the institutionalization of income maintaining retirement pensions means that they are freed from any expectation of income support towards their parents. They can moreover count on services such as grandparenting, and in many cases they can also expect material support. The public resource flow to the elderly has enabled the latter to transfer resources to their offspring in turn (Kohli 1999).

Recent research on *inter vivos* family transfers demonstrates that such transfers are considerable, that they occur mostly in the generational lineage, and that they flow mostly downwards, from the older to the younger generations. There may be expectations of reciprocity, or other strings attached, but by and large parents are motivated by altruism or feelings of unconditional obligation, and direct their gifts to situations of need. For Germany, our survey in 1996 showed that 32 percent of those above age 60 made a transfer to their children or grandchildren during the 12 months prior to the interview, with a mean net value of about 3,700 euros. Thus, part of the public transfers from the active population to the elderly was handed back by the latter to their family descendants. The aggregate net *inter vivos* transfers by the elderly population amounted to about 9 percent of the total yearly public pension sum. This link needs to be qualified, but the overall pattern is clear: the public generational contract is partly balanced by a private one in the opposite direction. These family transfers function to some extent as an informal insurance system for periods of special needs. Even more important in monetary terms are bequests. They are more frequent and much higher in the upper economic strata, but now also increasingly extend into the middle and lower ranks.

A similar picture emerges for other forms of support among adult family generations, as well as for their geographical proximity and emotional closeness. In all of these domains, the widespread idea of the nuclearization of the modern family and the corresponding structural isolation of the older generations – made popular not least by sociological theories of modernization such as those by Durkheim and Parsons – has proven to be highly exaggerated. Conflicts or isolation between family generations do exist to some extent, but not nearly

as pervasively as the conventional story of modernization has made us believe.

THE FUTURE OF GENERATIONAL CONFLICTS

There are still many issues where our current knowledge is severely limited. Due in part to the difficulties mentioned above, the generational framework has not yet been put to full use in accounting for political mobilization and cultural and economic innovation. The links between political, economic, and family generations need to be drawn out more clearly. The limitations are also partly due to the lack of appropriate data. Most studies so far have been limited to cross sectional evidence, or repeated cross sections at best. For a field in such rapid evolution this is especially regrettable.

Given these limitations, what can we say about the likely future? Much will depend on the opportunities and constraints created by institutions. The age grading of the life course, and thus the age based structure of benefits and obligations, may be expected to weaken somewhat, but it will not wither away. The discontinuities produced by the demography and the economy may even deepen, so that the potential for generational conflicts over issues of (re)distribution will remain strong. The bonds between the generations in the family and in the polity have so far been effective in defusing this potential, but whether this will remain so depends on whether there will be enough welfare state support for the family, and age integrating organizations in the political arena.

A crucial issue will be that of innovation. For aging societies, it is critical that the capacity to innovate should extend beyond adolescence and early adulthood into the later life phases. To some extent this would also lower the potential for generational conflict. Whether this will be the case obviously depends on the institutional incentives for continuing education and social participation.

genetic engineering as a social problem

Gabriele Abels

Genetic engineering (GE) is the technique and science of intervention into the genetic mechanisms of an organism, whether it be micro organism, plant, animal, or human. GE is one of the most socially contested of technologies. In the public debate, the terms GE and bio technology are often used synonymously; yet, in a narrower sense, GE is only one important technique in the field of biotechnology.

The first successful gene splicing experiment integrating genes from a different species into an organism was undertaken in 1973. Immediately a debate started – and is still going on today – about whether or not GE should be regulated, and in what way. Different regulatory approaches were developed (e.g., product versus process regulation), and (legal) regulations on GE and its various applications were adopted. Based on environmental, safety, and health concerns, GE was perceived as a risk technology from the beginning (Krimsky 1982). Sociologists of risk often refer to GE; for example, for Ulrich Beck, GE is a paradigmatic case for the risk society.

There are two main fields of application of GE: agriculture and food production and medical genetics. Both fields are socially contested, yet the latter is more complex with regard to the social problems involved. The medical field has been revolutionized by the Human Genome Project. Started in 1990 and led by US scientists, it was an outstanding international and multidisciplinary endeavor to map and sequence the human genome (Kevles & Hood 1992). The project was completed in 2004 and is now followed by a functional analysis of the genome (genomics, proteomics, and pharmacogenomics). The project led to an immense growth in knowledge on human genetics, contributing to the development of diagnostics and (pharmaceutical and genetic) therapies as well as population genetics. The project also fostered a trend toward “geneticization”: genetics is increasingly referred to as an explanation not only for

medical conditions, but also for social behavior (e.g., homosexuality, criminality, alcoholism). This shift is reflected in everyday culture where the gene has become a "cultural icon." The study of ethical, legal, and social impacts (ELSI) became an integral part of the Human Genome Project and numerous sociological studies were conducted on issues such as changing patient-physician relationships, the concept of autonomy, or the impact of the media on public perception.

For some time, GE has increasingly been combined with infertility treatment and embryo research ("reprogenetics"). Artificial reproductive technologies such as different techniques for prenatal testing (e.g., amniocentesis or chorionic villi biopsy), artificial insemination, and in vitro fertilization, first developed in the 1970s and today routine procedures, employ GE (e.g., pre implantation genetic diagnosis).

GE gives rise to a number of questions that relate to issues of social (in)equality, especially with regard to human genetics. Any kind of biological – including genetic – information can be socially powerful and used to stigmatize social and ethnic groups as well as individuals and to discriminate against them (Wilkie 1993; Nelkin & Tancredi 1994). There is ongoing debate about the specific status of genetic information: unlike other medical data, genetic information is permanent, cannot be altered, and has a prognostic power. It affects not only the individual, but also his or her relatives. Proponents of "genetic exceptionalism" argue for special legal regulation of genetic information, for example with regard to its use in the insurance sector or by employers. Others claim that a similar condition applies for a lot of non genetic biological information (e.g., use of blood samples in medical employment tests) and that there is no need for special regulation, but instead existing rules should be extended to genetic information and strengthened in order to protect individuals as well as the interests of third parties. Both positions share the concern that genetic information may create a new social cleavage between "genetically affected persons" and those deemed healthy, this cleavage potentially leading to genetic discrimination. The question of an individual's (or even a group's) control over the use of his or her

genetic data and access to this information by third parties thus becomes a prominent social and legal issue, that of genetic privacy.

Cultural perceptions about health, sickness, and disability are a further issue. Especially with regard to the use of GE in reproductive medicine, cultural meaning and social effects of disability are under debate. Radical disability rights activists raise the question of whether the (although until today imperfect) technical option to prevent babies being born with disabilities, so far usually by late term abortion, might lead to a negative cultural perception of disability as being avoidable and to discrimination against people with disability. Others object that only a few disabilities can be detected early on and most are acquired during one's lifetime, and, second, they emphasize the burden on parents and their reproductive rights. In this way, GE revives the old debate about reproductive rights and adds some new topics. Because of women's and men's different share in the reproductive process, GE affects women and men differently.

A third dimension of discrimination concerns race and ethnicity. Many genetic conditions are related to racial and ethnic origin, for example beta thalassemia is most common in the Mediterranean, African, and Southeast Asian populations, sickle cell anemia in the African population, or aggressive forms of breast cancer among African American women. This could give rise to a specific combination of racial/ethnic and genetic discrimination, above all if economically disadvantaged groups are affected.

Besides discrimination, GE in the human field has fostered safety, ethical, and philosophical debates about the future of humankind with regard to techniques such as different forms of gene therapy, enhancement, and human cloning. Gene therapy can be conducted on affected cells (somatic cell GE); the objective is to correct defective genes in individuals by inserting non defective ones. Conducted for the first time in 1990, it is still an experimental therapy and safety concerns dominate the debate. A more fundamental gene therapy would directly alter the genetic structure of the germ line, and thereby also change the genetic structure of future generations. This

could be done for therapeutic reasons in order to ultimately correct defective genes. However, germ line therapy also opens the way for enhancement of human beings for non medical reasons. This technical option is socially highly contested (cf. Bernard 2001; Fukuyama 2002; Habermas 2003). Critics argue that any form of enhancement is eugenics and leads to a slippery slope; they often recount Nazi "racial hygiene" as the historically most extreme case of eugenics. The major philosophical basis is Kant's reasoning that a human should not be instrumentalized by anybody for personal interests but has a value of his or her own. Proponents argue that there is no strong theoretical argument against enhancement. The selective choice of a fetus in order to later use the baby, for example as a bone marrow donor for an affected sibling, as well as human cloning have become contested issues for much the same ethical reasons as germ line therapy and enhancement.

The early debate over GE was dominated by a risk discourse. Increasingly, ethics has gained prominence and often even takes center stage in scholarly as well as political debates, especially with regard to the medical field. Yet, ethics is today also more prominent with regard to the agricultural and food sector. Along with this change in the framing of the debate went a shift from the narrow issue of legal regulation of GE to the broader one of social regulation. Legal regulation in the medical field pertains to issues of research (e.g., informed consent, use of embryos or stem cells) to application in (medical) practice (e.g., informed consent, access to data, safety standards) as well as to commercialization (e.g., coverage by health insurance providers). Most legal regulation is in the form of national laws or self regulation by professional groups such as physicians. In the last decade, there has been a growing trend for more international legal regulation of some issues, such as research and cloning, by organizations such as the United Nations, the Council of Europe, or the European Union.

Social regulation pertains to broader questions of science (genetics) and society including who should participate in decision making and policy deliberation on these contested issues, and what counts as relevant knowledge. This

is reflected in institutional change in policy deliberation. Since the 1990s, special bodies have been set up in many countries in order to advise policymakers on ethical, social, and legal policy issues concerning GE and its application to humans (e.g., national ethics committees). Along with this professionalization of the debate has been democratization, insofar as many social experiments with enhanced citizen participation in science policy have been conducted (e.g., consensus conferences or citizens' juries).

GE is a prominent topic in interdisciplinary social studies of science and technology (STS). A first strand in sociological research focuses on the social history of GE and conflicts within science as well as between science, politics, and the public. One strand of research addresses issues of public risk perception and media representation as well as different cultures of risk regulation, including the precautionary principle. Yet most of this research deals with regulation in the field of agricultural biotechnology, while the application to humans still requires scholarly attention. A third strand is concerned with social changes, for example geneticization effects on reproductive choice, disability rights, or the general topic of the social reinvention of nature, often including a gender perspective. While early research sometimes argued along the lines of technological determinism, today research is taking into account the complexity of how GE and society shape each other. Social justice and equality or, more specifically, Foucault's concepts of biopolitics and governmentality are prominent theoretical approaches.

The ongoing social conflicts over GE have recently been analyzed from a perspective of the changing relation between science and society and build on changes in political culture and "civic epistemologies" (Jasanoff 2005). "Science governance" is a keyword. This concept criticizes the older approach of "public understanding of science" as insufficient. It identifies public ignorance as the key factor in conflicts over technologies and holds that technology assessment is best conducted by experts. According to the science governance perspective, new methods for technology assessment have to be developed that include a variety of social actors. New "participatory" or democratic

models criticize the epistemological deficiencies of expert oriented policy deliberation and attend to the decreasing authority of scientific knowledge (expert dilemma). Proponents of participatory models argue for the need to integrate a plurality of knowledges and aim to democratize expertise. This governance perspective allows us to link conflicts over GE to broader social transformations. It requires above all a theoretical embedding of technology assessment as well as the broader concept of science governance in social theory. This is one of the major tasks for future research.

genocide

Susanne Karstedt

Genocide has been termed the crime of the twentieth century and in many ways it epitomizes this "age of extremes" (Hobsbawm 1994). It was in this century that the word genocide was first coined, and it was legally defined and criminalized. The international community committed itself to the protection of threatened populations and to the prosecution and punishment of those who were responsible for mass killings, and was successful in a number of high and low ranking cases; at the end of the century, international intervention in cases of genocide started. Most importantly, it was the century of the archetypical example of genocide in modern times, the Nazi Holocaust of the European Jews and other groups, the most horrible single crime in human history. On most accounts, it is the century if not with the highest numbers of incidents, then the highest numbers of victims of genocide in the known history of humankind.

The word genocide was coined by Raphael Lemkin, a lawyer of Polish Jewish origin, in 1944. It was legally defined in the United Nations Convention on the Prevention and Punishment of the Crime of Genocide in 1948, preceded by a resolution of the General Assembly proclaiming that "genocide was the deprivation of the right to existence of a group in the same fashion that homicide was the denial of the right to exist of an individual" (Rubinstein 2004: 308). The UN Convention's definition was drafted in response to the Nazis' extermination of the Jews, and was based on the experience of the Nuremberg Trials 1945–6, which became a landmark in the legal prosecution of perpetrators of genocide. However, it did not start to play a role in international law and politics until the 1970s, and in particular after the end of the Cold War, when the mass killings in Cambodia, and later in Latin America, the former Yugoslavia, and in Rwanda alerted the international community to the continuous and global threat of genocidal practices.

The Convention states that "genocide means ... acts committed with intent to destroy, in whole or in part, a national, ethnic, racial or

religious group.” Such acts as detailed in the Convention include: killing members of the group; causing serious bodily or mental harm to them; deliberately inflicting conditions of life calculated to bring about their physical destruction in whole or in part; imposing measures intended to prevent births within a group; and forcibly transferring children of the group to another one. The Convention’s definition is remarkable in two respects. First, it did not imply that genocide is the total destruction of a whole group; second, it included a range of acts besides mass killings, and thus took into account the *process character* of genocide. However, the definition limited genocide to these groups, and specific actions, and excluded groups defined by class and political affiliation. As such, the Convention’s definition was untenable in the light of the Universal Declaration of Human Rights adopted in the same year. In fact, the mass killings of peasants in the Soviet Union under Stalin, or the genocide of its own people by the Khmer Rouge in Cambodia, are currently counted as genocide by most authors.

The Convention’s limitations started an ongoing debate about the definition of genocide, and currently, the terms “mass killings” (Valentino 2004), “mass atrocities” (Osiel 1997), “democide” or “deaths by government” (Rummel 1994, 1998), and “murderous ethnic cleansing” (Mann 2005) are all in use. Most of these extend the scope of genocide beyond the groups to which the Convention still gives a special status. Though genocide is clearly set apart from war, in particular by its illegitimacy, which is enshrined in the Convention, national criminal laws, and evidenced by the secrecy and complicity in the conduct of genocide (Shaw 2003), a number of authors include specific types of acts of war as genocide (e.g., Kuper 1981; Rubinstein 2004). The scope of the definition is decisive in two respects: first for the estimates of victims and perpetrators, and second for the history of genocide.

Estimates for the victims of genocide and mass killings as distinguished from war deaths range from 60–150 million for the twentieth century alone (Valentino 2004), with most estimates at about 80 million, and some considerably higher (Rummel 1998). For the second half of the twentieth century since 1945, estimates range from 9–20 million in more than

40 episodes of genocide (Valentino 2004; Gurr 1993). These horrifying figures testify to the “discriminate targeting” of groups in mass killings and their finally “indiscriminate” victimization (Shaw 2003). The perpetrators in contrast are comparably small in numbers. A very conservative estimate gives the figure of Germans who directly participated in mass slaughters of Jews as 100,000, to which a considerable number of members of police and other forces should be added. An estimate of immediate involvement in the Rwandan genocide suggests 200,000 direct participants; however, the regular and irregular military forces who did most of the killing number about 10,000. A similar estimate is given for the perpetrators in former Yugoslavia (Osiel 2005). Genocide is the crime in which victims massively outnumber perpetrators, but the group of perpetrators is large enough to include a considerable proportion of the population. Bystanders, those who tacitly or openly approve of or witness all measures leading up to the killings and finally the mass killings themselves, can comprise large parts of the population, depending on the type of action taken against the targeted group. Historical accounts and counts of episodes of genocide put the twentieth century into perspective, depending on the scope of the definition used. Both Rummel (1998) and Rubinstein (2004) estimate high numbers of victims of genocidal practices before the twentieth century. Rubinstein (2004) identifies five distinct types and periods in the history of genocide: in pre literate societies, in the age of empires and religions (from 500 BCE to 1492), colonial genocides from 1492–1914, in the age of totalitarianism (1914–79), and contemporary ethnic cleansing and genocide since 1945. He concludes that pre literate societies were probably more murderous than modern ones, thus contesting the assumed link between modernity and genocide.

Genocide involves three distinct elements, which provide the basis for all attempts to explain why and how genocides happen, and why apparently “ordinary men” (Browning 1992) – and very rarely women – engage in the indiscriminate killing of men, women, and children, who might have been their neighbors. These elements are (1) the “identification of a social group as an enemy . . . against which it is justified to use physical violence in a systematic

way”; (2) “the intention to destroy the real or imputed power” of this group; and (3) “the actual deployment of violence . . . through killing . . . and other measures” (Shaw 2003: 37). Genocides are more often than not related to wars, mounting social crises, and threatening social change, including the total breakdown of social order (Staub 1989). Though genocide and mass killings at least in the twentieth century take place in comparably short time periods, and most of the victims are killed within a few months (Valentino 2004), the development of the three decisive elements and the process character of genocide can be clearly identified.

Three explanatory approaches have been most influential: genocide as the product of *modernity*, with Bauman (1989) as the most prominent proponent; the *structural and psychosocial perspective*, which focuses on broad social, cultural, and political factors; and finally the *strategic perspective*, according to which specific goals and strategies of high political and military leaders are decisive for the precipitation of genocide (Valentino 2004), and which links genocide to “degenerate wars” (Shaw 2003). The link between modernity and genocide is established by modernity’s defining features, such as new technologies of warfare, new administrative techniques that enhance the power of state surveillance, and new and “excluding” ideologies that categorize people. It is the development of the power of the modern state that finally facilitates genocide and makes it a defining characteristic of modernity. In contrast, the structural and psychosocial approach focuses on a number of preexisting structural and cultural factors, which are however neither sufficient nor universally necessary causes of genocide. Among these factors the most important are deep cleavages between social and ethnic groups, with a clear structure of domination and “superimposition of inequalities” (Kuper 1981). These are exacerbated in social crises and in difficult living conditions, which increase the competition between groups for power and economic gains. Even if genocide generally involves “irrational and fantastical beliefs” (Shaw 2003), it is also a “rational” strategy for the perpetrators to enrich themselves and firmly establish power. Cultural factors include dehumanizing attitudes towards

targeted groups, scape goating in times of social crises, justifications of violence and exclusion, moral disengagement such as the erosion of norms of social responsibility and solidarity, and a cultural pattern of authoritarian and obedient attitudes. The concentration of unchecked power in undemocratic and authoritarian regimes has been identified as a causal factor by a number of authors (e.g., Rummel 1998). The twentieth century provides ample evidence for the role of dictatorships and authoritarian states in conducting mass killings; however, the role of democracies as bystanders and facilitators should not be underrated. Mann (2005) makes the failure of democracy and democratization responsible for murderous ethnic cleansing and explains it as the “dark side of democracy.”

The strategic perspective (Valentino 2004) differs from both the above approaches in its focus on situational and process factors, as well as political ideological conditions. From this perspective genocide is a powerful political and military tool for leaders, elites, and their imminent followers to achieve strategic goals. Valentino argues that the impetus usually originates from a relatively small group of political and military leaders, for whom mass killings are part of an instrumental policy, and strong incentives exist to instigate these as a “final solution” to real or imputed threats. He identifies six types of mass killings which can be grouped into two general categories. “Dispossession” mass killing results from policies that strip large groups of the population of their possessions, their homes, their way of life, and finally their lives. Collectivization and political terror, ethnic cleansing, colonial enlargement, and expansionist wars are in this category. “Coercive mass killings” occur in major armed conflicts, when political and military leaders use massive violence to coerce large numbers of civilians and their leaders into submission, and when this escalates into genocide. Counter guerrilla, terrorist, and imperialist mass killings are in this category.

While the structural perspective identifies long term social and *collective* processes that contribute to the ultimate precipitation of genocide, the strategic perspective focuses on the short term *strategic* process of genocide, which involves only a small elite group and their

followers. Both provide widely differing explanations for the *individual* processes that turn mostly ordinary men into mass murderers. From the structural perspective, social and cultural preconditions create a large pool of potential perpetrators, so that finally everyone can become actively involved in mass killings should the situation arise. The Milgram experiments were mostly designed to confirm this assumption. In contrast, the strategic perspective (Valentino 2004: 6) implies that the “preferential selection of sadistic or ideologically fanatic individuals and the influence of situational and group pressures and elite manipulation,” including incentives for perpetrators, explains the behavior of most rank and file perpetrators of mass killings. Historical evidence and case studies do not give unequivocal support to either of these perspectives, but it is obvious that perpetrators go through a process of stepwise preparations and different stages of moral disengagement and justification of their actions, during which group pressures and incentives, as well as imputed threats, play an important role (Browning 1992; Waller 2002; Mann 2005).

The UN Convention obliges the international community to prevent genocide, which includes intervention into ongoing mass killings. Both require the observation of critical situations and the identification of warning signs. Prevention and intervention include international military intervention, economic sanctions, the deployment of international peace forces and the disarmament of groups involved, and the provision of humanitarian assistance. From the structural perspective of “root causes,” long term measures are preferable. These include the promotion of minority rights, democratic values that protect individuals, the rule of law, and democratic regimes. Democratization, however, appears to be a double edged sword, since genocide episodes often followed on the heels of failed democratization efforts (Valentino 2004; Mann 2005). With its focus on small groups, situational and precipitating factors, on the shorter time frame of the actual road to genocide, and the identification of steps towards the “final solution,” the strategic approach appears to be more suitable to design and implement interventions and preventive

measures, and to identify premonitions of potential genocides (Osiel 2005).

The UN Convention committed the international community to the prosecution and punishment of perpetrators, and made individuals accountable under international law. The acts punishable under the Convention comprise conspiracy, public incitement, and complicity, and thus allow for the indictment of “constitutionally responsible rulers, public officials or private individuals” (Article IV), for which the International Military Tribunal at Nuremberg had been a promising start. In addition, the Convention committed the ratifying nations to prosecuting perpetrators in their own territory. It was not until the last decade of the twentieth century that the international community developed the requisite institutional framework, first with the International Tribunals for the Former Yugoslavia (Hagan 2003) and Rwanda, and finally with the adoption of the Rome Statute of the International Criminal Court in 1998, and its establishment in 2002 (Schabas 2004). The tribunals and the court are confronted with numerous legal and procedural problems in the prosecution and punishment of mass atrocities. The sheer numbers of perpetrators and victims in particular pose problems to less developed systems of criminal justice as in Rwanda, or might exacerbate group conflicts in a situation of political and social crisis. Truth commissions, truth and reconciliation commissions, the combination of legal procedures with amnesties, or other frameworks of restorative justice are currently seen as promising solutions to the problems of making perpetrators accountable and doing justice to the victims of genocide.

genre

Roger Horrocks

A genre is any group of texts identified as sharing a cluster of characteristics (such as structure, theme, style, mood, spatial or temporal setting, or function). The term may imply a precise list of characteristics or be used more flexibly as a way of exploring “family resemblances” (in Wittgenstein’s sense of that phrase). New genres

are constantly being identified, but use value determines whether a proposed grouping gains long term acceptance. The most useful tend to be highly specific groupings of examples which are closely related in space and time as well as form, regarded as “subgenres” of traditional genres. The idea of genre is not only a conceptual tool of scholars, but is also employed constantly in everyday life in the production, distribution, and reception of media products. In that sense it calls for investigation as an important social and industrial (as well as creative) phenomenon. Indeed, it has been studied for so many centuries that sophisticated traditions of theory and criticism have developed around it, reflecting changing conceptions of the text and its relationship with social contexts. Those traditions have sometimes remained specialized and separate (within the arts, linguistics, and media industries), but in recent years there has been an increased emphasis on interdisciplinary approaches that seek to articulate the semiotic with the social.

The identification of a genre is the beginning rather than the end of analysis. Because of the breadth of the term it is important to specify the particular methods of construction or analysis linked with it, but basic to all is the activity of sorting or classification. Like “generalization” and “gender,” the English word “genre” looks back to *genus*, the Latin word for type or kind. The organization of textual study by genre is analogous to the biological classification of living organisms in terms of species and genus; and historical research on the development of genres may be likened to the study of evolution. Since genre analysis sees value in a researcher’s knowledge of many examples, it has potentially a quantitative as well as qualitative dimension. This aspect became increasingly important as the mass production of media products and their availability expanded. At the same time the term genre came to be associated with debates about the vulgarity of “mass culture” and the ideological conformity it was seen as promoting. Most scholars today would insist on a value free use of the term genre, but until recently genre criticism has tended to combine formal analysis with aesthetic or moral value judgments.

The idea of distinguishing genres and subgenres was already present (under various terms)

in the work of ancient thinkers such as Aristotle, who wrote in his *Poetics*: "Our subject being Poetry, I propose to speak not only of the art in general but also of its species and their respective capacities." Such criticism became a common activity in all the arts. It was often based on the aesthetic appreciation of ideal rather than typical examples, and social aspects such as the relationship with audiences tended to be analyzed by a process of deduction. In relation to artistic production and distribution, the idea functioned in very complex ways, since it not only described what had already been made, but reinforced the natural tendency for artists to learn and borrow from one another. Genres developed distinctive traditions and strict conventions, with specialist producers and connoisseurs. This tendency also assisted marketing. Shakespeare parodied its uncritical use in Polonius's remarks to Hamlet about a troupe of actors he regarded as the best in the world for all the main theatrical genres – "tragedy, comedy, history, pastoral, pastoral comical, historical pastoral, tragical historical, tragical comical historical pastoral . . . [etc.]."

In European art criticism, lists of genres (such as the list established by the *Académie Française*) tended to carry hierarchical implications. In the twentieth century a new approach to status was proposed by social theorists such as the Frankfurt School, who associated "genre" with the commercial products of mass culture, contrasting them with individualized examples of art that were too complex to be adequately discussed in generic terms. This tradition of genre analysis focused on standardization and gave rise to many Marxist studies of the ideology said to be embedded in particular genres. As an adjective, the term genre came to be widely used as a critical shortcut, with "genre films" (for example) contrasted with "art films." Later researchers have tended to reject the value assumptions implied by this tradition and its neglect of some of the complexities of reception. (They also see no reason why "art films" should not be analyzed in generic terms.) Nevertheless, the Frankfurt tradition retains relevance for any critique focusing on cultural mass production and the centralized control of media industries.

Less polemical forms of genre analysis developed in linguistics. Bakhtin's (1986) essay proposed a taxonomy of types of "utterance"

associated with various social activities. Literary readings or scientific lectures might be more complex than speeches of greeting or farewell, but all were part of the same spectrum of human communication, involving "relatively stable and normative forms." Artistic (or "secondary") speech genres such as the play or the novel drew upon everyday ("primary") speech genres and transformed them for their own purposes. Applied to both written and spoken communication, this type of generic analysis has come to be used not only in linguistics but also in general education, with students acquiring both social and linguistic competence as they develop a repertoire of "text types." In some respects this tradition looks back to the Renaissance study of rhetoric in its emphasis on generic conventions and social effectiveness. Many forms of social analysis – including organizational and business studies – have found it important to acknowledge the generic aspects of human communication. Each change in media technology has provided the linguist with new types of text to classify, such as Internet communication with its expanding genres of email, website, chatroom, and blog.

There have also been cognitive studies of the process of genre recognition at work in all forms of sorting, from Internet searching to library classification. Many American libraries use a standard system of generic classification known as GSAFD (Guidelines on Subject Access to Individual Works of Fiction, Drama, Etc.). Generic approaches compete or are combined with alphabetical, chronological, and geographical systems of ordering. Classification systems have become an important object of study in themselves, with changes in genre categories cited as historical evidence. Skeptical writers have sought to question the adequacy and social influence of all such systems. Jorge Luis Borges, once Director of the National Library of Argentina, created a witty cautionary tale in his story "The Analytical Language of John Wilkins," which imagined an encyclopedia based on a taxonomy that defied all conventional logic.

The concept of genre, in both judgmental and non judgmental forms, continues to pervade daily life. Faced with a proliferation of media products, consumers struggle to locate texts of the types that interest them. Advertising

and packaging for books and recordings, films and television programs (or channels) make use of generic terms as a marketing shorthand. Stores are divided generically to assist both the customer and the store assistant to locate a particular item or group of related items. Categories vary from country to country and from one retailer to another, but customers adapt quickly because they are familiar with the process. The discovery of a genre and evidence of public interest in it imply the existence of a particular audience or market niche, thus encouraging the creation of similar products to satisfy a known taste. This is important for expensive, high risk media such as film and television. As a genre attains stability, specialist producers emerge (publishers, film companies, writers, technicians, record labels, etc.), along with distribution and exhibition networks (such as specialized stores, film distributors, radio stations, television channels, cinemas, etc.).

There have been a number of studies in recent years of reading communities associated with particular genres of popular culture, seeking (in a non judgmental way) to analyze the uses and gratifications involved. Janet Radway's *Reading the Romance* (1984) was an influential study of women reading "romance" novels, combining textual analysis of the genre with an ethnographic study of reception. Such studies have made us more aware of the complex nature of the transaction with formulaic material. The genre enthusiast derives convenience and pleasure from the mix of old and new ingredients, developing a comfortable sense of familiarity and insider knowledge as well as the opportunity to attempt to predict and to be surprised. Recent reception and industrial studies have revealed an unexpected complexity in popular culture and popular genres, despite the calculated simplicity of their surface features.

Popular music offers some particularly striking examples both of these cultural phenomena and of the scholarly work that analyzes them. The increased size, energy, and diversity of popular music have undercut sweeping criticisms of its mass produced nature. Change is extremely rapid, with each genre generating a rapid succession of subgenres, reflected in the changing organization of any large music store. (The genre of Electronic Dance Music, for example, rapidly diversified as House, Jungle,

Drum and Bass, Techno, Gabber, Trance, Acid House, Trip Hop, Ambient, Breakbeat, and a myriad of other subgenres, sometimes mating with larger genres such as Hip-hop, Reggae, or Heavy Metal.) These changes have been particularly interesting for those involved in cultural studies because forms of popular music are often associated with distinctive subcultures (an area of study developed by Dick Hebdige). Such a subculture involves particular kinds of venue, slang, styles of dance, types of dress, iconic heroes, etc. These social and cultural conjunctions have been the subject of recent studies by Simon Frith, Steve Redhead, and Nabeel Zuberi.

Various forms of industrial analysis have been applied to the commercial contexts of genre. Many studies of the media have focused on texts and their production, or in recent years on reception. Distribution and retailing remain relatively neglected topics, despite the importance of those activities in limiting access to cultural products. Artists are highly aware of them because of the difficulty of gaining distribution or visibility for work that cannot be marketed in terms of current categories. Some academics have expressed a similar suspicion of the conservative functioning of genre in the marketplace. This is one area in which the concerns of Frankfurt School critics such as Adorno are still compelling. At the same time, there are many complexities to be taken into account, for the idea of genre has many stakeholders – including fans, production companies, distributors, retailers, censors, and critics, as well as creative people. While some groups are able to exercise greater power, each group has its own perspective and priorities, and all are to some extent interdependent.

In contrast to early genre criticism which tended to focus on a few ideal, permanent, uncontested types, the modern approach tends to be empirical and inductive, aware of diversity and rapid change, and fascinated by social context. But how to interpret the links between a genre and its audience? Psychoanalytical approaches have often been applied to genres such as the horror film. There are strong connections with the social sciences in the industrial, ideological, subcultural, and ethnographic methods of analysis discussed above. How a genre develops in textual terms can sometimes be linked to technological changes – for

example, the evolution of film musicals as sound equipment became more flexible, or the new wave of films based on fantasy and comic book characters made possible by computer special effects. Yet single factor explanations are seldom adequate in this complex field and researchers need to consider audience responses and commercial trends as well as production possibilities. Major social changes can have an obvious impact on established genres, for example in the more prominent roles played by women in western popular culture since the 1960s, or the more explicit treatment of sexuality. Such changes have had an impact on many genres, from the thriller to the romance novel. Yet cultural and media studies writers remind us that such trends within a stylized genre still involve a sophisticated process of mediation, for example by fulfilling escapist desires.

The subject of film studies has provided a particularly important site for the analysis of genre. The concept of the auteur (or director with a unique style and vision) has sometimes been opposed to the concept of genre, but French critics such as André Bazin valued the genre as a context in which auteurs could display their individuality – as John Ford reshaped the western and Alfred Hitchcock experimented with the thriller. Both auteur and genre forms of criticism are based on groupings of related texts. Artists in all fields have been attracted to genres, as rich concentrations of cultural activity and as useful frameworks. Some innovators, such as composer Igor Stravinsky, have found their very constraints creatively stimulating.

From the 1960s, however, structuralist criticism shifted attention from auteurs to the collective structures of language and culture. It also helped to move criticism away from value judgments, including its tendency to privilege realism. It applied Saussure's relational approach to language to the relationship between texts, and its genre studies drew upon Propp's analysis of folktales and Lévi Strauss's studies of myths – their variant versions, their "bricolage" (or recombination of existing elements), and their problem solving functions. Structuralist critics saw genres as mechanisms for mediating fundamental tensions – for example, oppositions in the western between law and disorder, civilization and wilderness, nature and culture, male and female, East and West, etc. But structuralism

tended to move beyond genre to a broader understanding of discourse. Gerard Genette saw genre as only one of a range of types of "transtextuality." Poststructuralism went still further in announcing the "death of the author" and rejecting any notion of the unitary text – or genre – as an illusion. Although the concept of genre was discussed by Barthes, Kristeva, and Derrida, their basic aim was to destabilize it. Though coming from a different angle, ethnographic studies of reception have also tended to shift attention away from genres as patterns of regularity towards the freedom and diversity of reading practices.

Despite these challenges to traditional criticism, the basic concept of genre has survived strongly – in everyday life, as a linguistic tool, and as a subject of industrial and cultural analysis. It has emerged from the debates of the last thirty years in a more flexible form, shedding any residual tendency to essentialism, reification, or moralism. It is expected today that any one doing genre criticism will at least consider the complexities of reception and production (though other industrial aspects such as distribution may still be skimmed over). While continuing to value skills of textual analysis, genre criticism has moved to a complex awareness of social contexts – such as readers, subcultures, institutions, and commercial networks – combined with an interest in historical change. This eclectic and sometimes provocative approach provides new perspectives on texts of every kind, regardless of their milieu or status. Genre building has itself been studied as a form of social construction and this has encouraged the activity to become more self critical and reflexive. The conventions, styles, and social contexts of text production associated with any academic field – such as genre criticism, or sociology – can be usefully subjected to genre analysis.

Such articulation of the semiotic with the social has so far mainly benefited the fields of cultural and media studies, but some sociologists have taken an interest. As an example of this fruitful exchange, Thomas Luckmann, one of the authors (with Peter Berger) of *The Social Construction of Reality*, has contributed to the study of communicative genres. Many aspects of sociological investigation can benefit from a more than perfunctory appreciation of their

linguistic, semiotic, or rhetorical aspects, and genre analysis offers a valuable set of tools.

gentrification

Jason Patch and Neil Brenner

Gentrification entails the reinvestment of real estate capital into declining, inner city neighborhoods to create a new residential infrastructure for middle and high income inhabitants. In coining the term “gentrification” in 1964, Ruth Glass emphasized that class relations lie at the core of the process, which has generally involved

the displacement of working class residents from inner city zones and the gradual influx of a new “gentry” of well off professionals.

Equally relevant, but often less noted, is the role of gentrification in accelerating the displacement of blue collar jobs from the urban core. Since the 1960s and 1970s, most manufacturing cities in the United States, Great Britain, and continental Europe have seen a steady decline in industrial production. As capitalists relocated manufacturing activities from the inner cities to the suburbs and abroad, disinvested property remained, and was often left in a derelict, decaying condition. Subsequently, as of the 1980s, information based financial and producer services industries gradually superseded the traditional manufacturing based urban economies of the Fordist epoch. Within the new, post Fordist configuration of urban development, professionals and white collar workers generated a new demand for upscale housing in closer proximity to revitalizing downtowns. Under these conditions, devalued inner city property was increasingly seen by large real estate capital as a basis for reinvestment and profiteering. As Neil Smith indicates, one crucial precondition for the process of gentrification is the existence of a “rent gap” enabling real estate capitalists to exploit the difference between the potential value of a property under some future “highest and best use” and its actual value under the inherited land use regime. While considerable debate persists among urban scholars regarding the degree to which the existence of rent gaps can effectively explain the timing and location of gentrification, there is today widespread agreement that this process has been facilitated in crucial ways through the speculative inner city investments of real estate capitalists.

As gentrification proceeds apace, inner city neighborhoods and other marginalized urban enclaves undergo significant sociospatial changes. Most significantly, there is a transformation of the built environment. New buildings are constructed; extant buildings are converted into luxury housing; industrial space is converted to mixed live work or residential space; and new commercial establishments (such as upscale restaurants, coffee shops, boutiques, art galleries, and high end clothing shops) are introduced. The New York City neighborhoods of SoHo in the 1960s and 1970s and Williamsburg,

Brooklyn in the 1990s represent classic instances in which the shift from small scale manufacturing factories to artist lofts, gallery spaces, and new retail activities has occurred. In addition, there is also a significant rearticulation of the social fabric. Established class based and ethnic milieus are destabilized or dissolved as new economic and cultural elites – often, but not always, composed of whites – move into the area. Philadelphia's Society Hill, with its predominantly African American community, was an early site of this wholesale change in a neighborhood's class and racial composition.

The first signs of gentrification became evident, albeit in highly localized forms, during the 1960s in the older inner cities of North America, Western Europe, and Australia. During this early phase, gentrification was guided by national and local governments concerned to counteract economic decline in inner city neighborhoods by encouraging private investment. Processes of gentrification became far more widespread throughout the older industrialized world following the global economic recession of the 1970s, as capitalists sought new opportunities for profitable investment in the real estate sector. Thus, between the late 1970s and the early 1990s, a second phase of gentrification unfolded. During this period, inner city reinvestment articulated with deeply rooted economic changes such as deindustrialization, the globalization of urban production systems, the enhanced urban concentration of corporate command and control capacities, and the rise of the so called FIRE (finance, insurance, and real estate) industrial cluster as an important engine of urban economic growth. During this period, moreover, the spatial frontiers of gentrification were expanded significantly as formerly marginalized neighborhoods, such as New York City's Lower East Side, were now targeted for extensive, high end real estate development. In the early 1990s, with the recession in the United States, some scholars predicted an "end to gentrification" as investor capital evaporated. Instead, following the recession of the early 1990s, a third wave of gentrification has begun to crystallize, as additional neighborhoods, located ever further from the city core, have experienced significant capital led redevelopment. In the US context, according to Smith & Hackworth (2001), this third wave of

gentrification has been supported, and in many cases directly financed, by local and national government agencies.

One major geographic consequence of gentrification in the US has been to unsettle the socioeconomic geographies that were inherited from earlier rounds of capitalist development, generating an urban sociospatial configuration that appears to be gradually inverting Ernest Burgess's famous concentric circle model. In the new model, the wealthy and middle classes have come to dominate the central zones of the city, whereas the working class and ethnic minorities are increasingly relegated to distant commuter zones. However, even as the process of gentrification spirals outwards from inner city zones to colonize new neighborhoods, it must also be viewed as a cyclical phenomenon in which individual neighborhoods often experience multiple rounds of reinvestment.

In addition to these structural, political economic, and geographical aspects, urbanists have also devoted detailed attention, on a microsociological level, to the *agents* of gentrification processes. In the earliest stages of gentrification, marginalized social groups – such as artists, gays, and middle class blacks – have played key roles. These "early" gentrifiers renovated dilapidated housing using their own sweat equity. These new residents have helped restore buildings, thus increasing their property value. Artists have often converted warehouses into mixed live work space; and they have aided in transforming formerly industrial areas into residential areas. City governments and local landlords have generally favored such small scale conversions, which are viewed as a means to increase property taxes and rents. In deference to these new residential patterns, city governments have often retroactively rezoned industrial areas to permit mixed uses. Ultimately, however, these gentrifying segments of the middle class have tended to colonize working class or ethnic minority neighborhoods and to price out long term and low income tenants. Furthermore, many early gentrifiers eventually become the victims of their own renewal efforts. By improving local property and lobbying for more city services, early gentrifiers increase property values and rental prices, thus creating the conditions for later, intensive rounds of gentrification and their own displacement.

As a subject for study, gentrification has generated multidisciplinary attention, especially among urban geographers and urban sociologists. While gentrification always unfolds in place specific forms, urbanists have debated extensively regarding its overarching features and consequences. In particular, Smith's rent gap theory, mentioned above, has provoked considerable debate. Smith's work emphasizes the essential role of real estate capital in animating the process of gentrification. In this manner, Smith's influential writings supersede earlier explanations that attributed neighborhood reinvestment to the renewed desire of middle class populations to live in the inner city. Concurrent with and subsequent to Smith's supply side analysis, however, other scholars have explored the demand side aspects of gentrification through a materialist lens. David Ley (1996), for instance, suggests that the new middle classes created a broad aesthetic appreciation for urban life in conjunction with the countercultural movements of the 1960s and 1970s and the subsequent round of urban restructuring. Similarly, Damaris Rose (1984) and Liz Bondi (1994) emphasized the distinctive gender patterns related to gentrification, in part due to the changing life conditions of middle class women. Indeed, the question of how to reconcile the demand side and supply side elements of gentrification remains an enduring, but productive, intellectual tension in this research field. Loretta Lees (2000), among others, has sought to pinpoint lacunae in gentrification research, and on this basis, to direct attention towards cross national comparisons and ethnographic forms of spatial analysis. Additionally, art historians have taken an interest in gentrified neighborhoods as venues for new forms of art production, as sites for artistic creativity, and as a source of political conflict within the art world itself. And finally, city planners and architects have approached gentrification less as a theoretical issue than as an opportunity to rethink key aspects of urban design and urban development strategy.

Multiple ethnographic and demographic case studies examine particular types of gentrifiers, such as artists, gays, college graduates, single women, and young professionals. Such studies create typologies between "early" or "marginal" gentrifiers (low income newcomers who

invest sweat equity into their residences) and "late", "super," or "yuppie" gentrifiers (those with the financial resources to purchase property outright). Gentrification may thus enable members of socially marginalized groups to secure their own property as well as community resources. Gays and lesbians, for instance, are often key players in the gentrification process as they seek to avoid areas of overt discrimination and to find locations in which they can be "out" in their own commercial enterprises and public social activities. Similarly, artists looking for large open studio spaces frequently agglomerate in former industrial zones and engage in extensive renovations of space. Zukin's (1989) study of SoHo in New York City discusses the archetypical case of artists appropriating manufacturing warehouses, with city government and landlord encouragement, leading in turn to subsequent waves of high end gentrification.

Many scholars use the case of gentrification as a basis for conceptualizing both the hopes and the horrors of urban living. In contrast to most of mainstream urban sociology, many writers on gentrification are influenced by radical or Marxist scholarly traditions, and thus tend to view middle class forms of urban reinvestment as expressions of growth machine politics and narrowly private accumulation strategies. Indeed, the struggle over neighborhood space, aesthetics, and resources is often thought to exemplify contemporary class and racial tensions within major metropolitan regions. However, many case studies show a more complicated picture. Often, the most fervent resisters to gentrification are themselves early gentrifiers who fear being priced out of neighborhoods to which they have grown attached. Many long term residents are able to partake in new services, and those who own property are often able to realize profits on long undervalued holdings. Also, the key concern about gentrification, the displacement of low income residents, is complicated by countervailing policy initiatives that sustain the location of minority residents in neighborhoods that are undergoing intense redevelopment. Still, many landlords, especially absentee and corporate ones, aggressively seek to remove low income tenants in order to realize higher rents. In this sense, as Neil Smith (1996) has argued in an influential intervention, gentrification can be viewed as a medium and expression

of the new forms of urban exclusion and “revanchism” that have been consolidated during the last two decades.

In the past decade gentrification studies have moved well beyond their original geographic homes in New York and London. Gentrification is now found throughout North America, Australia, Eastern Europe, and also in rural, industrial towns on the outskirts of major cities in the US and the UK. Its expansion may be expected to continue for the foreseeable future, and so too may scholarly attempts to decipher its origins, dynamics, and consequences.

Several other forms of urban restructuring – such as mass suburbanization – continue to surpass gentrification in terms of the number of people involved, the amount of capital invested, and political significance. However, gentrification’s prominence in contemporary urban scholarship rests in some measure upon its role as a metaphor for the urban condition under modern capitalism. As in previous rounds of urban restructuring, city life is still perceived as being precariously balanced between the worst manifestations of capitalism – the breakdown of traditional family, social, and cultural structures, alienation, and intensifying racial and class polarization – and initiatives oriented towards urban renewal, preservation, creativity, and the “right to the city.”

Germani, Gino (1911–79)

Arturo Grunstein and Louise Barner

Gino Germani legitimately stands as one of the founding fathers of academic sociology in Latin America. From the start of his academic career, Germani affirmed the need to overcome the two “anti positivist” dominant traditions in Latin American social analysis: abstract philosophical speculation and conceptually poor empiricism.

To many scholars, Germani was the pioneer and leading representative of structural functionalism and modernization theory in the region. Nevertheless, scholars have often missed the complexity of Germani’s work, particularly its rich theoretical eclecticism (including, among other influences, those of Max Weber, Durkheim, Parsons, Merton, Freud, Mannheim, and José Medina Echavarría) as well as its innovative empirical studies and comparative historical

sociological analyses of Latin American development. In the context of an ideologically polarized Argentina of the 1960s and 1970s, many of his contemporaries, particularly a younger generation of critical Marxian and *dependentista* scholars, singled him out as a stalwart defender of the capitalist status quo and a reactionary sociologist. However, from an early twenty first century post Cold War perspective, Germani emerges as an advocate of liberal democratic development.

Throughout most of his personal and professional life, Germani struggled against what he conceived as the retrograde forces of tradition and irrationalism including religious dogma, totalitarian fascism, authoritarian peronism, and left wing revolutionary extremism. He firmly believed that the promotion of a scientific study of society was part and parcel of the advancement of liberal democratic modernization, which he closely associated with the twin processes of secularization and rationalization.

Born in Rome in 1911, as a young man Germani participated in the opposition against Mussolini. As a result, he was jailed for almost a year. The experience of repression and incarceration was critical in the formation of his political and sociological ideas. One of his central concerns became the changing meaning of freedom in complex societies.

Shortly after being released from prison, Germani began taking classes at the University of Rome, studying economics and accounting. In addition to enrolling in courses, he read many of the great classic and then contemporary authors including Kant, Hegel, Marx, Pareto, Spencer, and Durkheim.

In 1934 Germani and his mother migrated to Argentina. While working as a mid level federal bureaucrat, he registered for classes at the University of Buenos Aires (UBA). In 1943, he concluded undergraduate studies in philosophy. By that time, he was already a researcher at the UBA's Institute of Sociology. However, his professional career was temporarily derailed with the rise to power of Juan Domingo Perón in 1946. Once established, the peronista fascist inspired regime embarked upon the persecution of opposition politicians and intellectuals. As part of this repressive campaign, Germani, along with other liberal

and antiperonista professors, was purged from the UBA. In response, Germani joined a group of other opposition scholars in establishing a private independent college, Colegio Libre de Estudios Superiores.

In 1955, Germani published his first book, *Estructura social de la Argentina*. This work constituted a landmark and a model of empirical research in Argentina and the rest of Latin America. In researching and writing *Estructura social*, Germani mainly utilized the national census of 1947. Arguing that the book could threaten "national security," peronista censors impeded its publication. Shortly after a coup d'état overthrew Perón, Germani returned to the University of Buenos Aires. In 1957, the Institute was complemented with the foundation of a sociology department. The late 1950s were a truly golden age for Germani as he became the nation's leading sociologist. With the sympathetic support of the Frondizi government and various US foundations, Germani garnered financial resources that enabled the Institute and department to recruit professors, train students, and bring prestigious guest lecturers from Europe and the US. He was also able to travel and enjoy short academic residences at Harvard, the University of Chicago, and the University of California at Berkeley, where he met and established solid links with several leading US sociologists, including Robert Merton, Seymour Martin Lipset, and Reinhard Bendix.

By the early 1960s, Germani's department and Institute came under heavy criticism from both the right and the left. The Catholic Right charged that sociology would undermine traditional beliefs about God, nation, and the family; the extreme left wing attacked Germani for accepting grants from "imperialistic" US foundations and adopting a "reactionary" structural functionalist perspective.

This irrational ideological polarization convinced Germani of the fragility of liberal democracy in Argentina and the inevitability of another military coup. He was quite prescient about his adopted country's debacle. Shortly after his arrival in the United States, another military coup ousted the constitutional government in June 1966. Germani spent most of the last years teaching at Harvard University. He died in his native Italy in 1979.

UNDERSTANDING THE “TRANSITION”: THE MODERNIZATION PROCESS IN LATIN AMERICA

A review of Germani's publications immediately reveals that he held multiple sociological interests and had a diverse research agenda. Nonetheless, it also clearly evinces a central intellectual concern: Latin America's modernization process. He was particularly interested in identifying the social, political, cultural, and psychological factors intervening in the transition from “traditional” to “industrial” society. Thus, in his principal studies, Germani consistently pursued two fundamental and closely interrelated objectives: (1) the elaboration of a general or ideal typical model of the transition process from traditional to modern society and (2) the historical sociological and empirical analysis of this process in Latin America, paying central attention to the case of Argentina.

Germani's definition of *social structure* is akin to Parsons's: “a conjunction of different interrelated parts in which people act and interact in accordance with shared sociocultural codes and environmental conditions.” From the outset, Germani acknowledged the diversity of traditional and industrial societies and, more importantly, the existence of “various forms of transition from the former to the latter.” Still, he singled out three basic types of social change: (1) changes in the normative structure that regulate social action and their corresponding psychosocial or “internalized” attitudes; more specifically, he refers here to the dwindling of prescriptive forms of action and the gradual rise, extension, and prevalence of elective action; (2) increasing specialization of values and institutions; and (3) the institutionalization of change. Thus, Germani explained that modern industrial society is characterized by the secularization of knowledge, an increasingly complex division of labor based on efficiency criteria, and the transformation of family from extended to isolated nuclear units.

Nevertheless these changes take place in an *asynchronous* fashion. In other works there are lags and disequilibria between sectors and spheres. In his analysis of Latin American political development, Germani underlined one fundamental form of asynchronism – the

imbalance between social mobilization and integration. These two sociopolitical notions, mobilization and integration, are essential to understanding the transition and particularly the dynamics of intergroup conflict in the context of long term processes of social change.

Germani defined an integrated society as one in which reciprocal congruence prevails in the normative, psychosocial, and environmental spheres. In an integrated society the system and subsystems of norms, statuses, and roles correspond sufficiently to allow a relatively stable functioning of society. Individuals have also adequately internalized compatible sets of values, roles, and attitudes. Finally, the environmental context (including material and non material conditions) is well matched with actions based on predictions and expectations stemming from the dominant normative and psychosocial structures. Conversely, social “disintegration” takes place when norms, values, their internalization, and the context in which actions evolve lack adjustment.

In some cases this lack of adjustment produces a state of anomie, affecting group behavior and the functioning of formally established legal spheres. According to Germani, under conditions of unsuccessful integration, anomie may lead to irrational social action on behalf of both elite and popular groups. Anomic tendencies initially emerge only in limited spheres of the social structure but frequently spread to others in a domino effect. Therefore, anomic forces commonly threaten the stability of systems and subsystems and impede or delay the modernization of normative spheres and adequate civic behavior. Specifically regarding the political system, a state of anomie can be catastrophic, as social discontent may result in unmanageable conflicts and the rise of opportunistic authoritarian leaders.

For Germani “integrated society” was only an ideal type. Virtually all societies manifest varying degrees of “disintegration.” Since social change is almost always asynchronous it entails a certain measure of disintegration, or the loss of adjustment within and/or between the three – normative, psychosocial, and environmental – spheres.

Germani then focused on participation as one particular, albeit fundamental, aspect of social integration. In traditional societies participation is spatially limited to small areas,

economic activities take place in isolation, most community members do not partake in political decision making, and a majority are excluded from enjoying the material and non material fruits of general culture. In contrast, in industrial society, mass participation is found in most or all of these social activities.

Subsequently, Germani further distinguished between “integrated participation,” that is, under conditions of normative, psychosocial, and environmental congruence, and “disintegrated participation,” that is, without correspondence to what is normatively and psychosocially expected and what is possible, given the existing environmental context.

Disintegration in one of the three basic dimensions mentioned leads to what Germani denominated “disposability,” indicating that “the groups affected must notice the change and perceive it as an alteration which makes former prescriptions inapplicable.”

Based on these concepts, Germani elaborated a transition model for Latin America. The following discussion focuses on the sphere of political development, which Germani privileged in his analysis. In specific reference to sociopolitical changes, he identified several fundamental stages:

- Wars of liberation.
- Civil wars, *caudillismo*, anarchy.
- Unifying autocracy.
- Representative democracies of limited participation.
- Representative democracies of extended participation.
- Representative democracies of full participation.
- National popular revolutions (as an alternative to the three previous stages).

Germani was perfectly aware of the important limitations inherent in such a scheme. First and foremost, considerable national and even regional or subnational variations could be found. He explained, however, that his scheme was merely a starting ground that would necessarily undergo corrections and modifications on the evidence of individual cases. The three phenomena – mobilization, integration, and disposability – are central in his sociohistorical analysis.

The first generation of creole political elites attempted to build modern democratic nation states disregarding their societies’ deep seated traditional structures. The Latin American bourgeoisie were in an embryonic phase and the remaining groups and classes – a large majority of the population – were deeply enmeshed in traditional normative and psychological structures. In addition, the power vacuum following the collapse of the colonial authorities led to severe cultural and territorial isolation of most of the population.

Consequently, independence was followed by a second phase of territorial disarticulation, political anarchy, and civil wars between *caudillo* led factions. As charismatic authorities, *caudillos* enjoyed broad popular support, but they seldom altered the existing traditional social structures. In many nations, this period of chaos and violence concluded when one *caudillo* was able to defeat his rivals and emerge as a dominant political figure nationwide.

During the third stage, “unifying autocracy,” the basic sociocultural traditional structures persisted, but some dictators forcefully promoted economic modernization by opening up their nations to international markets as producers of primary goods, foreign capital investments especially for infrastructural development such as railroads and ports, and, in some countries, the influx of massive immigration.

During the fourth stage, democracy with limited participation, personal dictatorship was replaced with oligarchic rule. Even though only a minority of the population were allowed to participate, the rules of the political game were being gradually institutionalized. Economic modernization led to a dual structure: the rapid growth of modern infrastructure and export enterprises in central zones accelerated urbanization and the emergence of new middle and working classes. Meanwhile, most of the nation’s inhabitants remained trapped in traditional patterns characterized by subsistence agriculture, small isolated communities, and local authoritarian forms of domination. In most instances, these social sectors remained politically passive. This was partly as a result of oligarchic authoritarian exclusion, but, as Germani pointed out, it was mainly due to enduring traditional psychosocial factors. In some nations, the process of mobilization, especially of the urban middle sectors,

gradually led to an awakening of some sectors and the widening of the sphere of political participation.

The next stage, which Germani termed “extended participation,” dawned with the formation of an alliance between the strengthened middle classes and recently mobilized segments of the mostly urban working class, also undergoing rising expectations regarding their incorporation into the national political arena. In the most advanced countries of the region, these previously marginal groups were successfully integrated and their participation was institutionalized. While intergroup conflicts frequently erupted, these new legitimate popular members of the national polity increasingly accepted the existing rules of the game. Still, during this phase, broad sectors of the population, particularly those living in rural areas, remained excluded.

“Total participation,” the sixth and final phase, takes place when these residual groups are finally integrated. Germani devoted considerable attention to this last period. By the mid twentieth century, no Latin American country had successfully institutionalized mass political participation. Most nations, including the most developed ones, experienced knotty transition processes marked by unrelenting cycles of progressive democratization and authoritarian regression. Not even Argentina, which had moved dynamically from extended to total participation, had managed to build stable integrative mechanisms.

Why had Latin America been unable to complete the transition to fully participatory modern democracy? Why couldn’t Latin America match the transition patterns and eventually catch up with advanced western nations? Based on his theoretical and historical sociological scheme, Germani identified three principal causes.

The first factor was that significant structural differences – in norms, values, etc. – were found between Latin America and western societies. In effect, one could refer to the existence of both traditional and modern aspects in general, ideal typical terms. Still distinctive, deep seated historical specificities led to a “relative inapplicability (of a higher or lower degree depending on individual cases) of the western model” to analyze the transition in Latin America.

Although asynchronisms were, indeed, present in every transition process, they were more acute and widespread in late modernizing societies such as Latin America’s. The fact that modernization was late and often triggered by external forces generated intense demonstration and fusion effects. Consequently, the pattern of social change diverged significantly from the western experience. Not only were the rhythm and speed different, but also the sequence of the transition was altered. Thus, for instance, social mobilization leading to popular consumption demands and unionization often exceeded the development of the national economy’s productive capacity and a fluent internalization of socio structural change. In many western nations, the equilibrium of the social system at different stages “was assured by the fact that the population not yet included does not exert pressure (or, at least, not a dangerous degree of pressure) because it remains passive, and the sequence is such that when it later becomes active there should be existing mechanisms capable of channeling participation without catastrophic disturbances for the system (although obviously not without relatively sharp conflicts).” In contrast to the European experience, the extension of political rights in Latin America was taking place in a swift if not explosive fashion, giving almost no leeway to building effective institutional channels of participation and the internalizing of adequate civic values and attitudes by mobilized groups.

Compared to the US and most of Europe, the historical ideological “climate” was overall adverse to the assumption of liberal democratic institutions as mechanisms for mass integration. In most Latin American nations, extensive mobilization took off in the age of the “welfare state.” In advanced nations, the “welfare state” was the culmination of a protracted developmental process, including the evolution from proprietary to corporate capitalism. However, by the mid twentieth century, the ideal of social citizenship was universalized. Consequently, mobilized popular groups in economically and politically laggard nations, among those many Latin American nations, demanded the extension of social rights within a compressed point in time. Just as this occurred, World War I led to a prolonged crisis of liberal democracy and it was challenged by both right and left wing

authoritarian and totalitarian alternatives, offering new forms of sociopolitical integration. Although fascism was defeated in World War II, during the Cold War soviet communism became an increasingly powerful modernization model for many late developing countries, including Latin America's. Thus, "ideologies of industrialization" in Latin America often assumed a mix of authoritarian conservative nationalism and socialism. These movements and regimes, which Germani classified as national popular, were difficult to classify on conventional right-left criteria.

Germani emphasized that the appearance of national popular movements is what made Latin America's transition to extended and total participation distinct from the classical western liberal democratic path. Elites usually elaborated these doctrinal hybrids in order to manipulate and contain the pressures stemming from mass popular mobilization. These elites allowed lower strata participation only to the extent that it did not effectively threaten existing social structures. In the process of social integration, nationalist symbols, a powerful means to integrate widely diverse mobilized popular groups, replaced liberal democratic values and institutions. The traumatic process of transition from traditional to industrial society in most of Latin America explained, according to Germani, the tendency of certain popular sectors to support authoritarian (both left and right wing) movements and regimes. However, sooner or later, participation for broad sectors of the population revealed itself as "ersatz" or illusory, and not as a genuine process of politically institutionalized integration. Such was the case of peronism, which, for obvious reasons, Germani studied at great length.

From its origins, peronism had a close ideological affinity with fascism. However, in sociological terms, the peronista version differed markedly from its European counterpart. In Argentina's sociopolitical context, Perón could not find and recruit large scale support from a mobilized petty bourgeois sector seeking to shut off proletarian participation. Instead, Perón maneuvered to build a strong popular basis of support for himself, consisting mostly of the recently mobilized working classes that migrated to Buenos Aires and other large urban centers from the interior provinces. These previously

marginalized groups had experienced radical and sudden social changes within the span of approximately a decade. While General Perón ostensibly opened up the gates of the national public arena for these social groups, once incorporated he rigorously conditioned and limited their participation. Unionization was encouraged, important wage increases were granted, and working conditions improved. Labor enhanced its bargaining position vis à vis employers. Still, the authoritarian regime managed to keep a tight lid on popular organizations and their political activities and demands. In other words, Perón conceded to the workers, so long as it could be done without compromising his regime's statist authoritarian project. Most importantly, reforms were never geared toward real long term structural changes such as the establishment of steady channels of participation. On the contrary, they were often aimed at preventing them. Under Perón, the working masses had been partially integrated but not on the basis of modern, liberal democratic institutions.

Why, then, did the masses stubbornly support peronism? Herein lies what Germani referred to as the "irrationalism" of Argentinean popular political behavior.

A central factor was the swiftness of the transition, including the spatial movement from relatively stagnant rural zones to rapidly modernizing urban centers. Mobilized groups surpassed the capacity of available integration mechanisms, thus becoming "disposable." Moreover, these mobilized and disposable masses had only partially internalized modern values, norms, and attitudes. About 57 percent of these migrants arrived in Buenos Aires after 1938, and by 1947 a majority had come from the most backward provinces, measured in terms of literacy, employment, and poverty levels. Partially stuck to traditional normative and psychosocial structures and lacking a sophisticated political culture, they were susceptible to Perón's charismatic leadership and national popular blandishments.

Germani acknowledged that the new working classes certainly had important reasons to back Perón. It was undeniable that they had enjoyed both the material and psychic benefits of "peronista freedoms" (to organize in unions, to gain public recognition and even respect as

laborers, to improve their working conditions and consumption levels). Nevertheless, the historic costs of these concessions were high and consequential: in exchange for short term gains, the workers lost political and organizational independence, thus blocking the possibility of attaining durable channels of effective participation.

As events following Perón's downfall revealed, Argentina persistently faced insurmountable difficulties in attaining adequate integration of the mobilized masses. Consequently, conflicts often culminated in extensive violence. Building and maintaining a stable participatory political and social structure based on liberal democratic institutions became virtually hopeless.

It would be erroneous to underestimate Germani's scholarship. Despite serious adversities, he was the principal force behind the foundation of academic sociology in Argentina. His theses concerning the asynchronic mode of late modernization, the dynamics of social mobilization and structural change, and the sociological meaning of different manifestations of authoritarianism are now considered as fundamental points of analytical departure in Latin American studies.

His principal works should also have inspired a more ambitious research agenda in macro comparative Latin American historical sociology. Thus, for instance, Germani's critics often overlook his comments on our lack of sufficient empirical and historical knowledge regarding working class ideologies and political culture, and his enthusiastic calls for such investigations. Only then, he contended, will we be able to elaborate firmer arguments on changing popular attitudes toward authoritarian and populist leaders, movements, and regimes. Using one of Germani's own concepts, the "historical climate" of his times may have been unfavorable not only for liberal democratic modernization, but also for a more balanced and productive evaluation of his theoretical and empirical findings. As the twenty first century dawns, his intellectual and political concerns have gained tremendous pertinence for contemporary debates on the region's future. This is particularly so regarding the structural obstacles to liberal democracy in Latin America based on both morally and intellectually compelling questions about the societal underpinnings of freedom and oppression.

gerontology

Jason L. Powell

Gerontology can be defined as the scientific and social analysis of aging. The discipline of gerontology is concerned with understanding age and aging from a variety of perspectives and integrating information from different social science and human science disciplines such as psychology and sociology. The concern of gerontology is in the definition and theorization of age. In western societies a person's age is counted on a chronological or numerical foundation, beginning from birth to

the current point of age, or when an individual has died. Chronological aging is a habit we all engage in: birthdays and wedding anniversaries, for example. Counting age is a social construction because it is a practice underpinned by the development of industrial capitalism.

Age has three main focal points of interest to gerontology. First, the aging of an individual takes place within a particular period of time and space. By virtue of this, individual experiences of age are enabled or constrained by their location in time, space, and cultural uniformity. Second, society has a number of culturally and socially defined expectations of how individuals of certain ages are supposed to behave and how aging impacts upon how they are compartmentalized into the "stages of life." Historically, the stages of life were presented as a religious discourse which formed the basis for the cultural expectations about behavior and appearance. The life stage model is still used in taken for granted popular usage in society, which impinges on how our lives are structured. Third, age and aging have a biological and physiological dimension, so that over time and space the appearance of physical bodies changes. This latter definition has been illustrated by "biomedical gerontology," advocating scientific explanations of aging.

Gerontology as a *scientific discipline* has been dominated with a preoccupation with biomedical sciences and its constituent elements of "decline" models of biology and psychology. Gerontology based on *social* explanatory models sees aging as a socially constructed category with differential epistemological prisms (e.g., functionalism and feminist gerontology). However, while both definitions are fundamental to the complexities of aging in the social world, the theoretical interpretations of aging are in their infancy when compared to the analysis and attention afforded to class, "race," and gender in sociological theorizing.

If we take the scientific and social dimensions of gerontology, we can illuminate both the relevance and importance they have for understanding constructions of aging. We can suggest that gerontology has two focal points in its broad conceptualization.

Psychological aging processes include changes in personality and mental functioning. According to Kunkel and Morgan (1999: 5), "changes

are considered a 'normal' part of adult development, some are the result of physiological changes in the way the brain functions." What is meant by "normal" development? The "decline" aspect of aging is something which was picked up by the historical rise of scientific discourse and Enlightenment discourses of truth and rationality. Indeed, age and aging have a biological and physiological dimension, so that over time and space the appearance of physical bodies changes. Physical aging, for the biomedical gerontology, is related to changing characteristics on the body: the graying of hair, wrinkling of the skin, decrease in reproductive capacity and cardiovascular functioning, etc. An interesting question is whether these physical changes are inevitable, "natural" consequences of aging.

Biological aging is related to changes of growth and decline within the human body. For example, Bytheway (1995) suggests that the notion of "growth" is a central scientific discourse relating to the true changes associated with human aging to the biological body. Growth is seen as a positive development by biologists in that a "baby" grows into a "child" who grows into an "adult," but then instead of growing into "old age" the person declines. This scientifically sanctioned perception is that growth "slows" when a person reaches "old age" and is subsequently interpreted as "decline" rather than as "change" that is taken for granted with earlier life course transitions.

The effects of the decline analogy can be seen in the dominance of biomedical arguments about the physiological "problems" of the "aging body." The "master narrative" of biological decline hides the location of a complex web of intersections of social ideas comprising an aging culture. Indeed, a distinctive contribution of sociology as a discipline has been to highlight how individual lives and behavior which were thought to be determined solely by biology (Powell 2005) are, in fact, heavily influenced by social environments in which people live and hence are heavily *socially constructed*.

The broad pedigree of sociological perspectives of aging can be located to the early post war years with the concern about the consequences of demographic change and the potential shortage of "younger" workers in the US and UK. Social gerontology emerged as a field of study which attempted to respond

to the social policy implications of demographic change (Phillipson 1982). Such disciplines were shaped by significant external forces: first, by state intervention to achieve specific outcomes in health and social policy; second, by a political and economic environment which viewed an aging population as creating a “social problem” for society.

This impinged mainly upon the creation of functionalist accounts of age and aging primarily in US academies. Functionalist sociology dominated the sociological landscape in the US from the 1930s up until the 1960s. Talcott Parsons was a key exponent of general functionalist thought and argued that society needed certain functions in order to maintain its well being: the stability of the family; circulation of elites in education drawing from a “pool of talent” (Powell 2005). Society was seen as akin to a biological organism: all the parts (education/family/religion/government) in the system working together in order for society to function with equilibrium.

A key point to note is that theories often mirror the norms and values of their creators and their social times, reflecting culturally dominant views of what should be the appropriate way to analyze social phenomena. The two functionalist theories contrasted here follow this normative pattern; *disengagement* and *activity* theories suggest not only how individual behavior changes with aging, but also imply *how* it should change. Disengagement theory is associated with Cumming and Henry (1961), who propose that gradual withdrawal of older people from work roles and social relationships is both an inevitable and natural process: “withdrawal may be accompanied from the outset by an increased preoccupation with himself: certain institutions may make it easy for him” (p. 14). Such withdrawal prepares society, the individual older person, and those with whom they had personal relationships for the ultimate disengagement: death. For this variant of functionalism, this process benefits society, since it means that the death of individual society members does not prevent the ongoing functioning of the social system. Cumming and Henry further propose that the process of disengagement as an inevitable, rewarding, and universal process of mutual withdrawal of the individual and society from each other with advancing age was normal and

to be expected. This theory argued that it was beneficial for both the aging individual and society that such disengagement takes place, in order to minimize the social disruption caused at an aging person’s eventual death.

Retirement is a good illustration of the disengagement process, enabling the aging person to be freed of the responsibilities of an occupation and to pursue other roles not necessarily aligned to full pay economic generation. Through disengagement, Cumming and Henry argued, society anticipated the loss of aging people through death and brought “new blood” into full participation within the social world.

A number of critiques exist: first, this theory condones indifference toward “old age” and social problems. Second, disengagement theory underplays the role cultural and economic structures have in creating, with intentional consequences, withdrawal. In order to legitimize its generalizations, disengagement theory accepted the objective and value free rigor of research methods: survey and questionnaire methods of gerontological inquiry. In a sense, arguing for “disengagement” from work roles under the guise of objectivity is a very powerful argument for governments to legitimize boundaries of who can work and who cannot based on age.

The second functionalist perspective in gerontology is called activity theory and is a counterpoint to disengagement theory, since it claims a successful “old age” can be achieved by maintaining roles and relationships. Activity theory actually predates disengagement theory and suggests that aging can be a lively and creative experience. Any loss of roles, activities, or relationships within old age should be replaced by new roles or activities to ensure happiness, value consensus, and well being. For activity theorists, disengagement is not a natural process as advocated by Cumming and Henry. For activity theorists, disengagement theory is inherently agist and does not promote in any shape or form “positive aging.” Thus, “activity” was seen as an ethical and academic response to the disengagement thesis and recast retirement as joyous and mobile.

Despite this, activity theory neglects issues of power, inequality, and conflict between age groups. An apparent “value consensus” may reflect the interests of powerful and dominant groups within society who find it advantageous to have age power relations organized in such a

way (Powell 2005). Such functionalist schools in gerontology are important in shaping social theory responses to them; such functionalist theories "impose" a sense of causality on aging by implying you will either disengage or will be active.

Marxist gerontology or the *political economy of old age* was coined as a critical response to the theoretical dominance of functionalism. This critical branch of Marxist gerontology grew as a direct response to the hegemonic dominance of structural functionalism in the form of disengagement theory, the biomedical paradigm, and world economic crises of the 1970s. As Phillipson (1982) pointed out in the UK, huge forms of social expenditure were allocated to older people. Consequently, not only were older people viewed by governments in medical terms, but also in resource terms. This brought a new perception to attitudes to age and aging. For example, in the US, political economy theory was pioneered via the work of Estes (1979). Similarly, in the UK, the work of Phillipson (1982) added a critical sociological dimension to understanding age and aging in advanced capitalist societies. For Estes (1979) in the US, the class structure is targeted as the key determinant of the position of older people in capitalist society. Estes's political economy challenges the ideology of older people as belonging to a homogeneous group unaffected by dominant structures in society.

A critical evaluation of the political economy of old age is that it over concentrates analysis on the treatment of older people in terms of class relations within capitalist societies and neglects differences between capitalist societies in the treatment of older people. The approach homogenizes and reifies older age by discounting potential for improvements in the social situation of older people. Hence, the complexity of social life is more of a continuous, never ending project with variable outcomes than the political economy theory allows.

Another emerging perspective is *feminist gerontology*. In recent years there has been a small but growing body of evidence that in mainstream sociological theory the interconnection of age and gender has been under theorized and overlooked. "Mainstream" refers to dominant theories in the gerontological field such as functionalist and Marxist theory that could be accused of being "gender blind." In their

pioneering work, Arber and Ginn (1995) point out there exists a tiny handful of feminist writers who take the topic of age seriously in understanding gender. They suggest that the general failure to incorporate women into mainstream theoretical perspectives on aging is a reflection of our resistance to incorporate women into society and hence into sociological and psychological research. They further suggest that because older women tend to occupy a position of lower class status (especially economic status) than men of all ages and younger women, they are given less theoretical attention.

In all known societies the relations of distribution and production are influenced by gender and thus take on a gendered meaning. Gender relations of distribution in capitalist society are historically rooted and are transformed as the means of production change. Similarly, age relations are linked to the capitalist mode of production and relations of distribution. "Wages" take on a specific meaning depending on age. For example, teenagers work for less money than adults, who in turn work for less money than middle aged adults. Further, young children rely on personal relations with family figures such as parents. Many older people rely on resources distributed by the state.

There is a "double standard of aging," with age in women having particularly strong negative connotations. Older women are viewed as unworthy of respect or consideration (Arber & Ginn 1995). The double standard is seen as arising from the sets of conventional expectations as to age pertinent attitudes and roles for each sex which apply in patriarchal society. These roles are defined as a male and a female "chronology," socially defined and sanctioned so that the experience of prescribed functions is sanctioned by disapproval. For example, male chronology hinges on employment, but a woman's age status is defined in terms of events in the reproductive cycle.

Unfortunately, feminist theories that focus upon the social problems of older people may have promoted the agism that many are arguing against. Old age as a term can no longer be used to describe and homogenize the experiences of people spanning an age range of 30 to 40 years. The pace of cohort differentiation has speeded up, with different age groups reflecting cohort differences in life chances that are created by

period specific conditions, policies, and economic transformations. Hence, there is differentiation of *subjective* experiences of aging in the lifestyles of older people.

As a reaction against macro theories of gerontology such as functionalism, political economy of old age, and feminist theorizing, postmodern gerontology has emerged as a school of thought. The work of Featherstone and Hepworth (1993) and Featherstone and Wernick (1995) is important in this respect, and has fed into wider debates on postmodernism in Canada and the US. They expose and deconstruct both the scientific gerontology and macro stances about old age, particularly claims of objectivity and truth about bodies. Featherstone and Hepworth (1993) maintain that old age is a mask that conceals the essential identity of the person beneath. That is, while the external appearance is changing with age, the essential identity is not, so that one may be surprised that one looks different than the unchanging image in one's head. Furthermore, Gilleard and Higgs (2001) claim that life course models that propose universal stages of life are fundamentally flawed. To exemplify the fluid and blurred nature of aging identity, Featherstone and Hepworth (1993) argue that in western society "children" are becoming more like adults and adults more childlike. There is an increasing similarity in modes of presentation of self – gestures and postures, fashions and leisure time pursuits – adopted by both parents and children. If correct, this can be seen as a move towards a uni age style. The "private sphere" of family life is becoming less private, as children are granted access to adult media such as television where previously concealed aspects of adult life (such as sex, death, money, and problems besetting adults who are anxious about the roles and selves they present to children) are no longer so easy to keep secret. A uni age behavioral style is also influenced by the advent of media imagery that, as a powerful form of communication, bypasses the controls that adults had previously established over the kinds of information believed to be suitable for children. Coupled with this, Katz (1996) and Powell (2005) have developed *Foucauldian* gerontology in analyzing power relations, surveillance, and governmentality in their applicability to understanding aging.

As a critique of postmodern gerontology and its emphasis on deconstructing universal narratives of aging, Phillipson (1998) suggests that in a restructuring of social gerontology we should acknowledge how the "global" and the "local" articulate and recognize that globalization is unevenly distributed and is also a western phenomenon indicative of the unequal power relations between the "west and the rest." Phillipson suggests that occidental globalization impinges on the poverty status of older people universally.

Gerontology is then multidisciplinary and is the principal instrument of orthodox theorizing about human aging. It provides a space for the search for meaning about what it is to be "old" in modern society, not for issuing prescriptions but for alternative interpretations about aging.

gerontology: key thinkers

All subfields in sociology have their own key figures beyond the more generally influential people discussed throughout this Encyclopedia. In this entry, several of the key figures (Beth Hess, Donald Kent, Mathilda White Riley, Ethel Shanas, and Donald Spence) in the history of the study of issues relating to gerontology are discussed. – GR

Hess, Beth (1928 2003)

Elizabeth W. Markson

The many scholarly contributions of Beth (Bowman) Hess to the field of sociology include those to the subfields of aging and the life course, gender studies, and friendship and its relationship to age cohort. Hess brought to her work intellectual curiosity, breadth of knowledge, analytic powers, impeccable editing and writing ability, and lack of pretentiousness.

The only child of upper middle class parents, Hess attended private elementary and high schools in Buffalo, New York and received her BA degree in 1950 from Radcliffe College *magna cum laude*, where she majored in government. After a brief interlude as a file clerk in a New York City advertising agency, she and her new husband, Dick Hess, moved to Paris. Returning in the mid 1950s to New Jersey where she lived for the rest of her life, she became, as she later described it (Hess 1995), temporarily enveloped in the *zeitgeist* of suburban motherhood. When her younger child entered kindergarten in 1962, Hess entered the graduate sociology program at Rutgers University. While a doctoral candidate working with Matilda White Riley, she began research on the sociology of aging, age stratification, and friendship, compiling the massive inventory of research findings in the first volume (1968) and editing each chapter of all three volumes of *Aging and Society*.

Her doctoral dissertation (1971) laid the basis for her seminal article, "Friendship" (1972). Hess examines how age influences friendship types developing between friends at various ages, whom one has as a friend, conditions in which friendships form, dissolve, or persist, and how friendships contribute both directly and indirectly to socialization throughout the life course. Age, a cohort attribute as well as indicator of life stage, signifies a common history that adds to friendship homophily as members of a friendship pair age

together, sharing the same sequence of life stages and historical events.

When Hess published her formulations on friendship, little research attention had been given to the topic and it was regarded more as a residual category rather than a major role. Indeed, Hess herself initially contrasted friendship with "major" social roles, and wrote her last full explication on friendship studies in 1979. Her work, however, prepared the way for a spate of interest on the import of social support, especially in later life. Subsequently, gerontologists have examined size of social networks, structure and process of friendships, and relationship to well being. The importance of gender for friendship roles – a theme highlighted by Hess in her later work both on aging and gender – has also become salient.

In 1969 Hess joined the full time faculty of the County College of Morris, where she was a professor until her retirement in 1997. Her decision to accept a position in a community college, largely governed by compatibility with family obligations and geographical convenience, could have been the entry into safe obscurity had she not had a strong commitment to advancement of the discipline. Drawing attention to race, class, gender, and social inequities before it was sociologically fashionable to do so, her contributions include textbooks such as *Aging and Old Age* (Hess & Markson 1980), the five editions of *Sociology* (Hess et al. 1996), and *The Essential Sociologist* (Hess et al. 2001). The first two editions of her reader *Growing Old in America* (1976, 1980) were published when courses in social gerontology were relatively new in college and university curricula and, like later editions (1985, 1991), carefully examined the current state of knowledge about later life. As a social gerontologist, Hess urged readers, whether colleagues or students, toward the essence of the sociological imagination: connections between personal problems and public issues and the interplay of race, class, and gender with the life course.

With a firm grounding in theory encompassing both often forgotten early feminist sociologists such as Harriet Martineau and Charlotte Stetson Perkins Gilman and the more usual male pantheon of Durkheim, Marx, Simmel, Weber, and others Hess was remarkably up to date on the latest findings and events. Whether scholarly books or journal articles, popular news articles, the most recent census data, or other government reports, she had not only read them, but also synthesized complex and often contradictory materials into a meaningful, sophisticated sociological argument, expressed with semantic precision. As a feminist scholar, she emphasized how gender organizes social arrangements, personality, and cognition. *Controversy and Coalition: Three Decades of the Feminist Movement* (three editions, Ferree & Hess 2000), *Analyzing Gender* (Hess & Ferree 1987), and *Revisioning Gender* (1998) illuminate the many ways in which feminist scholarship has transformed the social sciences.

Central to the governance and organization of many scholarly associations, Hess was executive officer of the Eastern Sociological Society, president of the Association for Humanist Sociology, Sociologists for Women in Society, the Eastern Sociological Society, and the Society for the Study of Social Problems (1994–5), secretary of the American Sociological Association (1989–92), and chair of the Behavioral and Social Science Section of the Gerontological Society of America. Listed in *Who's Who of American Women*, her scholarly contributions were recognized by the Lee Founders Award presented by the Society for the Study of Social Problems and as a Fellow of the Gerontological Society of America.

The many honors she received and offices held in sociological organizations are but a small token of her readiness to give her time and energy to advance the field. Amid her ability to balance the mastery of material, to write rapidly, coherently, and eloquently, to be active in the profession, and to mentor others, was her passion for integrity and justice reaching beyond the academy. As a feminist, she was dedicated not only to equality for women, but also a political activist and fierce defender of *all* human rights. Above all, Beth Hess was a passionate sociologist—passionate about clear and elegant writing, passionate about intellectual integrity, and passionate about the human condition. Her work, cross cutting many

venues from general sociology to the sociology of aging and feminist theory, reflects these passions.

Kent, Donald P. (1916–72)

Jon Hendricks

Donald P. Kent, a key figure in social gerontology, was both a sociologist and government official who helped ensure passage of the Older Americans Act and was instrumental in establishing the Administration on Aging. Born in Philadelphia, Kent received degrees from Pennsylvania State

University (1940) and Temple (1945), and his PhD from the University of Pennsylvania (1950). Following his undergraduate degree, Kent taught high school and declared himself a conscientious objector during World War II. While working on his dissertation, published as *The Refugee Intellectual* (1953), Kent served as an instructor at Penn and subsequently joined the sociology faculty (1950–7) at the University of Connecticut before becoming director of its Gerontology Center (1957–61).

While in the latter role Kent also chaired the Connecticut Commission on Services for Older Persons and in that capacity was not only a vocal advocate but also acceded to high profile involvements in the federal government's emerging concern with aging issues. Kent was instrumental in planning the first White House Conference on Aging (1961) and led the Connecticut delegation. Nominated by Senator Abraham Ribicoff, patron and sponsor, to become director of what was to become the Administration on Aging, Kent ran into a maelstrom over his status as a conscientious objector. Subjected to ringing personal derision, Kent was on the verge of withdrawing until Ribicoff convinced him to stay the course. In 1961 he became special assistant to the US Secretary of Health, Education, and Welfare and vice chairman of President John F. Kennedy's Council on Aging. As director of the US Office on Aging (1961–5), later renamed Administration on Aging, Kent worked tirelessly behind the scenes and on the hill to ensure passage of the Older Americans Act. Present at the Rose Garden signing of the OAA by President Lyndon Johnson, Kent's direct involvement in pressing the federal government's aging agenda was also drawing to a close. As he had previously, he continued to provide briefings for federal, state, and local governments on aging issues, and remained involved in study sections for NICHD, but longed to return to academia. In 1965 he was named chair, department of sociology and anthropology, at Pennsylvania State University, a position he occupied until his death. Kent's verve, statesmanship, and craft were invaluable during the arduous process leading to the implementation of the Older Americans Act and were characteristics that served him well throughout his governmental and academic service.

A firm believer in what would later be termed "action research," Kent was intent on bridging the gulf between social research and policy

formulation. He personified Cicero's admonition that "virtue without action is meaningless" and in research project after research project his agenda was to train and utilize indigenous staff, use them as a kind of "kitchen cabinet," and set them up for further employment. As part of a major study of inner city minority elderly in Philadelphia, Kent and colleagues implemented a volunteer referral service suggested by field staff not content to walk away from interviewees once unmet needs had been identified. Without cost to the funding agency an intervention network was implemented, as disembodied research was an anathema. Kent, Kastenbaum, and Sherwood's *Research, Planning and Action for the Elderly: The Power and Potential of Social Science* (1972) provides a comprehensive summary and prescription for action research on behalf of older persons and stands as a how to guide for generations of gerontologists.

Once back in academia Kent assumed editorship of the *Gerontologist* (1967–70) and took as his personal missions the mentoring of would be authors and the premise that outcomes of social research need to include practical and pragmatic implications. He utilized the occasion of his last publication to digest recommendations of the 1971 White House Conference on Aging in terms of whether they would directly benefit older persons or simply fuel the bureaucracy. He also stressed the need for robust and appropriate research methodologies to buttress policy recommendations and cautioned researchers about looking at real world experiences through a lens ground to their own specifications.

In recognition of Kent's many contributions, the Gerontological Society of America implemented the prestigious Donald P. Kent Award to recognize gerontologists embodying the highest standards of the field through teaching, service, and interpretation of gerontology to the larger society. The Kent Award remains one of the most prestigious recognitions a gerontologist may receive.

Riley, Matilda White (1911-2004)

Anne Foner

In her long and productive career Matilda White Riley devoted much of her scholarly work to setting forth and elaborating a sociology of age. This work followed her achievement as an innovative methodologist and her research on mass communications (with her husband, John Riley, Jr.), adolescent values, and family relations. The methodological sophistication and the interconnections between methods and theory that characterized this early work served to underpin her study of age as a social phenomenon. Her analysis of aging and society gave new understandings to a "taken for granted" phenomenon and helped establish the sociology of age as a key substantive field in the discipline.

Riley embarked on an academic career in sociology at New York University and Rutgers in 1950. Before that she had had a top position in market research, where she honed her skills in all aspects of survey research. When she started teaching research methods to sociology students she went beyond a narrow conception of methodology to demonstrate the interplay of theory and research and to explore the full range of quantitative and qualitative methods. This broad approach was elaborated in her 2 volume *Sociological Research* (1963), which examined how the conceptual framework of key classical studies was translated into empirical operations. In the process, she gave students a sweeping overview of some of the most significant sociology then available.

Riley turned her attention to the study of aging and society in the 1960s when she was commissioned to codify social science knowledge about the middle and later years. The project resulted in the monumental 3 volume *Aging and Society* (1968-72). It provided a synthesis of the considerable body of relevant research and in the process

identified methodological fallacies that had contributed to myths about old age and aging. In volume 3 it set forth an overarching analytical framework for understanding age as an element in the social structure and aging over the life course as influenced by and in turn influencing changes in the society.

In Riley's view human aging is a lifelong, complex, mutable process, shaped by social, psychological, and biological interdependencies. People in successive cohorts grow up and grow older in different ways as societies and their social structures undergo change. While the aging of individuals over the life course and historical changes in society are intertwined, these two dynamic processes have different rhythms, leading to pressures for structural changes, including changes in age criteria for filling roles, for access to social goods, and for social relationships.

These fundamental ideas of the *Aging and Society* paradigm became widely influential as Riley developed them in numerous publications and lectureships, in her roles as university professor, as president of the American Sociological Association and the Eastern Sociological Society, and as first associate director for Behavioral Sciences Research at the National Institute on Aging, where she initiated funded research on social and behavioral aspects of the aging process. As an exemplar and mentor she helped launch new scholars in the study of age and aging. Her contributions to the biosocial sciences have been recognized by many awards, including honorary degrees from Radcliffe, Rutgers, and the State University of New York, and election to the National Academy of Sciences. She continued to make contributions to and receive accolades from the discipline in her ninth decade.

Shanas, Ethel (b. 1914)

Gloria D. Heinemann

Born in Chicago, Ethel Shanas received her education from the University of Chicago. After receiving her doctorate in sociology, she remained at the University of Chicago as Research Associate/Instructor, Committee on Human Development (1947-52) and as Senior Study Director, National Opinion Research Center and Research Associate, Department of Sociology (1956-61). From 1965 to 1982, when she retired, she was Professor, Department of Sociology, University of Illinois at Chicago (UIC) and, beginning in 1973, Professor, School of Public Health, UIC Medical Center. Throughout her career, Shanas, who was a wife and mother, successfully combined a meaningful career and family life during a period when women had few supports for career development and advancement.

The courses Shanas taught at UIC exemplify her major areas of interest and contribution to sociology: medical sociology and sociology of aging, which included considerable material about aging, health, and long term care. She used the social survey to inquire about older persons, their families and intergenerational relationships, family help patterns, living arrangements, health status and incapacity, financial status, and work and retirement. These studies provided baseline data that debunked myths about and presented accurate portrayals of older persons living in the community. One of the major contributions from her research was the development of the Index of Incapacity.

Shanas also was a consultant to numerous international, governmental, and local university and community agencies and committees. Major

contributions resulted from her consultations, such as the Long Term Care Minimum Data Set and the National Institute on Aging. Other major contributions of Shanas include her service to professional organizations and her service on the editorial boards of professional journals. Much of her work was multidisciplinary and multicultural. This collaborative effort is evident in the research project and resulting book, *Old People in Three Industrial Societies* (Shanas et al. 1968) and in the two editions of the *Handbook of Aging and the Social Sciences* (Binstock & Shanas 1976, 1985), which presents perspectives from a broad array of social sciences.

Shanas was elected a Fellow of the American Sociological Association and the Gerontological Society of America. She was the Keston Memorial Lecturer at the University of Southern California (1972) and received GSA's Kleemeier Award (1977), the National Council on Family Relations' Burgess Award (1978), the GSA's Brookdale Award (1981), the American Sociological Association, Section on Aging's Distinguished Scholar Award (1987), and an honorary doctor of letters degree from Hunter College (1985). In 1979 she was elected to membership in the Institute of Medicine, National Academy of Sciences.

Spence, Donald L. (1930–89)

Victor W. Marshall

Donald L. Spence stands as a major influence in the sociology of aging and in the area of gerontology education. His 1965 doctoral dissertation at the University of Oregon, under Robert Dubin, was on retirement, and aging remained his lifelong passion. A member of the American Sociological Association continuously from 1959 and of the Society for the Study of Symbolic Interaction from 1977 until his death, he contributed effectively to an interdisciplinary field while maintaining a strong theoretical position as a sociologist and influencing many sociologists in the aging field.

Spence had a lasting impact on many sociologists working in the substantive area of aging. This was more as a mentor and role model than through his specific substantive research. He brought intellectual rigor and a commitment to theory to his own research, most of which was quite applied in nature, but mostly he is remembered for his commitment to theory and his mentorship of young investigators.

While “ABD,” Spence began teaching in 1962 in a new sociology department at the University of Alberta, Calgary, but he returned to his native California in 1965 to conduct aging research at the Langley Porter Neuropsychiatric Institute. There, he directed the Human Development Training Program in the department of psychiatry at the University of California, San Francisco. In 1973 he moved to the University of Rhode Island as associate professor, department of child development and family relations and coordinator of that university’s Program in Gerontology. He became director of the Program in Gerontology at the University of Rhode Island in 1976, professor of gerontology in 1982, and professor emeritus in 1989. During his period at URI he was also adjunct associate professor in community health at Brown University, where he served as founder and first director of the Southeastern New England Long Term Care Gerontology Center.

Spence left a multifaceted legacy. He was a dedicated and enthusiastic teacher, with a passionate and rigorous commitment to sociological theory. Initially, he could be characterized as a functionalist, and he also took pains to ensure that his students were well grounded in the philosophy of the social sciences. While at University of

California San Francisco he became a close friend of Anselm Strauss and formed a strong commitment to symbolic interactionism. His shift in perspective led to vigorous theoretical disagreements and his departure from the “Four Stages of Life” project, on which he was a project coordinator for several years. His commitment to theory inspired a small, informal grouping of sociologists who wanted to see a more theorized approach to gerontology and led to an increased appreciation of theory among gerontologists.

Spence’s later publications and papers focused on interdisciplinary health care teams and other aspects of care of the elderly, as well as on gerontological education. He was a founding member of the Association for Gerontology in Higher Education in 1974, served on every committee of that association and was its president (1982–3). He thus played an important role in the shaping of gerontology education during its major era of expansion. He was also a Fellow of the Gerontological Society of America.

ghetto

Joanna Michlic

The term ghetto is a concept with many meanings. It is frequently used to describe any dense areas of Jewish residence, even if no compulsory policies of residential segregation were imposed. It is also employed as a description of the geographical and social isolation of minorities other than Jews; for example, it is applied to African Americans and other ethnic communities in the US and to minorities in Japan such as ethnic Koreans. Scholars recognize that the term has assumed a life of its own

since its first application and have called for systematic examination of the history of its changing meaning from the time it was first used in connection with Jews until the present (Ravid 1992).

Originally, the term referred to the establishment of a compulsory segregated Jewish quarter, ghetto or *ghetti* in pre Enlightenment Europe. Although compulsory, segregated, and enclosed Jewish quarters had existed prior to 1516 in a few cities in Europe such as Frankfurt, the first involuntarily segregated quarter called a ghetto was established in Venice in that year. The Venetian government, motivated by utilitarian economic considerations of *raison d'état*, granted Jews charters, which allowed them to live in Venice. However, it required that as infidels Jews be kept in their place, both to demonstrate their inferiority for Christian theological reasons, and more practically, to restrict as much as possible social contacts, including sexual interaction, between them and the local Christian population. To ensure the complete segregation of Jews, the area allocated for their residence was walled up and the Christian owners of the dwellings within it were required by the Venetian government to evict their local Christian tenants. This was the first instance of a segregated compulsory quarter for Jews in a walled up form. The Venice ghetto existed for the next 281 years and was abolished in the early summer of 1797 in the aftermath of the dissolution of the Venetian government.

The term ghetto derives from the Italian word *gettare* (to pour or cast metal). The word was originally used to describe the old ghetto (*Ghetto vecchio*) and the new ghetto (*Ghetto nuovo*) for Jews in Venice. Both these quarters were located in the area where the municipal copper foundry was previously based. Subsequently, the term has been used loosely and imprecisely in Jewish history and sociology. The varied usages in different senses have created a certain blurring of the historical reality, especially when the term is used in phrases such as "age of the ghetto," "out of the ghetto," and "ghetto mentality," which are often applied to the Jewish experience in Central and Eastern Europe in the seventeenth, eighteenth, and nineteenth centuries (Ravid 1992). The term in the original Italian sense of a compulsory, segregated, and walled up Jewish quarter cannot be

used to describe the Jewish experience in Eastern Europe because the history of Jewish residence there lacks the main characteristic of the Italian ghetto. If the word ghetto is to be applied in its original literal sense in connection with Eastern Europe, then it must be asserted that the ghetto arrived there only during the German occupation of the region in World War II. However, unlike those Italian ghettos of the Counter Reformation era, which were designed to provide Jews with a clearly defined, permanent position in Christian society, the ghettos established in German occupied Eastern Europe constituted a stage in the Nazi anti Jewish policies, which culminated in the genocide of European Jewry.

The concept of the ghetto as a closed premodern environment that isolated Jews from the rest of society also had a major impact on early scholarly attempts to understand the forces that held together ethnic neighborhoods of European immigrants in American society in the early twentieth century. In 1928 the Chicago sociologist Louis Wirth published *The Ghetto*, in which he compared the Chicago ghetto – the voluntarily established Jewish immigrant neighborhood on Chicago's Westside – to the medieval Frankfurt Jewish quarter. Wirth assumed that Jewish immigrants in Chicago moved into a certain ethnocultural space because the centuries of separate settlement in Europe had imprinted the "ghetto experience" on the Jewish mind. Drawing on his mentor Robert Park, Wirth saw a correlation between the assimilation of immigrants and their residential mobility. For him, the Chicago ghetto was a passageway in time and space from premodern European ghettos into mainstream American society. Jeffrey Gurock (1979) dismisses Wirth's thesis about the ghetto like pattern of settlement of Jewish immigrants in the US.

The idea of the ghetto has also often been applied to describe the African American experience in different geographical localities of the US between 1900 and the 1960s. The African American ghetto is a creation of the early twentieth century and its historical origins are linked to the large scale black migration to cities such as Chicago and Detroit. The African American ghetto is the result of the forces of racial segregation. Although the US Supreme Court banned explicit zoning by race in 1917,

by 1920 the color line in Northeastern cities had been fully established. The reinforcement of ethnic and racial barriers was not limited only to anti black initiatives in Northern US cities. The South had created its vast array of Jim Crow laws at the end of the nineteenth century. In the West, whites also used restrictive covenants against Asians. African American segregation in ghettos – inner city communities such as Harlem in New York – continued to rise until it reached its peak in the 1960s. The abolition of legal restrictions in the 1960s meant that barriers that were needed to keep areas white were gone. However, this process has not resulted in the end of the African American ghetto. African American ghettos have not become any less black. The persistence of subtle forms of barriers and economic factors are cited in scholarly and public discussions about the persistence of the African American ghettos in contemporary North American cities (Glasser 1997).

In recent scholarly literature the concept of the ghetto has been linked to the ideal of multiculturalism. Kymlicka (2001), for example, argues that the ideal of multiculturalism in Canada encouraged the idea that immigrants should form “self contained ghettos” alienated from the mainstream. He calls this process ghettoization, which may mark the latest manifestation of the concept in the social sciences.

gift

Rodanthi Tzanelli

The concept of the gift has been explored by anthropologists, philosophers, sociologists, and social theorists, who recognized in it a heuristic tool for the study of kinship relations, exchange and reciprocity, and interconnections of power, economics, and morality. In all these cases the gift can assume the form of tangibles (material items such as artifacts or human beings) and intangibles (ideas, religious rituals, or titles).

Marcel Mauss's *The Gift* (1954) is considered the seminal work in this area, both because of its theoretical coherence and its plethora of ethnographic material. Mauss identified the practice of gift exchange as a universal phenomenon that exemplifies the pervasiveness of a sense of obligation in all societies, archaic and modern. He claimed that the nature of gift exchange is reciprocal; such exchange involves both individuals and groups (clans, families) that establish social relations and reproduce themselves through the act of giving and receiving. Controversially, Mauss claimed that the gift itself compels and ensures reciprocation, simply because the gift owner and the gift cannot be separated: the object received as a gift binds the giver and the recipient with a moral force. Therefore, to reciprocate becomes for the recipient obligatory insofar as the violation of reciprocation can lead to magical repercussions. The obligation of giving gifts and reciprocating them forms the basis of the archaic “system of total services” that aims to establish alliances (e.g., marrying one's daughter into another clan to secure friendly relations, offering military titles to an ally) or to seal rival relations. The latter is encapsulated in the potlatch (meaning “to consume”) tradition of Nootka Indians, in which competitors for social titles organize festivities and waste or distribute possessions to claim superiority. For Mauss, therefore, the practice of gift giving

has an inherently ambiguous nature that encompasses both self interest and selflessness, calculation and moral obligation.

These two types of gift giving have been reconceptualized by Marshal Sahlins and Karl Polanyi as reciprocity (gift giving for alliance) and redistribution (potlatch). Following Mauss's idea of "total services," they purported that reciprocal and redistributive exchange relations between two groups are continuous rather than separate in societies characterized by social differentiation. Whereas reciprocity regulates exchange between parties with different interests, redistribution is applied to the collective as a whole, as it is regulated by a central authority (e.g., the chief of a tribe) (Sahlins 1972). This argument presents redistribution as a more advanced, politicized form of gift giving that ensures social bonding in centralized communities, whereas reciprocity is viewed as a rationalized system of exchange that functionalizes gift giving. Bataille (1988) criticizes this dominant economic assumption as much as he rejects the idea that humans have a natural inclination to produce and save. His starting point is that human nature is inherently greedy and favors destruction and consumption. Social solidarity is thus secured through rituals that celebrate waste and go against the logic of social differentiation through wealth. To consolidate his thesis Bataille used as an example Aztec sacrificial offers and the potlatch ceremonies of American Indians, which are characterized by excessive waste of resources that could, according to the economic logic, be appropriated. For Bataille, this uncontrolled expenditure secures the situational power of the giver, which can, in turn, be challenged by reciprocal expenditure by the initial recipient. Generosity here is not inseparable from strategic calculation, but they form a continuum inherent in the "general economy" of giving (as opposed to the "restricted economy" of saving).

An empirically grounded approach to the gift in contemporary welfare provision was pioneered by Titmuss. Titmuss (1970) conducted a comparative study of the British and the American blood supply system, attempting to answer a fundamentally moral question: How is it possible for people to donate blood to strangers? Highlighting the difference between the British system, in which donation

is a voluntary act, and the American system, in which giving blood is formally remunerated, he argued for the superiority of morally bound forms of giving that stem from altruism, as opposed to those subjected to the laws of the market. Although situated in social and administration studies, Titmuss's research did not deviate from former anthropological studies that examined gift giving as a moral obligation. In a similar vein, Zelizer (1978) explored changing perceptions of life insurance in the American context. The initial commercialization of this service, and its presentation in monetary terms ("buying" life insurance for someone, subjecting life to the laws of economic transaction), was not welcomed by Americans. It was only when life insurance was presented as a way in which one can express care for one's family or spouse (by continuing to provide for the loved ones even after one's death) that hostile American attitudes towards this service subsided. According to Zelizer, the shift was enabled by the dissociation of life insurance from market exchange, and its presentation as a gift, a sacred offer that cannot be reciprocated by the living ones.

A thorough exploration of the gift's potential to restore collective bonding was offered by Berking (1999). Berking reconsidered the meaning of the gift and the messages of power, duty, and status that it communicates through an extensive excursus in anthropological and sociological theory. By exploring historical conceptions of the sacrifice, sharing, and giving as the basic institutions on which archaic societies were based, he attempts to reconcile modern self interest with the archaic ideal of communal good. Operating within the confines of the longstanding Durkheimian tradition, Berking argues for a moral economy that surpasses the market rationale and promotes the altruistic ideal.

gift relations

Craig D. Lair

Though the study of gift relations spans a range of intellectual disciplines (e.g., anthropology, ethnology, and sociology), one general theme has tended to unite the diverse works in these areas: more than being simply matters of economic transactions, gifts and gift giving are fundamentally *social* activities. That is, gifts are not exchanges of mere material objects, but rather objects and actions imbued with social meanings. Thus, to engage in a gift relationship is to engage in a *social relationship*.

The social nature of gift relations is a central theme found in the work that is often considered as being seminal in the study of gifts and gift exchange: Marcel Mauss's *The Gift* (2000). Mauss, drawing upon ethnographic data from Oceanic and Native American societies, as well as "ancient" legal and economic systems (e.g., Roman law), sees gift exchanges as a force that both engenders and sustains social solidarity. As Mary Douglas says in her introduction to *The Gift*: "A gift that does nothing to enhance solidarity is a contradiction" (p. vii). In part this is because, though gift giving appears as a voluntary action, it is in fact socially obligatory and socially regulated. In the study of gift exchanges in "archaic" societies, Mauss finds three obligations inherent in the gift giving process: to give gifts, to receive gifts, and to

reciprocate gifts given, often with "interest" (i.e., to give more than one has received). To refuse to engage in this process (i.e., to not give or receive) is "tantamount to declaring war" because gift exchanges are not simple economic transactions between individuals, but rather a "total service" – an activity that is a mixture of moral, juridical, economic, spiritual, religious, and social structural elements that is collectively carried out. To not engage in gift giving activities is to reject the whole of a society – its thoughts, beliefs, and entire worldview. However, to participate in this cycle of gifts and counter gifts, a cycle that once established is seemingly self-perpetuating, and thus one that acts to bind social groupings together over time, is to be engaged with, and intertwined in, the whole of a society. As such, the obligatory nature of gift giving acts to bind individuals and groups together in social relationships that are sustained over time and in this way they are mechanisms of social solidarity.

The social nature of gift exchanges has been a theme that has been picked up by most of those who have studied gift relations after Mauss. For Bataille (1989), gift exchange, in the form of the potlatch or competitive gift giving, was a means to obtain honor. That is, it was a means by which one could secure *social* status. Baudrillard (1993), before making his postmodern turn, saw in "symbolic exchanges" a non-acquisitive cycle of gifts and counter gifts, a radical alternative to both capitalism and socialism (both, in Baudrillard's mind, rested upon the same logic of production and utility, the only difference being how the fruits of this labor were distributed). Thus, for a time, Baudrillard saw in the gift relations of past and non-western societies a means by which modern *social* relations could be reordered in a fundamentally different manner. Helmut Berking, in his *Sociology of Giving* (1999), argues that modern individualism encourages not only self-centered views but also, and paradoxically so, altruistic values. Thus, for Berking, a "solidarity of individualism" is not incompatible with notions of charity and giving. Rather, individualism is a means by which these values can be given greater prevalence in social life.

From the early studies by Mauss, to more contemporary works exploring gift giving in modern times, one general theme has remained

the same: gifts, above and beyond any economic value they may have, are elements of a social exchange. Thus, to engage in a gift relationship is, at the same time, to engage in a social one as well.

Gilman, Charlotte Perkins (1860–1935)

Michael R. Hill

Charlotte Perkins Gilman was an influential and sometimes controversial contributor to early American sociology. Her *Women and Economics* (1898) launched a searching feminist sociological critique of the economic position of women in patriarchal societies. The primary site for Gilman's continuing sociological work was the *Forerunner* (1909–16), a monthly journal that Gilman wrote and self published. The socially problematic issues that Gilman explored in her works echo theoretical proposals of Lester F. Ward (1841–1913), a founding American sociologist who admired Gilman and vice versa. Ward's concept of gynocentric (i.e., woman centered) social theory reinforced Gilman's strong belief in the fundamental rationality of women's values and social contributions. Gilman developed this perspective at length in her non fiction works. Gilman was an early

member of the American Sociological Society, published in the *American Journal of Sociology*, was respected by contemporary sociologists, and was widely known by lay readers in the public generally.

Gilman shared the feminist pragmatist tenet, that women's values make for better societies, in common with American sociologist Jane Addams (1860–1935). Antecedent to Gilman's sprightly *Herland* saga is Addams's witty and biting essay, "If Men Were Seeking the Franchise" (1913). Addams, a friend and colleague of Gilman, described a hypothetical society of men and women in which women dominate the populace and have the political power to deny men the right to vote. Addams whimsically concluded that men cannot be allowed to share in government until they abandon their selfish and destructive ideas.

Gilman's *Herland* (1915), set in a fictional utopia populated only by women, is the first half of an accessible sociological critique of American life. *Ourland* (1916) continues and completes the *Herland* saga. In *Ourland*, Ellador (a native of Herland) and Vandyke Jennings (an American sociologist who discovered the remote Herland and subsequently married Ellador) leave the all woman paradise so that Ellador can tour and see the "real world" for herself. Suffice it to say, Ellador is appalled and aghast at the waste, wars, and patriarchal injustices that men have perpetrated around the globe.

In addition to *Woman and Economics*, Gilman's major non fiction sociological treatises, some serially published in the *Forerunner*, include: *Concerning Children* (1900), *Human Work* (1904), *The Dress of Women* (1915), and *Social Ethics* (1916), among others. In sum, wrote Gilman in *Social Ethics*, we have failed to teach even "a simple, child convincing ethics based on social interactions, because we have not understood sociology."

Gini coefficient

Ivan Y. Sun

The Gini coefficient is the most commonly used measure of inequality. The coefficient is named after the Italian statistician and demographer Corrado Gini (1884–1965), who invented the measure in 1912. While the Gini

coefficient is often used to measure income and wealth inequality, it is also widely employed to indicate uneven distribution in other social issues, such as industrial location and development, health care, and racial segregation. The coefficient ranges from 0 to 1, with 0 representing perfect equality (i.e., everyone has the same income) and 1 perfect inequality (i.e., a single person has all the income). An extension of the Gini coefficient is the Gini index, which equals the Gini coefficient multiplied by 100.

The Gini coefficient is calculated based on the Lorenz curve (Lorenz 1905) of income distribution. The graphical depiction of the Gini coefficient is shown in Figure 1. The Lorenz curve is plotted showing the relationship between the cumulative percentage of population and the cumulative percentage of income. The diagonal or 45 degree line indicates a perfect distribution of population and income (e.g., 30 percent of the population earns 30 percent of the income and 80 percent of the population earns 80 percent of the income).

The Gini coefficient is the ratio of the area between the Lorenz curve of income distribution and the diagonal line of perfect equality (the shaded area or area A in Fig. 1) to the total

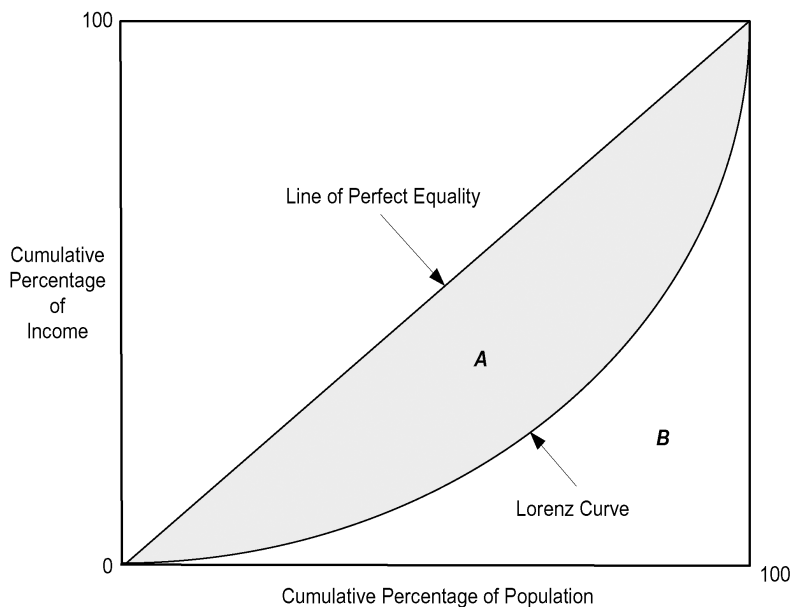

Figure 1 Graphical depiction of the Gini coefficient ($A/A + B$).

area underneath the line of perfect equality. Putting it into an equation: the Gini coefficient = area A/(area A + area B). The further the Lorenz curve is below the line of perfect equality, the greater the inequality in the distribution of income.

Countries with Gini coefficients between 0.2 and 0.35 are generally viewed as having equitable distribution of income, whereas countries with Gini coefficients from 0.5 to 0.7 are considered to have high inequality in income distribution. Most European countries and Canada have Gini coefficients varying from 0.2 to 0.36, while many African and Latin American countries have high values of Gini coefficients exceeding 0.45. Most Asian nations have Gini coefficients between 0.25 and 0.45 (United Nations 2005). Income inequality in the United States showed an upward trend over the past three decades, increasing from a Gini of 0.39 in 1970 to 0.46 in 2000.

One needs to be cautious about the national measures of Gini coefficients for they may obscure great variations in income inequality across sectors of the population within a country. In the United States, for example, minorities (African Americans and Latinos) have higher levels of income inequality than non Hispanic whites (US Census Bureau 2005). The Gini coefficient is also useful in understanding the impact of economic development. For example, a nation may experience rapid economic growth and an increasing Gini coefficient simultaneously, indicating that income becomes less evenly distributed and thus inequality and poverty are not necessarily improving.

global economy

Leslie Sklair

While they are often used interchangeably, the idea of the *global* economy should be clearly distinguished from the idea of the *international* economy. The international economy refers to the sum of all the relations between the national economies of all the countries in the world, particularly binational and multinational exchanges, whereas the global economy refers to the sum of all the relations between economic agents whether they are state or private or of other mixed forms. In practice, this distinction boils down to the analytic choice between a state centrist analysis of economic relations and regulation, and a transnational analysis of economic actors, practices, and institutions. This distinctive concept of the global economy comes from globalization theorists and researchers who have identified globalizing corporations and their local affiliates, those who own and control them, and those in influential positions who serve their interests as the dominant economic forces in the world today (Dicken 1998; Sklair 2001).

Theory and research on the global economy has focused on several interrelated phenomena, increasingly significant since the 1960s. The transnational corporations (TNCs) have attracted an unprecedented level of attention in this period, not only from academic researchers but also from activists in the fields of human rights in general and child labor, sweatshops, and environmental justice in particular. The ways in which and the consequences of how transnational corporations have facilitated the globalization of capital and the production of goods and services, the rise of new global forms of organization of the capitalist class based on ownership and control of TNCs, and transformations in the global scope of the corporations

that own and control the mass media, are no longer the sole province of international economists and trade specialists, but are now commonplace in many textbooks in the social sciences (Sklair 2002) and bestsellers read by students and concerned citizens alike (Klein 2000). In this respect, at least, the global economy has become popularized.

Interest in the connections between an increasingly globalizing capitalism and the rise of a global economy dominated by transnational corporations grew perceptibly from the 1960s. The context of theoretical and empirical interest in competing national capitalisms in the international economy was (and for many still is) the history of colonialism and imperialism. This is overlaid with several versions of the theory that capitalist states could more or less successfully plan their own economic futures. As direct imperialism and colonialism came to an end and as more and more very large TNCs began to emerge in the 1960s, attention began to shift decisively from the international to the global economy.

This manifested itself at first in the sociology of development, where the dependency approach to development and underdevelopment of Gunder Frank and the related world systems approach of Wallerstein, highlighted the systemic nature of capitalism as a worldwide phenomenon over several centuries. While both of these theoretical innovations can be said to have prepared the ground for it, neither entirely succeeded in establishing a coherent concept of the global economy. Wallerstein's analysis of core, semi periphery, and periphery in the world systems approach is based on national economies (Wallerstein 1979), though to some extent the theoretically more ambitious concept of commodity chains has been elaborated in more globalizing terms (Gereffi & Korzeniewicz 1994).

The novelty of theories of the global economy, in the sense used here, originates in the proposition that capitalism entered a new, global phase in the second half of the twentieth century. By the new millennium, the largest TNCs had assets and annual sales far in excess of the gross national products of most of the countries in the world. The *World Development Report* (published annually by the World Bank) for 2000 shows that only about 70 countries had

GNPs of more than US\$10 billion. By contrast, the 2000 *Fortune* Global 500 list of the biggest corporations by turnover reported that about 450 of them had annual sales greater than US\$10 billion. This comparison, however, underestimates the economic scale of major corporations compared with sovereign states, as TNC revenues are usually counted as part of GNP.

The global scope of TNCs has also expanded dramatically. Many major corporations earn more than half of their revenues outside the countries in which they are legally domiciled. This is true for TNCs from countries with relatively small domestic markets (for example, Switzerland, Sweden, Canada, Australia), as well as for those legally domiciled in the USA and Japan. Most of the biggest corporations are still headquartered in the First World, though several dozen companies originating in what is conventionally called the Third World – mainly the newly industrializing countries (NICs) – have been numbered in the *Fortune* Global 500. This group has included the state owned oil companies of Brazil, India, Mexico, Taiwan, and Venezuela (owned by the state, but increasingly run like private corporations), banks in Brazil and China, and Korean manufacturing and trading conglomerates like Hyundai and Samsung (Sklair & Robbins 2002).

Some scholars argue that the global economy is a myth because most major TNCs are legally domiciled in the US, Japan, and Europe, and because they trade and invest mainly between themselves. Against this conclusion, proponents of the global economy argue that an increasing number of corporations operating outside their countries of origin see themselves as developing global strategies of various types, as is obvious from the contents of their annual reports and other corporate publications (Sklair 2001). While all parts of all economies are clearly not globalizing equally, an increasing volume of empirical research indicates that the production and marketing processes of most major industries are being deterritorialized from their countries of origin and that these processes are being driven by the TNCs (Dicken 1998). The central issue for debates around the global economy is the extent to which TNCs domiciled in the US, Japan, and European and other countries can be more fruitfully conceptualized as expressing the

national interests of their countries of origin (sometimes termed the *global skeptic argument*) or what can be conceptualized as the private interests of those who own and control them. Even if historical patterns of TNC development have differed from country to country and region to region, it does not logically follow that TNCs and those who own and control them express any type of national interest or national character.

The formal ownership of capital and the corporations has been transformed since the 1960s. The ownership of share capital has increased throughout the world by means of greater participation (though still a tiny minority in most communities) of the general population in stock markets and the indirect investments that hundreds of millions of people, mainly in rich countries, have through their pension funds and other forms of savings. However, formal ownership rarely means effective control over the capital, resources, and decisions of TNCs.

The globalization of cross border finance and trading can be fruitfully analyzed in terms of the progressive weakening of the nation state and the growing recognition that major institutions in the global economy, notably transnational financial and trading organizations, are setting the agenda for these weakened nation states. Theory and research on this issue has, not surprisingly, led to an increased interest in the politics of the global economy.

The politics of the global economy is debated intensely inside and outside the social sciences. Since the disintegration of the Soviet empire from the late 1980s, the struggle between capitalism and communism has been largely replaced by the struggle between the advocates of capitalist triumphalism and the opponents of capitalist globalization. Many theorists have discussed these issues within the triadic framework of states, TNCs, and international economic institutions. From this perspective, the global economy is dominated by the relations between the major states and state systems (US, EU, and Japan), the major corporations, and the international financial institutions (World Bank, IMF, WTO, supplemented in some versions by other international bodies, major regional institutions, and so on). Such considerations draw attention to the management of the global economy as an ideological political project, closely

related to the rise of neoliberalism in the 1980s associated with the policies and practices of the Thatcher government in Britain and the Reagan administration in the US. This was theorized by some as the so called *Washington Consensus*, which sought to bring together a new orthodoxy of economic theory, a new theory of minimizing government intervention in the economy, and new strategies for development by the major international financial institutions. While controversy still rages over the effectiveness of neoliberalism (the *Washington Consensus* has not been much discussed since the 1990s), many policies promoted by their proponents have been adopted by governments all over the world. This has stimulated interest in who runs the global economy.

One explicit approach to this large question focuses on the concept of the transnational capitalist class (TCC). The TCC may be analytically divided into four main fractions: (1) TNC executives and their local affiliates; (2) globalizing politicians and bureaucrats; (3) globalizing professionals; (4) consumerist elites of merchants, media, and advertising (Sklair 2001). It is transnational in several senses: its members have outward oriented global rather than inward oriented national perspectives on a variety of issues (e.g., support for free trade and neoliberal economic and social policies); they are people from many countries, more and more of whom begin to consider themselves as citizens of the world as well as of their places of birth and residence (these might differ); and they share similar lifestyles, particularly patterns of higher education (in cosmopolitan universities and business schools) and consumption of luxury goods and services. The sociological analysis of the economic base, the political structure, and the culture ideology of the transnational capitalist class provides a fruitful research program for understanding the global economy and explaining its dynamics.

The dominant culture ideology of the global economy is widely agreed to revolve around consumerism, and many researchers argue that a globalizing effect due to the mass media is taking place all over the world. Ownership and control of television, including satellite and cable systems, and associated media like newspaper, magazine, and book publishing, films, video, records/tapes/compact discs, and a wide variety

of other marketing media (notably, the Internet), are concentrated in relatively few very large TNCs. The predominance of corporations from the US is being challenged by corporations from Japan and Europe in the global arena, and even by media empires from elsewhere (Herman & McChesney 1997).

While Marxist and Marx inspired theories of the inevitability of a fatal economic crisis of the capitalist global economy appear to have lost most of their adherents, at least two related but logically distinct crises have been identified. The first is the simultaneous creation of increasing poverty and increasing wealth within and between societies (the class polarization crisis), not to be confused with Marx's emiseration thesis, which failed to predict significant increases in wealth for rapidly expanding minorities all over the world. The second is the unsustainability of the global economy as it is presently organized (the ecological crisis). In most communities around the world the absolute numbers of people who are becoming global consumers have been increasing rapidly over recent decades. At the same time, in some communities the absolute numbers of the destitute and near destitute are also increasing, often alongside the new rich consumers. The best available empirical evidence (for which see the United Nations Development Program *Human Development Report*, published annually since 1990) suggests that the gaps between rich and poor have widened since the 1980s in many parts of the world. The very poor cannot usually buy the goods and services that the global economy offers in such abundance. While there is a long way to go before consumer demand inside the rich first world is satisfied, the gap between the rich and the poor all over the world is not welcome news for TNCs. In addition to the profits lost when poor people who want to buy goods and services do not have the money or even the credit to do so, the increasing visibility of the new rich and the new poor in an age of constant global media exposure directly challenges capitalist claims that everyone eventually benefits from the global economy.

The ecological crisis is also directly connected with consumerism, illustrated in the struggles over the concept of sustainable development. In recent decades most major TNCs

have formulated policies in response to the challenges of environmental harm and declining stocks of resources essential for the maintenance of the global economy. However, the persistence of problems of pollution, health risks, environmental degradation, and waste management intrinsic to the system suggests that ecological crisis will be difficult to avoid. In this context, the attempt by transnational corporations and their supporters in governments, international bureaucracies, and the professions (globalizing politicians, bureaucrats, and professionals) and the mass media to capture the idea of sustainable development and to reconcile it with the progress of the global economy is worth further study.

global justice as a social movement

Matthew Williams

The global justice movement is a transnational social movement, rooted in the confluence of the human rights, labor, environmental, indigenous, peasant, and feminist movements' shared opposition to neoliberal globalization and vision of a more democratic, equitable, ecologically sustainable world. Neoliberal globalization refers to those structural changes in the global economy being carried out under a discourse of free markets that weaken or eliminate policies that favor grassroots social actors, such as labor unionists, environmental activists, and indigenous peoples, while creating a regulatory apparatus that favors transnational corporations (TNCs). The global justice movement is truly global in scope, with strong constituent movements in western countries, Latin America, South and Southeast Asia, and parts of Africa; it is weakest in the Middle East, East Asia, and the former Soviet bloc. Constituent organizations range from traditional non profits and volunteer groups in the global North (first world), to large grassroots labor, peasant, and indigenous organizations in the global South (third world). The global justice movement is a relatively young movement, coalescing in the 1990s and only becoming highly visible with the massive 1999 protests against the World Trade Organization (WTO) in Seattle, Washington.

Given the movement's newness, sociologists have only recently begun to study it. Most research has focused on case studies of particular campaigns, coalitions, or social movement organizations using a combination of ethnography and in depth interviews, although surveys of global justice activists at various protests and conferences have been done as well. Some researchers have taken advantage of the heavy use of the Internet to communicate by global justice activists, mining online archives of email lists and websites as an additional source of data. It is as yet unclear how well traditional theories of social movements, which were developed based on analyses of movements in western

democracies, apply to the global justice movement, given its global scope and strong Southern character. Indeed, most research remains focused either on transnational coalitions or on the movement in the North, with relatively little work done by sociologists looking at constituent movements in Southern countries.

Often referred to, somewhat inaccurately, as the anti globalization movement, global justice activists oppose only the current form of economic globalization – neoliberalism – and favor what they sometimes call globalization from below. They critique neoliberalism for taking critical economic decisions out of the democratic, public sphere and placing them in the hands of either TNCs or intergovernmental organizations with little democratic accountability, particularly the International Monetary Fund (IMF), World Bank, and WTO. Critics charge that, under neoliberalism, decisions are made primarily on the basis of short term profit maximization, resulting in growing poverty and ecological degradation.

Global justice activists generally believe that democratic, public oversight of corporations and markets is needed to ensure an equitable, ecologically sustainable economy. In the more radical wing of the movement, this suspicion of markets takes the form of full blown anti capitalism. Global justice activists also stress the importance of political democracy; their vision of democracy is a participatory and deliberative one, moving beyond notions of democracy that are limited to elections and lobbying. Although most global justice activists would agree with the principle of subsidiarity – that decisions should be made at the most local level possible – there is much disagreement about what this would mean in practice, with some emphasizing the importance of a global regulatory apparatus, others stressing the empowerment of local communities. Although many global justice activists seek to strengthen nation states' capacity to regulate markets, many others are as suspicious of states as they are of markets. In its moderate form, this manifests as an emphasis on the need for a vigorous, global civil society to serve as a watchdog on both business and government. Among radicals, this often takes the form of emphasizing the need to create democratic spaces, autonomous from both markets and states. In the North, this

radicalism primarily takes the form of anarchism; while a minority in numbers, anarchists have been influential, playing an important role in organizing many major protests, thereby disseminating ideas about participatory democratic organization and the tactics of direct action. In the South, this radicalism is increasingly embraced by many large grassroots organizations of peasants, indigenous peoples, and the urban poor; these Southern groups generally do not share Northern anarchists' absolute rejection of nation states, but there is nonetheless an emphasis on fundamentally reshaping political relations to empower grassroots social actors over political and economic elites.

The global justice movement emerged as a response to the neoliberal transformations of the global economy that began in the 1970s. These changes resulted in social movements facing a new, more complex system of political opportunities and constraints, operating at multiple levels, both national and transnational, which led to the formation of transnational coalitions and changes in movements' tactical repertoires.

As Southern governments, in debt to and under pressure from the IMF and World Bank, began to reform their economies along neoliberal lines in the 1970s, they increasingly faced large anti-austerity protests. Although these governments would often reverse the reforms to quell the protests, they would later reimplement them in a piecemeal fashion that did not arouse public opposition but satisfied the IMF and World Bank. But just as neoliberalism closed many political opportunities at the national level, it created new, powerful targets at the transnational level, albeit targets that are far more difficult to pressure effectively. A number of campaigns evolved in the 1980s to challenge these organizations. Activists targeted the World Bank using traditional advocacy methods such as lobbying by environmental and indigenous rights activists, who charged that many of the development projects funded by the Bank, such as large dams and oil pipelines, were environmentally destructive and displaced indigenous people without adequate compensation. As TNCs increasingly moved production (and therefore jobs) between countries in an effort to cut labor costs, labor unions began to create transnational organizing campaigns targeting particular TNCs. In addition

to these adaptations of traditional tactics, activists developed a new, innovative repertoire of consumerist tactics such as economic boycotts to pressure TNCs guilty of particularly egregious actions into changing their environmental, labor, and other policies. Many of these campaigns depended on the ability of Northern allies to use their political or economic clout to pressure the World Bank or TNCs on behalf of Southern constituencies, who in turn provided the testimonies to legitimate the Northern activists' campaigns. Campaigns at this point in time focused primarily on changing individual TNC and World Bank policies, not the fundamental structures of the global economy.

The late 1990s and early twenty-first century saw a dramatic expansion of activists' tactical repertoires – alongside advocacy, labor organizing, and consumerist repertoires, global justice activists began to employ mass-based direct action. In the North, this has primarily taken the form of protests, starting with those against the WTO in Seattle, in which activists attempt to shut down or disrupt high-level meetings of international political and business leaders, such as the annual conferences of the IMF and World Bank and negotiations to create free trade agreements. These protests mark a dramatic shift away from the highly routinized, contained legal protests of the 1970s and 1980s. Police have, however, grown relatively adept at containing these protests through a number of counter-tactics, including mass, preemptive arrests. There has also been a wave of direct action in the South as well, particularly Latin America, where mass protests, road blockades, and other such actions have forced governments to reverse neoliberal initiatives and driven presidents from office. This also marks a noteworthy tactical shift, away from the armed struggles of the 1960s, 1970s, and 1980s. Even the indigenous Zapatista guerrilla army of Chiapas, Mexico, has focused more on mass protest and creating a parallel system of participatory democratic government than on armed struggle. Paralleling this shift to direct action, activists have expanded their demands from individual policy changes to dismantling the entire neoliberal system.

The results of this can be seen in the outcomes of the WTO talks in Cancun, Mexico and in the Free Trade Area of the Americas

(FTAA) talks in Miami, Florida, both in 2003. Although the protests outside these summits were relatively small, the WTO talks collapsed when Southern delegates walked out and the US was forced to compromise with Southern delegates in the FTAA talks to avoid a similar walkout. In part, this was the result of increasing discontent on the part of Southern elites, who often wish for more autonomy than neoliberalism grants them; but it was also in part a reaction to the growing unrest they face in their home countries. While some political opportunities closed as economic policymaking was moved from the national and public forums to transnational and closed ones, other opportunities opened at both the national and transnational level, in part because of the actions of social movements themselves.

The organizational networks of the global justice movement began to take shape during the initial campaigns of the 1980s, which usually involved partnerships between grassroots groups in the South and large development or environmental non profits in the North. As these networks thickened in the 1990s, the scope of the groups involved grew to include smaller, more confrontational and radical groups in the North. Many have stressed the importance of the Internet and other advances in telecommunications in the formation of the movement; more important, however, have been face to face meetings among activists, allowing people from very different backgrounds to build ties of trust between them, ties that were then maintained through the Internet. While in the 1980s, activists met primarily to work on specific campaigns, in the 1990s and early twenty first century, regular international conferences focusing on confronting neoliberalism as a whole began to take place, including the Zapatista *encuentros* (encounters) and the World Social Forum. Those activists who formed relationships at such meetings then served as brokers between their respective constituencies. They were able to bridge their differences and work together, forming a "movement of movements," by framing their particular issues in shared terms of global justice and opposition to neoliberalism. The 1990s also saw the development of several permanent transnational coalitions with broader goals, including Fifty Years is Enough, dedicated to either dramatically reforming or

abolishing the IMF and World Bank; Jubilee 2000, a network founded to abolish third world debt; and People's Global Action, an explicitly anti capitalist alliance of small Northern radical groups and some of the large Southern grassroots organizations.

The networks that have evolved, at both the national and international levels, have striven for democratic relationships between groups working together. The global justice movement has developed a flexible, inclusive collective identity, with most activists being willing to put aside ideological and other differences to work on concrete projects, emphasizing dialogue over conformity.

There are, however, also a number of tensions around issues of organization and democracy in practice. The participatory democratic character of the new wave of global justice activists does not mesh well with the bureaucratic organization of the older advocacy oriented non profits and labor unions, both North and South, leading to difficulties in working across these divides. Differences in power, resulting from both access to resources and location in the world system, have also produced tensions. Many Southern grassroots groups are dependent on Northern non profits for part of their funding; these tensions also exist between non profits and grassroots groups within Northern countries. In some cases, these power differences have resulted in Northern activists launching campaigns without consulting their Southern "beneficiaries," sometimes producing results Southerners find not in their best interests. There have also been issues because of Northerners conveying a different message than their Southern allies would like to TNCs, the IMF, and World Bank, to which the former have more access than the latter. Over time, activists have grown more conscious of the need to take into account these power differences. While they cannot be erased short of a radical transformation of the world economy, more dialogue between Northern and Southern groups has gone some way to addressing these problems, though tensions certainly remain.

It should be noted that despite the growing importance of transnational networks and campaigns, most groups remain locally rooted. They may address domestic issues, framing them in terms of global justice, or they may

address international issues by pressuring their national governments to either change their policies or press for reforms in intergovernmental organizations of which they are a part.

global politics

Lloyd Cox

Global politics refers to patterns of political relations and activities that stretch across state borders, and whose consequences are, potentially and/or actually, worldwide in scope. As such, global politics includes but is not limited to interstate relations, and is not explicable in terms of those approaches conventionally deployed by realist scholars of international relations (IR). The latter have routinely assumed the primacy of sovereign, bounded territorial states, which act in their own national interest in a sharply demarcated “external” political environment defined by zero sum power equations. Many theorists argue that such views do not accurately reflect the new realities of what some have

referred to as a post Westphalian or post international world. In this world, states allegedly have had their capacities eroded, the boundaries separating domestic and foreign policy are increasingly blurred, and the sources of political authority, legitimacy, and governance have multiplied beyond the territorial state. This has created a “democratic deficit” between the nominal sites of political participation (national states) and more remote global sources of political power and decision making, in turn raising questions about contemporary forms of political community and citizenship. These shifting realities have been prompted by a number of developments encompassed by the term globalization.

While the definition of globalization has been fiercely contested, it can be reasonably understood as the sum of those processes involved in the growth of worldwide interconnectedness and interdependence, where social relations are stretched across existing boundaries and time and space are compressed to an extent that the whole planet becomes an object of human consciousness and action. Although “globe talk” only really takes off in the 1980s, it is traceable by numerous intellectual threads to earlier intimations of a global political awareness. In 1774, Herder rhetorically asked: “When has the entire earth ever been so closely joined together ...? Who has ever had more power and more machines, such that with a single impulse, with a single movement of a finger, entire nations are shaken?” (cited in Hopkins 2002: 12). Similarly, in the nineteenth century, Marx argued that capitalism is predisposed to expand beyond its geographical point of origin, to “nestle everywhere, settle everywhere, establish connexions everywhere” across the entire planet. For Marx, such globalizing processes are inherently political, and would be further elaborated by the next generation of Marxists in various theories of imperialism (Hilferding, Bukharin; Lenin, Kautsky, and Luxemburg), and later still by dependency and world systems theorists (Frank, Amin, Wallerstein).

In non Marxist social science, theories of globalization and global politics were antipated from the 1960s in both sociology and political science. In a seminal article, Moore (1966) advocated the development of a “global sociology,” while Roland Robertson and his various co authors raised the specter of a global

comparative sociology of different paths to and through modernity (Nettle & Robertson 1968). In political science and IR there were similar trends among scholars dissatisfied with the dominant realist paradigm. Modelski's (1972) treatise on world politics was particularly significant in this respect, as it was one of the first works in the social sciences actually to deploy the concept of globalization. This was followed by Falk's (1975) appeal for mainstream political science and IR to take a more "global approach," and Keohane and Nye's (1977) important contribution on "complex interdependence." These and associated analyses were premised on the view that world politics could no longer (if indeed it ever could) be understood exclusively with reference to the interests of competing states within a largely anarchic interstate order, the central claim of realism. This resonated in subsequent analyses of "global governance," "transnational politics," "international regimes," and "global interdependence," which grew in stature in the 1980s and 1990s.

The periodization of political globalization has also been widely debated. Globalization has been variously described as being coterminous with European global expansion from the late fifteenth century, with European imperialism in the late nineteenth century, and with US led globally integrating economic and technological developments in the post World War II era. Regardless, most would agree that globalization has accelerated since the early 1970s. The breakdown of the Bretton Woods system of international financial regulation, the global resurgence of economic liberalism, the revolution in communications, the later emergence of global terrorism, and the collapse of the Eastern Bloc and its (and China's) incorporation into the circuits of global capitalism, are all viewed as important manifestations and constituents of globalization. These are trends that have frequently been analyzed through the lens of economic, technological, and cultural convergence, but they also clearly have important political dimensions that lend some substance to the notion of global politics.

One key element of global politics is the growth of "international regimes." An international regime can be defined as "implicit or explicit principles, norms, rules, and decision making procedures around which actor

expectations converge in a given issue area of international relations" (Krasner 1983: 2). Such regimes find an institutional embodiment in the proliferation of international non governmental organizations (INGOs) and intergovernmental organizations (IGOs) over the past century. The former increased from around 200 in 1900 to over 5,000 in 1996, while the latter increased from 27 to 260 over the same period (Held et al. 1999: 53). In both cases the largest absolute increases have occurred after 1960, in response to economic, technological, environmental, and security challenges that transcend the capacities of individual states, thus demanding new forms of transnational regulation and cooperation.

These increases have been paralleled by the consolidation and extension of military and trading blocs and other supranational institutions that are widely viewed as being more than the sum of their national parts. The European Union (EU), for example, is now much more than just a trading bloc of member states, but also encompasses a number of suprastate political functions and institutions to which member states agree to cede some hitherto taken for granted prerogatives and capacities. While the EU is a "regional" rather than a "global" institution, many would view it as an aspect of the broader globalization of politics, which has the potential to become a bulwark against US global dominance and which also portends similar suprastate arrangements in other parts of the world.

For many globalization theorists these developments signify the extent to which states have become more deeply enmeshed in webs of global political connections and multi layered governance, based on structures of overlapping authority. This implies a degree of "governance without government." Many of the functions of political coordination and regulation once the preserve of formal governments are now accomplished through more informal mechanisms, and with the participation of NGOs, IGOs (e.g., the IMF and WTO), transnational corporations (TNCs), and global media, which are allegedly beyond the jurisdiction of individual governments. If this is true, it clearly places serious limits on the exercise of democracy, which is still largely organized within the limited horizons of individual national states whose governments are increasingly beholden

to informal governance emanating from beyond their borders. This in no way entails the emergence of “world government” – a concept that suggests something far more unitary and directed than the realities of multi layered governance – though it has had implications for the United Nations (UN) system. In particular, since the early 1990s the UN has played a more interventionist role in policing a liberal democratic model of democracy on the one hand, and asserting a human rights discourse and practice on the other; albeit one that has been very unevenly applied. The former has been accomplished through the UN’s involvement in and monitoring of electoral processes in countries as diverse as Nicaragua and Angola, South Africa and Ukraine. The latter has been manifested in a multiplication of UN humanitarian interventions and peacekeeping missions across Africa, Asia, and the Balkans.

The idea of universal human rights that trump the sovereign rights of states to non interference by other states, and the realization of this idea in practices of humanitarian intervention, is a relatively recent one. Although universal human rights have been encoded in various covenants and protocols of international law since the late 1940s (including the UN Charter and Universal Declaration of Human Rights in 1948, the Convention against Genocide in 1948, the Covenant on Civil and Political Rights in 1966, and the Covenant on Economic, Social, and Cultural Rights in 1966), it has only been since the end of the Cold War that states and coalitions of states have been actively prepared to enforce these principles. Enforcement through armed intervention has only been applied, however, in faltering steps and in very selective cases, with geopolitical calculation and domestic political considerations still being very important in determining when human rights do and do not get defended. This has led many scholars to question the assumption that humanitarian intervention represents the opening up of a post Westphalian global political order where states are answerable to powers and principles beyond their borders. This draws into sharp relief what is perhaps the key debate surrounding global politics; namely, whether or not states are still the central actors of global politics and, therefore, whether or not a

post Westphalian, post international political universe has in fact emerged.

Scholars who argue that such a new global political universe now exists typically emphasize four related points: (1) that state capacities and *de facto* sovereignty have been compromised in various ways by the globalization of economic, political, and cultural processes; (2) that national borders are increasingly porous with respect to the movement of information, commodities, and people, which contributes to point (1) above and problematizes the clear demarcation of domestic and foreign politics; (3) that politics has been partially “deterritorialized” as a result of points (1) and (2); and (4) that taken together, (1), (2), and (3) represent a qualitative break from the state centric, international world order that is assumed to have characterized world politics for the 300 or so years following the Peace of Westphalia (1648). The latter concluded the Thirty Years War in Europe and is often taken to have initiated the modern era of state sovereignty, with its presumptions of absolute and indivisible territorial authority, and rights to non interference by external actors. Mutual recognition of these sovereignty rights is said to have regulated conduct between states and been the central ordering principle of the Westphalian system, which has now been transcended by the globalization of politics.

Many critics dispute these claims, and reject the whole idea of a post international, global political environment. They point out that so called Westphalian sovereignty was always more of a normative ideal than it was a political reality, with states throughout the “Westphalian period” frequently having their claims to absolute authority constrained and subverted by other states and non state actors. Furthermore, the suggestion that state capacities have been uniformly eroded neglects the massive power discrepancies between different states, and glosses over the strengthening of some state capacities (the policing of immigration) even as others are eroded (the capacity to determine some aspects of economic policy autonomously). The US’s recent shift to political unilateralism is held up as proof of the fundamental era of deprecating state powers. Finally, the idea that there has been a deterritorialization of

politics is said to be out of step with both the past (where clearly not all political phenomena could be explained with reference to relations between territorial states) and with the present (where politics still has a demonstrable territorial dimension, as reflected in the continued salience of territorialized nationalist conflicts). In this view, global politics is, and will always remain, filtered through the prism of national institutions.

More recently, synthetic contributions to the globalization debate have emerged that try to transcend the stark dichotomies outlined above. These scholars focus on the contradictions inherent in global politics, between simultaneous tendencies towards integration and fragmentation, universalism and particularism, which exhibit both continuities and discontinuities with the past. In this view, states and interstate politics remain crucial, but are now overdetermined by other global actors and processes.

global/world cities

Jamie Paquin

“Global city” discourse posits and investigates the emergence of a small number of cities occupying commanding roles in a globalizing economic system. The emergence of global cities signals the shift in the organization of capital accumulation and economic production since the late 1970s and a corresponding shift in the nodal functions of some cities away from local, regional, or national contexts to more varied and uneven connections to other cities and regions in the world. Specifically, the designation “global city” is applied to those urban areas consisting of a disproportionate number of major economic headquarters and services, including corporate management, banking, finance, legal services, accounting, technical consulting, telecommunications, computing, international transportation, research, and higher education (Friedmann & Wolff 1982: 320). To the extent to which the hypotheses of this literature with stand scrutiny, numerous questions arise regarding the social implications of a greater disjuncture between proximity and connectedness in urban life.

Though the concept of world cities in the recent and distant past is not entirely new (Geddes 1924; Hall 1966), it was Friedmann (1986; see also Friedmann & Wolff 1982) who first made a direct link between contemporary “global forces” and “urban processes” in his “world city hypothesis” essay. Elsewhere, Sasen (1994, 2001) provides key empirical data corroborating some of the assertions made about an emergent system of global cities as sites of concentrated global economic activity. This conceptualization of a global city problematic is essentially economic, as the designation of “world” or “global” city is applied to those cities which become central to the accumulation, control, and deployment of international

capital and whose morphologies are transformed by the needs of global capital. Yet, as we can see, this perspective leads to the view that despite their “command and control” functions, global cities are not really “in control” as they are themselves shaped and produced in relation to the interests and demands of external economic forces.

The result of the emergent urban order is then greater difference not only between cities but within them as well, meaning that a world of global cities is both hierarchical and polarized, for even within the “truly” global cities there is a growing divergence in incomes and rights to the city (Friedmann 1986; Knox & Taylor 1995; Marcuse & van Kempen 2001; Sassen 1994, 2001). This polarization stems directly from their articulating role in the global economy, for by serving as the base for global industries and institutions, an “elite” professional class who are “well educated, socially mobile, footloose and cosmopolitan in origin and outlook” (Clark 1996: 139) become a key driving force in the formation of a corresponding economy of low waged and low skilled employment. Sassen’s work (1994, 1996, 2001; see also Mellenkopf & Castells 1991) investigates in great depth this polarization, finding that in the cases of London, Tokyo, and New York the growth in elite professions and services creates the need “for a vast army of low skilled workers” (Sassen 1996), embodied by legal and non legal immigration flows and those displaced by the decline of manufacturing employment resulting from global restructuring.

Novel forms of concentration and dispersal also bring forth new uses and functions of urban space. For those cities capable of attracting the premier command and control functions, high tech business districts, convention centers, international airports, and other transportation linkages become crucial components of their infrastructures, while for lower tier cities – places hollowed out by the migration of manufacturing with little chance of becoming preeminent global cities – the strategy of economic survival is often to cultivate spaces and economies geared toward “culture” and consumption. Some cities like Manchester have been relatively successful in their efforts to rebound from the loss of traditional industries through such initiatives, while other large scale

revitalization schemes have failed to attract the desired capital, consumers, and jobs. Moreover, with the shift toward consumption activities, which often occur in older urban areas, already marginalized populations have sometimes been negatively affected, either because they are pushed from “revitalized” areas through gentrification, or more directly because they become subject to increased surveillance and policing aimed at making these spaces “safe” and desirable. Thus, to the extent to which spaces such as business and trade centers, airports, high tech zones, and even revitalized historical districts of contemporary cities exist as the result of responses to changes in the relationship between proximity and connectedness in an age of globalization, they signal a novel development in the history of urban spaces and the meaning of place.

The global cities literature enriches the globalization debates by perusing and interpreting its spatial causes, manifestations, and requirements. In placing emphasis on urban dynamics and spaces as both the bearers and generators of economic globalization it also brings important scrutiny to the longstanding state centrism of social science, which typically assumes and constitutes national entities with little consideration to the greater specificity of cultural, economic, and political activities and connections. Finally, the global cities literature raises crucial questions regarding the implications of these transformations both between and within cities, drawing attention to the potential for increased social and economic polarization and eroded political capacities associated with transnational economic restructuring. Such changes leave observers such as Sassen (1996) rightly asking, “whose city is it?”

However, global cities discourse and research suffers from significant evidentiary and conceptual limitations. Many critics have called attention to the empirical weakness – or what Short et al. (1999) call the “dirty little secret” of world cities research, since both the criteria for assessment and measurement are inconsistent and questionable (Taylor 2004). Additionally, some studies have found that for some cities, polarization is not necessarily accompanying globalization, and even where it has occurred, local and national policies may be as significant as global forces in intensifying

income and other inequalities. The biggest weakness of this literature, however, is the economic reductionism and determinism underlying the conceptualization and investigation of the global city. Finding certain cities to be disproportionately central in the articulation of global economic activity may provide important insight into some global processes and their implications, but given that concentration is not that new – think of London, Paris, or New York as colonial centers – what stands to be gained by this approach to investigating the relationship between globalization and the city? Secondly, what contribution can such a literature make to the broader sociological problematic of the life world of cities in an age of globalization?

One way to address these shortcomings is to expand inquiry into the global city beyond economic questions through more culturally attuned research which investigates the multiple ways in which global flows are affecting the composition and texture of everyday urban life and subjectivity (cf. Appadurai 1996). Smith's (2001) reconceptualization of the global city problematic as a matter of transnational urbanism is an important contribution in this regard, as it highlights the fact that the designation of global (with its connotation of homogeneity) is less accurate than a language of transnationality or translocality when dealing with the extra local forces shaping contemporary urban life. In transnational urbanism we have then a more particular yet expanded conceptualization of the city in a context of globalization which emphasizes the numerous and diverse networks and flows of people, objects, information, capital, remittances, and media which are major dimensions of place and cultural formation of a global character, regardless of their status in the world cities hierarchy. From this approach, then, many cities will appear uniquely and deeply "global(izing)" despite their peripheral significance to the articulation of global capital. For example, despite Tokyo's global economic preeminence, it lacks the ethnic diversity of a city like Toronto, which although much lower in the "world city" hierarchy, is one of the most demographically diverse cities in world history, and a place where the collective cultural imaginary is heavily attuned to this diversity as a part of living in a global age. Cities like

Toronto are thus places where "globalized" cultural forms are being worked out, and as such, they can be viewed as thoroughly "worldly," if not "global" – a designation just as sociologically significant as the emergence of a small number of "global" cities responsible for the command and control of global economic activity. By adopting an expanded conceptual framework then, we will discover that cities globalize in a variety of ways related to the particular forms of linkages and flows they are both constituted by and generate.

Despite the conceptual and empirical limits of global cities research, the attention it brings to the spatial dimensions of globalization constitutes a fundamental contribution to the study of both globalization and contemporary urbanism, as it enables the apprehension of actual global processes as they operate through and produce spaces and places in conjunction with actual social actors and institutions. And by expanding the conceptualization of the global city to include cultural and political questions in the context of everyday urban life, the global cities perspective can become an especially powerful approach to the study and delineation of globalization as a complex, variable, and spatially manifest phenomenon.

globalization

Larry Ray

Globalization has become one of the central but contested concepts of contemporary social science. The term has further entered everyday commentary and analysis and features in many political, cultural, and economic debates. The globalized world order originates in the international organizations and regulatory systems set up after World War II – including the United Nations, General Agreement on Tariffs and Trade (now the World Trade Organization), the International Monetary Fund, and the World Bank. However, the end of the Cold War was the prelude to the maturity of the concept of globalization, since after 1989, it was possible at least to imagine a “borderless” world in which people, goods, ideas, and images would flow with relative ease and the major global division between East and West had gone. A world divided by competing ideologies of capitalism and state socialism gave way to a more uncertain world in which capitalism became the dominant economic and social system. Coinciding with these changes, a major

impetus to globalization was the development and availability of digital communication technologies from the late 1980s with dramatic consequences for the way economic and personal behavior were conducted. The collapse of communism and growth of digital technologies further coincided with a global restructuring of the state, finance, production, and consumption associated with neoliberalism.

There are many views on the nature and impact of globalization, which is not a single process. Economic globalization refers to such things as the global dominance of transnational corporations, global finance, flexible production and assembly, and the rise of information and service economies. Political globalization can be understood in terms of the growth of international organizations, subnational regional autonomy, the spread of post welfare public policies, and global social movements. Further, globalization possibly weakens the effectiveness and cohesion of the nation state as its traditional functions are “hollowed out” – transferred “upwards” to international organizations and “downwards” to regional bodies. Again globalization is a cultural process, indicated by the growth of global consumption cultures, tourism, media and information flows, and transnational migration and identities. The latter half of the twentieth century saw the growth of global brands and media that carry both cultural and economic significance. A globalized world is one of increasing instantaneity, where events are experienced instantly even by people in spatially distant locations through access to digital communicative technologies. This creates a complex range of social interconnections governed by the speed of communications, thereby creating a partial collapse of boundaries within national, cultural, and political space. However, the meaning and significance of globalization remains far from clear. Some are optimistic (e.g., Friedman 2000), but some are more pessimistic and critical about globalization’s consequences (e.g., Falk 1999). Urry (2003) and Giddens (1999) regard globalization as an emergent process with effects in its own right, although this view is rejected by Rosenberg (2000), for whom it is the *effect* of a complex combination of social, economic, cultural, and political changes such as internationalization, imperialism, the “weightless economy,”

post Fordism, and neoliberalism. It might appear as though global western media create a homogeneous world culture dominated by global brands and TV networks. But at the same time they create increased heterogeneity between globalization winners and losers, global cities and surrounding locales, and eclectic hybrids of local and global cultures.

Globalization is a spatial process that has facilitated the emergence of a new kind of global city based on highly specialized service economies that serve specific, particularized functions in the global economic system at the expense of former logics of organization tied to manufacturing based economies. To enable global markets to function effectively, they need to be underpinned by specialized managerial work that is concentrated in cities. Further, privatization and deregulation during the 1980s and 1990s shifted various governance functions to the corporate world, again centralizing these activities in urban centers. In post industrial cities there is a concentration of command functions that serve as production sites for finance and the other leading industries, and provide marketplaces where firms and governments can buy financial instruments and services. Global cities become strategic sites for the acceleration of capital and information flows, and at the same time spaces of increasing socioeconomic polarization. One effect of this has been that such cities have gained in importance and power relative to nation states. There have emerged new "corridors" and zones around nodal cities with increasingly relative independence from surrounding areas. Networks of global cities densely connected by air have also emerged (Sassen 1996).

There is a wide range of social theories of globalization. Robertson was one of the first sociologists to theorize globalization and central to his approach is the concept of "global consciousness," which refers to "the compression of the world and the intensification of consciousness of the world as a whole" (1992: 8). Through thought and action, global consciousness makes the world a single place. What it means to live in this place, and how it must be ordered, become universal questions. These questions receive different answers from individuals and societies that define their position in relation to both a system of societies and the

shared properties of humankind from very different perspectives. This confrontation of worldviews means that globalization involves "comparative interaction of different forms of life" (1992: 27). Unlike theorists who identify globalization with late (capitalist) modernity, Robertson sees global interdependence and consciousness preceding the advent of capitalist modernity. However, European expansion and state formation have boosted globalization since the seventeenth century and the contemporary shape of the world owes most to the "takeoff" decades after about 1875, when international communications, transportation, and conflict dramatically intensified relationships across societal boundaries. In that period, the main reference points of fully globalized order took shape: nation state, individual self, world system, societies, and one humanity. These elements of the global situation became "relativized" since national societies and individuals, in particular, must interpret their very existence as parts of a larger whole. To some extent, a common framework has guided that interpretive work; for example, states can appeal to a universal doctrine of nationalism to legitimate their particularizing claims to sovereignty and cultural distinction. But such limited common principles do not provide a basis for world order.

By the end of the twentieth century, if not before, globalization had transformed the way people saw themselves in the world. Everyone must now reflexively respond to the common predicament of living in one world. This provokes the formulation of contending world views. For example, some portray the world as an assembly of distinct communities, highlighting the virtues of particularism, while others view it as developing toward a single overarching organization, representing the presumed interests of humanity as a whole. In a compressed world, the comparison and confrontation of worldviews are bound to produce new cultural conflict. In such conflict, religious traditions play a special role, since they can be mobilized to provide an ultimate justification for one's view of the world – a case in point being the resurgence of "fundamentalist" groups that combine traditionalism with a global agenda. A globalized world is thus integrated but not harmonious, a single place but

also diverse, a construct of shared consciousness but prone to fragmentation.

For Anthony Giddens the concept of time space distanciation is central. This is a process in which locales are shaped by events far away and vice versa, while social relations are disembedded, or “lifted out” from locales. For example, peasant households in traditional societies largely produced their own means of subsistence, a tithe was often paid in kind (goods, animals, or labor), money was of limited value, and economic exchange was local and particularistic. Modernization replaced local exchange with universal exchange of money, which simplifies otherwise impossibly complex transitions and enables the circulation of highly complex forms of information and value in increasingly abstract and symbolic forms. The exchange of money establishes social relations across time and space, which under globalization is speeded up. Similarly, expert cultures arise as a result of the scientific revolutions, which bring an increase in technical knowledge and specialization. Specialists claim “universal” and scientific forms of knowledge, which enable the establishment of social relations across vast expanses of time and space. Social distance is created between professionals and their clients as in the modern medical model, which is based upon the universal claims of science. As expert knowledge dominates across the globe, local perspectives become devalued and modern societies are reliant on expert systems. Trust is increasingly the key to the relationship between the individual and expert systems and is the “glue” that holds modern societies together. But where trust is undermined, individuals experience ontological insecurity and a sense of insecurity with regard to their social reality.

Ohmae’s (2005) concept of a “borderless world” epitomizes enthusiasm and the belief that globalization brings improvement in human conditions. Ohmae describes an “invisible continent” – a moving, unbounded world in which the primary linkages are now less between nations than between regions that are able to operate effectively in a global economy without being closely networked with host regions. The invisible continent can be dated to 1985 when Microsoft released Windows 1.0, CNN was launched, Cisco Systems began, the

first Gateway 2000 computers were shipped, and companies like Sun Microsystems and Dell were in their infancies. Back then, the economic outlook was gloomy and few saw this embryonic continent forming. Now, of course, it affects virtually every business. Transnational corporations increasingly do not treat countries as single entities and region states make effective points of entry into the global economy. For example, when Nestlé moved into Japan, it chose the Kansai region round Osaka and Kobe rather than Tokyo as a regional doorway. This fluidity of capital is creating a borderless world in which capital moves around, chasing the best products and the highest investment returns regardless of national origin. The cyberworld has changed not only the way business works but also the way we interact on a personal level – from buying and selling online to planning for retirement, managing investment and bank accounts. Decisions made on the invisible continent (the “platforms” that are created by businesses rather than governments) determine how money moves around the globe.

Giddens (1999) is less unambiguously enthusiastic about globalization than Ohmae and describes it as a “runaway world” which “is not – at least at the moment – a global order driven by collective human will. Instead, it is emerging in an anarchic, haphazard fashion, carried along by a mixture of economic, technological and cultural imperatives.” The global order is the result of an intersection of four processes – capitalism (economic logic), the interstate system (world order), militarism (world security and threats), and industrialism (the division of labor and lifestyles). However, Giddens does not say what the weight of each of these factors is and whether they change historically.

Similarly, David Harvey emphasizes the ways in which globalization revolutionizes the qualities of space and time. As space appears to shrink to a “global village” of telecommunications and ecological interdependencies and as time horizons shorten to the point where the present is all there is, so we have to learn how to cope with an overwhelming sense of *compression* of our spatial and temporal worlds (1990: 240–2). Time space compression that “annihilates” space and creates “timeless time”

is driven by flexible accumulation and new technologies, the production of signs and images, just in time delivery, reduced turnover times and speeding up, and both de- and reskilling. Harvey points for support to the ephemerality of fashions, products, production techniques, speedup and vertical disintegration, financial markets and computerized trading, instantaneity and disposability, regional competitiveness. For Harvey, flexibilized computer-based production in Silicon Valley or the "Third Italy" epitomizes these changes.

John Urry argues that the changes associated with globalization are so far reaching that we should now talk of a "sociology beyond societies." This position is informed by the alleged decline of the nation state in a globalized world, which has led to wider questioning of the idea of "society" as a territorially bounded entity. This in turn prepares the ground for claims to the effect that since "society" was a core sociological concept, the very foundations of the discipline have likewise been undermined. The central concepts of the new socialities are space (social topologies), regions (interregional competition), networks (new social morphology), and fluids (global enterprises). Mobility is central to this thesis since globalization is the complex movement of people, images, goods, finances, and so on that constitutes a process across regions in faster and unpredictable shapes, all with no clear point of arrival or departure.

Despite the contrasting theoretical understandings of globalization, there is some measure of agreement that it creates new opportunities or threats. For example, globalization offers new forms of cosmopolitanism and economic growth but also new threats and global risks such as ecological crisis, global pandemics, and international crime and terrorism. Globalization may be seen as encroachment and colonization as global corporations and technologies erode local customs and ways of life, which in turn engenders new forms of protest and assertion of local cultural identity. Enthusiasts argue that the effects are positive and that integration into the global economy increases economic activity and raises living standards. Legrain, for example, claims that in 2000 the per capita income of citizens was four times greater than that in 1950. Between 1870

and 1979, production per worker became 26 times greater in Japan and 22 times greater in Sweden. In the whole world in 2000 it was double what it was in 1962. Even more significantly, he argues that those countries isolated from the global capitalist economy have done less well than those that have engaged with it. Poor countries that are open to international trade grew over six times faster in the 1970s and 1980s than those that shut themselves off from it: 4.5 percent a year, rather than 0.7 percent. He claims that cross national data indicate how openness to international trade helps the poor by a magnitude roughly equal to each percentage increase in GDP (Legrain 2002: 49–52). By contrast, it can be argued that global patterns of inequality have become increasingly polarized. According to UN data, the richest 20 percent in the world "own" 80 percent of the wealth; the second 20 percent own 10 percent; the third 20 percent own 6 percent; the fourth 20 percent own 3 percent; and the poorest 20 percent own only 1 percent. Throughout the world, 2.7 billion people live on less than \$2 per day. These global inequalities predate globalization, of course, but there are global processes that are maintaining a highly unequal social system (Akyuz et al. 2002).

Contradictions in the global economy are illustrated in other ways too. Liberalization and globalization of capital may not have driven costs down in developed countries where few workers are prepared to tolerate the conditions this new model creates. Flexible global ordering systems need not just produce flexible labor, but flexible labor in excess, because to manage the supply of labor it is necessary to have a surplus. Migrants, many of whom are drawn into the North by collapsing agricultural prices at home, have met this need. But in the wake of hostility manifest in many developed countries, especially following threats of terrorist attack, migrants face tightening border controls and deportation of those who are not in areas where there is a shortage of skills.

Globalization has been the focus of extensive social movement activism and resistance, especially to neoliberal globalism represented by bodies such as the WTO. Glasius et al. (2002) identify the emergence of a "global civil society" in, for example, the growth of "parallel

summits” such as the 2001 Porto Alegre meeting in Brazil attended by 11,000 people to protest against the Davos (Switzerland) World Economic Forum. These are organized through multiple networks of social actors and NGOs operating on local and international levels. There may appear to be an irony that many of the internationally organized or linked movements use globalized forms of communication (notably the Internet) and operate transnationally, mobilizing a global consciousness and solidarities. However, many activists are not necessarily opposed to globalization as such but to economic neoliberal globalization and a corporatist agenda that is intent on constricting individual freedom and local lifestyles in the name of profit. Some further claim that globalization is a new form of imperialism imposing western (especially US) political and economic dominance over the rest of the world. For anti globalization critics, international bodies such as the World Bank and IMF are not accountable to the populations on whom their actions have most effects – for example, when loans are made conditional on structural adjustment and privatization of public facilities such as health, water, and education. Activists also point out that globalization creates a “borderless” world for capital and finance but not for labor, since strict and increasingly severe immigration controls exist in most developed countries while labor lacks basic rights in many developing countries. The movement (if something so diverse can be called a “movement”) is very broad, including church groups, nationalist parties, leftist parties, environmentalists, peasant unions, anti racism groups, anarchists, some charities, and others. If we take a broad view of globalization, though, these movements are themselves part of the process by which global solidarities (albeit rather weak and transitory ones) come to be formed.

globalization, consumption and

Beryl Langer

The terms globalization and consumption combine with reference to the emergence of a global consumer culture: the same products, services, and entertainment sold in the same kinds of retail and leisure spaces (malls, plazas, theme parks, cineplexes) to consumers around the world. From luxury cars and designer clothes to jeans, t-shirts, toys, snack food, and bottled water, markets are global rather than national. The same electronic equipment, cosmetics, children's toys, and grocery lines are consumed in cities as remote from each other as Sydney

and Stockholm, Bahrain and Birmingham. Product availability is less tied to specific places, first because the same global brands are on sale at the same time throughout the world and second because traders catering to deterritorialized immigrants recreate the retail environment of their homeland by importing familiar products. Starbucks, McDonald's, Pizza Hut, and Kentucky Fried Chicken are everywhere – as are family run restaurants selling “ethnic” food to customers in search of either the taste of “home” or the exotic. It is no longer necessary to go to Paris and Milan to buy Dior and Armani, the US to get a baseball cap, India to get a sari, or the Middle East and Southeast Asia for hijabs and burkas. All are on sale in cities around the world, although the different circumstances of their circulation serve to remind us that globalization is not one process, but many.

Globalization and consumption emerged as key concepts in social theory in the last decades of the twentieth century. Developments in electronics and information communication technology took what the geographer David Harvey calls “time space compression” to new levels, accelerating the flow of information, money, people, and goods across national borders to create a world market with a global division of labor and global consumers. Relocation of production in “newly industrializing countries” where labor was cheaper and less regulated turned subsistence farmers into urban workers (a process begun in England 200 years earlier), bringing new cohorts of consumers into the market and the global cultural economy. Human societies no longer can be understood in terms of bounded cultures within nation states. Social identities are increasingly defined and expressed through consumption and life style rather than work and class position.

Both terms are subject to conceptual, substantive, and evaluative debate. Globalization has been problematized in relation to its history, the extent to which its processes are separable from the activities of nation states, and whether its consequences are positive or negative. Debate on consumption has centered on a number of key issues: the continuing relevance of class as a basis for understanding social relations, whether consumer capitalism as a social

form represents an advance in freedom or a shift in the locus of exploitation, and whether the collective rights and responsibilities of citizenship have been replaced by diminished notions of consumer sovereignty based on individual choice and capacity to pay. At the intersection of these contested areas, questions focus on the implications of the global cultural economy for the survival of local cultures and national identities, the political economy of the global division of labor involved in its production, and its social and environmental consequences.

The question of what, if anything, distinguishes “global consumption” from the consumption of goods and culture distributed across borders by traders and invaders throughout human history is part of a broader debate about the status of globalization as a concept. Critics like Hirst and Thompson (1996) argue that neither the flows of trade, capital investment, and labor migration, nor the impact of new technology between 1950 and 2000, are remarkable when compared to the period between 1850 and 1914. On the other hand, proponents of the globalization thesis such as Castells (1994), Giddens (1999), and Held (1999) argue that the intensification of patterns of interconnectedness mediated by new information technology justifies the conceptualization of the contemporary global system as distinctive – a “global economy” that “works as a unit in real time on a planetary scale” (Castells 1994: 21).

From a Marxist perspective, the globalization of consumption is part of the systemic logic of capitalism, which can only sustain profits through continuous growth. While Marx's predictions of intensifying class struggle did not anticipate the capacity of capitalist mass production to offer workers consumer durables instead of “immiseration,” his observation that “the need of a constantly expanding market for its products chases the bourgeoisie over the whole surface of the globe” proved remarkably prescient. Marx's view that the globalization of consumer markets was a logical outcome of capitalism finds contemporary expression in the work of Immanuel Wallerstein and his followers in “world systems theory,” who argue that the processes to which the term globalization refers are not new, but have existed for the

500 year “life cycle of the capitalist world economy” (Wallerstein 1974).

From the “figurational perspective” of Norbert Elias and his followers, globalization and consumption are understood in terms of an even longer trajectory of human development involving population growth and geographic expansion from the earliest “survival units” of human society. According to this view, the economic processes of production and consumption theorized by Marx tell only one half of the story, in that the movement of goods and people across geographical space is also dependent on physical security – protection from pirates and brigands. Expansion of networks linking producers to consumers therefore required both faster transport and the monopolization of violence by states to secure trade routes. Norbert Elias’s early work on “the civilizing process” in Western Europe is thus seen as documenting “the middle part of the long term story of globalization and its antecedents in one region of the world” (Mennell 1990: 360), and his later work as extending this story back to the role of “survival units” in human prehistory and forwards to the dynamics of nuclear power between global superpowers in the second half of the twentieth century. The interdependence of global consumption and the monopolization of the means of violence can be demonstrated in relation to both “legal” and “illegal” commodities. Global consumption, whether of oil or heroin, depends on securing the sites of production and networks of distribution through the exercise of violence, whether by states or drug cartels.

Globalization of consumption is often equated with Americanization, an argument reinforced by the number of prominent global brands with corporate headquarters in the US, including Coca Cola, Disney, Levi’s, McDonald’s, Nike, Microsoft, and Starbucks. Coca Cola is in that sense iconic, with the term “Coca Colanization” used to signify economic and cultural domination by the US (Wagnleitner 1994). So, too, McDonald’s, its golden arches metonyms of American culture and its restaurants regular targets for anti American protest (Ritzer 2004a). From this perspective, “global culture” is in fact “American culture” and its consumers are “Coca colonials.” Critics of this view point out

that the sources of global culture are not all American, arguing that Ikea furniture, Indian (“Bollywood”) movies and food, Japanese animation, electronics, and sushi – not to mention the global audience for soccer, a sport in which the US is an inconsequential player – all point to more complex processes of global cultural flow.

Equating the globalization of consumption with Americanization is a variant of the claim that globalization of consumption eliminates cultural diversity, leading inexorably to a homogeneous world in which everyone everywhere is the same. Against this, however, are two kinds of arguments. The first focuses on the culturally specific ways in which global products are consumed, and the different meanings attached to global products in different cultural contexts. Ethnographic studies of McDonald’s restaurants in East Asia, for example, suggest that while the popularity of McDonald’s has had an impact on local eating habits, particularly among the young, local customs have equally affected McDonald’s by rejecting the “fast food” ethos and using McDonald’s restaurants as places to “hang out,” effectively turning them into leisure centers and youth clubs (Watson 1997).

The fact that people consume global products does not tell us what this consumption means to them. For example, Daniel Miller’s account of what drinking Coca Cola means in Trinidad suggests that the global product is appropriated into local culture and meaning, becoming “Trinidadian” rather than American – hence the title of his essay, “Coca Cola: A Black Sweet Drink from Trinidad” (Miller 1998). According to Hannerz (1996; Hannerz & Lofgren 1994), global culture is always consumed locally, resulting not in homogenization but in what he calls a “global ecumene” produced through the intersection of global and local in four social and organizational settings: the state, the market, social movements, and the form of life. What is available for consumption in the market is just one factor in a complex cultural process involving the appropriation of global products into different “habitats of meaning” – as, for example, when anti American activists drink Coca Cola or wear Levi’s while expressing hostility towards “US imperialism.”

The assumption that globalization of consumption leads to homogenization is also called into question by Arjun Appadurai's (1990) conceptualization of the global cultural economy as a "complex, overlapping, disjunctive order" that can no longer be understood in terms of center-periphery models. Globalization is not one process but many, not just the circulation of global products and media but of people who recreate "deterritorialized" versions of diverse homeland cultures in countries of immigration. "Global consumption" is as much a matter of buying a sari from an Indian shop in Chicago or Birmingham as of buying Levi's in Mumbai or Delhi, watching "Filipino television" in Los Angeles as watching Disney Asia in Manila.

Globalization has contradictory implications for consumption. On the one hand, the global flow of commodities undermines the viability of "local" products and contributes to the sense that cultural difference is being submerged beneath a global uniform of jeans, t-shirts, sneakers, and baseball caps, a nutritional regime of American fast food, and a cultural diet of CNN, MTV, and Disney. On the other hand, the global flow of people circulates cultural difference; diasporic groups create deterritorialized versions of "homeland" culture in restaurants and stores that serve two markets – one hungering for the familiar, the other for the exotic. Global tourism is similarly contradictory – packaged holidays and hotel chains that insulate travelers from different cultures, Lonely Planet Guides for those in search of authentic alterity. Global consumption is the spread of McDonald's and Disney to Asia, but it is also the availability of Thai curry paste and Hong Kong action movies in Sydney and Seattle. Such examples suggest *interplay* between the world market and cultural identity, between consumption and cultural strategies, rather than a one way process of cultural homogenization, which inevitably and inexorably renders us all the same (Appadurai 1990; Friedman 1990, 1995; Kahn 1995).

The idea that consuming global products involves interplay between global and local rather than cultural homogenization gives rise to the terms "glocal" and "glocalization" (Robertson 1995) to describe what happens

when consumers incorporate global culture into local practice and meaning to produce culture that is neither fully global nor strictly local. By implication, globalization of consumption increases cultural diversity, adding "glocal" hybrids to the existing pool of local cultures. A less optimistic view would see "glocal" cultures as replacing rather than coexisting with "local" cultures, with the balance between global and local shifting inexorably in favor of the global as what's left of the local in "glocal" decreases over time. Ritzer (2004b) has coined the term "grobalization" for this process – an interplay between "grobial" and "glocal" which leaches hybrid forms of locally specific content ("something") and offers global consumers an ever expanding universe of centrally conceived and controlled products that lack distinctive content or character ("nothing").

Global consumption raises questions of social justice and environmental sustainability that might be seen as more important than those of cultural diversity, although the three are inextricably linked. "Consumer culture" is not just hamburgers and Hollywood, but what Raymond Williams called "a whole way of life." To what extent is this way of life sustainable, and what are the consequences of extending its consumption patterns and expectations to all corners of the globe? Can the desire of people in newly industrializing countries for the comforts and conveniences taken for granted in the North – cars, air conditioners, refrigerators, and washing machines – be met without rendering the planet even less habitable? Writing in 1905, in *The Protestant Ethic and the Spirit of Capitalism*, Max Weber observed that the "tremendous cosmos of the modern economic order" in which material goods had "inexorable power" over people's lives had an inescapable logic, which would continue to determine the lives of all within it "until the last ton of fossilized coal" was burnt. A hundred years later, the "iron cage" of this logic circles the globe.

globalization, culture and

Roland Robertson

As the debate about globalization has rapidly expanded and become more, rather than less, contentious, there has emerged what might be called a “negative consensus” concerning the idea of global culture. While there is most definitely no widespread agreement, either “globally” or “locally,” about what we might mean by the term global culture(s), there is – for many, a seemingly reluctant – confirmation of the proposition that the issue of global culture is of paramount significance.

In this regard we are witnesses of and participants in the continuation of an older debate as to whether national societies function primarily within the parameters of a societal culture, variously called the dominant ideology, the hegemonic discourse, the central value system, the common culture, or whatever. The key point here is that social scientists and students of culture have at least converged on the thesis that the question of which particular modes of contested cultural expression and discourse are predominant at any given time and/or place is a matter of importance. This much has been conceded by even the most committed of those of a materialistic persuasion. Indeed, there are few serious analysts of the global human condition who would now claim that ideational perspectives and commitments are mechanical products of autonomous material processes.

The conventional treatment of culture in mainstream sociology, greatly influenced by social and cultural anthropology, was for long that of a binding agent, a phenomenon that provided ideational cohesion and normative guidelines to the members of a society. Over

time this perspective has undergone increasingly strong challenges and in this regard the recognition that societies are not insulated monads has played a crucial role. And it might well be said that it is strange to consider now that until recently in the social sciences – with the problematic exception of international relations – analysis hinged upon such a viewpoint.

Consideration of culture in global or at least transnational terms has led to much rethinking of the concept of culture and its part in social life, not least because practitioners of the meta discipline of cultural studies have made major interventions in the discussion of globalization, globality, transnationality, global modernities, and so on. Thus, the oft called cultural turn has had a major part in elevating culture to a position of significance in the globalization debate (Robertson 1992: 32–48; Inglis 2005: 110–36). This is not to say, however, that the cultural factor is totally accepted as central to the thinking of those working on matters global.

Almost certainly, the most controversial question in the general, non reductionist discussion of globalization concerns whether the world as a whole is being swept by homogenizing cultural forces, at one extreme, or whether the world is, on the other hand, becoming increasingly marked by variety and difference. The middle ground position between total homogeneity and total heterogeneity of global culture as involving sameness within difference (or, perhaps, difference within sameness) is somewhat analogous to Durkheim's ideas of a century or more ago concerning national societies. Durkheim argued that at the societal level the form of social solidarity had shifted over evolutionary time from a condition of mechanical solidarity, involving sameness, to one of organic solidarity, involving the "coordination" of difference. (While Durkheim saw this issue mainly in relational terms, the concern here is with the problem in cultural terms.) Total homogeneity entails such a lack of vitality in human life that there would be a very strong entropic tendency across the world as a whole, while total heterogeneity suggests a world so completely marked by difference that there would be little or no sharing of worldviews or lifestyles, no solidarity at all. Thus, put in these hypothetical but actually realistically impossible terms, the two extreme positions are really

descriptions of, or recipes for, the collapse of the global human condition. This is actually an interesting, if apocalyptic, line of deliberation, one worth pursuing, particularly in light of the global trauma of recent years, but which cannot be taken up here.

Insofar as the globalization equals homogenization thesis has been so much in evidence in recent years, often in tandem with the conceptually unacceptable claim that Americanization is the same as globalization (Beck et al. 2003), the emphasis here is more on heterogeneity than homogeneity. Nonetheless, the motif of sameness is not relegated to the background. For the relationship between universal (or universals) and the particulars is a crucial, indeed *the* pivotal issue in the study of globalization, considered as a long term, multidimensional process. Globalization – conceived, of necessity, as *glocalization* (Robertson 1992: 173–4; 1995) – is a self limiting process. In the light of the idea of glocality, globalization can only take hold unless globalizing forces can find or produce a niche in relation to the local and the particular. This is to be seen in the maxim that it is the particular which makes the universal work.

Put simply, globalization is defined as involving a move in the direction of unicity or oneness, with (1) a deepening and extending of reflexive global consciousness and (2) an increase in global connectivity and density. Both those phenomena are intimately related (Tomlinson 1999). One major manifestation of this relationship may be clearly seen in the current intimacy of economy and culture. They are complicitous in the specific sense that the worldwide production, promotion, distribution, and sale of goods and services has led to an increasing sensitivity to actual or constructed/cultural difference. In fact, cultural difference is a major selling point, in that the exotic alterity of a product is much used as a suggested rationale for consumption. On the other hand, the commodification of culture – in the form of cultural goods (Cowan 2002; Brown 2003) – makes them increasingly open to economic considerations and analysis.

PERSPECTIVES ON GLOBAL CULTURE

The idea of reflexive global consciousness is a critical aspect of any intervention in the debate

about global culture. It can usefully be approached via Marx's distinction between a class in itself and a class for itself. Clearly, global humanity has existed for millennia, but without possessing anything like the degree of widespread, but contested, sense of the fate of the concrete world as a whole in which we are participants in these early years of the twenty first century. In other words, the *problem* of the world for itself is increasingly constitutive of the Durkheimien conscience collective of our time. This can be seen in various manifestations, most notably since the near global trauma of September 11, 2001. For in this very recent – and still ongoing – case, many, many people around the globe have been drawn in one way or another to consider the future and nature of our planet and its inhabitants, although increasingly in recent decades a way was prepared for this in millennialistic movies and books.

Notwithstanding the significance of access to the oil of the southern republics of the former Soviet Union, as well as the issues of Realpolitik, there can be no denying that the September 2001 attacks on the World Trade Center and the Pentagon, and the airplane that crashed near Pittsburgh, Pennsylvania, have brought cultural issues to the forefront of the global arena. This is to be seen in the way in which the theme of civilized versus uncivilized and the clash between different values and beliefs has been a conspicuous aspect of the post September 11 world situation (Barkawi 2006). In addition, the theme of anti Americanism is clearly a cultural phenomenon, even though much of the anti Americanism refers to the exercise of the economic and political strength of the US.

But the significance of September 11, 2001 should not be exaggerated. Or, conversely, there have been many events and circumstances recently, as well as in past centuries, that have extended and intensified the sense of a world for itself. One crucial factor in this respect is the extent to which consciousness of such events and circumstances is widespread and no longer confined to relatively small and/or isolated elites. Leaving any truly careful consideration of the latter reservation largely on one side, in relatively modern times the voyages of “discovery” of the fifteenth and sixteenth centuries; the Napoleonic wars; rapid improvements in means of travel and communication

during the nineteenth century; plus a large number of global events; natural catastrophes; and the inauguration of supranational or global institutions during the twentieth century (Robertson 1992) – all of these have heightened the sense of globality, as experienced now. On the other hand, much has been done of late to show that the sense of oneness of the world has been closed to modern scholarship. Only relatively recently have we come to recognize that consciousness of globality is much, much older than we have been led to believe, this being due in large part to the blinkering effect of disciplinary.

Quotations from two recently published books can illustrate these themes. In their study of the Renaissance entitled *Global Interests: Renaissance Art between East and West*, Jardine and Brotton (2000: 8) write of their recognition that “for purposes of artistic and other material transaction, the boundaries between ... East and West were thoroughly permeable in the Renaissance.” They go on to say that along with recognizing cross fertilization and a two way traffic in influence “comes the inevitable recognition that cultural histories kept utterly distinct and kept traditionally separate, are ripe to be written as shared East/West undertakings.” Accentuating the elitist nature of global consciousness more fully, Wills (2001: 3) writes in his *1688: A Global History* that “even today, with all our opportunities for world travel and our instantaneous communications, the number of people who have a steady sense of the world as one world or even among several major parts of it is not as great as we would like to think.” Wills adds that “in 1688 a full sense of the variety of the world's places and peoples, of their separations and their connections, was confined to a few Europeans,” such as philosophers, Jesuit missionaries, travelers, and literate urbanites, although elite Chinese, for example, “were aware of the Europeans as a new element on the far margins of their ‘All under Heaven,’ but hardly at all of Africa and the Americas.”

Now, of course, we live at a time when via numerous world events and worldwide trauma – not to speak of worldwide ecological problems and pandemics, as well as space travel – our global consciousness continues to grow in reflexivity in both senses of the latter term. On the one hand, we think and act in unreflective

reaction to global events. On the other hand, we are also constrained to think and act reflectively in relation to these, this being the most important conception of reflexivity involved here.

Although not unconnected with the theme of global consciousness, the issue of a global culture raises rather different considerations. The study of culture in global terms is not merely somewhat different from the study of culture in societal terms, but that the concern with globalization has led to a rethinking of the study of societal cultures. However, without relinquishing this thesis, it must be said that this argument can be taken too far. Whether there is a global culture can be considered by invoking the work of Boli and Thomas (1999:17): "Culture lies at the heart of world development. Technical progress, bureaucratization, capitalist organization, states, and markets are embedded in cultural models, often not explicitly recognized as such, that specify 'the nature of things' and the 'purposes of action.' These cultural conceptions do more than orient action; they also constitute actors." The same authors go on to argue that it is worldwide "cultural principles" that define actors in certain ways – as having needs, emotions, and capacities and by providing templates for identities, roles, and selves. In the same way, cultural models also "define" collective identities and interests of such entities as firms, states, and nations. Moreover, actors do not act so much as they *enact* (Jepperson 1991). Boli and Thomas (1999: 18) go further and maintain that "the enactment of cultural models ... thus represents broad homologies, with actors everywhere defining themselves in similar ways and pursuing similar purposes by similar means, *but specific actions in specific contexts vary almost without limit*" (emphasis added). The end of this sentence is highlighted because it draws attention to *glocal* issues and also because it inhibits any temptation to consider the propositions of Boli and Thomas as presenting a classical dominant culture model. Nonetheless, these writers do clearly insist on there being a definite world or global culture. And in this regard they are posing an extremely important question: Why do we find so much similarity with respect to "actors" and institutions across more or less the entire world? This query is discussed with much sophistication by Lechner and Boli (2005).

While Boli, Thomas, and Lechner are keen to recognize that individual and collective actors "actively draw on, select from, and modify shared cultural models, principles, and identities" (Swidler 1986), they show much more interest in world cultural models than processes of selection and rejection of such. Moreover, such processes appear in their work as more or less confined to selection from (or rejection of) *world cultural* models rather than models presented by other actors. These authors (Boli and Thomas in particular) might well respond that since *all* "actors" are subject to the constraints of world cultural models, then ostensible emulation of other societies means that such emulation is in effect still enactment of such models.

In any case, the key consideration is that we find here a persuasive argument for the idea of a single global culture, one which derives in large part from the perception that there is a remarkable similarity in general terms among institutions across the world, as well as in the cognitive construction of "definitions, principles, and purposes" (Boli & Thomas 1999: 19). Thus, in a sense, the existence of a single global culture is largely derived from the observation of such homologies and isomorphisms. This is very different from Wallerstein's "metaphysical presuppositions" that are sometimes invoked as a way of accounting for the continuity of his world capitalistic system. In fact, indirectly, the stance of Boli and Thomas derives its significance partly from a cogent rejection of Wallerstein's general approach (Robertson 1992: 65–8).

The contested nature of world cultural models is by no means denied in the Boli–Thomas perspective, but nonetheless they maintain that conflicting models and discourse "share fundamental conceptions regarding actors, agency, technique, societal purposes, and much more" (Boli & Thomas 1999: 19). Moreover, universal cultural principles may in themselves produce conflict in that, if actors have identical goals, they are likely to compete for the same resources. However, this concession – if such it may be called – concerning competing cultural models tends to underestimate discontinuities, discontinuities that can and do lead to conflict and contestation. This is clearly the case with respect to the current "war on terror." That having been said, the program of Boli and

Thomas, as well as other members of the so called Stanford School who have been much influenced by John Meyer (Boli & Thomas 1999: v), has been undeservedly neglected.

In summary, it can be said that the approach to global or world culture of Meyer, Boli, and Thomas et al. is in a number of respects very cogent. For, working mainly from the observation of homologies and isomorphic connections, it comes to the almost inevitable conclusion that there must be "something" upon which these are based. On the other hand, there is a kind of disconcerting neatness about this over all argument, leading to a neglect of what might be called the messiness of world culture. Indeed, this is precisely why there is a need to present *other* ways of considering the latter. (It is worth stating here that the work of Lechner with Robertson has led to an important convergence with respect to the discussion of world or global culture.)

Perhaps the most neglected of all the ingredients of global culture is that which is involved in interactions – better, interpenetrations and comparisons – between nation states, indeed of international blocs and of entire civilizations. To put this somewhat abstractly, we can envisage the contemporary world as being made up of a large series of dyadic relations between nation states. Thus – to take a few salient cases – we could consider the following as exemplars: France–Germany; the US–UK; China–Japan; Greece–Turkey; France–US; Argentina–the UK; Israel–the US; Russia–China, and so on and so forth. Each of these cultures of nation state interaction has unique features although, of course, no dyad stands alone. Each is embedded in a vast complex of networks. Probably the most crucial point that should be made here, without going into the specifics of any particular dyadic case, is that to some large extent national identities are formed with respect to the interpenetration of sociocultural features of each society, or one nation state internalizes the image that the other nation is perceived to hold of "self." A very interesting case of national identity interpenetration is provided by the Japan–US relationship in historical perspectives.

Quite closely related to this is the way in which externally generated characterizations of

a nation state become central to a nation state's identity. The classic example is how de Tocqueville's *Democracy in America* – written over 150 years ago – has been continuously reproduced in order to declare the central tenets of US American identity within the American context. Parallel examples abound of other societies' reliance on the interpretations of external observers. And it should be said that the general – not to say highly problematic – notion of national "identity" illustrates the sameness/difference question very well. For while the very mention of identity summons up ideas concerning uniqueness and difference, the fact is that there is something like a global recipe or template for the production and presentation of national identities, this having much to do with models of and for the well worn theme of the invention of tradition that blossomed globally at the beginning of the twentieth century (Robertson 1992: 146–63).

Westney (1987) has well described the growth of selective emulation (in tandem with national identity formation) in Meiji Japan. In so doing she has emphasized that Meiji emulation of selected features of western nation states was greatly facilitated by the fact that it was also occurring among European nation states themselves. This late nineteenth century scenario may usefully be generalized to relations among all nation states in more recent times. In this regard there has been institutionalized, at the international level, an ongoing series of processes of comparison, with the academic observer becoming increasingly interested in what could be called the comparison of comparison. As has already been implied, this has much bearing on the issue of homologous and isomorphic relationships between and among the "appearance" of similar phenomena in a variety of societies. This emulation, as well as the rejection, process, provides a dynamic addition to the Meyer–Boli–Thomas position described previously.

At the same time, the circulation of practices, ideas, and institutional forms around the world is a central aspect of global culture. This has in the past often been indicated by the term cultural diffusion. But the latter term in itself lacks explicit sensitivity to the globalizing character of the circulation of sociocultural

phenomena. The same is true of what are frequently cast as flows from one context to others. In recent times non governmental organizations (NGOs) have played a big part in this as they have in the promotion and sustaining of diasporic relations with the "homeland." In this case the multiplication of loyalties via population movements has become a crucial element of global culture. In particular, the assimilation of immigrants in the fully fledged sense is rapidly declining, so much so that the vast question of national societal membership and citizenship is a central and increasingly controversial problem of our time, particularly since 9/11 and, in the UK, 7/7. Thus, the increasing significance of transnational communities with their own cultures (Portes 2000), the prominence of these being greatly facilitated by the new and still expanding forms of electronic communication, the relative cheapness of air travel, and the growth of the illicit traffic in human beings.

The culture of images of the constitution of the world as a whole is a perspective on culture that pivots upon the different forms in terms of which the world as a whole is envisaged (Robertson 1992: 61–84). In addition, however, there is a need to indicate the ways in which what have been called global futures also constitute a significant element of contemporary global culture. While there have been for many centuries both utopian and dystopian prognoses of the future of the world, the current concern with the processes of globalization (however defined) has led increasingly to speculation about and programs for its future. What were for the most part conceived as "anti globalization" movements have become transformed inexorably into movements advocating alternatives to the currently perceived views of the state of the world.

These two aspects of images of the world – rather simplistically divided into normatively diagnostic and normatively prognostic – are closely linked. The "global futures" trend has meant that serious theoretical and empirical typifications of "really existing" images of the world have been neglected, to the detriment of the "realism" of projected utopias. For example, the much flourished phrase "globalization from below" entails virtually no attention as to how the structure of the world in its most general contours is or can be envisaged.

So we must turn to "really existing" images of the world. In the present frame of reference images of how the world is constituted may be cast in terms of four fundamental components of the world arena: nation states; individual selves; international relations (or the system of modern societies); and humankind. Images of the world, whether upheld by individuals or by small or large collectivities, revolve around these tendencies. In one sense, this is a purely hypothetical perspective. On the other hand, it reflects closely the form that globalization has taken in recent centuries (Robertson 1992: 25–31, 58–9, 75–83). Holton (1998) sketches four main images of world order: (1) a single worldwide community with strong bonds; (2) a world of bounded communities with weaker bonds at the global level; (3) a world government in federal form, with relatively strong bonds; and (4) a world composed of bounded nation states that are not strongly bonded but are relatively open and guided primarily by conceptions of national interest. As Holton (1998: 41) remarks, this kind of work on world images "assists in opening up excessively economic or political accounts of globalization to wider issues of cultural representation and evaluation." He goes on to say that in this perspective globalization is as much about ideals and values as economic development, about ideals of what the world should be as well as what it currently is or is thought to be. This nicely captures the significance of images of world order, thinking that is as much empirically rooted as it is about ideals for the future.

Nonetheless, the advocacy of globalization from below, to repeat, must surely entail a realistic form of utopianism. Otherwise globalization from below simply becomes a kind of culture of resistance, something which is true of much of so called postcolonial and subaltern theory.

CONCLUSION

Four major, non exclusive aspects of the theme of global culture have been explored in the foregoing. The conclusion may be drawn that the inexhaustive list of themes that have been indicated shows that what can be reasonably

included under the rubric of global culture is considerable. In fact it would be perfectly plausible to insist that global culture is much richer and "thicker" than the culture of any given nation state. It is indeed more than a pity that so much intellectual energy has been expended in debating the homogenization cum Americanization thesis, as well as in arguing about the degree to which global (or any other) culture should, if at all, be considered epiphenomenally, when there is so much to address with respect to the diversity of global culture or cultures.

A return to the events of September 11, 2001 and their aftermath is more than appropriate. Presciently, Bamyeh (2000: 84–5) suggested well before that day that Huntington's (1996) prognosis of a "clash of civilizations" could in fact become a self fulfilling prophecy; although Bamyeh surely errs in attributing "the shift to the cultural" as "the victory of capitalism," for while capitalism has indeed been a major vehicle in recent times for the resurrection of the cultural factor (Robotham 2005), the latter's significance had been hidden previously by capitalism itself. We should not be tempted by or pushed into averting our attention to the cultural factor simply because Huntington "wrote the script" for September 11. For surely on that very day culture sprang back, perversely, into its rightful place in the analysis of processes of globalization. All the millions of words that have been uttered about it so far, as well as visual representations of it and its aftermath are, it should be heavily emphasized, *cultural* by definition.

globalization, education and

Keiko Inoue and Francisco O. Ramirez

The globalization of education refers to the expansion and increased interconnectedness of education related activity throughout the world. Much of the sociological research on this broad subject has focused on the following dimensions of the globalization of education: expansion of educational enrollments at all levels, nationalization of schooling, standardization of education, and the rise of an international educational sector. These studies are guided by functionalist, conflict, and institutional theories of education.

EXPANSION

Access to education has become a primary concern for states, societies, and transnational organizations. Education as human capital and education as a human right are widely held principles that fuel this concern. Earlier fears of the “overeducated” or “diploma diseases” have given way to efforts to identify and correct enrollment deficiencies. The achievement of universal primary education by 2015 is a United Nations Millennium Development Goal that commands great consensus. And indeed, primary, secondary, and tertiary enrollments relative to the appropriate age cohorts have sharply increased since World War II. The world primary enrollment ratio increased from about 80 percent in 1970 to nearly universal (99 percent) in 2000. Similar expansionary trends are found for both secondary and tertiary enrollment ratios. The corresponding change for secondary schooling is also impressive, with the secondary enrollment ratio more than doubling, from 32 percent in 1970 to 75 percent in 2000. Yet the most striking growth is found at the level of tertiary education, which more than quadruples in this period, from 7 percent in the earlier period to nearly 30 percent by the end of the century. While secondary and tertiary enrollments were concentrated in developed countries in the earlier periods, much of the current observable growth is due to

expansionary trends in less developed countries. What started as a “world educational crisis” (Coombs 1968) in primary schooling has now dramatically transformed education worldwide, with more optimistic world education agendas prevailing (Meyer et al. 1992).

To explain this phenomenon functionalists tout the role of education in development, often using human capital theory to argue that investments in education produce a well trained labor force spurring economic growth (Schultz 1961). Increased exposure to schooling, and especially to quality schooling (Hanushek & Kimko 2000), enhances individual productivity, and subsequently, economic growth. Modernization theories emphasize broader skills and capacities, but they too suggest that education grows because it contributes to the well being of individuals and of society (Inkeles & Smith 1974). These arguments are often restricted to lower levels of schooling, since the link of higher education to economic growth is more questionable. The crucial assumption underlying these theories is that education is primarily a process of socialization.

Conflict theories view educational expansion as the outcome of competition between different social classes and ethnic groups seeking to monopolize or to acquire certification advantages (Collins 1979). Within this perspective education is primarily a process of allocation to differentially valued positions within society. To the degree that allocation via education rules triumph worldwide, one should expect to find worldwide educational expansion. In a world of unequal economic and political relations, the preference for education allocation rules in core states should result in their adoption in peripheral ones, leading to educational growth but also undercutting local educational autonomy (Altbach 1977).

Institutional theories share some of the skepticism of conflict theories regarding the functions of education. These theories emphasize the widespread belief in education as the driving source of economic growth and social progress. This belief in turn reflects the degree to which education is a process of legitimation, defining what constitutes proper knowledge and reasonable personnel in society (Meyer 1977). From this perspective the worldwide growth of education is shaped by world models

Figure 1 Mean educational enrollment ratio by level, 1970–2000.

of progress and justice and the degree to which an increasing number of countries are linked to these models.

Whether driven by processes of socialization, allocation, or legitimation, or a combination of these processes, the phenomenal expansion of education is the first and perhaps most significant manifestation of the globalization of education.

NATIONALIZATION

There are several indicators of the degree to which education has been nationalized over time. One measure is the extent to which a national compulsory rule has been adopted. Earlier debates about the reasonableness of such a rule or the right of the state to compel schooling (see Mangan 1994) have disappeared. The proportion of countries which adopted such a rule increased to over 80 percent by the late 1980s (Ramirez & Ventresca 1992). Failure to fully comply with this law is widely regarded as a problem, as evidenced by current debates about attendance rates in some countries. A similar measure of nationalization involves the establishment of national ministries of education, that is, state agencies with direct or indirect authority over schooling. For instance, data from the *Stateman's Year Book* series from 1814 to 2003 show that the founding of ministries of education has been fairly constant over the past two centuries. Almost a third of the national ministries of education

were established during the nineteenth century, mostly in Western Europe but also in Latin America as well as in Japan and Ethiopia. With decolonization after World War II, many more countries nationalized their expanding school systems.

From a functionalist perspective, states take over schooling because states assume managerial controls over all societal activities deemed important. Conflict theories have emphasized the degree to which the nationalization of schooling is a reaction to multi ethnic conflicts (Collins 1979) or class based contestations (Spring 1972). Instead of social fragmentation, national integration is maintained via state controls over education. Lastly, from an institutional perspective the issue is one of identity. The proper nation state commits itself to schooling and to a school system linked to transnationally validated national goals and purposes. In other words, the nationalization of education is driven by the need to affirm proper nation state identity. There is little evidence that nationalization is more likely to occur under the conditions of expanded education or increased conflict imagined by functionalist and conflict theories (Ramirez & Robinson 1979). However, recent developments in the direction of educational decentralization, privatization, and marketization were unanticipated within the institutional perspective. Addressing these new developments, functionalists assume that considerations of efficiencies constitute the underlying dynamic, while conflict theorists contend that transnational capitalist elites are

 Source: Data are from the *Stateman's Year Book*, 1814–2003.

undermining national states, and thus, the nationalization of education.

Further studies are needed to ascertain which features of the nationalization of education are withering and which continue to thrive. National goals and purposes may continue to be affirmed, even as schooling increasingly relies on subnational sources of funding. These studies need to take into account the multidimensional character of the nationalization of education, as well as the multiple and at times inconsistent sources of influence that impinge on national educational decision making bodies.

STANDARDIZATION

Broad and common principles of education as human capital and education as a human right inform national educational goals, structure, curricula, and reform discourse. National education goals are remarkably similar, with economic growth and social progress at the top of the list. Human development, of course, is the key to both economic growth and social progress. Additionally, human development is to unfold within classrooms, within schools. Deschooling society proposals linger but are weak, while informal education is almost always coopted and becomes part of formal schooling. In practice, education has become schooling and the structure of schooling has become standardized.

Curricular content has also become more similar across countries (Meyer et al. 1992). What is to be taught and how much of it commands overall curricular time varies less than one would expect if national school curricula were truly distinctive. History and geography subjects, for example, tend to be bundled around a more child-centric social studies curriculum (Wong 1991). Even the study of science undergoes change to become more socially and personally relevant (McEneaney & Meyer 2000). Standardization is more evident with respect to primary and secondary schooling, but increasingly more and more universities converge on the principle that universities should be more broadly accessible, socially useful, and organizationally flexible. In Europe the driving force is the Bologna Declaration, but elsewhere standardization is conditioned by more associational processes reflecting the influence of educational professionals and organizations worldwide.

Does standardization take place because there are optimal forms of structure and curricula that trump everywhere? Do within nation and between nation conflicts lead to common compromises in the form of common educational structures and curricula? What is it about some structural forms and curricular emphases that make them more likely to be associated with a more legitimate nation state identity? These are the research questions that the different theoretical perspectives need to tackle in the face of growing educational standardization. More

broadly, a robust sociological inquiry into the globalization of education needs to engage educational reform discourse to make more explicit its taken for granted assumptions. Does not the search for “best practices” in education presuppose a high degree of transnational portability? And does not this assumption fly in the face of calls for a nationally distinctive and relevant curriculum? Is “lifelong learning” an extraordinarily optimistic assessment of human malleability and capacity? Or does the retreat of the state and welfare safety nets give rise to the lifelong learning mantra? Similar sociological probes need to be undertaken with respect to “teaching for understanding” and “developing higher order skills.”

INTERNATIONALIZATION

The globalization of education has also involved the formation of an international educational sector. The latter consists of the organizations and professionals that articulate educational standards, setting forth appropriate educational goals and targets that foster the expansion and standardization of education discussed earlier. The school systems and universities of the more developed or more dominant countries have influenced educational developments throughout the world for over a century (Epstein 1994). This influence may be due to the greater attractiveness of the educational system of economically or politically successful countries. Alternatively, coercive processes reflecting power dependency ties between countries may shape educational outcomes in the more dependent ones (Altbach 1977).

In addition to mimetic and coercive mechanism, normative ones stemming from professional influence may also be at work. With the founding of the United Nations Educational, Scientific, and Cultural Organization (Unesco) in 1946, a series of international educational conferences have been the sites for much educational standard setting and international cooperation in education discourse (Chabbot 2003; Mundy 1998). These conferences have given greater visibility to shared or privileged educational goals and to portable school and university curricula, pedagogy, and structures. They have thus fostered globalization of

education via internationalization and international influences as well as globalized international interrelated educational activities.

To illustrate internationalization, consider the case of the Education For All (EFA) initiative, with world conferences held in Jomtien in 1990 and Dakar in 2000. The EFA movement created a space for governments of developed and developing countries, as well as their non governmental counterparts, to embrace the task of achieving universal primary education by 2015. The movement is orchestrated by Unesco, the World Bank, the United Nations Children’s Fund (Unicef), and the United Nations Development Program (UNDP), but non governmental organizations have become increasingly active in the promotion of universal primary education. Global Campaign for Education, for instance, has brought together NGOs and teachers’ unions in over 150 countries, creating a transnational web of organizations behind the EFA movement. Such networks of international organizations in turn act as “teachers of norms” (Finnemore 1996), resulting in increased standardization in goals and structures of educational systems around the world.

Addressing inequalities of access to schooling by gender and other social characteristics has also been a special focus of EFA and related international initiatives. For instance, the United Nations Girls’ Education Initiative addresses the gender gap in primary education enrollment. Though gender disparities are evident, the worldwide trend has been in the direction of greater equality at all educational levels. In fact, the growth rate for women’s share of educational enrollment was greater than the increase in overall rate of educational expansion between 1970 and 2000. With respect to higher education, for instance, women’s share of higher education has increased from 5 percent in 1970 to 32 percent in 2000. Even in fields traditionally regarded as male dominated, such as science and engineering, women’s enrollment has increased (Ramirez & Wotipka 2001).

In light of this discussion, the argument commonly held by conflict theorists involving the hegemonic influence of powerful donor countries or multilateral organizations is worth revisiting. The active participation of southern NGOs at the World Education Forum in Dakar in 2000 is a testament to the extensive

Figure 3 Mean female share of educational enrollment by level, 1970–2000.

Source: All data are from the *World Development Indicators 2004* database (available online at www.worldbank.org/data/wdi2004/index.htm).

grassroots engagement fueling the movement. In fact, non governmental contribution produced the *NGO Declaration on Education for All* in Dakar, reflecting civil society's long term commitment to the movement. NGOs have also been crucial to the formation of other education related initiatives, including active promotion of the United Nations Decade for Human Rights Education (1995–2004).

Why have governmental and non governmental organizations unvaryingly embraced the global initiative to promote education, particularly universal primary schooling? A closer examination of EFA and other education related initiatives highlights the great faith placed on education in eradicating obstacles to development and overcoming other social ills. The proclamation in the Millennium Development Goals is straightforward in linking EFA with economic growth: education is development. The Global Campaign for Education not only correlates EFA with poverty alleviation, but it also bases its work on the belief that education is a universal human right that can produce "sustainable human development." Education is a means to national economic growth and stability, as well as a source of individual empowerment. The penetration of the EFA movement at the global and local levels demonstrates the extent to which education has become the most legitimate mechanism for pursuing common goals of economic productivity, political democracy, and social justice.

SYNTHESIS

To better understand the nature of educational globalization, further research should focus on three areas. First, given the interconnected relationship between the global and the local, a multilevel analysis that takes into account international activity and its link to grassroots work is pertinent. Currently, researchers tend to focus solely on broad trends at the global level or the impact of globalization in a particular context at the local level. Second, researchers should take advantage of newly available education related variables and further explore the persistent gender, income level, and regional gaps. Third, more research is needed to problematize the assumed link between education and economic productivity and individual empowerment. The commonly held belief that education is the key ingredient to progress and justice should also be questioned and revisited.

More direct tests of the implications of alternative theories of the globalization of education would further our understanding of this worldwide dynamic with multiple repercussions. The possible coercive and hegemonic nature of educational expansion also needs to be reconsidered. And finally, a further examination of the taken for granted character of educational globalization would allow for a broader understanding of the political and cultural dimensions of the massification of education. Functionalist, conflict, and institutional theories continue to

frame sociological research questions about the mechanisms underlying the globalization of education.

globalization and global justice

Dieter Rucht

Global justice movements (GJMs) are a loose alliance of contemporary leftist movements whose common denominator is their resistance to globalizing neoliberalism that promotes free trade, deregulation, and privatization as keys to universal progress. In the eyes of its critics, neoliberalism serves the interests of economic and political elites at the cost of the large majority of the population within, but especially beyond, the most developed countries (Rucht 2003). GJMs identify the driving force of neoliberalism in relentless profit seeking that causes a plethora of evils, such as violation of human and civil rights, destruction of

indigenous cultures, growing unemployment and increasingly precarious jobs, environmental degradation, and the widening gap between the affluent and the poor.

According to most mass media, the birth of what they dub the “anti globalization movement” was marked by the protests of a broad transnational coalition, ranging from left wing radicals to trade unionists to Catholic associations, against the 1999 summit of the World Trade Organization (WTO) in Seattle. While many groups initially accepted their designation as the anti globalization movement, they now widely reject it. Rather, they refer to themselves as global justice movements (or global solidarity movements) because, first, they deliberately create transnational networks and organize transnational, if not global, campaigns; and second, they oppose only some forms and aspects of (economic) globalization while promoting globalization of democracy, justice, and solidarity. Hence, they are anti global in some respects and pro global in others.

Contrary to common perception, GJMs had already emerged before the Seattle protests. The creation of loose alliances relating different issues and mobilizing transnationally to some degree can be traced to the nineteenth century (Boli & Thomas 1999). Also, challenging official summits is not a new tactic. As early as 1972, a counter summit took place at the UN Conference on the Human Environment in Stockholm. In 1985 dozens of groups protested against the G7 summit in Cologne and in Bonn (though most of these groups came from the summit’s host country). The Berlin meeting of the World Bank and the International Monetary Fund in 1988 was accompanied by a “week of action” that culminated in a protest rally attended by some 80,000 people (Gerhards & Rucht 1992). More recent protests, such as the one against the G8 meeting in Genoa in 2001, attracted more than 200,000 participants. Some of these protests were marked by severe clashes between a minority of mostly young demonstrators and police.

Most GJMs can be seen as an outgrowth or second generation of the so called “new social movements” that have flourished since the 1960s, focusing on issues such as human and citizen rights, participatory democracy, peace and disarmament, environmental protection,

urban renewal, and third world problems. Compared to this older family of “new” movements, GJMs focus more on transnational and even global issues, they target international governmental bodies and multinational corporations, and they create transnational movement infrastructures (della Porta & Tarrow 2005; Tarrow 2005). Because they identify the globalizing market economy as a source of a number of acute problems, many trade unions that tended to keep the new social movements at arm’s length have also become allies or even integral parts of the GJMs.

Groups associated with the contemporary GJMs differ widely regarding their social, cultural, and organizational background. Among them are well known scientists, impoverished farmers, professional trade union organizers, and unemployed, gray haired activists from the Old Left, in addition to politically inexperienced students, delegates from Northern religious congregations, and representatives of Southern indigenous people. The organizational forms include local and informal grassroots groups, firmly structured national and transnational non governmental organizations (NGOs), scientifically oriented think tanks, loose alliances and campaigns, leftist parties and sects, trade unions, farmer associations, student bodies, etc.

Unlike many earlier left movements that were often preoccupied with internal cleavages (if not bitter fights), the GJMs, in general, tend to exhibit a more tolerant attitude in terms of internal differences. This has caused many GJM groups to praise their overarching unity and identity as a new “movement of movements.” However, some observers rather stress the differences and cleavages among and within these movements. Apart from anti neoliberalism as the negative common denominator of almost all GJMs, numerous gaps exist that make it difficult to speak of one unified movement. Some currents pursue a reformist course aimed at mitigating the negative side effects of economic globalization, while other groups promote a strictly anti capitalist course and maintain the need for a revolutionary change. Accordingly, there is disunity about the questions of whether to cooperate with or instead fight against national and international governmental bodies, whether a free market has to be applied in a restricted manner or whether it should be rejected

altogether, and whether disruptive actions or even violence on the part of the movements is a legitimate means of pursuing the movements' goals. These differences are not only verbally expressed, but sometimes also have led to the physical separation of different ideological currents. This separation can be observed in the various parallel protest marches that occasionally take place at one single event, as well as at various Social Forums that have been split into a mainstream component and a – normally smaller – radical counterpart.

Thus far, the GJMs have been visible to the larger public mainly through three kinds of activities. First, they have organized counter summits and protests at official meetings of the World Bank and the International Monetary Fund, the WTO, G8, and EU summits, thematically oriented UN conferences, and the like (Pianta 2001). Second, they have launched several major campaigns on issues such as land mines, the Multilateral Agreement on Investments, the trading of toxic waste, debt relief (or debt cancellation) for the poorest countries, and precarious working conditions in Europe, etc. Some of the more regionally focused movements, such as those addressing the struggles of the Mexican Zapatistas, landless farmers in Brazil, and the people against the Narmada dam system in India, received worldwide attention and support. Third, GJMs have created their own infrastructures. Some of the most significant examples are the Social Forums, which today exist from the local to the global level. A starting point was the World Social Forum (WSF) in Porto Alegre (Brazil) in 2001. This WSF, with some 20,000 participants, was conceived as a critical counterpart to the elitist World Economic Forum that has been held in the Swiss mountain resort of Davos annually since 1970. In the past few years the WSF has become a major event in its own right (Sen et al. 2004). The fifth WSF in 2005, again taking place in Porto Alegre, was attended by 155,000 participants from 135 countries. In the past few years, continental and national forums have also been held in Asia, Africa, Latin America, and Europe. The European Social Forums that took place in Florence, Paris, and London were each attended by tens of thousands of participants. Yet the forum idea spread very disproportionately. For example, social forums are marginal

in the USA – a country that otherwise has an active community of global justice groups. In Germany the forum idea only gained momentum in 2003. By the end of 2005 around 60 local forums had come into existence. In Italy, where the concept of forums emerged in the wake of the protests against the G8 summit in Genoa in 2001, perhaps as many as 150 local forums already exist.

Thus far, the social forums at the continental and global levels have mainly been a marketplace of ideas for how to expose domestic and cross national problems, exchange experiences, make contacts, and create new networks. The WSF, in particular, has been defined as an open platform for a heterogeneous mix of groups which excludes only leftist guerrilla fighters, right wing extremists, and political parties. The platform concept, however, does not remain unchallenged. Some leftist groups have criticized the forum as being a kind of “talk shop,” unwilling and unable to engage in political activity that has any visible impact. These radicals would like to turn the WSF into a more unified actor that takes binding decisions and engages in joint action. While these radical groups have occasionally organized separate marches or camps within the WSF framework in previous years (most notably in Mumbai in 2004), it seems that fewer of these groups participated in the 2005 event, which was not marked by an identifiable split. Another point of internal criticism against the WSF is the somewhat opaque recruitment procedure for the International Council, which decides the location and structure of the WSF.

An additional significant infrastructural component are those groups and networks that are not coalitions of preexisting groups focusing on women's rights, climate change, rainforests, etc., but which have been genuinely created to promote the overarching ideas of the GJMs. One example of these new creations is “Fifty Years is Enough,” a group that was established to deliberately challenge the uncritical celebration of the 50th anniversary of the International Monetary Fund and the World Bank in 1994. Another such group is Attac, which was first established in France in early 1998 and then spread to dozens of other countries. Although initially created to promote a tax designed to reduce the cross border flow of speculative

capital (the Tobin Tax), Attac soon broadened its agenda, becoming a multi issue group that incorporated the majority of relevant themes and claims of the GJMs. Attac exerts a strong influence on the WSF process. Even though the group is nonexistent in several large countries such as the US, Attac has become a central player of the GJMs in many other countries. In Germany, media tend to equate Attac with the movements at large. Attac Germany was successful in building an alliance with major trade unions; one of these, representing approximately 2.5 million members, has even joined the much smaller Attac group (16,000 individual members).

A third significant infrastructural component is the creation of Indymedia, a network of alternative media groups that basically utilize the Internet for their purposes. The first local group was set up during the Seattle protests in late 1999. In its mission statement, which clearly mirrors the essential creed of the GJMs as a whole, the group defined itself as "a grass roots organization committed to using media production and distribution as a tool for promoting social and economic justice . . . We seek to generate alternatives to the biases inherent in the corporate media controlled by profit and to identify and create positive models for a sustainable and equitable society." By summer 2005 the Indymedia network was comprised of 153 groups, most of which are located in the US and Europe.

In sum, these growing infrastructures contribute to creating a backbone of the GJMs, which otherwise would hardly be more than a conglomerate of disparate groups who occasionally join forces.

Within a relatively short time period GJMs have become known to a worldwide public. They can no longer be ignored as a critic of established (international) politics. Not surprisingly, media, political and economic elites, movement activists, and even scientific observers differ widely in their evaluations of these movements. While conservative media and established elites tend to view the movements' positions and claims as unfounded, naïve, or even dangerous, liberal and left media react in a more differentiated, if not supportive, way. Even some representatives of international and national governmental bodies, without embracing the GJMs per se,

perceive these as legitimate political actors who point to undeniable problems and, for the most part, ask the right questions. Some proposals of these movements, such as the Tobin tax, have been seriously considered by both political leaders like French President Jacques Chirac and by economic experts. The moderate wing of the movements, and knowledge based NGOs in particular, are accepted as discussion partners and occasionally become part of official delegations. These developments are met with suspicion by more radical groups, who fear that parts of the GJMs are in the process of being coopted and thus compromised.

GJMs were successful both in building an agenda and in undermining the neoliberal creed (often dubbed the "Washington Consensus"), which had previously largely gone unchallenged. Their critique has triggered self reflection and moderate procedural as well as institutional changes in some international governmental bodies, but it has not been able to influence the overall direction of these institutions thus far. Only in some areas and regarding some issues can a substantial impact be observed. The Multilateral Agreement on Investment, for example, was cancelled, landmines have largely been banned, and a partial debt relief of the poorest countries has been announced.

globalization, religion and

Peter Beyer

Globalization describes the historical process by which all the world's people come to live in a single social unit. Religion constitutes an important dimension of globalization through its worldwide institutional presence, its importance in structuring individual and collective cultural difference, and as an effective resource for local and global social mobilization for various goals. Religion is a highly contested, occasionally powerful, and often conflictual domain of some consequence in the global social system.

GLOBALIZATION AND RELIGION AS CONTESTED CATEGORIES

Various scholars in the social sciences started using the neologism “globalization” in the 1980s. The first sociologist to do so consistently was Roland Robertson. Since that time, it has become a highly charged and popular word with diverse meanings. The most widespread of these refers primarily to recent or modern developments in global capitalism, through which this world economic system comes to have a determinative influence in all people's lives, for good or for ill.

Other, often connected, meanings emphasize the international political system of states, the recent intensification of the worldwide network of communications and mass media, or

other transnational structures and phenomena ranging from non governmental organizations and crime syndicates, to global migration, tourism, and sport. Some observers, in subsuming the latter, argue for the existence of a transnational civil society that parallels economy and the state system. Many of these perspectives also understand globalization in terms of a sometimes contradictory, sometimes complementary relation between local and global forces. The world is not just becoming a more homogeneous place; resistance to these processes or their heterogeneous particularization in diverse regions is as constitutive of globalization as capitalism and international relations. In comparatively little of the vast literature on globalization, however, has there thus far been much discussion of the role of religion, the only real exception being analyses of Islamicist and other religious militancy under such headings as fundamentalism. That situation may be changing.

Although there is currently no general agreement on what religion means and what should count under this heading, a limited set of institutionalized religions is accorded broad legitimacy in virtually every corner of the globe, most consistently Christianity, Islam, Buddhism, and Hinduism. To these, different people and different regions add a variable list of other religions, such as Judaism, Sikhism, Daoism, Shinto, Candomblé, and African Traditional Religion (ATR), as well as other less institutional phenomena ranging from morality and fundamental worldviews to ecstatic experiences and anything that is deemed to offer access to transcendence of the everyday. Moreover, like globalization, religion is often a highly contested category, especially with respect to what does or does not belong to a particular religion and what role religion should play in social life. If nothing else, such conflict over religion shows that it maintains its importance as a field of human endeavor and understanding under conditions of globalization.

RELIGION AS GLOBAL INSTITUTION

Sociological discussion about the relation of religion and globalization has for the most part focused on institutional religion, although

certain perspectives argue that highly individualistic and non institutional forms under headings like spirituality are becoming increasingly dominant. Three aspects of the institutional variety have received the most attention: the importance of religion in the context of transnational migration, the global extension of a great variety of religious organizations and movements, and the role of religion in social and political movements that respond specifically to the globalized context.

Literature on human migration, whether from rural to urban areas, into neighboring countries, or to other parts of the world, often focuses on the various problems migrants face when adapting to a new environment. These problems include issues of integration into the host society, questions of personal and cultural identity, differences among first generation migrants and their locally born children, relations between migrant communities and the countries of origin, and links among diverse diaspora locations of the same cultural group. Although the majority of studies in this area pay scant attention to religion in these matters, a substantial and growing number center specifically on the role of religious institutions. Churches, temples, or mosques are frequently the first collective institutions that migrant communities will found. These are established for centrally religious purposes, but they most often also serve a host of other functions including as places of cultural familiarity, social service providers, educational and recreational centers, and resources for community and political mobilization. At least as critical, these religious institutions facilitate important transnational links with the countries of origin and other diaspora communities, thus contributing to the communicative networks and flows across the world that are such an important feature of the globalized context. Although much of the literature on such subjects focuses on migrants that have come from non western to western countries, a sizable portion of it looks at different situations, such as Japanese communities in Latin America and Southeast Asians in Middle Eastern countries.

The religious establishments founded by migrant communities are far from the only way that religious institutions have created a worldwide presence. In fact, the spread of

religious ideologies, institutions, and specialists has been a major factor in the historical establishment of the contemporary globalized situation, as well as in the creation of different sub global but still vast civilizations of the past. The part that the Christian church played in medieval European civilization after the fall of the Roman Empire is one instance; but even more impressive is the role of Islam in the creation of empires from North Africa to Central and South Asia after the sixth century. At its height, Islamic civilization extended from Southeast Asia to Central Africa, structuring the most global of all social systems before the modern era. The trading links created by Muslim merchants, the networks of Sufi brotherhoods, the system of Islamic centers of learning, Muslim pilgrimage, and Islamic political empires informed by Islamic legal systems, were all vital social structures in this regard.

In the development of modern globalization, however, Christian missionary movements have played a critical role up until at least the middle of the twentieth century, with the result that Christian churches, including but by no means limited to the Roman Catholic Church, today make up a complex and worldwide network of non governmental organizations and transnational social movements. The linkages that these institutions establish have long since ceased to be unidirectional, from the dominant western core to the rest of the world. Christian Pentecostalism during the twentieth century grew in a highly multi centered way to become the second largest Christian identification in the world, with hundreds of millions of adherents distributed across virtually every region of the globe. Its highly diverse and localized forms maintain a wide variety of links with one another through publications, conferences, electronic media, and travel. Like many of the more tightly organized denominations such as the Anglican and Seventh day Adventist churches, Pentecostalism's demographic center of gravity is not in western countries but rather in Africa, Latin America, and parts of Asia. Indeed, one of the general peculiarities of global religious organizations and movements in comparison with other institutional domains is that the bulk of religious action occurs away from the economic, political, media, and scientific core of the global social system. While this

fact is perhaps more obvious in the case of religions such as Hinduism, Islam, and Buddhism, it is only somewhat less the case for Christianity. This different distribution manifests itself in a variety of ways. Missionary activity, for example, such a critical element in the initial global expansion of western influence, now takes a number of different directions, with South Korean and Latin American Christian missionaries in Africa, and African Christians seeking to "return the favor" by reevangelizing Western Europe and North America.

Buddhist and Muslim movements, organizations, and leaders have likewise established and expanded their presence in various global regions beyond their historical heartlands, such as, for instance, the Chinese Buddhist Fo Guang Shan, the Japanese Buddhist Soka Gakkai, the West African Murid Sufi order, or the South Asian Islamic Tablighi Jamaat. To these selected examples one could add the international organizations and movements that represent a great many other religions, from Rastafarianism and Judaism to Baha'i and Sikhism.

Although these explicitly religious institutions are the foundation of religion's global social presence, it is the implication of religion in other social, but especially political, movements that has thus far received the most attention in social scientific literature. It is no mere coincidence that the political impact of religion in developments ranging from the Islamic revolution in Iran and the New Christian Right in the United States to the Hindu nationalism of the Bharatiya Janata Party in India and the religiously defined cleavages of Orthodox, Catholic, and Muslim in the former Yugoslavia, appeared on the global scene at roughly the same time as the notion of globalization. The often invidious term fundamentalism has gained a corresponding popularity, referring to religious movements like these, ones that advocate the public enforcement of religious precepts or the exclusive religious identification of state collectivities. Characteristic of such movements is that they seek to enforce highly particular and frequently absolutist visions of the world in their countries, but with explicit reference to the globalizing context which they deem to be the prime threat under such epithets as "global arrogance" (Iran) or "one worldism" (US). The religious visions that inform them are the

basis for this combination of a claim to universal validity with being centered in a particular part of the world among a particular people. Thus does religion serve as a globally present way of making cultural difference a prime structural feature of a globalized world that also relativizes all such differences by incorporating everyone in a single social system.

RELIGION AND RELIGIONS AS GLOBAL SYSTEM

A further approach to the relation of religion and globalization focuses on the degree to which both modern institutional forms and modern understandings of religion are themselves outcomes of globalization. During the long historical development of today's global society, religion came to inform a global religious system consisting primarily of mutually identified and broadly recognized religions, especially the ones indicated above. These religions, as noted, have an institutional presence and broad legitimacy in virtually every region of the globe. While the idea that religion manifests itself through a series of distinct religions may seem self evident, that notion is historically of quite recent provenance. In Europe, where this understanding first gained purchase, it dates back at the earliest to the seventeenth century. Elsewhere, such as in most regions of Asia, one must wait until at least the nineteenth century. The development and spread of this understanding of religion is entirely coterminous with the period most theories identify as the prime centuries of globalization.

The emergence of this religious system is not only recent. It is also quite selective; not every possible religion, not everything possibly religious, counts. Symptomatic of both aspects are ongoing and recent debates among scholars of religion concerning the meaning of the concept and its supposed Eurocentrism. One perspective insists that religion is at best an abstract term, but not something "real" that is actually out there in the world. A prime argument in support of this position is how the ideas of religion as a separate domain of life and of the distinct religions are so demonstrably products of relatively recent history and so clearly implicated in the concomitant spread of Christian

and European influence around the world. Another is that "the religions" is empirically too narrow, that what is meant by them does not cover enough of what is manifestly religious using slightly different notions of religion. These criticisms, however, do not exclude the conclusion that a peculiar way of understanding religion and institutionally embodying religion has nonetheless developed in conjunction with and as an expression of the process of globalization. Similar to global capitalism and the global system of sovereign states, the institutionalization of this idea excludes as well as includes. It also involves power and imposition, as do all human institutions. And just as anti-globalization movements are themselves important manifestations of that which they oppose, so too is controversy around the idea of religion and the religions symptomatic of the social and cultural reality which it contests.

FUTURE DIRECTIONS FOR RESEARCH

The explicit study of religion in the context of globalization is only in its beginnings. The sociological neglect of this topic may be due to the fact that religions usually ground themselves in tradition as opposed to contemporary developments, to the close relation between religion and local and regional culture, and perhaps to the lingering effect of secularization perspectives which have led many social scientists to expect religion to be irrelevant in the modern world. Be that as it may, a now rapidly growing literature that sees religion as an important player in today's global context heralds a much needed new direction in this regard.

globalization, sexuality and

Jon Binnie

The globalization of sexuality refers to the sexualized and embodied nature of processes associated with the movement of people, capital,

and goods across national boundaries. It also refers to how the consciousness of the world as a single place is sexualized. The globalization of sexuality is manifest in a range of processes and phenomena that are often couched and approached in highly emotive terms (e.g., the trafficking of women into prostitution, mail order brides, the development of the sex industry and sex tourism). It is also characterized by the AIDS pandemic, mass international tourism, and the development of cyberspace. Each of these has in turn intensified consciousness of the status of sexual minorities and the unevenness of their treatment across the globe. Key to our understandings of the globalization of sexuality is the relationship between sexuality and economics. While debates on the globalization of gay identity have been marked by an ambivalence over the development of gay identities and politicized communities outside of the West, work on the globalization of sexuality more generally has tended to have been marked by concerns with the worse excesses of what Smith (1997) has termed the "satanic geographies of globalization." Here we are concerned with the trafficking of women forced into prostitution. Contemporary moral panics on the scale and extent of the trafficking of women for prostitution across national borders mask the extent to which sex work has been intimately connected to the development of the global capitalist system. The transnational migration of sex workers has taken place for centuries. However, there is a perception we are seeing an acceleration in the scale of the phenomenon resulting from increased mobility across national borders – as witnessed by the increasing numbers from Eastern Europe working in the sex industry in Western Europe.

One dominant discourse on the global sex trade within western feminism is that third world women working in prostitution need rescuing from their plight and need to receive moral guidance, as they are incapable of making decisions about their sexual practice. They are passive victims who are uneducated and have no choice but to be forced into prostitution. Kempadoo and Doezema (1998) argue that this way of conceptualizing the global sex trade is redolent of neocolonialism, as it takes no account of the agency of women involved in sex work. The conditions of work for sex workers

in developing areas may be poor, but so it is argued are conditions for other workers. It is claimed that some anti trafficking campaigns may also cause harm to the very women they are designed to assist. For instance, Murray (1998) argues that in Australia anti trafficking campaigns targeting Asian sex workers may cause harm in reinforcing racist stereotypes of Asian women as weak victims, which may mark them out as easier targets for abuse. She argues that feminists who seek the abolition of prostitution speak for all women and do not listen to working class women who work in the sex industry. Murray suggests that there is complicity between feminists involved in groups such as the Global Alliance Against Traffic in Women (GAATW) and homophobic right wing religious fundamentalists who seek to control and regulate all forms of non procreative sexual practices.

Buss and Herman (2003) argue that academic discussions of transnational social movements tend to stress their progress, radical nature, and agency in contrast to conservative global organizations such as the World Bank. In their discussion of the transnational organization of the Christian Right they note a forging of alliances across religious boundaries on the basis of a common moral agenda around the protection of the sanctity of the family. These alliances lobby the United Nations to promote anti abortion agendas. Buss and Herman note that Christian Right groups are increasingly targeting homosexuality despite the fact that lesbian and gay rights activist groups have had little success at the global level – reflected in the failure of the International Lesbian and Gay Association to regain its consultative NGO status at the UN since this status was withdrawn in 1994.

One of the main vectors of the globalization of sexuality is the global AIDS pandemic. Indeed, AIDS has often been seen as a metaphor for globalization itself, as it has brought into sharp relief how lives on the planet are interconnected with the impotence of nation states to control flows of people with HIV across national borders. While helping to shape our consciousness of the world as a single place, the AIDS pandemic has impacted disproportionately on specific localities – the impact of the pandemic is experienced unevenly. Policy

responses to the AIDS pandemic have been held responsible for the promotion of modern western models of gay identity as opposed to indigenous or folk models of sexual identity in developing countries. The globalization of sexuality is often assumed to mean the export of a western model of sexuality (Wright 2000). However, can we simply see the West as the original starting point from which other models of sexuality are considered or studied? Folk or indigenous models of sexuality are often set in opposition to western models of sexuality; however, to what extent can we generalize about an egalitarian model of same sex relationships within the West? For instance, men who have sex with men in western countries may not identify with a gay identity or community.

A considerable body of work has been produced on the globalization of gay identity (Altman 1996, 2001; Philips 2000; Stychin 2003). We have witnessed the growth of a global gay consciousness and an associated activism and politics. For instance, the International Lesbian and Gay Association founded in 1978 now represents 370 organizations in 90 countries. The Internet is also playing a major role in facilitating the intensification of transnational activism around the rights of sexual dissidents. At the same time, global gay tourism has become visible through the development of global mega events such as the Gay Games and pride events such as Sydney's Mardi Gras.

Debates on the globalization of gay identity have focused on whether the export of a western model of gay identity reflects the imposition of cultural imperialism, or whether the development of a global gay consciousness is a positive and empowering example of a cosmopolitan cultural politics which is forging transnational solidarities against homophobic policies and regimes. At the same time, it should be noted that groups and organizations such as the Christian Right that are hostile towards sexual dissidents also operate on a global scale. Post colonial writers have challenged the ethnocentricity of the notion of a global gay identity and the ethnocentricity of lesbian and gay studies more generally (e.g., Puar's (2002) study of gay tourism in the Caribbean). Research on the globalization of sexuality is now drawing critical attention to the sexualized nature of the politics of nationalism, as this has often been overlooked

in debates on sex tourism and the politics of global gay identity.

Technological change is driving the acceleration of the globalization of sexuality. The development of the Internet in particular is significant in facilitating globalizing processes at a mundane level – for instance in aiding men's search for mail order brides, but also enabling those involved in campaigning against the trafficking in women to maintain and develop transnational activist networks. However, the Internet also plays a powerful role in shaping sexualized identities and desires in late capitalism. The Internet therefore encourages the development of what Schein (1999) terms an "imagined cosmopolitanism" – the commodification of desires for worldliness reflected in global media and advertising. This is the desire for foreign products that reflect a sophistication and yearning to transgress the boundaries of the nation state through, for instance, window shopping and gazing on displays of imported foreign consumer goods. Schein's work on cosmopolitan commodity culture in contemporary China is an example of work on the more mundane ways in which global capital and desire intersect.

Future work on the globalization of sexuality will need to examine critically the everyday ways in which economic, political, and cultural components of globalization are sexualized and resist the moralizing tendencies of those who would seek to police sexual practices and sexual dissident communities.

globalization, sport and

Joseph Maguire

Modern sport is bound up in a global network of interdependency chains that are marked by uneven power relations. Consider the consumption of sports events and leisure clothing. People across the globe regularly view satellite broadcasts of English Premier League and European Champions League matches. In these games the best players drawn from Europe, South America, and Africa perform. The

players use equipment – boots, balls, clothing, etc. – that are designed in the West, financed by multinational corporations such as Adidas and Nike and hand stitched, in the case of soccer balls, in Asia using, in part, child labor. This equipment is then sold, at significant profit, to a mass market in North America and Europe. Several transnational corporations are involved in the production and consumption phases of global soccer – some of whom own the media companies and have, as in the case of Sky TV, shareholdings in the soccer clubs they screen as part of what sociologists term the “global media sport complex.”

The sport/leisure wear industry is an example of how people's consumption of cultural goods is bound up with global processes. As a fashion item, the wearing of sports footwear has become an integral feature of urban lifestyles and consumer culture. One premier brand is Nike. The purchase and display of Nike footwear by soccer players are but the final stages in a “dynamic network” involving designers, producers, suppliers, distributors, and the parent or broker company. Though Nike's headquarters are located in Oregon, US, the range of subcontractors involved straddles the globe. Its suppliers and production companies are located in a host of Southeast Asian countries, including Thailand, Singapore, Korea, and China. Its designers provide soccer boots with a worldwide demand that will also appeal to local tastes. Local franchise operations ensure appropriate distribution backed by global marketing strategies. Here again, Nike uses the media sport production complex by endorsing sports stars such as the Brazilian soccer player Ronaldo and/or sports-leisure festivals such as soccer's World Cup. In addition, Nike uses advertising within the television schedules that carry these sports and other consumer targeted programs. In the 2000–1 Premier League season it was reported that Nike was to become the official sponsor of Manchester United with a deal brokered at some £300 million over 15 years. In brief, elite sport now occurs on a worldwide scale and is patterned in connection with “global flows” of capital, culture, and people.

Global flows involve several dimensions: the international movement of people such as tourists, migrants, exiles, and guest workers; the

technology dimension is created by the flow between countries of the machinery and equipment produced by corporations and government agencies; the economic dimension centers on the rapid flow of money and its equivalents around the world; the media dimension entails the flow of images and information between countries that is produced and distributed by newspapers, magazines, radio, film, television, video, satellite, cable, and the worldwide web; and finally, the ideological dimension is linked to the flow of values centrally associated with state or counter state ideologies and movements. All five dimensions can be detected in late twentieth century sports development. Thus the global migration of sports personnel has been a pronounced feature of recent decades. This appears likely to continue. The flow across the globe of goods, equipment, and "landscapes" such as sports complexes and golf courses has developed into a multi billion dollar business in recent years and represents a transnational development in the sports sphere. In economic terms, the flow of finance in the global sports arena has come to center not only on the international trade in personnel, prize money, and endorsements, but also on the marketing of sport along specific lines. The transformation of sports such as American football, basketball, golf, and soccer into global sports is part of this process.

Closely connected to these flows have been media led developments. The media sport production complex projects images of individual sports labor migrants, leisure forms, and specific cultural messages to large global audiences. Consider the worldwide audience for the 2004 Olympic Games: over 300 television channels provided 35,000 hours of Olympic coverage delivering images of Athens 2004 to an unduplicated audience of 3.9 billion in 200 countries and territories. The power of this media sport complex has forced a range of sports to align themselves to this global model that emphasizes spectacle, personality, and excitement. At the level of ideology, global sports festivals such as the Olympics have come to serve as vehicles for the expression of ideologies that are transnational in character. Note, for example, how the opening and closing ceremonies of the Athens Games were designed to project traditional images and "modern" messages about Greece to both its own people and to a global audience.

Three additional points need to be grasped in linking sport and globalization. First, studies of sport that are not studies of the societies in which sports are located are studies out of context. Here, emphasis is being placed on the need to examine the interconnected political, economic, cultural, and social patterns that contour and shape modern sport. Attention has also to be given to how these patterns contain both enabling and constraining dimensions on people's actions – there are "winners" and "losers" in this global game. Societies are no longer and (except in very rare cases) were never sealed off from other societies. Ties of trade, warfare, migration, and culture have existed through human history. Witness, for instance, the connections made throughout Renaissance Europe. More recent globalization processes have unleashed new sets of "interdependency chains," the networks that have (inter) connected people from distant parts of the globe. It is in this context of global power networks that the practice and consumption of elite modern sport is best understood. Secondly, in order to trace, describe, and analyze the global sports process it is wise to adopt a long term perspective. A historical and comparative approach enables us to explain how the present pattern of global sport has emerged out of the past and is connected with a range of what Maguire (1999, 2005) has termed "civilizational struggles."

The third point of significance concerns the concept of globalization itself. What does the concept refer to? This is a matter subject to intense debate. Here is not the place to examine the merits of these arguments. It is sufficient to note that the concept refers to the growing network of interdependencies – political, economic, cultural, and social – which bind human beings together, for better and for worse. Globalization processes are not of recent origin, nor do they occur evenly across all areas of the globe. These processes involve an increasing intensification of global interconnectedness, are long term in nature, and gathered momentum during the twentieth century. Despite the "unevenness" of these processes, it is more difficult to understand local or national experiences without reference to these global flows. In fact, our living conditions, beliefs, knowledge, and actions are intertwined with unfolding globalization processes. These processes include

the emergence of a global economy, a transnational cosmopolitan culture, and a range of international social movements. A multitude of transnational or global economic and technological exchanges, communication networks, and migratory patterns characterize this interconnected world pattern. As a result, people experience spatial and temporal dimensions differently. There is a "speeding up" of time and a "shrinking" of space. Modern technologies enable people, images, ideas, and money to cross the globe with great rapidity. These processes lead to a greater degree of interdependence, and to an increased awareness of a sense of the world as a whole. People become more attuned to the notion that their lives and place of living are part of a single social space: the globe.

Globalization processes, then, involve multidirectional movements of people, practices, customs, and ideas that involve a series of power balances, yet have neither the hidden hand of progress nor some all pervasive, overarching conspiracy guiding them. Although the globe can be understood as an interdependent whole, in different areas of social life there is a constant vying for dominant positions among established (core) and outsider (peripheral) groups and nation states. Given this growth in the multiplicity of linkages and networks that transcend nation states, it is not surprising that we may be at the earliest stages of the development of a "transnational culture" or "global culture," of which sport is a part. This process entails a shift from ethnic or national cultures to "supranational" forms based upon either the culture of a "superpower" or of "cosmopolitan" communication and migrant networks. In this connection there is considerable debate as to whether global sport is leading to a form of homogenized body culture – specifically, along western or American lines. There is some evidence to support this. Yet global flows are simultaneously increasing the varieties of body cultures and identities available to people in local cultures. Global sport, then, seems to be leading to the reduction in contrasts between societies, but also to the emergence of new varieties of body cultures and identities.

In making connections between globalization and modern sport several findings stand out. Globalization processes have no "zero starting

point." It is clear that they gathered momentum between the fifteenth and eighteenth centuries. These processes have continued apace since the turn of the nineteenth century. Research has identified several recent features of these processes, including an increase in the number of international agencies, the growth of global forms of communication, the development of global competitions and prizes, and the development of standard notions of "rights" and citizenship that are increasingly standardized internationally. The emergence and diffusion of sport in the nineteenth century is clearly interwoven with this overall process. The development of national and international sports organizations, the growth of competition between national teams, the worldwide acceptance of rules governing specific (that is, "western") "sport" forms, and the establishment of global competitions such as the Olympic Games and the men's and women's soccer World Cups, are all indicative of the occurrence of globalization in the sports world.

It would also appear that global sport processes are not solely the direct outcome of nation state activities (e.g., the International Olympic Committee (IOC) operates independently of any specific nation state). Rather, these processes need to be accounted for in relation to how they operate relatively independently of conventionally designated societal and sociocultural processes. In addition, while the globalization of sport is connected to the intended ideological practices of specific groups of people from particular countries, its pattern and development cannot be reduced solely to these ideological practices. Although elite sports migrants, officials, and consumers are caught up in globalization processes, they do have the capacity to reinterpret cultural products and experiences into something distinct, as the local acts back on the global. Furthermore, the receptivity of national popular cultures to non-indigenous cultural products can be active and heterogeneous; that is, local lives make sense of global events. That is not to overlook, however, that there is a political economy at work in the production and consumption of global sport products. Globalization then is best understood as a balance and blend between diminishing contrasts and increasing varieties, a commingling

of cultures and attempts by more established groups to control and regulate access to global flows.

The emergence and diffusion of modern sport is therefore bound up in complex networks and interdependency chains marked by unequal power relations. Political, economic, cultural, and social processes contoured and shaped the development of sport over the past three centuries. This global development has undoubtedly led to a degree of homogenization – in common with broader globalization processes. In addition, the spread of British/European/western sports has had elements of cultural imperialism infused with it. Further, while there was no “master plan” in the early phases of this process, more recently transnational corporations have sought to strategically market their products to consumers across the globe. Westerners have been the global winners at their own games both on and off the field. The male members of “western” societies were acting as a form of established group on a world level. Their tastes and conduct, including their sports, were part of this, and these practices had similar effects to those of elite cultural activities within “western” societies themselves. They acted and act as signs of distinction, prestige, and power. Yet, this is not the whole story.

The rise of the “West” was contested and its “triumph” was not inevitable. Furthermore, “western” culture had long been permeated by non western cultural forms, people, technologies, and knowledge. In sum, these cultural interchanges stretch back to long before the “west” momentarily achieved relative dominance in cultural interchange. It also needs to be recognized that both the intended and unintended aspects of global sport development need inspection. That is, while the intended acts of representatives of transnational agencies or the transnational capitalist class are potentially more significant in the short term, over the longer term unintended, relatively autonomous transnational practices predominate. These practices “structure” the subsequent plans and actions of the personnel of transnational agencies and the transnational capitalist class.

In addition, global sport has not led to complete homogenization: the consumption of non indigenous cultural wares by different national

groups is both active and heterogeneous. Resistance to global sportization processes has also been evident. Yet there is a political economy at work in the production and consumption of global sport/leisure products that can lead to the relative ascendancy of a narrow selection of capitalist and western sport cultures. Global sport processes can therefore be understood in terms of the attempts by more established white, male groups to control and regulate access to global flows and also in terms of how indigenous peoples both resist these processes and recycle their own cultural products. We are currently witnessing the homogenization of specific body cultures – through achievement sports, the Olympic movement, and sports science programs – and simultaneously the increase in the diversity of “sports”/body cultures.

It is possible, however, to overstate the extent to which the West has triumphed in terms of global sports structures, organizations, ideologies, and performances. Non western cultures resist and reinterpret western sports and maintain, foster, and promote, on a global scale, their own indigenous recreational pursuits (e.g., Kabbadi, a traditional game/sport reputedly developed in India and now played in many parts of South Asia). Clearly, the speed, scale, and volume of sports development is interwoven with the broader global flows of people, technology, finance, images, and ideologies that are controlled by the West, and by western men. In the longer term, however, it is possible to detect signs that the disjunctures and non isomorphic patterns that characterize global processes are also leading to the diminution of western power in a variety of contexts. Sport may be no exception. Sport may become increasingly contested, with different civilizational blocs challenging both nineteenth and twentieth century hegemonic masculine notions regarding the content, meaning, control, organization, and ideology of sport. By adopting a multi causal, multi directional analysis that examines the production of both homogeneity and heterogeneity, we are better placed to probe the global cultural commingling that is taking place.

globalization, values and

Christine Monnier

Global values refer to the moral and normative conceptions shared by individuals and social actors (such as international governmental and non governmental organizations, transnational corporations, and global institutions) across national boundaries and that pertain to the future cultural shape of globalizing society. Global values have to be understood in the larger framework of cultural globalization and the globalization of culture. Far from being the product of a harmonious consensus, the delineation of global values is a contentious work in progress that reflects the complexities and ambiguities of the whole globalization process.

As defined by Roland Robertson (1992), globalization refers "both to the compression of the world and the intensification of consciousness of the world as a whole ... both concrete global interdependence and consciousness of the global whole." As a process of social change, globalization involves deterritorialization – the lifting off of social relations from territorial boundaries as well as the transformation of local relations. And as Robertson's definition indicates, globalization is also a reflexive process that involves a greater awareness of the

impact of global phenomena on people's lives as well as of the potential impact of local matters at the global level. Globalization is therefore a process marked by unevenness (it produces winners and losers and integrates different regions at variable speeds and intensity), complexity (different global processes, economic, political, cultural, are not synchronized), and contention.

Cultural globalization refers to the global expansion of cultural flows – transmission of symbols, ideas, artistic and consumption products – on a global scale. Technologies of transportation and communication have facilitated such cultural diffusion and the corresponding emergent global consciousness. Arjun Appadurai (1996) delineates these flows (or "scapes") as part of the process of cultural globalization. They comprise mediascapes (flow of information through the mass media, television, the Internet), financescapes (flow of capital through the global financial system), technoscapes (flow of technology or flows made easier thanks to technology), ethnoscapes (flow of people, immigration, refugees, tourists), and ideoscapes (flow of ideas such as consumerism, market, democracy or human rights). The arena of cultural globalization is where the future moral contours of global society and conflicting value systems are debated.

The globalization of culture refers to the ways in which different cultures are shaped by, and respond to, culturally globalizing flows. It points to the emergence of a global culture, or, as Frank Lechner and John Boli (2005) conceptualize it, a world culture. World culture is the "culture of world society, comprising norms and knowledge shared across state boundaries, rooted in nineteenth century western culture but since globalized, promoted by non governmental organizations as well as for profit corporations, intimately tied to the rationalization of institutions, enacted on particular occasions that generate global awareness, carried by the infrastructure of world society, spurred by market forces, riven by tension and contradiction, and expressed in the multiple ways particular groups relate to universal ideals." As this definition shows, if people and social actors share a global consciousness, they do not share consistent views of what the global order should look like. These different

imagined global futures display contrasting value systems and are promoted by different groups.

Jan Nederveen Pieterse (2004) delineates three major global value systems: cultural differentialism, cultural convergence, and hybridization. The cultural differentialist paradigm postulates the preeminence of the local. If there is to be a global culture, it is a global mosaic, composed of discrete territorial, cultural entities anchored in different regions of the world. This is the view popularized as “clash of civilizations” or the “West vs. the Rest”: different regional blocs have radically different values that can only generate conflicts between civilizational blocs. As Samuel Huntington postulates, the value system of a global society should be based on the universalization of western values, founded on the Enlightenment, democracy, and free markets. Whereas Huntington argues for the universalization of a particular value system (the West), other cultural differentialists argue for a strong version of cultural relativism. A global culture should be based on the preeminence of local values, free from outside interferences necessarily perceived as threat of cultural destruction. Such a view is popular among the anti globalization movements, especially in groups focused on the preservation of indigenous societies and the assertion of their cultural rights. In such a view, the core global value is preservation of cultural diversity. Both the clash of civilizations and cultural relativism views are based on an essentialist view of culture based on territory and boundaries. They reify cultural systems and promote open air museums in the guise of local empowerment. They ignore historical traditions of cultural exchanges as well as contemporary global flows and global deterritorialization.

The main fear articulated by cultural relativists is the fear of cultural convergence or cultural synchronization: the spread of American or western values, especially values related to the sphere of consumption, akin to cultural imperialism. In this view, the spread of global capitalism and western imperialism creates a world society based on a consumerist universalism. Borders and locales no longer matter as individuals all become part of a homogeneous world culture guided by principles of McDonaldization (Ritzer 2004) and Disneyization

(Bryman 2004) whereby most social relationships become commodified, including locales, in the case of international tourism. Mass consumption becomes the one and only significant universal value at the expense of all the local value systems that constitute the human mosaic. This dystopic view of world culture is also endorsed by world system analysts who view it as the ideology of the world capitalist system generated in order to sustain it. The homogeneity created within nations, at the expense of local culture and particularist values, produces a form of hegemony: global culture is the culture of capitalism. The universalist values it promotes are those of individualism and satisfaction through material comfort alongside the predominance of rationalized modes of production (McDonaldization) and consumption (Disneyization). In this view, a global ideology is being created that is spread worldwide through the western controlled mass media to sustain the consuming needs of the world economy. However, there is a utopian side to the view of the global spread of western capitalism, popularized as “creative destruction.” In this view, global mass consumption expands the menu of choice offered to individuals no matter what particular society they live in. There may be more cultural homogeneity between societies, but the expansion of the market provides more consuming diversity within societies as more objects of consumption become globally available. Cultural convergence produces greater individual choice irrespective of territorial base. In the utopian version of this view, the spread of western values can only be conducive to more democracy and choice where individuals are liberated from the tyranny of place – a view convincingly debunked by Amy Chua’s analysis of the rise of market dominant minorities in the face of politically dominant majorities. Chua shows that globalization as the double process of democratization (popular access to political institutions) and increased wealth concentrated in the hands of a few minority groups (such as Chinese in the Philippines) creates the conditions not for utopian combination of democracy and mass consumption but rather for brutal ethnically based conflict.

Such a cultural imperialist view is simplistic as it assumes that globalization is unilateral, from the core to the periphery: wherever

western values and institutions spread, they automatically become dominant and the cultural forms they encounter cannot resist. In other words, both cultural differentialist and cultural convergence analyses assume that global cultural processes flow one way, with no obstacles in their path: from imperialist core areas (western consumption patterns) to a passive recipient periphery powerless to stop such flows.

Both the cultural differentialist and the cultural convergence views assume that global values are part of a process of universalization of the particular (Robertson 1992), that is, the universal application of values specific to certain cultural systems. The reality of global culture and values is more complex, contentious (as the previous two paradigms indicate), and multidirectional. As much as there is determination of local circumstances through global structures, this does not eliminate the possibility of local impact in global processes, such as the Zapatistas' rebellion in Mexico in reaction to NAFTA. What does get threatened is the functionalist emphasis on coherence and boundaries that create social integration as transcultural flows shape both the local and the global. Global values may involve universalization of the particular, but they also involve the reverse process of particularization of the universal. This process has been variously called hybridization (Nederveen Pieterse 2004), creolization (Tomlinson 1999), or glocalization (Robertson 1992). All these designations involve the complex dynamics through which global processes and values are integrated into local contexts to produce cultural hybrid practices, such as world music.

In this context, western values may not so much be imperialistically delivered to peripheral areas as much as they are glocalized. Western values such as individual freedom, democracy, human rights, gender equality, and sexual autonomy as well as scientific and technological rationality are undeniably spreading globally, supported by the development of global movements, institutions, and infrastructures. However, how these values are integrated into local contexts, that is, glocalized, involves a complex interplay of local and global factors. For instance, feminist social movements are different in Japan than in western countries as

they adapt the general concept to their local circumstances.

At the same time, cultural and institutional globalization has seen the emergence of global values that have originated not in western countries but either in peripheral areas or in global institutions. For instance, cultural diversity and sustainable development, as global moral imperatives, have generated resistance both in core and peripheral areas. In core areas, cultural diversity is perceived as a threat to rather homogeneous populations and long established nations. For instance, the veil controversy in France illustrates how any encroachment on secular institutions can generate nationalist reactions in the face of multiculturalist demands. Similarly, sustainable development demands serious economic and moral reconsideration of western consumption practices that are perceived as impediments to the "freedom to consume," so to speak. On the other hand, peripheral countries have sometimes perceived intimations to sustainable development as normative impositions that impede sovereignty and development choices. Similarly, Muslim countries have consistently insisted on opt out options regarding human and women's rights out of respect for local traditions. It is precisely in the process of glocalization that areas of contention emerge regarding how global values are to be integrated or assimilated into local contexts.

As Lechner and Boli (2005) show, although world culture is riddled with conflict regarding what value system should prevail and shape the future of world society, the different United Nations world conferences on global topics (such as population, environment, or women's rights) reveal a global consensus on certain basic premises (the value of global negotiation and a common definition of global problems to be addressed in a global forum where all voices can be heard, even if confrontation arises), processes, and structures. In spite of such contentious debates, global responsibility is a value whose legitimacy is implicitly agreed upon although who/what is responsible for whom/what is precisely what is vigorously debated. Similarly, global responsibility becomes a moral imperative that displaces the perceived outdated morality of proximity (Tomlinson 1999)

where one is only responsible for one's own limited and localized circle of territorial relationships. Instead, the appeals to the global community are multiplied to intervene to stop genocides, provide relief against famines and natural disasters, and unite against the threat of global terrorism. Conversely, the intimation to "think global, act local" injects global responsibilities into personal actions.

Similarly, the anti globalization movement does not stand outside of globalization but asserts a value system with global claims, another instance of universalization of the particular in the constantly contentious debate regarding the value foundation of global society. In this case, anti globalization activists assert the global relevance of their value system even if what they demand is de globalization, that is, a return to the local. The claim may be for the preeminence of the particular, but it is asserted globally as having global relevance and legitimacy. In this sense, as much as they advocate for a return to the local and traditional values and social organizations, such groups as religious fundamentalists and indigenous populations' rights activists are promoting their own version of global society based on local values understood as the only source of legitimacy.

Indigenous populations present an interesting case of how global cultural values, far from being a reflection of western imperialism, promote emancipation. The visible struggle for respect for indigenous traditions and rights obscures that the cultural and political form most responsible for the silencing of minority voices has historically been the nation state. As Anderson (1983) has shown, the creation of nations as imaginary communities involved a deep imperialist process of nationalization, that is, elimination (cultural or physical) of marginal populations and their cultural practices, traditions, and values. The very possibility for indigenous populations to have their struggle recognized as legitimate on the global stage and their rights included in global documents, such as the Earth Charter, reflects a value shift in favor of cultural diversity and multiculturalism as opposed to national homogeneity. When the Zapatistas appeal to the global community to support their struggle, they recognize the legitimacy of the global stage as proper institutional context. They also

promote an ethical globalization: the integration of the global when liberating (global networks of support), but its rejection when oppressive (World Trade Organization).

There is no set of neatly defined global values. Rather, because global society is connected and integrated (through flows) but neither unified nor centralized or harmonious, the sources of value systems are multiple, contradictory, and contentious. Such value conflicts reflect the often underestimated cultural nature of globalization and its complexity as traditional or popular explanations, clash of civilizations or cultural imperialism, fail to account for the hybrid nature of globalizing culture and values.

glocalization

Melanie Smith

The neologism “glocalization” has emerged in recent years in economic, sociological, and cultural theories in response to the proliferation of writings about globalization and its local implications. It might best be described as the relationship between global and local processes, which are increasingly viewed as two sides to the same coin rather than being diametrically opposed (e.g., Robertson, 1992). The age of global mobility has created more fluid and seamless relationships. For example, the work of Castells (1996) on the network society and Appadurai’s (2001) discussion of flows gives some indication of how global mobility has affected local environments and their inhabitants.

Giddens (1998) suggests that globalization was originally a political and economic term. It could be argued that glocalization, on the other hand, represents the intersection of political economics and sociocultural concerns, with its emphasis on the local and community impacts of global structures and processes. Ritzer (2004: 73) defines glocalization as “the integration of the global and the local resulting in unique outcomes in different geographic areas.” Glocalization can thus represent the consequences (both tangible and intangible) of globalization, e.g., the creation of heterogeneous or hybridized cultures, communities, and identities. In business terms, it might represent the local orientation of global product marketing, taking into consideration local social and cultural characteristics and traditions. In postmodern architecture, it may include “organic” approaches to the construction of new buildings (i.e., taking into account local environmental and historic features). In the context of global tourism, international visitors are brought into contact with local environments and their communities, thus influencing cross cultural exchange. Tourism can also sometimes help to strengthen the importance of retaining place identities and local character.

Nevertheless, glocalization could also be viewed somewhat negatively. For example, Bauman (1998) suggests that the term glocalization is best thought of as a restratification of

society based on the free mobility of some and the place bound existence of others. Tourist flows, for example, are mainly unidirectional (e.g., West to East, or developed to less developed countries). For this reason, tourism has sometimes been described as a new form of imperialism, which causes acculturation and radical social change rather than hybridization (the inevitable consequence of sustained foreign influence over time). Similarly, global economic and business developments are often deemed “imperialistic,” even where they have a local orientation.

Ritzer (2004) suggests that this dominance of capitalist nations and organizations might be termed “grobalization” rather than “glocalization.” He argues, like Robertson (1994), that the key characteristics of glocalization are sensitivity to differences, the embracing of cosmopolitanism, and respect for the autonomy and creativity of individuals and groups. The notion that the local is largely passive in the face of globalization is therefore a misrepresentation. For example, Barber (1995) sees “Jihad” as being the local response to the homogenizing influence of “McWorld.” Friedman (1999) sees “healthy glocalization” as a process by which local communities incorporate aspects of foreign cultures that enrich them, but reject others that would negatively affect their traditions or identity. The accessibility of new communications and technology also allows many societies to propagate local cultures globally.

Overall, therefore, glocalization could be seen as a positive interpretation of the local impacts of globalization, that is, a process by which communities represent and assert their unique cultures globally, often through new media.

Goffman, Erving (1922–82)

Gregory W. H. Smith

The work of Erving Goffman centered on explicating the structures and processes of the “interaction order,” the domain of social life brought about and facilitated by the physical co presence of persons. In a series of extraordinary writings published from the early 1950s through the early 1980s, Goffman developed an utterly singular vision of social life, expressed in a highly distinctive language that reflected his extraordinary observational acuity and his unmatched sociological grasp of metaphor and irony.

Born in Mannville, Alberta, Canada to Jewish migrants from the Ukraine, Erving Manual Goffman was educated at the universities of Manitoba (1939–42), Toronto (BA 1945) and Chicago (MA 1949; PhD 1953). His doctoral studies included a spell at Edinburgh University’s department of social anthropology, which sponsored and funded 12 months of fieldwork on the remote Shetland island of Unst. Following research posts at Chicago and with the National Institute of Mental Health (where he conducted fieldwork at St. Elizabeth’s Hospital, Washington, DC for *Asylums*), he was appointed to the faculty of the University of California, Berkeley’s sociology department in 1958, becoming a full professor in 1962. While teaching at Berkeley he influenced a number of

graduate students, including John Lofland, Dorothy Smith, David Sudnow, and Harvey Sacks. He also used his proximity to Nevada to undertake participant observation of casino life, first as a gambler, then as a croupier. Goffman relocated to the University of Pennsylvania in 1968, where his work became increasingly sensitized to sociolinguistic and gender issues. He remained there until his death in 1982 from stomach cancer.

Goffman’s primary contribution to sociology was to show how social interaction was fundamentally organized in social terms and amenable to close sociological investigation. He demonstrated how the building blocks of social encounters – the talk, gestures, expressions, and postures that humans constantly produce and readily recognize – were responsive not to individual psychology or social structural constraints but to the locally specific demands of the face to face social situation. This central analytic aim was pursued through a score of papers and eleven widely read books, including *The Presentation of Self in Everyday Life* (1959), *Asylums* (1961), *Stigma* (1963), and *Frame Analysis* (1974). In opening the interaction order as a distinct sub area of sociology Goffman brought a novel analytic attitude, a spirit of inquiry, and a persistent skepticism that connected narrow disciplinary concerns to wider social currents.

INTELLECTUAL AND SOCIAL CONTEXTS

While Goffman’s sociological project was unprecedented, his development of the sociology of the interaction order bore the imprint of the early social and intellectual contexts he encountered. Often characterized as a leading exponent of symbolic interactionism, Goffman brought a modulated determinism and critical edge to this perspective that owed something to the cultural influence of his Canadianism. At Toronto important influences were anthropologist C. W. M Hart, who introduced students to then untranslated portions of Durkheim, and the founder of kinesics, Ray Birdwhistell, whose class exercises involved close observation of ordinary behavior in natural settings.

These initial interests were firmed up after 1945 when Goffman moved south to join the talented cohort of students and faculty some times referred to as the second Chicago School of Sociology. Chicago proved to be the crucible in which a number of critical influences were condensed into the distinctive approach now immediately identifiable as “Goffman’s sociology.” Social psychological, sociological, anthropological, and literary lines of influence shaped the emergent Goffman. First, there was the legacy of G. H. Mead’s social psychology, codified as “symbolic interactionism” by Mead’s student Herbert Blumer in 1937. While Goffman absorbed Mead’s teachings about the formation of self through social interaction, he did so critically, acknowledging that in complex contemporary societies where the sources of moral consensus were increasingly differentiated, role taking was often more problematic than Mead envisaged. Cooley and Dewey were also major influences. A leading sociological influence was Simmel’s formal sociology, mediated via the Chicago School’s founding figure, Robert E. Park, who attended Simmel’s lectures at Berlin. One of Park’s students, Everett C. Hughes (whom Goffman considered his most important teacher at Chicago), passed the Simmel torch to the postwar generation. Simmel’s pioneering “sociational” conception of society that prioritized interactions between persons over large scale structures and institutions was congenial to Goffman, as was his proposal that sociology’s core method was to extract the “formal” features of sociation. As a formal sociologist, Goffman sought to elucidate and analyze a variety of forms of the interaction order, such as the basic kinds of face work, the forms of alienation from interaction, the arts of impression management, or the stages of remedial interchange. The anthropological influence on Goffman’s thought derives from the late “symbolic” Durkheim of *The Elementary Forms of the Religious Life*. This line of influence passed from Durkheim to British social anthropologist A. R. Radcliffe Brown – whom Goffman almost met in 1950 – through to W. Lloyd Warner (another significant Chicago teacher, and adviser for the research element of Goffman’s two graduate degrees). The literary influence was represented by Kenneth Burke’s writings, especially from *Permanence and Change*

(1935), from which Goffman extracted Burke’s method of perspective by incongruity, evident in the many irreverent comparisons and unexpected contrasts that became a Goffman trade mark. Burke himself apparently approved of *Presentation of Self* as a sociological application of his own dramatic approach.

These lineage lines contextualize the formation of Goffman’s sociology, but do not explain its unique shape and preoccupations. Goffman grew exasperated by critics who sought to label – and thus assimilate – his ideas to sociology’s major paradigms. In his view, sociological traditions were there to be creatively applied and modified, not slavishly followed. Throughout his career Goffman showed a remarkable facility to respond to and incorporate into his analyses ideas drawn from other theoretical approaches (game theory, ethology, phenomenology, feminism, conversation and discourse analysis). While his writings displayed clear systematic intent, the drive to build a single system was absent. Goffman was much more at home with the essay mode, never providing a final cumulative statement of his sociology. His judgment was that interaction analysis was too undeveloped to aspire to anything more than some robust conceptual distinctions. More than many significant twentieth century sociologists, Goffman’s oeuvre demands to be reconstructed by the reader; Goffman did not provide any obvious interpretive key to his work.

MAJOR SUBSTANTIVE CONTRIBUTIONS

Goffman burst onto the scene with the 1959 US publication of *The Presentation of Self in Everyday Life*, a book that breathed new life into the ancient “all the world’s a stage” metaphor. Embarking from a psychobiology that emphasized the immediate symbolic functions of the expressions humans constantly “give” (through the content of their talk) and “give off” or exude (through tone, posture, gesture, facial expression, and the like) when in the presence of others, Goffman brilliantly analyzed the “dramaturgical” aspects of this conduct. Using a wide range of illustrative materials – ranging from respectable treatises, ethnographies, and social histories through memoirs,

popular journalism, and novelistic accounts to his own acute observations of human conduct – Goffman showed how interactional details could be cogently understood in sociological terms as “performances” fostered by an “audience” requiring cooperative “teamwork” among performers to bring off a desired definition of the situation. Performances may be presented in “front” regions (such as workplaces or formal ceremonial settings) that are usually differentiated by “barriers to perception” from “back regions,” the back stage areas (bath rooms, restaurant kitchens, private offices) where performers prepare themselves. Goffman went on to examine how “discrepant roles” and “communication out of character” can threaten the fostered reality. A recurrent theme in his writings was that successful interaction needs not Parsonsian role players enacting the institutionalized obligations and expectations of a status, but rather “interactants” skilled in “the arts of impression management.”

In Goffman’s subsequent writings a range of figures – notably game, ritual, and ethnological metaphors – were used as methodological devices to highlight otherwise taken for granted features of social encounters. Face to face interaction was a species of social order, which he named “the interaction order” (a term coined in his 1953 PhD dissertation, then seemingly forgotten, and only revived for his posthumously published, valedictory American Sociological Association Presidential Address; see Goffman 1983). Confining his analytical attention to this face to face realm of embodied expression, Goffman produced both systematic examinations of the general forms of the interaction order (including *Behavior in Public Places*, 1963; *Relations in Public*, 1971; and *Forms of Talk*, 1981) and dissections of certain of its problematic aspects (notably *Asylums*, 1961; *Stigma*, 1963; and *Gender Advertisements*, 1979). Though Goffman always sought to maintain his own distinct position, his later work was increasingly preoccupied with issues that ethno methodology had brought to the fore of sociological analysis, and his longest book, *Frame Analysis* (1974), can be read as a sustained response to Garfinkel’s *Studies in Ethnomethodology* (1967). One major point of difference was the social self, which was for Goffman an abiding sociological referent.

Most generally, Goffman’s interaction analysis acknowledged the centrality of informational (or “communicative” or “system”) and ritual demands on interaction. The former concerned the communication and control of information given and exuded by the interactant (mood, intention, competence, trustworthiness, etc.) and was ultimately constrained by the physical limits of the human body’s vision, voice, hearing capacities, and so forth. Goffman mobilized dramaturgy and game theory to analyze the levels of mutual awareness that can emerge in inference making in ordinary encounters. It was these emphases that yielded complaints about Goffman’s “cynical” or “Machiavellian” view of human nature. The ritual model offered very different imagery. Ritual elements concern the expression and control of the interactant’s feelings towards both self and others. Here Goffman creatively adapted Durkheim’s theory of religion, applying it to the secular world of social encounters. In his work on face work, deference and demeanor, and supportive and remedial interchanges, Goffman showed how greetings and farewells, apologies and avoidance practices illustrated the need for persons to monitor their interactional conduct when in the presence of that sacred deity, the self of the other. From first to last, Goffman was a Durkheim revisionist.

Goffman’s analyses constantly distinguish out of awareness features of encounters that, once identified, become instantly recognizable. His pivotal distinction between focused and unfocused interaction is a case in point. Focused interaction, with its single joint focus of attention (e.g., a card game, a conversation, a physical task jointly carried out), is straightforward enough to grasp. But unfocused interaction, when persons orient their conduct simply by virtue of the co presence of others (e.g., walking down a busy street), opens up for sociology hitherto unenvisioned sources of social orderliness. A rule of “civil inattention” constrains the conduct of unacquainted others on the street, persons walking past each other silently being likened to passing cars dipping their lights. Civil inattention is one of a special class of social rules that regulate interaction known as “situational proprieties,” departures from which Goffman found especially instructive. Situational *improprieties* were less a

matter of psychopathology as they were an expression of alienation from the community, social establishments, social relationships, and encounters.

Goffman arrived at this conclusion after his monumental study of the plight of mental patients in *Asylums*, and his psychologically astute analysis of the identity implications of departures from normality in *Stigma*. Like his dissertation, in *Asylums* Goffman strove to overcome the limitations of his case study by generating an analytic ethnography that pursued selected conceptual themes. The mental hospital was seen as part of the larger class of “total institutions” that also included prisons, concentration camps, and monasteries. Social processes of “mortification” were common to them all. Mental patients underwent shared changes in self conception – a shared “moral career” that was at once cause and consequence of their current predicament as they were sucked into a “betrayal funnel.” Patients developed an underlife, rich in “secondary adjustments,” which created space for conceptions of self at odds with officially prescribed conceptions. The practice of psychiatry was described as a form of service work, a “tinkering trade” that offered precious little real service to the mental patient. *Asylums*, however, was not simply an influential critique of mental hospitals that brought Goffman to the attention of non sociological audiences: it remains a vivid exploration of resistance to authority and the social sources of selfhood under extreme conditions.

Stigma also drew acclaim from outside academic sociology. It provided a careful analysis of normality and those temporarily or more extensively excluded from full social acceptance. Although Goffman defined a stigma as a “deeply discrediting attribute” and was much concerned with the situation of groups such as the disfigured, the differently abled, and ethnic minorities, his emphasis was once again on acts and relationships, not personal attributes. *Stigma* also anticipated identity politics. Later, and in part in response to his feminist oriented students, Goffman presented an “institutional reflexivity” theory that saw gender difference as a thoroughly social construction. He illustrated his approach to gender difference through an analysis of some 500 advertising

images in *Gender Advertisements*, a book that still stands as an unrivalled piece of visual sociology. While Goffman’s thinking on gender difference did not attract the acclaim of his earlier ideas, it anticipated many of the key points of Judith Butler’s celebrated performative theory by more than a decade, and showed Goffman’s continuing sensitivity to social currents beyond the academy.

Goffman deepened his perspective with his longest book, *Frame Analysis*, which provided a modulated phenomenological dimension to his sociology. Frames are perceptual principles that order events, sustained in both mind and activity. For Goffman, frames were constantly shifting features of situational social life, analyzable into primary frameworks and two kinds of transformed frame, the keying and the fabrication. We can make sense of two persons quarreling in terms of a primary framework, a “domestic argument,” but can also come to see it as keyed if the couple are rehearsing a scene in a play, or as fabricated if one party is being set up for a reality TV program. Frames structure events, but our understandings can also be altered if participants seek to shift from a literal frame to a joking one. Goffman emphasized both the determinative characteristic of frames and the capacity of interactants to change the currently prevailing frame. This theme is refined in his last book, *Forms of Talk* – concept of “footing” is designed to capture the shifting alignments of persons to their own and others’ talk. Goffman’s later work focuses more consistently on the syntactical relations between the acts of co present persons, but the self does not disappear from view. Goffman’s earlier two selves viewpoint (where an unsocialized self seems to lie behind the presented self, directing it) gives way to a more sociologically consistent view of the self as a “changeable formula” with no more depth than is encoded in interactional conduct.

RELEVANCE TO HISTORY OF CONTEMPORARY SOCIOLOGY

One of the more readable (and certainly one of the most quotable) of twentieth century sociologists, Goffman’s deceptively accessible writings can be understood at many levels and in a

range of different ways. This is evident in the proliferation of a range of readings of his ideas: interactionist, structuralist, existentialist, ethogenic, modernist, and postmodernist. His sociology has attracted extremes of assessment from extravagant commendation to outright dismissal – the latter evaluations tending to originate from within sociology. The core of these objections concerns his cavalier approach to questions of method. Goffman was master of his own craft and did not have a method in the conventional sense of a set of procedures that can be taught to graduate students. His principled indifference stemmed from a conviction that actual research practice was always going to be at variance with proclaimed methodological procedures. Alternative valuations have concentrated on Goffman's artful use of a range of rhetorical devices. Goffman's texts adopt a distinct format made up of several components: the essay mode; conceptual framework development as a preferred discursive structure; pressing the deployment of metaphor to the point of exhaustion; and use of a range of sociological tropes, including perspective by incongruity, parataxis, irony, and humor. But the deconstruction of Goffman's texts in this way does not explain the ongoing fertility of his ideas. The brilliance and idiosyncrasy of his writings have so far proved a tough act to follow.

In the image originally applied to Simmel, Goffman left a cash legacy to be spent as successors consider fit. The primarily conceptual character of Goffman's legacy has proved to be adaptable to a variety of analytic enterprises. Theoretically, Goffman's ideas play an important role in the grand syntheses of Giddens and Habermas. Practically, *Asylums* impacted the deinstitutionalization movements of the 1960s and 1970s. *Stigma* remains a pivotal text for groups advancing the interests of the differently abled. In empirical terms, researchers have developed more fully explanatory theory from Goffman's initial conceptions. Examples include theories of politeness, interaction ritual chains, the centrality of frame analysis to social movements theory, and social psychological versions of impression management theory. Ethnographers of various hues have been equipped with an extensive and powerful analytic vocabulary. As might be expected from the cash legacy notion, the influence of Goffman's

sociology, both direct and diffuse, continues to be far reaching.

Gökalp, Ziya (1876–1924)

Serif Mardin

Turkish sociologist Ziya Gökalp was the first to use western sociological theory as a foundation of his thought. He is known as the originator of a systematic theory of Turkish nationalism. This theory was elaborated in the confluence of three problematic issues in the Ottoman Empire at the end of the nineteenth century.

One was the policy of “Ottomanism,” an attempt by the reformist Ottoman bureaucracy to modernize the empire. Ottomanism attempted to present Ottoman reform to the Concert of Europe (composed of Russia, Prussia, Austria, and Great Britain) as having modernized the structure of the empire and granted a new status to non-Muslim communities. It was hoped this would make Turkey worthy of acceptance in the Concert. This strategy was successful (1856), but met with much criticism from various groups inside the empire. The second Ottoman problem was the question of the viability of a union of all Muslims under Ottoman leadership. This issue was known as Islamism or *İslamcılık*. The third issue was an option increasingly discussed among Ottoman intellectuals in the 1890s, i.e., the ideology of rallying all Ottomans around “Turkishness.”

In Cairo in 1904, an article appeared in the Young Turk periodical *Türk* entitled “Three Types of Policies” that weighed all three alternatives, condemning Ottomanism and “pan Islamism” but expressing a hope for the promotion of a Turkish national culture. The author was Yusuf Akçura, a Turkic émigré from Russia. Exactly the same issue was later to be discussed in a set of articles by Gokalp with the title “Underscoring One’s Turkishness, Islamicness and Modernity” (*Türkleşmek, İslamlaşmak, Muasırlaşmak*), with *modernity* as an added option in the list of alternatives.

Gokalp’s birthplace, Diyarbakır, was a provincial center distant from the Ottoman capital. However, it had profited from more of an input of the western oriented reform movement, the *Tanzimat*, than might be imagined. Diyarbakır had an official gazette published by Gokalp’s father, and it had a lycée (*idadi i mulki*), a product of reform that Ziya attended. Ziya came from a prominent local family and his father’s house had a large library, presumably containing nineteenth century geographical atlases and other reference works.

There was a sufficient number of secular intellectuals around to alert Gokalp to the ideas of materialism that came out of the West. He appears to have been introduced in his youth to Dr. Abdullah Cevdet, an intellectual who was to become a key representative of nineteenth century western secular materialism in Turkey. One of Gokalp’s mentors, a Greek physician

who was his teacher of biology in school, had a permanent influence on his intellectual development. His uncle, Hasip Efendi, introduced him to Islamic mysticism. These cross currents resulted in a depression that led to an attempted suicide (1895).

Gokalp was involved in a number of subversive activities encouraged by the Young Turk presence in Diyarbakır for which he was imprisoned in 1898. He thereafter went to Istanbul to study at the Veterinary School, from which he graduated. In 1903–7 Gokalp occupied a bureaucratic position in Diyarbakır. In 1907, leading a group of protestors, he occupied the Diyarbakır telegraphic office and sent a collective telegram to the sultan asking him to stop the depredation of a local tribal sheikh who was taking advantage of his position as a quasi gendarme to fleece the local population. Following the Young Turk Revolution and their accession to power on July 23, 1908, Gokalp was once again in Diyarbakır filling the position his father had occupied as the editor of the province’s official journal.

Gokalp was a local delegate to the Young Turk Congress of Salonika in 1909 and impressed the leaders of the party. Traveling back and forth between Salonika and Diyarbakır, he found time to increase his knowledge of western philosophy and sociology in Salonika where he read books ordered from Europe. He also taught sociology in the Salonika lycée in 1910 and established relations with a literary group and its publication, *Genç Kalemler*. *Genç Kalemler* paid special attention to linguistic issues and the elaboration of a literature expressed in the vernacular Turkish.

In the election of 1912 to the reestablished Ottoman parliament, Gokalp was elected as representative from Ergani. During World War I he took up the role of ideological mouthpiece for the Young Turks, following in his writings their various shifts of interest from Pan Turkism to Islam. He may be considered to have adumbrated some of their emerging secularism in articles he wrote before the war.

In 1911 Akçura had started a new review, *Türk Yurdu* (*The Turkish Hearth*). It was here that Gokalp published his article “Underscoring One’s Turkishness, Islamicness and Modernity” in 1912. According to Akçura, *Türk Yurdu* itself was a continuation of the

Tercuman, edited by Gaspiralı İsmail (Ismail Gasprinski) in the Caucasus since 1883. Akçura therefore underlined the much earlier interest of the Turkic population of Russia in the questions he reviewed in “Three Types of Policies.” This emphasis on the greater experience and sophistication of the Tatar as compared to the Ottomans was to remain a sticking point between the two men and led to a break in their relation after 1912. At the time, Ziya Gökalp was immersed in a much wider intellectual Ottoman debate about the three options detailed by Akçura. In this debate figured Süleyman Nazif (1869–1927), an “Ottomanist,” Ahmet Ağaoğlu (1869–1934), a “Turkish nationalist,” Babanzâde Ahmet Naim (1872–1934), an “Islamist,” Ali Kemal (1867–1922), an “Ottomanist,” and Yusuf Akçura, a “Turkist.”

During World War I, Ziya Gökalp was increasingly enmeshed in the ideological themes promoted by the Young Turks. With the financial help of the Party of Union and Progress, he founded in 1914 the bi monthly *İslam Mecmuası*, which continued publication until 1917. The review went along with a new interest of the Young Turks for the reform of the Ottoman Islamic institutions. This interest concentrated on the ways in which religion could be integrated with the state the Young Turks were constructing. Gökalp wrote a report for the 1916 Convention of the Union and Progress Party where he explored the same issue.

Following the defeat of the Ottoman Empire, the Young Turks abolished the Party of Union and Progress on November 5, 1918. On December 21, the Young Turk leaders fled, the Ottoman parliament was dissolved, and Gökalp was interrogated over his involvement in the Armenian deportations. On January 30, 1919, allied occupational forces landed in Istanbul, picked up a number of prominent Young Turks, and sent them into exile or prison in Malta. As a member of the Central Committee of the Young Turks, Gökalp was among their number. After returning from Malta in 1921, he went to Ankara where the new (later republican) regime was being organized. His return to Diyarbakır in 1922 probably reveals the suspicion Ankara still felt toward a former Young Turk responsible for the ruin of the empire.

In Diyarbakır Gökalp published a new review, *Kuşuk Mecmua*. This phase of his life

shows he was somewhat insensitive to the acceleration of the new regime’s secularist policies. On November 1, 1922, the sultanate was abolished and on November 18 an Ottoman prince was nominated as caliph without the title of sultan. Following the abolition of the sultanate, Gökalp discussed the issue of the caliphate, maintaining that it was a religious institution that should only be concerned with matters of faith (see Gökalp 1959: 223–7). Unfortunately, this view, which tacitly accepted the role of a purely religious caliph in Turkey, was diametrically opposed to the position taken by the minister of justice Seyyid Bey in the Turkish parliament on March 3, 1924. Seyyid Bey argued that the caliphate was a purely political position and therefore had no role to play in a republic that did not allow devolution of power. Seyyid Bey’s speech led to the abolition of the caliphate on the same day. The coolness that developed at the time between Gökalp and Ankara is therefore understandable. However, this difference seems to have been patched up when Gökalp was asked to direct the bureau in charge of publication and translation. He thereafter applied himself to promoting the ideology of the government in a brochure *Doğru Yol (The Right Way)*.

GÖKALP’S INNOVATIONS

Gökalp’s key concepts of the *umma*, the nation, and the international community show an evolutionist view of society. Although he outlined the stages of the process, it was difficult for him to specify the specific stage at which the Ottoman Empire found itself in the early twentieth century. Many of his statements should therefore be seen as part of a general program to be implemented in relation to “social facts” and their change over time.

Up to the time of Gökalp’s writings, the critique of the policies implemented in the empire was focused on their capability and efficacy in confronting western ideologies promoting “progress” and “civilization.” Gökalp turned the defensive attitude around. He stated that one should build a response to these pressures by observing social facts as components of Ottoman society. In his view, these had been approached by the *Tanzimat* with a somewhat

superficial understanding of the processes involved both in western influences and in the internal social changes the empire was under going. For instance, a structuring element of modernity the reformers had not taken into account was the division of labor that produced a general differentiation in social, economic, and political functions of society. A more general process could be observed that furnished the dynamic element of modernization and stood behind the division of labor, namely “new life ... an ideal which is in the process of emerging from the [*sic*] social consciousness. Today this ideal has to remain somewhat ambiguous. This ambiguity will be cleared by time and by the guidance of social convention” (Gokalp 1959: 315)

The central point of departure for Gokalp's sociology was the *umma*, the Islamic community at large. The *umma* could not be kept intact in the changing social structure of the Ottoman Empire, but, nevertheless, it had to remain in a modified form as a receptacle of faith. The remaining element of the *umma* was to be given a new foundation by retaining the Arab alphabet (a common feature of Muslim culture), by working on a common terminology for all Muslims, by promoting *umma* wide congresses taking up common educational policies to establish communication links between Muslims of all nations, and by keeping the crescent as a common symbol.

Even in the Ottoman Empire the social division of labor had expanded and had given rise to a society of occupational groups. Consequently, the collective consciousness of Muslim and Christian communities had begun to weaken. The ground was thus set for the emergence of a new type of society, the nation. This process was propelled by three types of forward motion: first, the social density that would create the effervescence necessary for change (something that Gokalp probably picked up from Durkheim's view on religion). This effervescence, in turn, brought to the surface of society the component of its specific “ethos.” The integration of the component of the ethos produced a “culture” (*hars*) and its expression in a language. People of the same language tended to embrace the same faith. This somewhat confusing aspect of Gokalp's ideas has had a prolongation in contemporary Turkish

nationalism, and can only be fully understood in the following quotation from Gokalp: “As language plays a part in decoding religious affiliation, so religion plays a part in determining membership in a nationality. The Protestant French became Germanized when they were expelled from France and settled in Germany. The Turkish aristocracy of the old Bulgars became Slavized following their conversion to Christianity” (1959: 81).

The society to emerge from this process was the nation. The forces that propelled the nation ahead, however, were not simply those of a social structure. They also depended on changes in communication patterns that accompanied the division of labor. According to Gokalp, Gabriel Tarde discerned two levels in this innovation. The first was the newspaper. The newspaper, using the vernacular version of a language, created a sense of shared identity among its readers, uniting them into a public. The second element was the book, which worked to promote a further associational bond in the sense that it addressed itself to persons who shared abstract ideas, e.g., the scholar and the scientist. This was the foundation of the international community, the next stage of social evolution with which the Ottomans had to integrate.

The nation is thus seen by Gokalp “as that ethnic group which, as it emerges after a long period of fusion in an empire, strives to regain and revive its identity.” The emergence and maintenance of this identity, however, can only be understood in relation to Gokalp's belief in a “social mind” of a transcendental character in relation to organic social phenomena.

Although many of Gokalp's speculations on Turkism show the use of the concept of race (1959: 75), in 1917 he was clear in preferring the new use by the French geographer Vacher de Lapouge of the concept of *ethnie*. He stated his preference for the term “ethnic family” instead of race when speaking of groups of smaller units, *kavm*, a group of individuals who have a common language and usage (Gokalp 1959: 127).

The name Turk was both a repository of *mores* and the name of a vernacular folk language that had been overlaid by a hybrid court culture. The nation, having once emerged, would be supported by systematic research concerned with retrieving Turkic folk motifs,

symbols, and usages. The emergence of the nation did not mean that the function of the *umma* disappeared. What had to happen was the creation of an “up to date Turkism” (1959: 76). The Turks would still consider themselves to be of the *umma* of Islam, the Qur’an to be their sacred book, and Muhammad their sacred prophet. However, many of the items that the *ulema* saw as part of the *şariat*, such as the approval of polygamy, had no relation whatsoever to religious commands.

For Gokalp, the map of a future Turkey was Turkism, which included the search for authentic culture still buried in the culture of the people, doing away with the Ottoman written language and reforming language to fit the vernacular of folk literature. Like many of his contemporaries, Gokalp promoted populism and probably received these ideas from Turkic Russian émigrés. He contributed to a periodical entitled *Towards the People*, in which the Russian populist ideology was echoed. His populism, however, shows the element of authoritarianism that appears in many of his ideas.

Gokalp’s idea of solidarity rests on Durkheimian foundations and on Durkheim’s use of solidarity. However, Gokalp’s solidarity is to be distinguished from French solidarism. It had an authoritarian content that is evident in his views on property: “Individual ownership is legitimate only insofar as it serves social solidarity. The attempts of the socialist and communist to abolish private property are not justified. However, private wealth which does not serve social solidarity cannot be regarded as legitimate” (1959: 312).

Influences on Gokalp included Durkheim’s concepts of the division of labor as well as the social bond of solidarity. The contrast of *Gemeinschaft* and *Gesellschaft* appears without a clear reference to Tönnies, and Fichte is mentioned in relation to the “Germanic ideal.” The ideas of Gabriel Tarde and Fouille’s *idées force* are part of Gokalp’s theoretical foundations. He thought Bergson the most original thinker of his time. Gokalp took from him the idea of an *élan vital* and that of creative evolution. But even in their cumulation, these vitalist foundations can only be understood in relation to Gokalp’s less often expressed view of an active social mind that was transcendental in

character. He may have been predisposed to this view by his conviction of the profundity of Islamic Sufism.

Conscience collective and collective representation were both concepts Gokalp received from Durkheim, but he used them somewhat differently. In Durkheim, collective conscience is the source of control of moral transgressions. In Gokalp, it is the cement of nationality. This is an illegitimate extension of the term that may have links with his admiration of Ibn Arabi and Arabi’s theory of eternal essences. Gokalp’s use of “collective representations” as mental patterns common to members of a society expressed through symbolism as part of the culture of that society is closer to the Durkheimian use.

Ziya Gokalp’s *Turkleşmek, İslamlaşmak, Muasırlaşmak*, later transformed into his *The Principles of Turkism (Turkçuluğun Esasları)* (1921), was used as an ideological frame for nationalists of the republican era. Intransigent Kemalists nevertheless neglected the central role that Gokalp still gave to Islam. It appears that this role had already disappeared in his *Principles of Turkism*. The extreme nationalist right has also found a source of inspiration in his ideas. The poem *Turan*, with its references to a Central Asian Turkic “hearth” as an ideal to be followed by all Turks, has kept its force as an inspiration for Turkish nationalists. Although Gokalp had investigated the status of Kurdish tribes in his birthplace and published the result of his investigation, there is no mention of Kurds in the *Principles of Turkism*.

Goldman, Emma (1869–1940)

Melissa Sandefur and Vicky M. MacLean

Emma Goldman was a social and political writer, revolutionary activist, and one of the most accomplished speakers in American history. Goldman was a proponent of individualistic anarchism, which she described as the philosophy and theory that government and man made laws are intrinsically coercive and harmful to individual liberty (Goldman 1969). Her commitment to anarchism and to the ideal of freedom led her to champion the causes of labor, anti militarism, freedom of religion, prison reform, and sexual and reproductive freedom. Her most important contributions to political and social thought include the incorporation of sexual politics into anarchism and her many essays on contemporary issues such as education, birth control, women's emancipation, modern drama, national chauvinism, and crime. A passionate feminist, Goldman believed that a

purely political solution was not the answer to inequality between the sexes, but that equality would come only from a massive transformation of values and from women themselves.

Emma Goldman was born on June 27, 1869 in the Jewish quarter of Kovno, Russia (now Lithuania) to innkeeper parents Taube Bienowitch Goldman and Abraham Goldman. Goldman spent a harsh and sometimes violent childhood (at the hand of her father) in Kovno, Popelan, and Königsberg. In 1881 when Emma was 13, the Goldman family moved to St. Petersburg, just after Tsar Alexander II's assassination. It was there that she was influenced by the radical student circle of St. Petersburg (Wexler 1984). Goldman attended school for 6 months, but because of family economic hardships she dropped out to work in a glove factory. Goldman's father attempted to arrange a marriage, but Emma, then only 15, refused with threats of suicide. She escaped the harsh conditions of Russia by moving to the US with her half sister Helena; they joined another sister, Lena, in Rochester, New York. Her 2 volume, 56 chapter autobiography *Living My Life* (1931) begins with her arrival in the US. Goldman worked at a clothing factory where working conditions were hazardous and where she was subjected to anti-Semitism, low pay, and 15 hour workdays. Goldman discovered that for a Jewish/Eastern European immigrant, America was not the Promised Land. These early experiences and her readings on communist anarchy, socialism, and Marxism influenced Goldman's belief that many problems of individual freedom stemmed from the social conditions resulting from capitalism.

Goldman was first drawn to anarchism following the Haymarket Square Strike and the subsequent Riot of 1886 in Chicago. This tragedy began as a confrontation between police attempting to disperse marchers protesting police violence, and striking workers in Haymarket Square. A riot ensued when an unidentified person threw a bomb, triggering a gun battle. Eight anarchists were arrested, charged, and tried for crimes and deaths associated with the riot; seven were found guilty, sentenced to death, and eventually four were hanged. Goldman followed the events intensely and on the day of the hangings resolved to become a revolutionary. As an anarchist Goldman

adopted syndicalist leanings, rejecting private property ownership and promoting free worker cooperatives in place of capitalism (Wexler 1984).

In 1887 Goldman married fellow factory worker Jacob A. Kersner, thus gaining US citizenship. Ten months later, she divorced Kersner and moved to New Haven, Connecticut, where she worked at a factory and met other Russian socialists and anarchists (Wexler 1984). Goldman then relocated to New York City, where she met her mentor, German anarchist Johann Most, editor of *Die Freiheit*, and her closest friend and lifelong comrade, Alexander Berkman. As a writer and prominent orator, Most encouraged Goldman to become a public speaker and deepened her interest in anarchist philosophy. Goldman's initial lectures were delivered in Yiddish or German, but in time she gained confidence and considerable skill as a speaker in English. Most also stimulated her interest in the social revolutionary potential of the arts. However, Goldman became dissatisfied with Most's attitude toward her as a woman, believing that he viewed her as his subordinate and mistress more than an equal comrade. She gravitated toward Berkman, who became her lover and closest comrade in the anarchist movement. Of the many men in her life, Goldman felt that only Berkman treated her as an equal, never pressuring her to fill the traditional roles of wife and mother (Solomon 1987).

Early in her anarchist career, Goldman advocated violence as an acceptable means to an end. She helped Berkman plot to assassinate industrialist Henry Clay Frick in 1892 after Frick used force to suppress strikers, leaving 9 dead. Goldman and Berkman hoped that the assassination of Frick would ignite a revolution. The assassination attempt was a failure, however, as Frick was only slightly injured, and the workers were not incited to revolt. Berkman received a 22 year prison sentence for the attempted assassination, but Goldman's involvement was never proven (Wexler 1984). In her autobiography, Goldman unburdened herself of her clandestine involvement with Berkman in the Frick debacle. She wrote: "my connection with Berkman's act and our relationship is the leitmotif of my 40 years of life" (Falk 2003: 3). As her thinking evolved, Goldman rejected violence in favor of political organizing. For

the next 30 years she lectured, studied nursing, edited and wrote for the radical anarchist magazine *Mother Earth*, and mobilized political protests advocating anarchism, free speech, and civil liberties.

Though Goldman did not support the women's suffrage cause, she criticized the social and economic subordination of women and was an early advocate of the right of women to practice birth control. She was arrested several times for violating the 1873 Comstock Law prohibiting the distribution of birth control literature. She saw birth control as a social issue and argued that the choice to have sexual relations without fear of unwanted pregnancy was critical to the human spirit and liberty as well as necessary to the empowerment of women (Wexler 1984). In her writings on women, Goldman argued that pursuing the vote would not bring women true emancipation. Instead, she advocated for institutional changes, particularly related to women's sexual freedom, economic independence, and marriage. Goldman discussed marriage as an impediment to love and to the ideal relationship between the sexes. Because of her belief in absolute freedom and her own disappointing experience of marriage, Goldman believed individuals should enter into and leave personal relationships without restriction. "If I ever love a man again," she said in 1889, "I will give myself to him without being bound by the rabbi or the law, and when that love dies, I will leave without permission" (Goldman 1931: 36). Marriage, in her opinion, was a legalized form of prostitution, in which women traded sex for economic and social standing (Solomon 1987). Building on her critique of women's suffrage, Goldman claimed that no political solution would free women from the internal constraints of public oppression. Goldman argued that if women are to be emancipated they must stand on their own ground and insist on unrestricted freedom (Goldman 1969).

During the depression of 1893, Goldman was arrested in New York's Union Square and convicted for "inciting to riot" (Wexler 1984). She was sentenced to a year at Blackwell's Island Penitentiary where she served as a nurse to the inmates, studied, and read freely. She became more fluent in English while working with prisoners and resolved to address

English speaking audiences in promoting “real social changes” (Goldman 1931: 155). Her experience with prison, both from her own internment and from the writings of Berkman, led her to address the deplorable conditions of prisons and the failure of the criminal justice system. Her 1917 publication *Anarchism and Other Essays* included an essay on “Prison: A Social Crime and Failure.” Pointing out that the methods used by society to deter crime were unsuccessful, Goldman promoted understanding of the social conditions leading to criminal behavior and called for a radical restructuring of political and economic institutions. She further advocated for the importance of providing prisoners with meaningful work and adequate pay as the primary mode of rehabilitation (Solomon 1987). “My Year in Stripes,” published in the *New York World* the day after Goldman’s release, told the story of her arrest and of the humiliating living conditions in prison. Goldman later declared before a crowd of supporters that if the representatives of government intended to prosecute women for talking, they would have to “begin with their own mothers, wives, sisters and sweethearts” (Falk 2003).

On September 6, 1901, self proclaimed anarchist Leon Czolgosz shot President William McKinley in Buffalo, New York, at the Pan American Exposition and later stated that a lecture by Goldman motivated his attack. Authorities arrested and interrogated Goldman but found no evidence linking her to the assassination (Wexler 1984). Goldman continued her public tours and gained much public favor among the middle class and liberal organizations that supported progressive causes and opposed 1903 legislation banning anarchists from entering the country (Solomon 1987). Goldman also began a new series of lectures on the Russian Revolution as tensions in Tsarist Russia mounted. In 1903 the Jewish community suffered a wave of pogroms: planned campaigns of persecution or extermination sanctioned by the government. Hundreds of Jews were killed in Kishinev and the final blow came in 1905 during “Bloody Sunday” when political dissidents demonstrating at the Winter Palace were slaughtered by Russian troops. For 2 years, Goldman toured and drummed up support for the Russian Revolution (Wexler 1984).

In the years between 1908 and 1916, Goldman’s lecture tours throughout the US and Canada took on a new level of intensity after she met and became the lover of Dr. Ben L. Reitman, a gynecologist who began to manage her engagements. Her prominence as a speaker is evident in the expansiveness of her audience. According to Solomon (1987: 26), in a 6 month tour in 1910 Goldman spoke in 25 states to an audience of 40,000 and she sold 10,000 articles of literature. Another boost to Goldman’s popularity came in 1906 when Berkman was freed from prison after serving out 14 years of his 22 year sentence. Together, Goldman and Berkman resumed their advocacy for political education. Berkman wanted to achieve anarchism through the labor movement, while Goldman’s ideology cut across class lines and attracted followers from the middle class. They founded *Mother Earth*, a radical periodical edited by Goldman until it was censored by the US government in 1917 (Wexler 1984). Many of Goldman’s lectures and writings were devoted to drama, a venue that allowed her to promote radical ideas through the arts. *Anarchism and Other Essays* contained writings on anarchism, social criticism, women’s emancipation, prison reform, and modern drama; it received wide spread publicity and reviews. In 1914 Goldman published a series of lectures (*The Social Significance of the Modern Drama*) critiquing social morality as represented by modern playwrights. Goldman addressed plays such as *A Doll’s House*, a critique of women’s roles and marriage, Shaw’s *Major Barbara*, and Ibsen’s *Ghosts*. Through her use of drama Goldman brought her social critique to a new audience (Solomon 1987).

“Red Emma,” a prime target of the US government, was arrested 16 times and jailed on several occasions. In 1917 Goldman and Berkman were imprisoned for protesting military conscription. Then in 1919, during the post World War I anti Bolshevik fervor, the government revoked Goldman’s citizenship and both Goldman and Berkman were deported to Russia (Wexler 1984). After 2 years Goldman fled the new Soviet Union, profoundly disillusioned with the authoritarian state and its disregard for civil liberties. Goldman subsequently wrote *My Disillusionment in Russia* (1923) and attempted to discredit Bolshevism and to

defend her own revolutionary principles. She wrote of her experiences in Soviet Russia from 1920 to 1921 and what she saw as the Bolsheviks' betrayal of the Revolution. Goldman argued true communism was never present in the Soviet Union, as the class system there was never abolished – just reformatted. In addition, Goldman noted that the Bolsheviks wielded even more power than the tsars they overthrew, and party officers spent most of their time seeking greater influence and prestige.

Emma Goldman spent the last two decades of her life traveling between France, England, and Canada, still actively promoting her humanist brand of anarchism. In June 1925, still exiled from the US, Goldman married a British friend and anarchist, James Colton, in order to secure British citizenship. She then moved to a small cottage, purchased by friends, near St. Tropez, France, where she wrote her autobiography with Berkman's editorial assistance. Goldman maintained her friendship with Berkman, who lived in exile in Nice, and helped to support him financially. However, as Berkman's health and financial situation deteriorated he became depressed and in June 1936 he shot himself, leaving Goldman feeling devastated and hopeless. Goldman was reenergized, however, when she was invited by Augustine Souchy, head of a Spanish anarchist syndicalist group, to support the Spanish workers' rebellion. While fundraising for the Spanish revolutionaries in Canada, Goldman suffered a paralyzing stroke and died 3 months later, on May 14, 1940. At the request of friends, she was buried at Waldheim Cemetery in Chicago, near the graves of the Haymarket strikers (Solomon 1987).

Emma Goldman's contributions to sociology are most evident in her political critiques of major social institutions: the family and marriage, religion, industrial capital, education, and most importantly, the state. Mentored by the most prominent anarchists of her time, she incorporated various strains of anarchy into a social movement reflective of a historical period of American radicalism often lost to historians. Rather than simply advocating anarchism as an intellectual exercise, she tested and expressed her theory through public speaking and her published works in the tradition of sociological "praxis." Goldman was concerned both with

educating the public about anarchism as well as providing a critique of social problems that stemmed from society as it was structured. Although Goldman was interested in political and social issues, she gave theoretical primacy to the individual and to the principle of self-determination. Despite what was sometimes an absence of logic in her oratorical rhetoric, Goldman's emphasis on freedom was always at the center of her activism and of her revolutionary thinking. Goldman's lasting influence on American history is evident in the fact that many of her historical proclamations continue to ring true today.

governmentality and control

Susanne Kramann

In his lectures at the Collège de France at the end of the 1970s, the French philosopher Michel Foucault developed a new analytics of power, making the concept of governmentality the focus of his interest. This concept first of all refers to the historical emergence of an “art of government”: governing becomes an object of problematizing the best possible mode of exercising power. “Art,” therefore, alludes to an artificiality of government, something fabricated by humans and implying certain techniques and forms of knowledge, and to a capacity of producing effectiveness. The rationality of government, then, does not consist in a substantial reason, as what seems to be rational results from a relation between the object operated on, the objective pursued, the application of suitable means, techniques, and so forth. In short, rationality is itself a reflection of the conditions of government. It is by no means timeless valid; rather, the historical context and the perspectives of a society or a local culture give the structure that facilitates its emergence, and here especially the knowledge itself that comes into use. *Governmentality studies* examines rationalities of government that form the techniques, procedures and ways of action, and the economy of power that these technologies create.

In this sense, the concept also refers to a type of power that, according to Foucault, has become preeminent throughout the West: the art of “governing people,” which makes the individual become an active subject of its own government. Accordingly, the notion of government does not just refer to state and politics in its common use sense today, but also means the education of children, the organization of household and family, management strategies, the government of communities, and the control of social problems. The term already implies this wide range of meanings in modernity, and Foucault reconstructs the genealogy of the art of government as a history of problematizations. These in the first place concentrate on the inquiry into the reason of state: what is the

convenient way to go about fostering and defending the power of the state independently of the person of the ruler? Later on, the population will be discovered as an object of government in itself. Demographic developments and problems, like diseases and poverty arising from the growing industrial work and developing urban structures, were being made operational – and thus controllable – using statistical methods. Finally, the economy is becoming an independent science, posing the question of how the functioning of the economy can be reconciled with social welfare. Consequently, the economy, the social, and the political came out of these kinds of rationalizations as objects of knowledge and government. Their separation in different spheres therefore is on no account timeless, but the product of historical processes.

The exploration of governmentality departed in the 1990s from the Anglo Saxon reception of Foucault’s lectures (cf. Burchell et al. 1991). Studies on the history and the effects of contemporary technologies of government made the most diverse social fields objects of investigation, ranging from genetics via philosophies of management to crime control. Yet, it is no accident that the “history of the present” was first written in the Anglo Saxon countries, in particular in Great Britain under Thatcherism (cf. Barry et al. 1996), as the concept is especially suitable for critically dealing with the political rationality of neoliberalism. Liberalism in this perspective is conceived of not as a theory or a philosophy defending freedom as a civil right only, but as an art of government recognizing liberty as an indispensable element for effective government. Freedom therefore is not a naturally preexisting entity, not something we own. Rather, it is presupposed artificially and thus becomes a resource of government, the use of which at the same time has to be organized.

Historically, liberalism initially expressed itself as a critique of too much interference and dissociated itself from the police science of the seventeenth and eighteenth centuries that was constantly concerned with the social order and its regulation. Nevertheless, Foucault above all regards a liberal government as a specific type of power which has to be dissolved from this historically specific constellation, a mode of governing people operating on the

basis of possibilities that are being created, structured, and restricted. According to liberal reason, in order to conduct the behavior of people it is not necessarily indispensable to exercise force; rather, it is more effective to grant and structure the practice of freedom. Thus, freedom might take the effect of a promise mobilizing the capacities of individuals. They will learn to conceive of themselves as free subjects, as entrepreneurs that invest, citizens claiming their rights, creative persons on their way to self realization – and thus governing themselves. To be governed and to govern oneself is, according to Foucault (1993), inextricably linked together.

But liberalism also threatens the liberty that it itself founded, and this too can be deciphered as a kind of strategy: the free play of the market forces that it presupposes, the freedom of personal development, or the safety of the citizens it claims to guarantee, all these rights have to be secured. Insecurity, then, is a complement of liberty taking the effect of a negative promise – the threat of dangers, risks, and insecurities demands the implementation of security mechanisms that themselves constrain freedom. Security and liberty represent not only two main cornerstones of the liberal constitutional state, but also basic elements of technologies of government. By playing them off against each other and at the same time interweaving them, individuals are being convinced that they have had to subordinate their personal concerns in favor of the safety of all, or that in their own interests they have had to undertake endeavors to secure their own existence. Also insecurity is a precondition that allows for regulating the proper use of freedom politically (cf. Hindess 1996; Lemke 1997).

There are at least four aspects under which the concept of governmentality is opening up a new perspective for the analysis of power and domination, whereas the term “government” has to be posed in between these two poles. It refers neither to a spontaneous, ephemeral form of exercising power restricted to situations nor to conditions of domination already consolidated. Focusing on an intermediate level of rationalities and technologies of government, the concept firstly allows for scrutinizing the manners in which political tactics and strategies mold the subjectivities of people, how political

programs first of all produce imaginations, necessities, and endeavors and thus indirectly steer the behavior of people and their lifestyles. Forms of subjectivation are the effect of technologies of power but at the same time their vanishing point: we cannot presume a subject capable of creating itself in an act of free will any more than that this is determined socially. Rather, it can be deciphered as a point of resistance, making the forms of exercising power visible at the same time as they are being bent, refracted, varied. Therefore, a category like that of homosexuality might equally reflect a social strategy of stigmatization and an emancipating countermovement. Differently from the term “social control,” the concept of governmentality does not focus on individuals as mere objects of control ambitions but is interested in scrutinizing how the exercise of power on the one hand results in producing subjects and the activation of people, and how on the other hand it brings about counterpower, which is what the term of the subject implies.

Secondly, government is a practice, and the knowledge it requires is always also a practical knowledge, a *knowhow*. Technologies of government therefore cannot merely be deciphered as systems of meaning or ideology but as techniques and procedures that themselves are capable of bringing really new objects and subjects of government into being. Technological inventions thus made it possible to gather, copy, and retrieve data according to respective requirements, seemingly resulting in more efficient procedures of administration and control. Persons, therefore, find themselves sorted according to the most different criteria into a variety of risk groups. Computer programs may identify them as recipients of social benefits or, depending on their habitual drug consumption, as prospective patients or, as a result of a drag net investigation, as suspects. Each time, the control technology focuses only on certain aspects of a person recorded into technically codified samples of data. The individual thus becomes a “dividual” (Gilles Deleuze).

Being concerned with the analysis of how historical forms of knowledge tie together with practices of government and how political rationalities form the view of people, of society and its problems, governmentality studies thirdly focuses on the power of political programs to

produce reality. Programs, in stating problems and aspiring to appropriate strategies of dealing with them, not only describe reality but also shape it. They create the preconditions of their own acceptance, singling out certain aspects of reality and problematizing them according to their own rules. They not only indicate the direction of the change to be performed, but also offer the criteria for the evaluation that seems proper according to the respective rationality. They fabricate reality, telling what one could and should do, and at the same time presuming what kind of person one is and could be. They prescribe while seeming to describe. Sure enough, this does not predicate the conditions under which problematizations will prevail. But this is precisely the question to which governmentality studies applies. It does not refer to a general theory of society, but rather maps out society along the lines of its practices. It examines how these practices are being implemented and rationalized, whether they come up against resistance or acceptance, and thus shape society.

Fourthly, rather than conceiving the state as a singular actor, pursuing its own interests, the state has to be analyzed as an effect of heterogeneous technologies of government. This means not searching for functional logics and ultimately postulating the state as a historically continuous figure. This normative perspective finds itself too easily approved, attesting, for instance, to a loss of sovereignty in the face of dominating interests of the economy or of processes of transnationalization. The examination of technologies of government, in contrast, allows processes of constant readjustment to be traced: spheres deemed to pertain to the state and to be subjected to its competence vary historically, as does the meaning of "public" and "private." Foucault in this sense alludes to a "governmentalization of the state": it is less instructive to apply the analysis to the state, understood as a unifying principle of power, in order to trace the *étatisation* of society in history than to the technologies of government shaping state and society (cf. Foucault 2004).

Governmentality studies has repeatedly been accused of playing down the power of the state or the economy, and of fancying liberalism, putting freedom at the center of its analysis. Indeed, it has concentrated particularly on making visible forms of "governing through

freedom" that guide the conduct of people through incentives and options rather than through enforcement or direct interventions. Moreover, in this perspective the neoliberal restructuring of the state and society, noticeable in the West since the 1970s, does not appear as an "unleashing of capitalism" rolling back the state, and in the face of which politics feels itself powerless and at its mercy; finally, nor do the most recent ambitions of providing security appear as a reemergence of a surveillance state.

Government studies, in contrast, has been able to stress that relations of power cannot adequately be described by dichotomies such as consensus or violence, manipulation or free will; rather, power is effective just at that point at which individuals display their own subjectivity. It has also stressed that forms of political participation and civil commitment originate beyond common divisions such as public versus private, state versus citizen. Thus "the retreat of the state" appears not as a political necessity but as a strategy rearranging social realms and privatizing, for example, fields of responsibility once genuinely run by the state: security is commercially provided, community crime prevention programs demand civil commitment.

Analyzing political rationalities allows for conceiving an orientation on the market not only as a particularity of "the economy" but also as a mode of thinking that might prevail in society and that also affects politics itself, enhancing the "economization of the social" (cf. Bröckling et al. 2000). This might result in measuring the success of social work, for example, less in terms of quality and outcome than in terms of quantity and output, not according to the intensity of the support of "clients" but according to the number of "customers" showing up; this might result in the (neo)liberal ideal of economic government taking shape in strategies of crime control that no longer aim at changing, medicating, or amending people but shift to preventing crime by design, by architectural arrangements, and at the same time locking up the incorrigible for life. This might also finally result in a rearrangement of the relation between the state and citizen itself, so that, for instance, social benefits can no longer be claimed as a social right but derive from contractually defined accomplishments. The activity of those receiving benefits becomes a social duty, while responsibility for

their conditions of life will be delegated to themselves.

In view of new security laws and strategies, a new formation of a state of surveillance and security is currently being discussed. However, this is misleading insofar as security has not to be taken as the singular concern of a unilateral power of the state but involves both the participation and the provision of commercial security. To conceive of the state as a varying entity means to grasp that the designation of public or private, and of state concern and legitimate interference, is not only a question of jurisdiction but also changes with the techniques of government.

Liberal modes of government are not limited to liberalism; even despotic regimes rely on cooperation. Conversely, liberal modes must not be equated either with more freedom or with soft forms of control; rather, they are about *powers of freedom* (Rose 1999) that are inextricably linked to other forms of exercising power: to violence, force, and exclusion.

If governmentality studies has recently centered on “insecurity” as a systematic component of technologies of government and programs of mobilization (cf. O'Malley 2000), this also demonstrates the challenge the Foucauldian concept poses to our present: forms of violence and of threat are not extrinsic to technologies of freedom but are generated systematically by them (cf. Dean 2002).

The combat against social insecurities (unemployment, the precariousness of a safe existence) or against threats to one's physical integrity (from disease, crime, or war) is carried out as a combat against external threats and in the name of freedom, while not refraining from violence and force, and with the result that the freedom of the individual is restricted.

graduate study

Baranda J. Fermin

Graduate study, including the master's degree but more specifically the pursuit of a PhD, is an extremely focused educational experience that is designed to produce a professional trained in the research, creation, and critique of knowledge within a given field. Graduate study is an essential part of the modern knowledge economy. The processes of graduate study create scholars, research, and academic criticism through an increasingly technological, yet staunchly traditional study, apprenticeship, and sponsorship model.

The nineteenth century ideal of uniting advanced study and research training with the work of individual scholars engaged in scientific research was heavily based on the German model popular at that time. Over time and across national systems graduate education has shifted away from this model. Today, the form and content of graduate education are heavily

influenced by the US model of prescribed curriculum, coupled with more formalized research training, culminating in a largely independent research project and the thesis or dissertation that demonstrates an original empirical or theoretical contribution to one's field. Due to the particular constraints of national systems and cultures, the extent to which this model is observed in its purest form varies considerably from country to country.

The idea and development of the research university first began in Germany with what is known as the Humboldtian model of study. Central to this model was the pursuit of new knowledge through academic research. In the nineteenth century, research, teaching, and study were brought together in academic settings where skilled veteran professors worked closely with students to focus on the creation and development of particular areas of knowledge. As the nineteenth century was drawing toward an end, German universities were by far considered the most advanced in the world and attracted students and scholars from many other countries. However, as a result of political and social tension, within the first four decades of the twentieth century this shifted. Thus, after World War II, the US emerged as the preeminent force in graduate education.

Graduate education in the US is historically a rather young endeavor. The first formal graduate program was at Yale University, where in 1861 three doctoral degrees were awarded to students of its Scientific School. Previous attempts to establish graduate education in the US had failed, despite outspoken proponents from among social and political leaders. When the Association of American Universities (AAU) was first organized in 1900, a central concern was the opinion of US graduate programs by institutions overseas. Today, this opinion can be measured not only by the quantity and quality of social networks and collaborations between US institutions and those abroad, but also by the high volume of doctorate degrees granted to students from other countries by US graduate programs.

In general, across national models, master's programs are larger and more diverse, and doctoral programs are smaller and more concentrated. However, prominent in the organization

and practice of graduate education is the structural requirement for a sequence of prescribed courses and for research training experiences. A master's degree (Master of Philosophy, Master of Education, Master of Arts, Master of Science) typically involves a combination of comprehensive coursework and a culminating project or examination. The project may be a thesis, a lengthy theoretical or empirical research project, or some other capstone activity showcasing the skills gained through study. The completion of a master's program for a student enrolled in full time study is typically anywhere from one to two academic years.

Even within the same national system, master's programs are tremendously varied in terms of their type, purpose, and expectations. The primary function of many programs is the preparation for doctoral study. Others function solely to advance the student's stock of knowledge in a particular field. Still others provide the student with a marketable skill or vocational qualification. This variation in part contributes to the fact that there is more debate surrounding the consistency of standards of master's degrees than either the baccalaureate or doctorate.

When students begin doctoral studies, coursework and research tasks are often similar to those involved in the master's degree. Earning a doctorate, however, involves the completion of a dissertation: an in depth, extensive, independent, and original research and writing project. The undertaking of independent and original research for the dissertation is the culminating experience of doctoral study. A graduate committee, advisor, and/or chair provide guidance and approval of the coursework and research activities of a PhD student. The primary advisor or chair closely guides, advises, and supports the student through the arduous process, including aspects of professional development and professionalism in the academy in addition to academic and research expectations.

Although the financing of graduate education is costly across all national systems, the US has the most diverse base of funding for graduate study. Unstable as it is, the organizational arrangement for the finance of graduate education in the US is the least tenuous in comparison to Japan, Germany, the UK, and

France. Institutions in the US and the students who pursue graduate study at these institutions must tenaciously seek funds from a variety of sources. This is an arduous but feasible task, as institutional endowments, philanthropic foundations, and (since World War II) the national government are major sources of loans, grants, and fellowships to defer, totally or in part, the costs of graduate education.

In the other countries the source of funding is also unstable, but concomitantly more focused, as the French, Japanese, German, and British national ministries of education are responsible for managing the financing of graduate education in their respective national systems. In these countries the central location of funding constraints illuminates two primordial problems within the systems. The first is the extreme dependence of higher education institutions on their respective national governments. The second is the increasingly lucrative and organized research units that exist outside academia. As an extension of these two issues a paramount concern, especially in the UK, is the quality of graduate education.

Due to the particular constraints of national systems and cultures, the extent to which the model present in the US is observed in its purest form varies considerably. The US model is by far the largest and most complex system for graduate level training. The German, British, French, and Japanese systems have smaller enrollments, more homogeneous institutions, and less elaborate structural arrangements for student progression through their graduate programs in comparison with the US model.

The systems of both the UK and Japan have struggled with an insufficient critical mass. The highly selective nature of the systems results in relatively small populations of advanced graduate students and the nature of research study and training results in even smaller numbers of earned doctoral degrees. Intense fiscal constraints on the advanced educational sector, particularly in comparison to industry research development and training, exacerbates the problem.

The German and French systems have had difficulty providing opportunities for hands on research training to the advanced students in their systems. Particularly in the case of

Germany, there has been, since the closing of the twentieth century, an issue with preserving the unity of research, teaching, and study. Segments of the national system have abandoned this Humboldtian ideal, while others struggle to maintain it. At the center of this struggle is finding the organizational and funding patterns that will keep the commitments of this model intact.

In the UK, although there has been increased enrollment in graduate programs, on the whole, graduate studies remain a small and marginalized sector of education within the nation's system. In the Japanese system, large enrollment numbers in the overall university sector mask the challenges the graduate sector faces regarding size. Although 60 percent of Japanese universities have graduate programs, only 7 percent of university graduates advance to master's programs and the total graduate student population – including doctoral students – accounts for a mere 4 percent of the total university population (United States Library of Congress 1995). The German system suffers from unevenness across fields in its graduate sector. Although overall enrollment may appear sufficient and stable, the disproportionate distribution of enrollments across sectors in graduate education is problematic for the entire system of advanced study in Germany due to the effects this has on faculty and fiscal capacity.

Due to its social and historical context, the US has virtually eluded contemporary issues concerning sufficient size and critical mass. However, in part due to huge demand and in part as a result of historical structural discrimination, the noteworthy issues facing the US graduate education sector have centered on educational equity in relation to race and gender. Over the last 20 years the number of US racial-ethnic minority doctorate recipients has grown as a result of the social movements impacting higher education access during the 1960s and 1970s. Overall, the gains in doctorates awarded to Asian Americans and Latinos have been far greater than the gains experienced for Native Americans and African Americans. In the last 25 years the number of women doctorate recipients has increased in the social sciences, humanities, physical sciences, and life

sciences. Women were the recipients of 45 per cent of all the doctorates granted in 2003; 25 years previously they represented only 27 per cent of the doctorate recipients in the US (Hoffer et al. 2004).

Despite advances in technology in engineering, physics, and medicine, and the advent of new methods of data analysis in the social sciences, the process of earning graduate degrees mirrors a quaint form of apprenticeship and sponsorship in most national systems. This is true despite differing social, political, and fiscal contexts. The significance placed on the various aspects of graduate education – research, study, and teaching – varies across contexts. Differences across systems are strongly influenced by the diffusion or centrality of fiscal contributors to the nation's education sector. As all systems experience fiscal constraints, the research arena in Germany, Japan, France, the UK, and the US is becoming increasingly segmented as private and industry sector actors involve themselves in research more intensely.

Gramsci, Antonio (1891–1937)

Alastair Davidson

Antonio Gramsci was born in Ales, Sardinia, on January 22, 1891, and died in Rome on April 27, 1937. Gramsci's father was a petty bourgeois notable employed in the Land Registry and his mother was from a local landowning family. At 4 years old Antonio was left a hunchback after a fall. His father was imprisoned for malpractice in 1898 and the family lived in straitened economic circumstances. Antonio took a job. Then sent by his mother to middle and high school, in 1912 he won a scholarship to Turin University to study arts. Quickly involved in socialist politics, he discontinued his study and renounced a future career in linguistics. In 1913–16 he was a journalist for the socialist press. In 1917 he started to formulate his novel views in the single number of *La Città futura* and became a firm supporter of the Russian Revolution, which he typified as a “revolution against Marx,” understanding it to have reversed all determinist understandings of Marxism as a messianic creed by refocusing socialist attention on the force of willful mass proletarian action to change the world. Together with Palmiro Togliatti, Angelo Tasca, and Umberto Terracini, in 1919 he established the newspaper *Ordine Nuovo* whose object was to promote an Italian version of “soviets” or workers’ councils in the factories of Turin. The *ordinovisti* established close links with the workers’ organizations in 1919–20, becoming their voice during a mass occupation of factories in Northern Italy. This action was endorsed by Lenin. Gramsci became a founder of the Italian Communist Party in 1921 when it split from the Socialist Party, which was blamed for “missing out” on the Revolution. He went to work in the Communist International in Moscow.

The rise to power of the Fascists in Italy in 1922 put both the communists and socialists on the defensive. Internal disputes over reunification led to Gramsci returning to Italy and emerging as party leader in 1924. He was elected to parliament and created the newspaper *l'Unità*.

In 1926 the Communist Party was made illegal by the Fascist regime and in 1928 Gramsci, with much of the leadership, was imprisoned, in his case for over 20 years. His incarceration started as Stalinism imposed itself. Gramsci's relations with the CPSU and Communist International, already tense because of his opposition to the cult of the leader, took on harsher forms. The Party almost disappeared under Fascist oppression until his death.

While in prison he made the notes for a contribution *fur ewig* on the nature of the “popular creative mind” and how it was produced. By 1937 he had filled 29 notebooks on that subject and supporting themes. They constitute a major contribution to Marxist theory, whose “red thread” is the concept of hegemony (in 2003 the subject of 650 titles). Today, his work is the most translated of any Italian. While fragmentary, as he never wrote a synthesis of his work and died of prison exacerbated illnesses, it is in these works that we find his main reflections on sociology.

GRAMSCI AND THE MASTERS OF SOCIOLOGY

The social Darwinism of Cesare Lombroso and Alfredo Niceforo and the determinism of Achille Loria dominated Italian social sciences in Gramsci's childhood and youth. The first two applied a social determinism (using even phrenology) to show that Southern Italians like Gramsci were naturally primitive. Gramsci detested both authors and their widely shared belief in deterministic social laws. His first published article was on Achille Loria, professor of sociology in Turin – who influenced Weber. Gramsci wrote, scathingly, that Loria had established that the most perfect human type, the ideal of eugenics, was the university professor. To their elitism and determinism he preferred the liberal idealism of Benedetto Croce, with its emphasis on individual endeavor in creating freedom.

Gramsci was at Turin University when Robert Michels (Weber's protégé) and Gaetano Mosca were professors there. Vilfredo Pareto also maintained links with the university. There is no evidence that any of these people influenced him at the time, but their elitist political

sociology and (in the case of Michels and Pareto) early institutional links with Fascism could have predisposed him to further associate sociology with anti humanism and elitism.

After 1917, his growing knowledge of Marxism and Leninism and their view that sociology was expressly anti Marxist meant that there was little reference in his writings to the great masters of social science. His first real interest was provoked by Nicolai Bukharin's *Historical Materialism: A Popular Textbook of Marxist Sociology* (1921). This book stated that historical materialism was a sociology. It thus departed from the Marxist and Leninist orthodoxy that sociology was simply a bourgeois science and it relied heavily on the sociological masters, particularly on the equilibrium theory in Pareto's *Trattato di sociologia generale*. Gramsci made a critique of this book and the converse views of Henri de Man a central theme of his Prison Notebooks. In it he develops his understanding of sociology and its limits, denies that historical materialism is a sociology and yet intimates that it might contain a sociology.

GRAMSCI'S THEORY OF SOCIOLOGY

Gramsci (2001: 1432–3) asks “What is sociology?” and replies: “Is it not an attempt at a so called exact science [that is, positivist] of social facts ... that is philosophy in embryo.” He proceeds to state that it had been an attempt to create a scientific method based on evolutionary positivism for explaining history and politics. As a “philosophy of non philosophers” it tried to classify historical facts systematically using the natural sciences as a method. Its object was thus to establish laws of evolution of society so that it could foresee the future with “the same certainty as an acorn grows into an oak.” It could not therefore grasp any social transformation that was qualitative. He thus identifies as its limits (1) that it applies natural scientific laws to social facts and (2) it sees causes in what is merely nominal classification. “One describes a series ... of facts by the mechanical process of abstract generalization and derives a statement of similarities; this is called a law and assumed to have a causal function” (p. 1433).

It followed that he had great reservations about the “laws of large numbers” and statistical series. This did not mean he dismissed them outright, admitting that when social groups and structures were relatively unchanging and “passive,” statistical inquiry might have some limited validity. On the other hand, its application could have disastrous consequences if used to guide political action. It encouraged laziness and superficiality in a domain where the object was action, which destroyed the validity of statistical laws.

Objective historico social reality was merely the “historically subjective.” Reality, including the “laws” of natural science themselves, was no more than historically valid. Historical facts had to be studied scientifically and non scientifically. The propositions made in the first realm had no force until taken up by great masses and made “practical.” This meant that any foresight was made true only because great masses of humans acted as if it were (Gramsci 2001: 1403–5). He regarded technological determinism as nonsense. Necessity was linked to “regularity” as revealed by series only when there was a premise to which human beings had been driven which could be formulated along the lines of the Ricardian “given that . . .” So to the calculable material presence there had to be added that complex of passions and imperious sentiment that led to action (p. 1480).

It was the essential “premise” of “popular belief” that Gramsci wished to study and this brought him closest to the traditional concerns of some Italian and European sociology. It bore resemblance to Pareto’s concern with residues and to Mosca’s theory of sentiments and to de Man’s desire to establish how groups felt and thought. Gramsci’s theory of common sense might be described as a study of the “passive” group. But what concerned him as a believer in the *Theses on Feuerbach* was how such common sense could become “good sense.” He therefore regarded de Man as inferior to both Proudhon and Sorel (Gramsci 2001: 1501). For him, de Man took the position of a determinist scientist, a zoologist studying a world of insects, who studied popular feelings, and did not feel *with* them to guide and lead them to catharsis. He argued that de Man’s book *Il superamento di Marx* stimulated us to inform ourselves about

the real feelings of groups and individuals and not the feelings that sociological laws suggest exist. So de Man raised an empirical criterion to a scientific principle without knowing how to limit the criterion sufficiently. He thus ended up creating a new statistical law and (unconsciously) a new method of social mathematics and external classification, a new abstract sociology (Gramsci 2001: 1430–1). To accept what was thought by the mass as eternal would be the worst form of fatalism (pp. 1501, 1506). De Man’s work resulted in a commonplace based on the error that theory and practice can be separate and not act on each other constantly. For Gramsci, the only way to understand was to work “with.”

There are few secondary comments on Gramsci and sociology. They started at the Gramsci studies conferences in 1958 and 1967. Subject to limitations, they confirm the above account. Where the implicit relation with later Parsonian and “social action” theory has been touched on, the commentary adds nothing to challenge the overall thesis advanced above (Calello 1986: 209ff.). There has been an interesting attempt to suggest a Gramscian sociology or post sociological method (Misurata et al. 1977: 485–505).

grandparenthood

Maximiliane E. Szinovacz

Grandparenthood can be considered at three distinct levels: the societal level (referring to societal norms, functions, and esteem of grandparents), the family level (referring to interactions and supports among grandparents, parents, and grandchildren), and the individual level (referring to the meaning and significance of grandparenthood to the grandparents). The meaning and significance of grandparenthood often derive from societal and familial contexts that are beyond grandparents' own control. On the societal level, the prevalence and duration of grandparenthood as well as the normative underpinnings of the grandparent role reflect cultural and demographic change. On the familial level, grandparents' functions within the family context are often shaped by special needs of the children or grandchildren rather than by grandparents' own aspirations. On the personal level, individuals experience the transition to grandparenthood as a countertransition, contingent on the fertility decisions of their children, and access to grandchildren is often mediated by the parent generation.

GRANDPARENTHOOD IN SOCIETAL CONTEXT

Grandparents' Status and Esteem

At the societal level, grandparenthood reflects norms about kinship and kin responsibilities. The definition of grandparenthood itself depends on kinship norms. Some societies may acknowledge grandparents only on the paternal or maternal side, while bilateral kinship rules in modern western societies assign grandparent status equally to paternal and maternal grandparents. However, increases in the divorce rate, adoptions, and artificial fertility methods can render assignment of grandparenthood status problematic in western societies. Grandparents of adopted grandchildren or of stepgrandchildren sometimes express ambiguity about their grandparent status.

Societal contexts further influence grandparents' functions and their interactions with

grandchildren. Recent anthropological research suggests that increases in longevity during the Upper Paleolithic (about 30,000 years ago) provided the foundation for grandparents' functions as childcareers and culture transmitters, both functions contributing to population expansion and increased creativity. In more recent times, the drug and AIDS epidemics have been partially responsible for the growing number of grandparents raising grandchildren, while the high divorce rates since the latter part of the twentieth century promoted the development of legal statutes regulating grandparents' visitation with their grandchildren. Grandparents also play a significant economic role, both as consumers (e.g., of children's toys) and as service providers (e.g., care of grandchildren by grandparents can enable mothers to remain in the labor force).

Grandparents' social esteem and image are often tied to the status of elders in societies. Although modernization sometimes undermines elders' status and implicitly that of grandparents by reducing their economic control and their importance as transmitters of knowledge, it can also enhance their status through elders' access to old age security entitlements. Furthermore, lack of familial authority on the grandparents' part may promote more congenial grandparent–grandchild relationships. In the US, Grandparents' Day or the proclamation of 1995 as Year of the Grandparent speak to the social significance of grandparenthood. The image of grandparents in the media has tended to lag behind times, providing stereotyped images that depict grandparents as old, passive, and powerless, although more recent research suggests a shift toward positive grandparent portrayals in children's books.

Demographics of Grandparenthood

In contrast to many other family transitions, the demographics of grandparenthood are defined by events in two generations, that of the grandparent and that of the grandchild's parent (referred to as the "middle generation" below). To become a grandparent requires that both oneself and one's children bear children. Contingent on medical advancements both in the treatment of infertility and in birth control

as well as on economic conditions, rates of childlessness varied considerably during the twentieth century. Childlessness peaked during the Depression era, then declined sharply until the last quarter of the twentieth century, and is now again on the rise (Uhlenberg & Kirby 1998).

Similarly, grandparents experienced a significant decline in the number of grandchildren born during the last century – from an average of over 12 to about 5–6 currently (Uhlenberg & Kirby 1998) – although the relatively high prevalence of early deaths among children at the beginning of the twentieth century curtailed the supply of older grandchildren. This trend is likely to continue well into the twenty first century. Between 1976 and 2002 the average number of children born to US women declined from 3.09 to 1.93 (Downs 2003), and even more dramatic declines in fertility are evident in many European countries. Within the US, this trend applies across racial and ethnic groups, but fertility remains somewhat higher for African Americans and especially Hispanics. Thus, by the middle of the twenty first century, many grandparents will have only 3 or 4 grandchildren. Both trends imply a significant decline in the supply of grandchildren well into the twenty first century.

In contrast, trends in longevity have altered the significance of grandparents in grandchildren's lives. Uhlenberg and Kirby (1998) estimate that in 1900 fewer than a quarter of grandchildren had all four grandparents alive at the time of birth, and fewer than 1 percent had all four grandparents alive at age 20, compared to 68 percent and 10 percent, respectively, in 2000. However, survival of grandparents is also contingent on the timing of births. Early childbearing especially during the baby boom period meant a relatively early transition to and a long duration of grandparenthood at the end of the twentieth century. Delays in childbearing since this time period will reverse this trend. Because increases in the delay of childbearing will probably be more pronounced than in creases in longevity, the supply of grandparents to grandchildren (both in terms of number of living grandparents and duration of grandparenthood) may well have peaked at the end of the twentieth century. By the middle of the twenty first century, exposure to grandparents'

deaths will again occur at earlier ages of the grandchildren, the transition to grandparenthood will be moved to later ages, and fewer grandchildren will be able to enjoy contacts with grandparents into their adulthood. Once again this trend will vary considerably by race and ethnicity. Delayed childbearing predominates among non Hispanic whites and Asians and Pacific Islanders and is less common among Hispanics and African Americans (Downs 2003). Thus, by the mid twenty first century we can expect considerable racial and ethnic variations in the supply of grandparents to grandchildren and in grandparents' roles and relationships with their grandchildren.

GRANDPARENTS IN FAMILY SYSTEMS

Grandparents' interactions with their grandchildren and grandparents' roles are intricately linked to dynamics of the family system as a whole and especially to circumstances surrounding the children's parents. These linkages are most evident in research referring to parents' mediation of grandparent–grandchild contacts and to grandparents' roles as caregivers and care recipients.

The mediation of grandparent–grandchild relationships through the middle generation is both direct and indirect. Indirectly, asymmetry in maternal and paternal kinship ties leads to a matrilineal advantage that furthers stronger bonds to maternal grandparents in general and maternal grandmothers in particular. Because proximity exerts a strong influence on grandparent–grandchild relations, grandparent–grandchild contacts are also affected by mobility decisions of the parents at least as long as grandchildren are young or reside with their parents. More direct mediation is evident from the strong associations between closeness between grandparents and the middle generation and closeness of grandparent–grandchild ties, although it is not clear whether grandparents' attachment to their own children or to their children in law is more significant.

Grandparents are often described as family stabilizers or family watchdogs, signifying that their role is augmented during times of family crisis. Research has focused on two such crises, namely, parents' divorce and parental inability

to raise their children. Divorce in the middle generation can both enhance and undermine grandparent–grandchild relationships. On the one hand, grandparents often step in to help their divorced children through supports that include grandchild care or help grandchildren in adjusting to the parents’ divorce. On the other hand, tensions among divorcing parents are often transferred to the grandparent generation, leading to disruption of grandparent–grandchild ties, especially for non custodial parents. In extreme cases, grandparents have attempted to overcome such barriers through court ordered visitation rights.

During the past two decades, grandparents’ role as surrogate parents has been the dominant research theme in grandparent research in the US. The number of grandchildren raised in grandparent headed households increased dramatically during the last decades of the twentieth century, from 2.2 million or 3.2 percent of children under 18 in 1970, to 3.9 million or 5.5 percent in 1997, but has since leveled off (3.8 million or 5.2 percent) in 2003 (US Bureau of the Census 2003). Among children in grandparent headed households, over one third lived in skip generation households (neither parent in the household) and close to one half with single parents and grandparents. According to the 2000 Census, 5.8 million grandparents co resided with grandchildren. However, a sizable number of grandparents who co reside with their adult children and grandchildren either play a secondary caregiver role or are themselves dependent on their adult children (Simmons & Dye 2003). Surrogate parenting can put considerable strain on grandparents. They not only have to deal with the adverse circumstances resulting in the surrogate parenting arrangement (e.g., children’s drug addiction, AIDS, incarceration) and the demands of grandchild care, but also complain about problems with custody, finances, and grandchildren’s behaviors, as well as conflicts with the grandchildren’s parents. Such problems manifest themselves in lowered well being of the grandparents themselves, such as increased depressive symptoms (Minkler et al. 1997; Hayslip & Goldberg Glen 2000).

Less attention has been paid to situations where grandparents are physically or economically dependent on adult children, and

grandchildren participate in grandparents’ care. Grandchildren in this situation lament lacking attention by their parents, reduction in leisure due to the demands of “grandma” sitting, and household upheaval caused by demented grandparents.

GRANDPARENT ROLE: SIGNIFICANCE AND FUNCTIONS

Despite concerns that grandparents have “opted out” of the grandparent role (Kornhaber 1996), research in the US and other western countries indicates that most grandparents maintain close contacts with grandchildren on a regular basis, fulfill various functions in their grandchildren’s lives, and derive satisfaction from the grandparent role (Attias Donfut & Segalen 1998). For example, a nationally representative US study of grandparents conducted in 1997/98 revealed that over one half of grandparents had contacts with grandchildren on a weekly basis and only 16 percent had fewer than monthly contacts. Furthermore, over three quarters of these grandparents reported talking with their grandchildren about personal concerns or sharing activities with them, and 80 percent attributed extremely high salience to the grandparent role (Silverstein & Marengo 2001). The frequency of grandparents’ contacts with grandchildren depends on multiple factors, including geographical proximity, urban versus rural background, kin relationship (matrilineal advantage), age and number of grandchildren, family structure, and closeness to the grandchildren’s parents.

The occurrence and relative prevalence of specific functions and activities in a grandparent’s role repertory has led to diverse typologies of grandparents’ roles. Such classifications refer to such dimensions as comfort, significance, style, role meaning and salience, frequency of contacts, instrumental assistance, relationship quality, type of activities with grandchildren, or influence of grandparents in their grandchildren’s lives. The major functions performed by grandparents are socializing, support, and information. Grandparents’ engagement in social activities with grandchildren has led to labels such as funseekers, buddies, or companions. Grandparents also provide various supports

either to the grandchild's parents in the form of babysitting and childcare or to the grandchildren themselves through emotional comfort, gifts, or help with transportation and school work. In addition, grandparents function as socialization agents, as transmitters of values and culture, and as family historians. However, grandparents' role as socialization agents remains ambiguous and is constrained by norms of noninterference into the parents' domain, although this norm seems weaker among African American families. Native American grandparents have been instrumental in the transmittal of tribal traditions, while Hispanic and Asian grandparents serve as cultural conservators.

FUTURE RESEARCH

Grandparent research has bloomed during the past two decades. This research demonstrated that grandparenthood remains a significant role in modern societies, and that grandparents fulfill important support functions, especially in times of family crisis.

Despite the multitude of recent studies devoted to grandparenthood, most research was limited to a few themes (extent and predictors of involvement, grandparents as caregivers, satisfaction with the grandparent role). Given ongoing and expected demographic changes, other themes may deserve more attention in the future. Declines in fertility and thus in the supply of grandchildren may increase competition between paternal and maternal grandparents, while delays in childbearing will increase relatively young grandchildren's exposure to frail grandparents and to grandparents' deaths. There is also a need for expansion of old themes. We need to know more about grandparents' roles in cases of parental divorce and about the long term influences of grandparents' care on the grandchildren. Diversity among grandparents from different racial/ethnic, rural/urban, and socioeconomic backgrounds also deserves increased attention in future research.

Great Depression

A. Allan Schmid

On "Black Thursday," October 24, 1929, the New York stock market dropped precipitously and then recovered. On Monday, it dropped again but did not recover. Tuesday was the

most devastating day in the history of the exchange as everyone wanted to sell, but there were no buyers. After nearly a decade of extraordinary growth, business leaders insisted business was still sound. Yet, a year later factories were shuttered, production fell, and upwards of 30 percent of the workforce were to be unemployed. The depression lasted for 10 years and spread around the world. Industry did not suddenly rust and become inoperative. Resources and knowledge did not evaporate. This was an institutional failure, not a technological one. It was a function of cognition, human organization, and relationships, not one of physics. Years of rising expectations, greed, and a sense that it was possible to be rich without working turned into hopelessness and despair.

The spectacular rise in stock prices between 1922 and 1928 was built on borrowed money, innovations such as investment trusts and holding companies, and deliberate manipulation. Speculators could borrow as much as 90 percent of the cost of a stock from their brokers, who in turn borrowed from the banks, who in turn borrowed from Federal Reserve Banks. All is well until prices drop and margin calls occur. Investment trusts were early versions of today's mutual funds allowing even small investors to diversify. People speculated in the stock of the trust, and supertrusts borrowed money to buy other trusts. Pyramid schemes and Ponzi finance using new investors' money to give dividends to previous investors were common. There were no conflict of interest laws to prevent banks organizing a trust to buy its own stock. Pools of large investors aggressively bought a block of stock, driving up its price, spread rumors of some mysterious factor that would further increase its value, and then sold out to the unsuspecting general public.

Investment in plant and equipment or in financial instruments is a function of expectations. Expectations are a social artifact – reinforced and spread similar to a social movement. Shared expectations are learned images of what might be as much as civil rights or feminist movements. The investment of others increases the chance of success of the ideas of an entrepreneur or speculator. In a climate of optimism, banks are eager to make loans. The rising expectations are self fulfilling prophecies, but eventually the returns to investment do not

meet expectations and investors withdraw. The lowered expectations and investment reduce aggregate demand and actual profits. Firms cut employment to remain solvent. This makes sense for the individual firm, but as many firms follow suit the layoffs reduce incomes and aggregate demand falls again. Again the firm has excess inventory and again reduces the number of employees (circular and cumulative causation). This new equilibrium at less than full employment lasts until investors are convinced there is no way but up or until governments use fiscal policy to stimulate aggregate demand. In the case of the Great Depression, the US government became the employer of last resort and hired the unemployed to build public infrastructure. Still, massive unemployment lasted until the outbreak of World War II when government military procurement put people back to work.

Economists are divided on the causes of the Great Depression. Friedman blamed it on too little money supply, while others said it was too much. Kindleberger blamed it on the decline in foreign trade. The US had loaned large sums to Western Europe to finance their imports of American goods after World War I that could not be repaid when faltering banks called loans. Galbraith (1979: 169) argued that “Far more important than rate of interest and the supply of credit is the mood.” Since no definitive experiment is possible, it remains a matter of what one finds persuasive. If you like numbers and assume the underlying rationality of market participants, then you prefer explanations in terms of money, gold, and mistaken public policy. There are no comparable data series on mood and attitude. Still, some are persuaded by the written expressions of participants.

The popular, and even academic, literature on crashes often uses language suggestive of sin to describe booms and busts. After the fact, an unsupported runup in investment and stock prices is regarded as excessive greed, or in the words of Alan Greenspan, Federal Reserve chief, “irrational exuberance.” Keynes referred to the phenomenon as “animal spirits.” Nevertheless, while many know all bubbles burst, it is hard to resist the sirens and find a Ulyssian solution. For example, a trust manager who goes liquid too soon and misses a big runup will have no customers long before the crash

proves itself. Even those responsible for the health of the financial system, such as the Federal Reserve bankers, found it hard to act to burst the bubble, even though some recognized that an earlier bursting would wreak less havoc than later. No one wanted to be recognized as the one who had destroyed the promise of ever-growing riches that many began to believe was their birthright. Whether president or banker, it is better to let the system destroy itself and blame it on impersonal forces than to be seen as the one who “sabotaged prosperity.”

Bubbles and their bursting are not new phenomena. Tulip Mania, the South Sea Company, John Laws’s Banque Générale, and the Mississippi Bubble have entered into folklore. The only economic system to avoid booms and crashes was that of the Soviet Union, but the price was rather constant doldrums.

In the context of the global economy it is becoming even harder for a nation to insulate itself from other faltering economies. For example, South Korea’s collapse in 1997 caused financial organizations to call loans all around the world. The chain reaction threatened the solvency of international banks, which was only contained by extraordinary coordination led by the US central bank. The latest cycle of boom and bust was the information technology referred to as the dot.com business. In the 1990s, few proposals went without enthusiastic backers. Then when profits were not realized, investors wanted out and the stock of the new (and old) IT firms collapsed. In contrast, after a period of rapid growth, Japan suffered a prolonged recession throughout the 1990s. History has not yet written the conclusion on these episodes.

globalization

J. Michael Ryan

Globalization is a term coined by sociologist George Ritzer (2004) in his book *The Globalization of Nothing*. It is meant to serve as a companion to the widely employed concept of glocalization. While glocalization represents the unique combinations resulting from the interpenetration of the global and the local, globalization represents “the imperialistic ambitions of nations, corporations, organizations, and the like and their desire, indeed need, to impose themselves on various geographic areas” (p. 73). Thus, glocalization would be most closely associated with postmodern, pluralistic ideas of heterogeneity, whereas globalization represents a more modern, imperialistic, and homogenizing perspective.

It is important to note that no value judgments are intended for either glocalization or globalization. Many things which are glocal (as well as local) can be “bad” (e.g., discrimination) while many things which are global can be “good” (e.g., the spread of medical technology).

Globalization theorists would generally argue that the world is becoming increasingly less diverse as transnational economic, cultural, political, and social entities seek to impose their influence throughout the world. The agent in this perspective has relatively little power to maneuver within, between, or around structures. Their ability to construct their own identity and world is seriously impinged on by the growing forces of global powers, particularly commodities and the media. Social processes are deterministic and overwhelm the local, limiting its ability to interact with, much less act back against, the global.

Although globalization encompasses a number of subprocesses, the main three are Americanization, McDonaldization, and capitalism (Ritzer & Ryan 2003). The quest for profits under capitalism, the most powerful of the subprocesses, has led corporations to seek ever expanding global markets. The process of McDonaldization has facilitated the expansion of corporate entities and cultural patterns. Americanization can be closely tied to the dominant influence of the US in the world today. Taken together, these three subprocesses constitute some of the main drivers of globalization.

grounded theory

Kathy Charmaz

The term grounded theory refers to a set of methods for conducting the research process and the product of this process, the resulting theoretical analysis of an empirical problem. The name grounded theory mirrors its fundamental premise that researchers can and should develop theory from rigorous analyses of empirical data. As a specific methodological approach, grounded theory refers to a set of systematic guidelines for data gathering, coding, synthesizing, categorizing, and integrating concepts to generate middle range theory. Grounded theory methods are distinctive in that

data collection and analysis proceed simultaneously and each informs the other. From the beginning of the research process, the researcher analyzes the data and identifies analytic leads and tentative categories to develop through further data collection. A grounded theory of a studied topic starts with concrete data and ends with rendering them in an explanatory theory.

Barney G. Glaser and Anselm L. Strauss developed grounded theory methods when they studied the social organization of dying in hospitals. They articulated their methodological strategies in their cutting edge book, *The Discovery of Grounded Theory* (1967). Prior to its publication, field researchers had learned qualitative methods through an oral tradition combined with lengthy immersions in field work. Glaser and Strauss revitalized qualitative research in sociology and brought new impetus to pursuing it through explicating systematic methods for analyzing qualitative data. They called for reestablishing the qualitative tradition in sociology at a time when quantification had achieved disciplinary dominance. Quantitative researchers had embraced a logico deductive model and derived hypotheses from grand macrosociological theories. A sharp division of labor between theorists and methodologists had deepened, while the gap between grand theories and empirical realities had widened. Glaser and Strauss argued that qualitative research could generate theory and qualitative methodologists could close the gap between the theory and the empirical world. Thus, they proposed that (1) qualitative inquiry could make significant theoretical and empirical contributions in its own right, rather than merely serve as a precursor to quantitative research; (2) qualitative analysis could be codified in analogous ways as quantitative analysis had been; (3) inductive methods could be used to develop middle range theory; and (4) the divide between theory and methods was artificial.

Glaser and Strauss introduced grounded theory as a comparative method for analyzing basic social and social psychological processes. Glaser built on his quantitative training at Columbia University and aimed to codify qualitative methods as his mentor Paul Lazarsfeld had successfully codified quantitative methods. Glaser developed the language of grounded theory from his quantitative background and imported

certain positivist objectives and assumptions into the method. Hence, the logic of grounded theory relied on discovery, externality, neutrality, and parsimony. Strauss brought Chicago School traditions of ethnographic fieldwork, pragmatist philosophy, and symbolic interactionism to grounded theory. Thus, he emphasized first hand data, assumed an agentic actor, viewed social life as emergent and open ended, and acknowledged the crucial role of language, symbols, and culture in shaping individual and collective meanings and actions.

These early grounded theorists searched for discoveries in an external empirical world – and in theory construction. For Glaser and Strauss, and particularly Glaser (1978, 1992, 1998, 2001), theory construction was and is an emergent process accomplished through systematic engagement with data. They advocated that grounded theorists delay the literature review to avoid relying on extant ideas.

Glaser and Strauss and a number of their followers adopted roles as neutral scientists who subjected data to dispassionate, systematic analysis. Although grounded theory methods inform the entire research process, both Glaser (1978, 1992, 1998) and Strauss (1987) emphasized the analytic phases. They assumed that thorough analyses remedied researchers' possible biases and made grounded theory a self-correcting method.

The originators of grounded theory shared commitments to analyzing social processes, using comparative methods, accepting a provisional view of truth, fostering the emergence of new ideas, and providing tools for constructing substantive and formal middle range theories. Glaser's (1978) emphasis on the fit, relevance, modifiability, and usefulness of a grounded theory remained congruent with Strauss's pragmatist conceptions of inquiry and truth. Nonetheless, the marriage of positivism and pragmatism in grounded theory produces tensions in the method. Glaser (1978, 1998) stresses objectivist analyses based on variables, a concept indicator approach, and context free theoretical statements. Strauss emphasizes rich contextual analyses of meaning and action and the development of substantive and formal theories of action.

Since its publication, *The Discovery of Grounded Theory* has struck a resonant chord

among aspiring qualitative researchers, many of whom have cited it to legitimize their studies. However, many researchers still misunderstand grounded theory and relatively few adopt all of its guidelines. Divisions between Glaser and Strauss, their separate revisions of grounded theory, and new variants of it complicate these misunderstandings. Now what grounded theory is, which and whose innovations and revisions are acceptable, and which version should hold sway are contested issues.

Despite epistemological and practice differences, grounded theorists of various persuasions assume that (1) theory construction is a major objective of grounded theory, (2) the logic of grounded theory differs from quantitative research, and (3) the grounded theory emerges from rigorous data analysis, not from adopting preconceived theories. What stands as preconception, however, differs among grounded theorists. Glaser (1998) remains adamant about delaying the literature review to avoid forcing data into preconceived categories. He implies that researchers can come to their studies without prior influences shaping their views. In contrast, Dey (1999), Charmaz (2000, 2006), Bryant (2002), and Clarke (2003, 2005) contend that researchers' interpretive frameworks, situations, and interests influence what they see and how they render it. Charmaz emphasizes using sensitizing concepts to open the research process. Henwood and Pidgeon (2003) enter the fray with the sound advice that grounded theorists adopt the critical stance of "theoretical agnosticism."

When involved in conducting their studies, diverse grounded theorists do agree on the following strategies: (1) collecting and analyzing data simultaneously; (2) using comparative methods during each analytic stage; (3) devising analytic categories early in the research process; (4) engaging in analytic writing throughout; and (5) sampling for the purpose of developing ideas. How researchers interpret and enact these strategies may reveal sharp differences. Yet researchers' rigorous analytic scrutiny of data can inform their further data collection and spur developing successively more abstract interpretations that explicate what is happening in the field setting.

Currently, most qualitative researchers engage in early analytic work, but it seldom

takes the systematic form of the grounded theory method. Coding in grounded theory is at least a two phased process: *initial* and *focused*. During initial coding, researchers ask: “What category does this incident indicate? What is actually happening in the data?” (Glaser 1978: 57). Grounded theorists attempt to be open to all possible answers. Then they define what is happening by assigning brief categories to each line or incident in the data. Coding for actions furthers the grounded theory goal of studying process. As grounded theorists do initial coding, they compare lines of data or incidents to define the properties of what is happening, learn how it developed, and what it means. Even during this early phase of analysis, grounded theorists move beyond concrete description and take their data apart. Close examination of data combined with comparisons between data prompts researchers to see their data in new ways. Initial coding also alerts the researcher to potential *in vivo* codes given in the setting or participants’ direct statements.

Focused coding increases a researcher’s analytic control and precision. As researchers engage in comparing and coding data, certain codes assume greater analytic power than others and often appear more frequently. They select these codes as focused codes to sift large batches of data. Through focused coding, researchers can reassess tacit meanings and actions in earlier data and generate preliminary categories for the emerging theory. This coding also provides the grist to interrogate the data and to contemplate what’s missing in it.

Memo writing is the pivotal intermediate strategy that bridges coding and report writing. Memos are analytic notes covering all the researcher’s ideas and questions about the codes that occur at the moment. From the beginning of the research, grounded theorists see through the lens of their codes. Memos commit to writing what they see. Such writing helps to avoid meandering data collection and losing flashes of insight. Early memos record and discuss hunches and begin taking the data apart to explore meanings and actions. Rather than follow recipes for writing memos, researchers draw on their analytic sensibilities and follow the analytic leads they define in their memos. In early memos, grounded theorists raise certain codes to preliminary categories and then explore them.

In later memos, they develop specific categories through making more incisive comparisons and begin to integrate their categories. Hence, they compare category with category, as well as compare data with the relevant category.

After establishing analytic categories, researchers typically find gaps in their data, if not gaping holes. They seek more data through theoretical sampling, a selective, systematic, and strategic way of gathering specific additional data to develop the emerging theory. Theoretical sampling has been poorly understood and applied. Many researchers mistake theoretical sampling with purposive or representative sampling. In contrast, grounded theorists use theoretical sampling to elaborate the properties of a category, to make the category more precise, and to discover variation in it or between theoretical categories and make them more precise. Theoretical sampling may lead to returning to earlier research participants and settings. It often means seeking new research participants and settings that answer researchers’ *analytic* questions – and reveal the relative generality of their theoretical categories. Hence, grounded theorists may move between types of people and across settings to conduct theoretical sampling. Although many researchers stop short of theoretical sampling, it can increase the definitiveness, generality, and usefulness of their work.

The first major division among grounded theorists occurred after Strauss and Corbin published *Basics of Qualitative Research* (1990). They introduced new techniques, treated grounded theory as a set of procedures, and advocated verification. The flexible guidelines and comparative methods of earlier texts are less apparent, although Strauss and Corbin show how to study contextual relationships and to specify causes, conditions, and consequences of social processes. Glaser (1992) rejected Strauss and Corbin’s innovations because he saw them as preconceived procedures that forced data into categories. For Glaser, their approach resulted in conceptual descriptions, not grounded theories.

Charmaz (2000, 2006) articulated the second major division by distinguishing between constructivist and objectivist grounded theory. Constructivist grounded theory (1) places priority on the studied phenomenon rather

than techniques of studying it; (2) takes reflexivity and research relationships into account; (3) assumes that both data and analyses are social constructions; (4) studies how participants create meanings and actions; (5) seeks an insider's view to the extent possible; and (6) acknowledges that analyses are contextually situated in time, place, culture, and situation. In this view, researchers and their participants *produce* data through interaction and therefore construct the meanings, actions, and situations that researchers observe and define. Constructivists realize that grounded theorists can import preconceived ideas into their work when they remain unaware of their starting assumptions. Thus, constructivism fosters researchers' reflexivity about *their* interpretations as well as those of their research participants. In short, constructivism moves grounded theory further into interpretive social science.

In contrast, objectivist grounded theory (1) seeks discoveries in an external, knowable world; (2) assumes a neutral, passive observer but active analyst; (3) studies the phenomenon from the outside as an objective external authority; (4) treats representation of research participants as unproblematic; (5) distinguishes between facts and values; and (6) regards completed analyses as objective reports. Objectivist grounded theorists learn the parameters of the worlds they study and analyze processes within them, but they do not become immersed in these worlds. They often aim for thoroughness and accuracy, although Glaser (1998) takes a *laissez faire* stance toward data collection and rejects quests for accuracy and detail as derailing the analytic process. Despite some differences, the objectivist approach contains inherent positivist assumptions and practices.

Although Charmaz (2006) states that most grounded theory works contain elements of both constructivism and objectivism, Charmaz (2000) views both Glaser's and Strauss and Corbin's methodological statements as different forms of objectivist grounded theory. Corbin and Strauss's (1988) empirical work, however, assumes an interpretive approach and demonstrates its constructivist antecedents.

Glaser (1992, 1998, 2001) remains in the objectivist camp. Nonetheless, he has somewhat altered his earlier grounded theory guidelines

sufficiently to constitute a third revision of the method. Although his revision leaves the pragmatist underpinnings behind, Glaser claims his version represents classic grounded theory. Glaser still argues for a direct and often narrow empiricism consistent with mid century positivism, but he has grown more insistent about opposing a quest for accurate data. He aims to develop emergent theoretical categories and advocates using comparative methods and constructing abstract theoretical analyses, all of which have fundamentally defined the grounded theory method. In a major departure from earlier statements, however, Glaser (1998) has abandoned the objective of studying a basic social process because he views it as forcing inquiry. Instead, he favors analyzing a core category, although criteria for such a category remain vague. For him, the goal of grounded theory should be a theoretical analysis of how people resolve a major concern. Glaser has also revised his earlier endorsement of line by coding because he now views it as generating a hodge podge of unintegrated codes that clutter and encumber the analytic process.

Charmaz (2000, 2006), Bryant (2002), and Clarke (2003, 2005) aim to use grounded theory methods without allegiance to its positivistic presuppositions. They acknowledge the contextual positioning of data and theory and encourage a reflexive stance on the research process. Moreover, they each see building on symbolic interactionism as a way to undermine what Bryant (2002) views as "any inclination toward object centered, mechanistic, and technicist thinking." Clarke (2005) and Charmaz (2006) call for extending the direction of grounded theory inquiry to include theorizing difference, controversy, and injustice. Clarke (2003, 2005) argues that grounded theory has always contained properties now attributed to postmodernism, such as the provisional, multiple views grounded theorists routinely take toward their data. She explicitly aims to integrate postmodern concerns into grounded theory and to go beyond them to reposition grounded theory in a reflexive pragmatism that addresses all kinds of differences explicitly and maps them in fluid, abstract forms of theorizing. In short, releasing grounded theory from positivism and reconstructing it from pragmatism holds

enormous potential for revitalizing the practice of theorizing.

group processes

Jeffrey W. Lucas

Sociology's group processes perspective is one of the three "faces" of sociological social psychology (Smith Lovin & Molm 2000). The perspective is characterized by theoretical development and basic research on fundamental social processes that occur in group contexts. Work in the group processes tradition dates to scholars who were interested in the interactions of individuals in small groups. As the perspective has developed, its focus has largely evolved to an interest in the processes that occur in group contexts rather than in groups themselves.

Much of the work in sociology's group processes tradition has its roots in the work of Bales and colleagues in the 1950s (see, e.g., Bales 1950). Bales developed a procedure called interaction process analysis (IPA) to code interactions in groups. The procedure treated each behavior in a group as an "act" and involved classifying acts into various categories. Bales's approach allowed investigators to objectively study interactions in groups and spurred researchers to develop new ways to classify group behavior.

A focus on group processes, of course, implies an interest in two things – groups and processes. As the group processes perspective has developed, the focus of the area has shifted to a greater interest in processes than in the groups in which the processes occur. In large part because of the perspective's roots in the classification of behavior in small groups, however, sociologists not in the group processes perspective will frequently treat studying "small groups" and studying "group processes" as interchangeable.

What interests those in the group processes perspective is how various social processes operate in groups. The groups in which the processes operate need not be small. Two of the processes that dominate work in the perspective are power and status. These processes occur in groups both large and small, and they provide examples of the perspective's major focus on processes that occur in groups rather than on the groups in which processes occur.

Power, in simple terms, is the ability to control resources that people value. Your boss, for example, has the ability to fire you from your job. If you value your job, this ability gives your boss power. Early treatments of power generally focused on the characteristics of powerful people that made them powerful. This research was limited by the fact that almost anyone put in the right position can be powerful. In other words, nothing about your boss herself gives her power over you. Your boss's power comes not from individual traits but instead from a position in a structure. Group processes scholars focus their efforts on discovering the conditions of groups rather than of people that give rise to power differences (see Markovsky et al. 1988 for an excellent example). Note that the groups in which these conditions arise need not be small. The president of a university, for example, has power (the ability to control resources) over a group (the university's employees and students) because of her structural position.

Status is a position in a group based on esteem or respect. Perhaps the most well developed group processes theory is a theory of status named *status characteristics theory* (Berger et al. 1977). Status, like power, is relative; in other words, people do not have status or power in and of themselves, but instead only in relation to other people. It is meaningless to say that medical doctors are high in status, for example, except in the context of other, lower status occupations.

Status characteristics theory specifies the processes that lead some people to have more status in groups than others. According to the theory, status orders in groups develop out of the characteristics held by group members. Examples of status characteristics include gender, age, appearance, race, and education. Status characteristics theory proposes that individuals act as though they develop performance expectations consistent with larger cultural beliefs about the characteristics held by themselves and other group members. Members with characteristics accorded higher expectations have higher status positions in the group and are likely to be evaluated more highly than others and to have more influence.

A few of the other processes studied in the group processes perspective are justice, legitimacy, identity, and bargaining. Although they

do not necessarily follow from an interest in group processes, most work in sociology's group processes tradition shares two additional features: formal theoretical procedures and experimental investigations.

Investigators adopting formal theoretical procedures construct theories with explicitly defined concepts, general propositions that logically follow from theoretical assumptions, and well specified scope conditions that lay out the domains of their theories. Tests of the theories then operationalize theoretical concepts in empirical settings and formulate hypotheses that provide tests of the theory's propositions (see Cohen 1989 for a discussion of formal theoretical procedures).

In experiments, investigators test hypotheses in carefully controlled environments in which different groups of participants are randomly assigned to different experiences. In that experiments usually involve the study of small groups of participants, the fact that most group processes research is carried out in experimental laboratories might seem to contradict the assertion that group processes scholars are not typically interested in small groups. The use of experimental methodology in group processes studies, however, follows not from an interest in small groups but rather from an interest in testing formal theories of basic social processes. The use of experiments, in fact, results from an interest in social processes. Group processes scholars attempt to understand the fundamental nature of the processes they study, independent of any particular group context. Experiments have the advantage of allowing researchers to simplify natural environments, eliminating aspects of the environments not germane to an understanding of the basic process under study.

Although experimental investigations in the group processes tradition follow from an interest in understanding the fundamental nature of basic social processes, their use nevertheless contributes to the misconception that the concepts "group processes" and "small groups" can be used interchangeably. The group processes perspective is young, however, and as knowledge from the area is applied to ever larger and more diverse groups it will likely shed its association with small groups, with a greater recognition of the primary emphasis on the "processes" in "group processes."

groups

William Bezdek

The term “group” refers to at least two distinct forms of social cooperation. On the one hand, it refers to small groups where local patterns of order emerge from the abilities, needs, and interests of the members. On the other hand, it refers to formal organizations where order is imposed by formal rules and sanctions imposed by appointed authorities. Groups structured according to attributes of the group members are generally informal, face to face groups. Groups structured by rules and authorities are generally large scale business, service, and governmental organizations.

Associations are a type of organization in which a small core of specialists performs all the work of the association on behalf of a large membership. Associations do not structure the daily work life of their members; associations advise their members, act as advocates for them, and plan activities for them. As Alexis de Tocqueville noted in the 1830s, Americans

were distinguished from their European ancestors by forming an enormous number of associations to promote a varied assortment of special interests. Today, the number of special interest groups in the US ranges from the Association of American Alumni Associations to the American Zoological Association, from the Pagan Web Crafters' Association to the Association for the Freedom of Association.

In addition to small groups and large scale organizations and associations, there is another category of groups referred to as aggregates or collectivities. Membership in a collectivity is defined by a common attribute (such as race, gender, or age) or a common interest (such as hunting or farming). Members of collectivities are generally dispersed, unknown to one another, and have no intrinsic form of organization. Collectivities, however, provide a constant source for the development of small groups, associations, and organizations, particularly as selected members of a collectivity organize to publicly advocate for, serve the interests of, or protest the treatment of an entire collectivity. Members of dispersed collectivities share no obligatory social relations with one another, still their natural affinities enable them to mobilize for social action. Collectivities have an increasing effect in the modern world because modern technologies of mass communication make possible the mobilization of collectivity members into virtual associations that can coordinate the actions of dispersed and anonymous individuals who share the same interest or attribute. Many small groups working for the benefit of the same collectivity can unite in a social movement. The many phases of the women's movement provide an example of the ebb and flow of social movements that depend on grassroots support from small groups that promote the interests of a collectivity.

Crowds are a special type of collectivity distinguished by their being together in the same general location at the same time. Crowds can share a focus of attention such as a football game or a military parade, focal points that provide the crowd with a shared experience that creates a temporary sense of social solidarity that can be mobilized for collective action under certain circumstances. Not all crowds, however, share a central focus of attention. Workers, shoppers, and tourists who overflow

the sidewalks at closing time in the downtown areas of large cities constitute a crowd whose members display a rudimentary form of social organization in which individuals will generally keep both bodily and eye contact to a respectful minimum as they maneuver along crowded side walks. This minimal social orientation creates orderly patterns of movement in the crowd. When individuals in a crowd shove, push and trample on others during life threatening catastrophes such as a fire, the social order of a crowd degenerates into a social disorder.

All individuals are assumed to have two personal attributes critical for the study of all types of group life. First, it is assumed that all individuals have the capacity to act as self directed agents who optimize their self interest. Second, it is assumed that all individuals have the capacity to engage in symbolic communication. Taken together, these characteristics form a foundation for all life in human groups. G. H. Mead proposed that symbolic interaction provides the ability to "take the role of the other" during any interaction, thus making it possible for individuals to anticipate the reaction of others at the same time as they plan their own actions. This ability, according to Mead, provides the foundation for the development of both self and society. Jürgen Habermas emphasizes communicative action as the backbone of all human social formations. Because those with a vested interest in a particular issue tend to distort their persuasive communications, he was forced to construct an ideal pattern of communication to demonstrate that departures from it were in fact distortions in communication that impeded the development of effective communication. An ideal pattern of communication requires truthfulness, normative sensitivity, and personal authenticity, orientations that he took to be necessary prerequisites for the rational formation of a just society. Symbolic communication plays a secondary role for rational choice theorists, who are more likely to begin their study of group life by examining how individuals adapt their self interest to the self interest of others in order to develop the cooperation required for many forms of human group formation.

Because groups can be studied as the intersection between individuals and society, and because they constitute a readily accessible site

for gathering information, they have served different research and theoretical agendas in different eras of sociology's history. During the first two decades of the twentieth century, sociologists were preoccupied with defining the subject matter and the methods appropriate to their field. Georg Simmel (1858–1918), an influential German theorist who began publishing articles in American sociology journals in the 1890s, called attention to the unsuspected significance between a group comprised of two persons, and a group comprised of three (or more) persons. In a group of two persons, if one person leaves, the group ceases to exist; in a three person group, one person may leave, and the group can continue to exist. In principle, a three person group can last indefinitely if the following condition is met: when one current member leaves, she or he is replaced with one new member. This potential for a group to persist, even with a total change in membership, has been used to investigate the way group norms and practices maintain themselves or change over time. The ability of groups to replace their membership, with minor changes in the group's goals, practices, and organization, highlights the concept of a group as a relatively enduring set of relationships and social practices as distinct from the specific individuals that constitute a group at any given time. Because any group can be recognized as the "same group" in spite of changes in its membership, they have been, and will continue to be, a prime site for studying social development, social control, and social change.

Georg Simmel, among others, was also important in distinguishing two major types of groups: those in which personal attributes dominate the relationship (as in friendship and family groups) and those in which an individual's official position or role dominates the relationship (Simmel gives the example of the way in which the official role of a Catholic priest dominates his relationship with his parishioners). This distinction between groups constituted by personal relationships and groups constituted by impersonal duties toward one another is now known mainly as the difference between primary group functions (more typical of small groups) and secondary group functions (more typical of organizations and associations). Emphasizing primary and secondary functions

instead of primary and secondary groups suggests that individuals in all groups will have some relationships that are more personal and some that are more impersonal, although it is still possible to distinguish primary groups from secondary groups in terms of the dominant mode by which individuals relate to one another within the group. Ferdinand Tönnies (1855–1936), perhaps the original sociological source for the primary/secondary group distinction, used the German terms *Gemeinschaft* (roughly corresponding to primary groups) and *Gesellschaft* (roughly corresponding to the forms of association found in impersonal groups, but more specifically he sought to identify the principles of social formation in modern, urban societies as opposed to social formation in pre-modern societies). In the 1920s, Robert Park (1864–1944) insisted “all social problems turn out upon analysis to be problems of the social group.” In differentiating sociology from psychology, he emphasized that collective action precedes individual action: since all individuals are born into preexisting group cultures, they must learn the ways of the groups before they can take part in the group’s activities and through these activities find ways to give social expression to their individual interests. John Searle (1995) gives collective interests equal philosophical footing with an individual’s self interest. Collective interest, as analytically distinct from self interest and symbolic communication, provides a third dimension for theorizing group formation and maintenance, adding to self interest and communicative action to form the foundations of group life.

In the 1930s and 1940s there were several innovations in the study of groups. Lewin, Lippitt, and White, for instance, invigorated the field of social psychology in an experimental study with obvious references to the threat posed by Hitler to democratic regimes. The importance of this study lies as much in its methodology, a sophisticated experimental design, as in its findings that group members in the long run, though not in the short run, are more productive and more satisfied with democratic leaders than with authoritarian leaders. At the same time, W. W. Whyte (1914–2000) published his pathbreaking study of a small, street corner gang exposing the gang’s internal structure as it was related to the larger

community. The success of Whyte’s book *Street Corner Society* (1943) succeeded in spreading participant observation methods in sociology as an alternative to both experimental methods and detached observational methods. In this same period, J. L. Moreno asked members of small groups simple questions, such as “Who are the persons in this group who are your three best friends and who are your three favored co workers?” He plotted the results in a sociogram, where each individual was represented by a dot on a piece of paper, and lines connecting the dots displayed a visual pattern of friendship and work relations within the group. This technique was the predecessor of network analysis, one of the major tools for mathematical modeling of subjective preferences that exist between individuals in groups. Subjective preferences (such as friendship and work preferences) help social investigators understand the stability or instability of a group, and network analysis, which depends on the individual’s subjective preferences, has become a major empirical method for sociologists who favor rational choice and self interest as the preferred foundation for the study of group life.

Beginning in the second half of the twentieth century, the major thrust of sociological theory and research in small groups was possibly the work of R. F. Bales, particularly in his collaboration with the dominant American theorist of the time, Talcott Parsons. Using a sophisticated observation technique, Interaction Process Analysis (IPA), Bales developed instructions for a detailed analysis of group conversations. Sitting behind one way windows, research assistants observed groups of five or six individuals, often assembled together for the first time, as they tried to reach agreement on a hypothetical problem presented by an academic investigator. Each group’s conversation was recorded and the words divided into small units, which were then coded into one of 12 preestablished categories. Studies using this method demonstrated the relation between task oriented phases of group problem solving and socio emotional phases in group problem solving, a finding that constituted an empirical demonstration of Parsons’s theoretical analysis of societies as organized around the division of task functions (i.e., the functions generally associated with secondary groups) and socio emotional functions

(i.e., the functions generally associated with primary groups). Some have criticized these findings as a tautological restatement of the 12 categories used to code the behavior of the group members. George Homans provided a major alternative to Parson Bales's structural functional orientation when he explained the interpersonal dynamics of a professional work group in terms of "social behavior as exchange." Homans observed that the less competent workers in the group continually asked for help from a more accomplished co worker. To help them, the more competent member was forced to reduce the time spent on his own work. In return, he received expressions of respect from his colleagues. The tradeoff was peer deference in exchange for expert help and advice. This study enlarged the theoretical boundaries of economic exchanges to encompass theoretical accounts of social exchanges.

George Herbert Mead (1863–1931) shifted the emphasis from groups as foundational social units to the process of interaction that leads to the formation of groups. For Mead, it is the communicative action between individuals that establishes the social reality of groups. Later, in the 1960s, theorists would embrace the perspective of "interaction" and "communication," without paying particular attention to the structure of the concrete groups in which interactions take place. Near the end of the 1950s, for instance, Erving Goffman began his series of publications on what he was later to call the "interaction order." Initially inspired by Emile Durkheim (1858–1917), who had theorized the importance of sacred rituals in the maintenance of social order, and following the lead of the philosopher John Locke (1632–1704), who had substituted the term "self" for Descartes's sacred "soul," Goffman made the leap from sacred rituals to rituals in everyday life. Individuals in everyday interactions, he concluded, would consider the self as possessing some of the mystery and authority associated with the soul, and would thus feel a deep impulse to show respect for the sacred like expressions of self displayed by their companions. When individuals are denied the respect they believe is their due as persons possessing a sacred self, Goffman saw the simple rituals of everyday life as a means to restore an

individual's lost self respect, drawing attention away from the emotional disturbances caused by threats to the self, and restoring the group's attention to the predominant functions of the group. More recently, Randall Collins (2004) has expanded the rituals of everyday life to examine a wide variety of social relationships.

Emmanuel Schegloff, a student of Goffman, collaborated with Harvey Sacks and others to develop Conversation Analysis (CA) as a method for recording and analyzing face to face interactions. Schegloff and Sacks conceptualize social interactions by examining written transcripts of conversations recorded during everyday interactions. The transcripts are enhanced by a notational system for capturing many of the verbal intonations, pauses, and overlapping speech patterns that are important for mutual understanding in face to face interactions. As with the previous attempt by Bales in constructing Interaction Process Analysis, CA analysts also exclude interior, private experience (such as the experience of the self as directing one's actions). CA differs radically from Bales's analysis, however, in that it rejects the idea of using preestablished categories to code social meanings in conversation. Instead, CA relies on a close examination of the structure of the conversation to construct its meanings. This method of sociological analysis even challenges what seems to be a necessary and reasonable assumption in sociology – that all symbolic communication is built around shared, intersubjective meanings. Schegloff's (1992) criticism of intersubjectivity as the basis for social formation presents a serious alternative to the concept of norms as shared, intersubjective understandings as the underpinning of orderliness in everyday social life.

CA was one way to address Howard Garfinkel's program of ethnomethodology, an ontological position in sociology opposed to the dominance of grand theorizing, as exemplified in the work of Talcott Parsons. Garfinkel, a student and admirer of Parsons, proposed that social organization does not exist independent of everyday social practices. For Garfinkel, social order is recreated in the living, ongoing achievements of everyday life. He believed that abstract conceptual and cognitive approaches to human relations only get in the way of the

proper study of sociology, and that CA provides a way to demonstrate this. In his famous phrase, individuals in everyday life "are not cultural dopes." Feminist sociologist Dorothy Smith finds ethnomethodology congenial to the problems faced by women who live in a world of concepts developed by men who had conceptually marginalized women in everyday life, relegating them to care of children and home. She sees ethnomethodology and allied view points as counteracting the one sided view of society that comes from male dominated conceptualizations and by logical extension from abstract conceptualizations in general. More recently, Garfinkel's emphasis on everyday social practices has influenced organizational studies as well as small group studies.

At the beginning of the twenty first century, the study of communicative interaction (read communication in groups) was spread among several disciplines. In addition to sociology and anthropology, communicative interaction is studied in linguistics, social psychology, hermeneutics, cognitivist psychology, communication theory, computational neuroscience, and computer mediated interaction studies (see Grant 2003). The linguistic turn in both the humanities and the social sciences has emphasized the study of social interaction as social communication, and the techniques of CA have become its preeminent methodology. The shift from the study of groups to the study of the communicative interaction within groups makes it possible, in principle, to track styles of discourse and persuasion as they travel back and forth between the centers of social power and the interactions of everyday life. This project, if rigorously pursued, could form an important bridge between the particularities of social interaction and the abstractions that allow us to conceptualize groups and total societies.

One may clarify the relations between groups and interaction as the relation between a social process and a social outcome: social interaction is the process; the group is the outcome. Both the concept of group and the concept of interaction are at least one step removed from the everyday practices of social life. Theorists like Howard Garfinkel and Dorothy Smith have suggested ways to balance the simplifications inherent in the use of conceptual terms in the study of human associations.

growth machine

Andrew E. G. Jonas

The growth machine concept first appeared in 1976 in an article published in the *American Journal of Sociology* (Molotch 1976). It describes how in America city politics is generally a politics of growth. Although the concept in fact explains the systemic properties of cities, it has also been interpreted as referring to the presence in almost every American city of property dependent business interests actively engaged in local politics and civic affairs. This is so much so that the city itself can be seen, in its very essence, to be an instrument of profit for land based interests. Moreover, those involved frequently form coalitions with other players like wise dependent on local development, and mobilize to shape the policies and institutions of local government in a fashion such that future urban growth patterns and land use policies profit all participants; in this way, the city

building process operates like a growth machine. Growth machine actors promulgate an ideology of growth, which often proves a potent force to such an extent that all other interests either become incorporated within the essential logic of the machine or face defeat.

The growth machine thesis arose as a critical reaction against the sterility of extant social science approaches to the city: social ecology, the rank size rule, community power, and the like. Conventional social science was preoccupied with matters of urban social, spatial, and political form. In comparison, the growth machine concept gets to the substance of urban economic power, the structures and agents of urban development, and those day to day actions of urban growth dependent economic elites, which are so decisive in shaping land use and the distribution of resources and jobs within localities and through the urban system (Molotch 1999). The concept materialized during a time of growing skepticism about the role of government, increased public awareness of the limits to growth, and the brute materiality of the urban fiscal crisis, notably New York City's in 1975. Already in the 1970s, there were signs that the American growth machine system was facing new challenges and an emergent counter coalition appeared to be redirecting the focus of local government away from growth and towards stronger environmental regulation (Molotch 1976). Although the US federal government had not yet abandoned urban policy, the New Federalism and anti tax revolts pointed to the neo conservative, anti urban, and devolutionary trend that was to follow. The growth machine focused attention on how powerful economic interests tied to particular places (such as developers) depend on the power, resources, and authority of local and state government in order to create conditions conducive to their profit making activities.

The growth machine concept injected fresh ideas into a corpus of empirical urban research generally lacking in concepts linking urban form to broader political and economic trends. If community power studies had taught social scientists about who wields influence in the city, the growth machine thesis demonstrates what they do with their power. It makes an argument about how cities, suburbs, and metropolitan

areas are constructed, who constructs them, their role in the national political economy, and what the fiscal, social, and environmental consequences of untrammelled growth are likely to be for people who live in these urban places (i.e., the majority of the national population).

After teaming up with John Logan, Molotch coined the term "rentiers" to describe collectively the growth machine players and their various auxiliaries, such as the media, universities, utilities, professional sports franchises, chambers of commerce, and the like (Logan & Molotch 1987). More than a case of instrumental manipulation of local government, rentiers strive to ensure that the local citizenry are receptive to growth by engineering a sense of community around which locals can unite. Here the growth machine toils to connect the social standing of a place, village, township, city, or urban region to its economic fortunes. However, the growth promotion activities of rentiers are shot through with conflict, actual and latent. The main source of conflict around growth is that of the use of land versus its exchange. Use values are rooted in the neighborhood or community as a living place inhabited by residents with deep psychological attachments to their homes and communities, or as a place to trade or produce goods. Threats to such attachments might arise from land use and demographic changes which satisfy the objective interests of growth machine players in maximizing exchange value, but represent serious disruptions to the livelihoods and personal psyche of residents. Conflicts result when factions compete to harness the legislative, fiscal, and legitimating powers of local government. Local government is not a value free interest in this process because, dominated by growth profiteers, it strives to influence land use outcomes and the distribution of resources within and between cities, often rationalizing desired outcomes as a source of fiscal betterment. It, too, is a participant in the growth machine system (Logan & Molotch 1987).

Unlike urban regime theory (Stone 1989), growth machine analysis is not primarily concerned with the detailed division of labor between state and market actors in urban politics and institutions. Nevertheless, the state – its organization and geography – is important

because neighborhoods, cities, metropolitan regions, and states form a hierarchy of territories possessing different powers and resources potentially of use to the growth coalition. Growth oriented coalitions will tend to coalesce around that level of government seen as having capacity to bestow the relevant fiscal and infrastructural capacities (Molotch 1976). Interest groups sometimes in competition for federal, state, or local resources within a city or region may well collude for the growth of the city region as a whole. In this way, the formation and activities of growth machines are scalar dependent and their organizational scope is contingent upon how they access the geography of the state apparatus.

Economic globalization has contributed to a rethinking of the spatial context in which economic growth oriented urban regimes exist and operate (Horan 1991). Localities, cities, and regions are inserted into a global economic development system. In some cases, international capital works in partnership with local property interests to circumvent local resistance to inward investment (Molotch & Logan 1984). By the same token, land development interests and activities are much more globalized. This implies a weaker link between local property dependence and a propensity to be involved in local growth coalitions (Cox & Mair 1989). Yet the growth machine concept remains durable in part because of the extent to which in many countries land use planning and the urban land market have been deregulated. Moreover, the state continues to be important if perhaps for different reasons than an earlier emphasis on local government manipulation by growth coalitions. National states have sought to activate local business–local state partnerships along the lines of the public private redevelopment partnerships found in many US cities. In this way, the growth machine may have been retooled in a neoliberal age remarkable for its fiscal austerity and hyper mobile capital (Jessop, Peck, & Tickell 1999).

Close engagement with the growth machine concept has prompted critique and further elaboration of the theory. Research has tried to prove empirically the presence or absence of a growth coalition and of the distributional and land use effects of its activities. In a

comprehensive survey, Logan, Whaley, & Crowder (1997) demonstrate the concept's resilience, but conclude that the changing nature of regional economic development and matters of social distribution pose questions for empirical research. Others have questioned its theoretical assumptions. A lack of understanding of the causal properties of geographically immobile versus mobile businesses, workers, residents, and local states in a capitalist mode of production is viewed by some to be a particular weakness in the thesis; the overriding emphasis on land use dynamics overlooks a variety of alternative forms of, and participants in, local and regional development (Cox & Mair 1989). Further research is required into the activities and interests of the poor, working women, racialized groups, unions, non profits, and so forth as these engage with development agendas and interests in cities. Additionally, business elites, chambers of commerce, and booster clubs have cultural and organizational logics, which can defy a straightforward political economy interpretation. Extensions of the growth machine concept emphasize at least three general issues: the generative and receptive contexts for discourses and ideologies of growth; the role of incentives, participants, and wider policy networks in growth machine like economic development coalitions; and the internationalization of the growth machine concept (Jonas & Wilson 1999).

First, the growth machine thesis is essentially all about local boosterism: the conscious attempt to (re)present a city or region in a positive light to a wider constituency such that it becomes more attractive to inward investment, outside visitors, government expenditures, etc. The growth machine thrives, not only by creating the material preconditions for urban development, but also by convincing people of the importance of growth to their well being. The emphasis on ideologies of community in the original thesis arguably fails to delve more deeply into the metaphorical power of "other" discourses (e.g., those of "race" or class) often associated with, for instance, the redevelopment and gentrification of central city neighborhoods (Wilson 1996). Growth coalitions are especially adept at shaping public values about the necessity for growth and

identifying the locality's potential civic and moral saviors, the local heroes whose influence transcends the local yet somehow captures the essential moral virtues of the place (Cox & Mair 1988). As Molotch himself recognized, this takes politics into realms far beyond the formal conventions of programs, policies, and regulations, which nonetheless continue to preoccupy urban political theorists.

The second concern sees the growth machine thesis as a place based model of urban governance, yet these days more of a process oriented and global approach is required. This is not an argument for studying the city *qua* the local as determined by global trends; globalization is itself a deeply misunderstood process. Not only is there an uplink from the growth machine to wider state structures and the global economy (Gotham 2000), but there are also cross links between all sorts of urban places connected by growth networks and entrepreneurial modes of governance (Molotch 1999). Moreover, urbanists now realize that cities and regions are locked into international flows of commodities, which serve to undermine the essential causal integrity of the urban, the fundamental spatial field of play for the growth machine. Yet, in its defense, the growth machine thesis is not so much an argument for an urban scale theory as laying out a general approach to the political economy of place. For example, cities, it seems, are making a comeback as sites of creativity, innovation, and drivers of national economic recovery. A growth machine perspective on the idea of the "resurgent city" would perhaps attempt to identify a necessary condition for resurgency in a collective place dependent agency, a redistribution of government resources, interventions in land development, and/or a class of property interests.

Third, the jury is still out regarding the transferability of the growth machine thesis outside the US. Comparative growth machine analysis has enabled us to identify the range of conditions essential to rentier like activities, emphasizing the diverse ways in which urban land is commodified and regulated, how inward investment is managed, and the scope of state intervention in urban development in different national settings (Molotch 1990; Molotch & Vicari 1988). Given differences between states in terms of functions and geography, it is

difficult to determine *a priori* whether the growth machine exists or operates the same way in other countries, especially those that have very different institutions, ideologies, and cultural traditions governing land use, urban development, or territorial integration than the US (Kirby & Abu Rass 1999). Extra territoriality is a significant factor in understanding the geography of urban growth networks at the international scale (Leitner & Sheppard 2002). Claims about the hollowing out of the nation state and the changing geography of economic development indicate the value of looking at cross national and interregional differences in the organization of growth coalitions and attendant activities.

The attraction of the growth machine thesis is its ability to articulate an essential feature of the political economy of place development in capitalism: the political role of various locality dependent economic interests and their capacity to shape institutional structures and spatial patterns of land development in ways that can be socially and environmentally detrimental for the vast number of people who live in cities and their immediate surrounding regions.

Guattari, Félix (1930–92)

Gary Genosko

French activist intellectual Pierre Félix Guattari was inspired by Jean Paul Sartre’s political sociology and trained as a psychoanalyst by Jacques Lacan. Guattari was internationally recognized for his collaborations with Gilles Deleuze on the capitalism and schizophrenia volumes *Anti Oedipus* (1977), *A Thousand Plateaus* (1987), and *What is Philosophy?* (1994).

In *Transversality and Psychoanalysis* (1972), Guattari developed his key concept of transversality that became the cornerstone of a new kind of analytic practice he called schizoanalysis. Beginning in 1953, Guattari and his colleague Jean Oury organized the Clinique de la Borde (his workplace for almost 40 years) around a complex, rotating system of tasks and responsibilities that scrambled power relations among staff and patients by having them change roles and take on unfamiliar duties. Called “the grid,” this made possible detailed analyses of relations of power by providing a context in which the institution itself could be exposed, and if necessary modified in a way that encouraged patients to accept new responsibilities and answer new demands within innovative universes of reference.

Guattari developed a Sartrean inflected theory of groups by distinguishing non absolutely between subject groups that actively explored self defined projects and subjugated groups that passively received directions; each affected in divergent ways the relations of its members to social processes and potential for maintaining an irreducibly polyphonic subjectivity.

Guattari described schizoanalysis as a non neutral, politically progressive, and provisional transformation of situational power relations in a little known book, *The Machinic Unconscious* (1979). Eschewing neutrality, the schizoanalyst’s micropolitical task is to discern among expressive assemblages of components those with mutational potential, explore the textures of their matters, and produce and extract singularities from them for the sake of the subject’s self invention.

Guattari rejected sociological definitions of groups. Rather, subjectivity is a group phenomenon, but defined as an assemblage of heterogeneous types of components with varying existential consistencies undergoing certain kinds of transformations in self-generated fields with describable semiotic features and observable pragmatic consequences. Guattari introduced the machinic as a principle of productive connectivity irreducible to specific technologies; machines form assemblages of component parts whose molecular becomings the schizoanalyst then helps to facilitate.

In *Schizoanalytic Cartographies* (1989) and *Chaosmosis* (1995), Guattari elaborated four ontological functions of the unconscious – material Fluxes, existential Territories, machinic Phyla, and incorporeal Universes – and explained how the schizoanalyst tries to bridge virtuality and actuality by discerning how virtual universes become real by gaining existential consistency, balancing manifestation and surplus potentiality as subjectivity emerges and pursues dissident vectors of singularization sitting astride abstract Phyla and material Fluxes.

As a political testament, Guattari called for ethico-aesthetic responsibility of subject formation that resists Integrated World Capitalism (globalization) at the intersection of art and ecology in *The Three Ecologies* (2000).

Gumpłowicz, Ludwig (1838–1909)

Bernd Weiler

Around 1900, Ludwig Gumpłowicz was internationally regarded as one of the most influential sociological theorists and, together with his fellow countryman Gustav Ratzenhofer (1842–1904), as the leading representative of the so-called Austrian Struggle or Conflict School. Born into an assimilated Jewish family in the quarter of Kazimierz in the Free State of Cracow, which was incorporated into the Austro-Hungarian Monarchy in 1846, the young Gumpłowicz strongly identified with Polish culture and fervently supported the movement for greater autonomy of Galicia. After graduating in law from the Jagiellonian University in 1861, Gumpłowicz joined the liberal democratic and positivist circles of his deeply conservative hometown and, as a lawyer, journalist, political activist, and chief editor of the progressive newspaper *Kraj* (“The Country”), took an active part in the educational, social, and political affairs of Cracow. Disappointed at his failure to bring about the desired reforms, he left Cracow in 1875 and moved to Graz, where he became a lecturer and in 1893 a full professor of law. Throughout his life, however, he maintained a strong interest in the politics of his native Galicia. Apart from numerous works on Austrian administrative and constitutional law, the prolific writer Gumpłowicz dedicated his scientific work to the newly emerging discipline of sociology. After the publication of his booklet *Rasse und Staat: Eine Untersuchung über das Gesetz der Staatenbildung* (1875), in which he first sketched his sociological principles, Gumpłowicz wrote *Der Rassenkampf: Sociologische Untersuchungen* (1883),

followed shortly thereafter by his most famous work, *Grundriss der Sociologie* (1885), *Die sociologische Staatsidee* (1892), *Sociologie und Politik* (1892), and the posthumously published *Social philosophie im Umriss* (1910). Already during his lifetime his main sociological works were translated into several languages, including English, French, Italian, Spanish, Polish, Russian, and Japanese. His theories were especially influential in Italy and the US. In 1909, two years after his retirement, Gumpłowicz, who suffered from an incurable cancer of the tongue, and his half blind wife committed suicide.

Impressed by the rise of the natural sciences in the second half of the nineteenth century and entrenched in the tradition of positivism, Gumpłowicz forcefully argued that it was sociology's prime function to prove that social phenomena were governed by universal laws. Several years before, Émile Durkheim, the Polish born scholar, who sought to establish the autonomy of sociology, claimed that the laws of social life were not reducible to biological, psychological, or environmental factors, but constituted a field of investigation *sui generis*. As Gumpłowicz is often classified as a social Darwinist, it is worth mentioning that he was highly critical of the applicability of Darwinian principles to social life and that he developed his sociological theories in explicit reaction to biologicistic understandings of society.

Differing from most of his predecessors, Gumpłowicz rejected not only the organicist holistic conception of society as a biological organism (Comte, Spencer, Schäffle, etc.), but also the atomistic viewpoint according to which social phenomena had to be explained in terms of the purposeful actions of independent individuals (Smith, etc.). Gumpłowicz claimed that sociology was essentially the study of groups (hordes, tribes, races, social elements, etc.) and their interrelations. Society was nothing but an aggregate of groups which, in turn, completely determined the individual's thoughts, actions, and emotions.

Gumpłowicz saw no need to undertake empirical investigations as he believed that sufficient data had already been collected in order to deduce the laws governing social life and to establish a grand and final sociological system. Drawing primarily upon ethnographic and prehistoric material but also upon his personal

observations of the national struggles in the Habsburg Empire, he argued for the polygenic origin of humanity, the presence of diverse groups in all societies, the high degree of intragroup solidarity – “syngenism” in Gumpłowicz's terminology – and the inherently hostile nature of intergroup relationships. Whereas this emphasis on the inherently hostile character of intergroup relations led him to deny the optimistic view, held for example by L. F. Ward and many of his contemporaries, that humanity was steadily moving upward, his emphasis on the inevitability of the laws governing social life and of the impotence of the individual to influence those laws in turn led him to criticize reformist attempts to interfere with the course of society and history. On the practical side, sociology could prove the futility of any human intervention.

In Gumpłowicz's sweeping, conjectural, and at times contradictory interpretation of the history of humanity, the time of the formation of the state assumed particular importance. In prestate societies the encounters of ethnically different groups had usually ended with one group exterminating the other. States came into existence when one group conquered and subjugated another group, thereby institutionalizing slavery or other forms of economic exploitation. In this so called “conquest hypothesis,” it was always the minority that ruled over the majority. Over time new groups might emerge by differentiation, “amalgamation,” or further subjugation. Rejecting the ideas of the inalienability of human rights and of the impartiality of law in general, Gumpłowicz argued that the legal system at all times reflected the actual power relations between the various groups within the state. Despite its more complex structure, modern political life was still characterized by the incessant struggle of groups. Similar to the elite theorists Mosca and Michels, who were both well acquainted with his work, Gumpłowicz argued that the essential character of social life had remained unchanged throughout history. Because of this emphasis on social constants, he also saw no need, in contrast to Weber, Simmel, or Durkheim, to develop a sociological theory of modernity. Despite the fact that he offered no analysis of modernity, and despite the conjectural and highly deductive nature of many of his historical interpretations, his radical

anti individualism, and his nineteenth century positivist outlook, Gumpowicz's almost obsessive focus on the differential power relations within society and his thorough attempt to replace the study of society at large by the study of intergroup relations still deserve attention.

Gurvitch, Georges: social change

Phillip Bosserman

On June 22, 1962, Georges Gurvitch and his wife Dolly were victims of a terrorist attack aimed at assassinating this deeply dedicated Sorbonne professor of sociology. He had enormous intellectual gifts and possessed a dazzling

legal mind with a wonderfully creative sociological imagination. The distinguished social historian Fernand Braudel proclaimed him the brightest person he had ever known.

Gurvitch found himself opposed to French groups such as the OAS (Organisation de l'Armée Secrète) seeking to keep Algeria a French colony. Students poured into Gurvitch's sociology classes from North and Sub-Saharan Africa longing for independence from their French occupiers. Freedom was in the air and Gurvitch favored decolonization. In all likelihood, then, it was OAS terrorists armed with plastic bombs who destroyed the Gurvitchs' Paris apartment on that summer night in 1962, bringing paralyzing fear into their lives. They took refuge in the home of the celebrated painter Marc Chagall.

The moral facts, those principles upon which Gurvitch acted, were centered in a commitment to liberate Algeria from French colonialism. Gurvitch headed an academic activist group at the University of Paris that viewed the brutal and bloody Algerian war as unjust. His leadership tells much about the sociology he taught and lived. The roots of this spontaneous act of creative freedom came from living through the turbulent revolutionary years in Russia, experiencing the vast cataclysmic social changes that reverberated throughout his native land.

Georges Gurvitch was born October 20, 1894, in the Black Sea port of Novorossisk, Russia. About 1910, the family moved to Dorpat, Estonia, where the young Gurvitch's intellectual journey began. The first years of his university training (1912–14) were divided between summer sessions in Germany and winter classes in Russia. During these years he visited scholars in Germany and Central Europe who awakened in him a growing interest in the rising popularity of phenomenology as taught by Scheler and Husserl. Through them, Gurvitch gained a fundamental appreciation of the emotional, intuitive, and affective side of social reality. He absorbed the writings of Bergson and Fichte, who expanded on these approaches. Frederic Rauh provided Gurvitch with the basis for his sociology of moral life.

Just prior to the outbreak of World War I, Gurvitch studied with Emil Lask, who introduced him to Max Weber's thought. Later Gurvitch would make Weber's typological

approach a prominent feature of his social change theory. Lask's rigorous dialectic, mostly indebted to Fichte, eventually led Gurvitch to see *we ness* as ontologically prior to the individual, thus making the social real.

The defining experience that deeply affected Gurvitch's whole being was the Russian Revolution that erupted during February and March 1917. He joined a group of students on the margins of that chaotic political storm. Gurvitch saw creative freedom break forth spontaneously "in the faults or interstices of the determinisms [then in place]" (Choi 1978: i; see also pp. xiii–xiv). His group of students would ask a withering barrage of questions about the changes being made by Lenin's Bolshevik party.

Gurvitch became increasingly displeased with what he was seeing and experiencing. In the spring of 1920, after a memorable walk and talk with his wife Dolly along the banks of the Karpovka River in St. Petersburg, they agreed to leave Russia for Czechoslovakia. Gurvitch taught in the Russian Institute of the University of Prague for four years before moving to Paris. During World War II he accepted an invitation from the New School of Social Research in New York City, returning to France in 1945, eventually occupying Durkheim's chair at the Sorbonne.

Gurvitch's lived experiences of societies in crises and revolution led him to ponder the causes of social change. Mirroring the current challenging work of Michael Burawoy, Gurvitch in the 1950s and 1960s called for sociology to be a *vocation*, not a job, a calling that would make a positive contribution to the group or global society of which sociologists are a part. Gurvitch personally felt motivated to do something about the colonial wars in Algeria and elsewhere. As described above, his actions invited the 1962 terrorist attack against his home.

Central to Gurvitch's sociological thought on social change is the freedom or liberty to act. He went so far as to say sociology's underlying principle is this freedom to question the status quo, to dissent, to go against and change what is. Such freedom gives every human being the possibility of creative, positive activity. Gurvitch identified six degrees or stages of freedom:

- 1 *Arbitrary liberty* relies on subjective preferences which are driven by unconscious,

repetitious patterns similar to the movements of a mobile; such liberty takes precedence over needs or desires; contingency remains strongly present; it is a lazy kind of liberty.

- 2 *Innovative freedom* rests on a stronger, more determined will resulting in a more concrete application of rules and directives that constitute a moderated, patient, and attentive choice of action.
- 3 *Liberty choice* employs a more intense, clairvoyant will to guide actors in overcoming closed minds and total negativism by choosing the multiplying alternatives.
- 4 *Innovative liberty* is a means by which to escape those alternatives that are too cumbersome, present, and too menacing by inventing some possibilities for reorienting the will. Inventive freedom is an invitation to consider new strategies and new maneuvers for overcoming obstacles staring one in the face. This inventive liberty can rely on cunning, or can discover new models, signs, symbols, values, ideas, and the like.
- 5 *Decisive liberty* intends to overturn the present order, break down, destroy, and eliminate every obstacle that voluntary actions find in their path (Gurvitch 1963: 101). It seeks to confront the purest obstacle, i.e., a committed heroic role, prepared to risk everything.
- 6 *Creative liberty* is the profoundest level of human freedom. From this degree of human freedom change agents emerge who consciously strive to produce art, religion, and knowledge. They possess god like skills whose creative impulses are renewed by the other degrees of freedom (Balandier 1974: 17).

The vast capacity of all the degrees of liberty is often called *agency*; the collective acts of agents create social change. Individual and collective efforts to change the status quo are nearly always vigorously opposed by other actors who do not want any tinkering with what is. For Gurvitch, all of these actions make history.

Freedom plays off of determinism. Human actors function within groups, and groups possess a dynamic oneness resulting from the constant motion within what Gurvitch and Mauss called the *total social phenomenon*. Constantly in

motion, these total social phenomena are evidenced in ever present structuration and destructure.

Gurvitch's discussion of sociability, what he calls microsociology, contrasts mass, community, and communion in terms of the intensity of *we ness*. What becomes apparent is that change is as critical to Gurvitch's sociological program as freedom or liberty. By employing radical (hyper)empiricism, he can observe the dialectical dance of freedom (free will) and determinism (the centripetal forces of each group's unity).

Gurvitch saw the struggle for change as a primary characteristic of human social life. The human actor, both individual and collective, possesses the freedom to act. "[This] liberty attempts not only to modify obstacles external to the action, but also to modify its own agents . . . [This freedom] aims to consider all the data, all the fluctuations of collective experience, *and* to take . . . account of the fact that in perceiving them it modifies them" (Balandier 1974: 17). Gurvitch's hyperempiricism requires fidelity in examining every type of experience, whatever it takes.

The dialectic illuminates social change. Gurvitch saw three primary aspects to its character. First, it is a concrete, constant movement to find unity (totality) while struggling with instability. Second, the dialectic is a method for grasping and understanding this real, changing human totality. Third, all the while this dialectical character underlines the engaged aspect of the human being who is wholly involved (Gurvitch 1962: 36–7).

In short, the dialectic rejects the pat answer, the hardened system, the simple explanation. Social reality's nature is a fluid, dynamic, ever changing, explosive, paradoxical, affective domain, the opposite of stable, static, and rigidly functional. Gurvitch proposed five dialectical processes:

- 1 *Complementarity*: No social whole is reducible to any one factor.
- 2 *Mutual implication*: What seems to be heterogeneous such as psychological and sociological phenomena overlap and combine, each implying the other.
- 3 *Ambiguity*: Thanks to Freud, social wholes are moving toward a tentative equilibrium

or go in the opposite direction of destruction.

- 4 *Polarization*: Conflict, extreme tension, the tearing apart of the structures and subjacent levels are good examples.
- 5 *Reciprocity of perspectives*: The opposite of polarization in which the immanence or presence of the other is nearly total.

These operative processes immensely help one grasp Marcel Mauss's ingenious admonition "to reconstruct the whole." Gurvitch agreed with Mauss that social scientists have divided and abstracted social phenomena too severely. In fact, he would make Mauss's conception of the total social phenomenon (TSP) his own. Furthermore, the TSP is horizontally arranged on a continuum of varied social frameworks from simple social bonds to friendship circles, family groups, neighborhoods, sports teams, social classes, and full blown global societies. The TSP is also vertically anchored, occupying different levels varying in terms of accessibility. The surface level of ecology is easiest to view and describe. Gurvitch identified ten levels but always left the exact number open. As one plunges into the depth levels of social organization, roles, collective behavior, and to the collective mind itself, the task of discovering how each contributes to the whole of social reality becomes increasingly difficult to discern. Dialectical analysis becomes indispensable. These intersecting relationships are dynamic and moving. "All of these depth levels interpenetrate; more than this, they are in perpetual conflict, tension, and threatened by estrangement or antinomy. The degree of their discontinuity and continuity, their mutual implication, or their polarization is a question of fact, and fact only" (Gurvitch 1963: 103).

Dialectics particularly aid in developing social change theory as it relates to the types of global, historical societies. Gurvitch called them Promethean for they possess "the elements of collective and individual consciousness concerning the capacity of human liberty to be an active and effective intervention in social life" (Gurvitch 1963: 221). Gurvitch rejects Weber's ideal types. These contemporary historical societies are *real*, and committed (engaged) sociologists will be using the dialectical processes to study them.

Because their field of labor is human social reality, sociologists cannot be enclosed in an ivory tower or a laboratory. There is no escaping the human condition. Moreover, if it is human, it is social. Again, *we ness* is ontologically prior to the *I*. Those whom sociologists examine are thinking, willing, conscious persons – they are also a part of the same global humanity.

As noted above, a striking contemporary voice to Gurvitch's view of practicing sociology is that of Michael Burawoy, president of the American Sociological Association (2004). "A critical, engaged sociology ought to be a sociology about the public, for the public," as Burawoy puts it. "The vocation of science can not survive without the vocation of politics." Burawoy sees four types: professional politics, the politics surrounding policy issues, the politics stimulating public discussion, and the engagement with the students we teach, calling for critical deliberation. In short, sociologists are *engagés*. There is no alternative.

Gurvitch's dialectic allows the sociologist to acknowledge the implicit relationship between values and method, between the subject and object, the observer and the observed. Social reality is dialectical by nature, requiring each program of research to be dialectical as well. A researcher or teacher cannot avoid taking a position based on certain values. Howard Zinn asserts this in the title of his autobiography, *You Can't Be Neutral On a Moving Train* (2002). He explains why by asking this question: "Does not the very fact of concealment (failure to reveal to your students who you are and where you come from) teach something terrible – that you can separate the study of literature, history, philosophy, politics, and the arts, from your own life, your deepest convictions about right and wrong?" (2002: 7). Gurvitch would have approved of Zinn's stance. Indeed, Gurvitch made it clear which type of global society he favored by self disclosing his preferences. He was deeply committed to realizing a society that rests on democratic

principles of justice and fair play, where all citizens are participants, and decisions move from local grassroots councils upward so the rights of all are kept in balance. Ownership is federalized, i.e., property is jointly owned by individuals embedded in community. To this end, while still in New York, Gurvitch wrote an ambitious blueprint entitled *La Déclaration des droits sociaux* (1944) for post World War II France that could guide those who had oversight of the vast job of reconstruction. The project was an example of planned social change.

H

habitus/field

Anne F. Eisenberg

European sociology serves as an interesting contrast to American sociology in terms of theory and theoretical development, as exemplified by Pierre Bourdieu's writings and particularly with his ideas of habitus and field. On the one hand, most typical of theoretical development in American sociology is to build on an existing body of theoretical work rather than seeking to create something novel, and secondly to attempt to find ways to link theory to empirical research by operationalizing the theory. Examples of such programs include theories addressing justice, balance, and identity (micro level theories) as well as institutionalism, social change, and revolutions (macro level theories). European, particularly continental, sociology has tended to take a somewhat different approach by focusing on integrating key theoretical ideas across different perspectives, as well as creating new language with which to express such integrative ideas. Additionally, another key distinction between American and European sociology is that American sociology highlights what some writers consider to be false distinctions and dichotomies in a range of areas – such as theory versus research methods, objective versus subjective, qualitative or interpretive methods versus quantitative or positivistic methods, macro versus micro, and structure versus agency. European sociologists argue against creating and maintaining such arbitrary boundaries in describing and explaining the social world. Bourdieu's ideas of habitus and field provide a new way of explaining key aspects of the social world that integrates key ideas from different sociological perspectives.

In the first chapter of *Outline of a Theory of Practice* (1977) Bourdieu explicitly addresses the problems inherent in limiting our understanding of human society to the false distinctions that represent typical sociological explanations – particularly, the distinctions between objective versus subjective and structure versus agency. He argues that the structure of society (as represented by social institutions and macro structures) is far more dynamic than as normally portrayed, and that human agency has far more input in shaping social structures and social institutions than is normally discussed by sociologists. This discussion provides a natural segue to his discussion of habitus in the second chapter. Habitus epitomizes Bourdieu's interest in linking phenomenological and symbolic interactionist perspectives (sometimes equated with the subjectivist view) with the more structuralist approach (sometimes equated with the objectivist view) of American and some European sociologists. Additionally, habitus also illustrates the intimate connection between structure and agency as represented in the social actor, where the social actor can be an individual, a group, or any large collectivity.

Bourdieu defines habitus as the way in which actors calculate and determine future actions based on existing norms, rules, and values representing existing conditions. It is important to understand key aspects of habitus. One key element of this definition is that Bourdieu argues that existing norms, rules, and values have been mentally and cognitively integrated into the actor's frame of reference, and that they represent general social standards as well as specific situational and personal experiences. This illustrates his way of integrating the macro elements of a structured social world that imposes its will on actors with the dynamic agency that enables actors to engage in individually determined actions. Additionally, this

illustrates the integration of an objective reality created by existing structural elements in society with the subjective reality of the social actor. A second key element of habitus is that “future” actions refer to a range of possible actions, from what you do immediately upon reading this entry to what you might plan to do on your next vacation. Bourdieu states that social actors engage in a continuously dynamic interaction with their environment and other actors such that they are aware of negotiating from a range of possible actions to take. A third key element associated with his definition of habitus is that, in identifying actors’ agency in calculating actions, Bourdieu explains that this process is rational in that it takes into account potential outcomes for any specific action as well as something other than rational in that it also takes into account subjective motivations. In other words, habitus reflects actors’ emotional and spontaneous reactions to particular situations and the other actors involved. The final key element of the idea of habitus is that it represents a fluid set of guiding principles for the social actor. While actors in similar positions in society may share similar habitus, as their environment and the other actors in the environment change, so does the habitus. It is consistent across actors, which allows us to understand particular settings and cultures as well as what is unique to each individual.

Bourdieu’s idea of field also serves to demonstrate the intimate connection between objective and subjective realities as well as between structure and agency. His discussion of fields also integrates a Marxist focus on conflictual relations with a Weberian focus on formal hierarchies. Fields represent the network of relations between and among positions actors hold within particular structural or organizational systems. For example, Bourdieu examines artistic or literary fields and he describes them in terms of the positions actors hold relative to one another. Additionally, he argues that there are several hierarchies of fields as well as hierarchies within each field. The specific positions held by actors linked in terms of similar structural or organizational systems are embedded in fields of power, which are then embedded in fields of class relations. The connection to Marxist and Weberian ideas is immediately evident when you view the

field as a set of interconnecting positions that occur on several different levels – similar to 3 D chess, where the players must be aware of not only the first board, but also how the chess pieces on two other levels of boards are interacting with, and affecting, the primary or first board. There are several ways that Bourdieu’s idea of fields overcomes the dichotomies of American sociology. First, in his discussion of the network of relations among positions, Bourdieu allows the actors to be individuals as well as corporate actors. Along with the interlocking levels of fields, he bridges the perceived gap between micro and macro levels of social phenomena. Second, Bourdieu argues that while the positions reflect objective reality through their organizational or structural existence, they also reflect the subjective reality of individual actors who occupy such positions. Third, in the tradition of the early French anthropologists, Marx, Weber, and Durkheim, Bourdieu uses empirical research to develop this theoretical concept.

Halbwachs, Maurice (1877–1945)

Suzanne Vromen

The French sociologist Maurice Halbwachs was a prominent representative of Durkheimian sociology during the interwar years, and an important contributor to the *Annales sociologiques*. He was also a statistician, a demographer, an expert at analyzing working class budgets, and an urban sociologist. His pathbreaking contribution to sociology, however, consists in the way he conceptualized how memory is socially constructed.

Maurice Halbwachs was born in Reims, France, in a Catholic family of Alsatian origin that opted to remain French when Alsace was annexed by Germany in 1871. Liberal in political ideas, the family moved to Paris in 1879. Influenced by Henri Bergson, his teacher at the Lycée Henri IV, Halbwachs studied philosophy at the Ecole Normale Supérieure, the elite school where most great French teachers are educated, and in 1901 he obtained his *agrégation*, the competitive diploma required to teach in the French secondary system.

Halbwachs soon became attracted to the social sciences, acquired two doctorates and sharpened his mathematical skills. He joined the Durkheim group, and from 1905 he contributed extensively to the *Année sociologique*. Bergson's influence on him, however, remained undeniable. Halbwachs's central program, the analysis of memory, was a lifelong attempt to reconcile some Bergsonian insights into consciousness, time, and remembering with Durkheimian perspectives.

With the end of World War I, higher education opened up for Halbwachs. From 1919 to 1935 he taught at the University of Strasbourg, first as professor of sociology and pedagogy, and from 1922 as France's first professor of sociology. Thanks to his reputation and the university's interdisciplinary climate, Halbwachs was invited to serve on the editorial committee of the *Annales d'histoire économique et sociale* launched by his historian colleagues Lucien Febvre and Marc Bloch, and he became a valued contributor. During the Strasbourg

years he produced major works, among them *Les Cadres sociaux de la mémoire* (*The Social Frameworks of Memory*) (1925), *Les Causes du suicide* (*The Causes of Suicide*) (1930), and *L'Évolution des besoins dans les classes ouvrières* (*The Evolution of Needs in the Working Classes*) (1933).

In 1935 he moved to the Sorbonne, where he occupied positions in the history of social economics (1935–7), the methodology and logic of the sciences (1937–9), and sociology (1939–44). At the same time, official honors were showered upon him, including membership of the Academy of Moral and Political Sciences (1932) and in the International Institute of Statistics (1935), and presidency of the French Institute of Sociology (1938).

In May 1944 he was appointed to the Chair of Collective Psychology at the Collège de France. But in July, detained by the Gestapo following his son's arrest for resistance activities, father and son were deported together to Buchenwald, where Halbwachs died in March 1945.

In the interwar years Halbwachs was a major promoter of Durkheimian sociology in France, broadening its development in dialogue with other disciplines such as psychology and history. A prolific worker and sophisticated statistician, with an expansive intellectual curiosity, he engaged critically with Durkheim's theories of suicide and of social morphology (*Morphologie sociale/Social Morphology*, 1938), and he also analyzed empirically aspects of urban and working class life in contemporary societies, subjects neglected by other Durkheimians.

With his theory of collective memory Halbwachs opened for sociological analysis a subject formerly left to literature and psychology. He intended to sociologize consciousness and to bring out the dependence on the social context of faculties traditionally considered uniquely and totally individual. For him, individual memory was shaped by the very fact of social existence. He postulated temporality and spatiality as intrinsic parts of consciousness, and considered memory as the convergence of multiple solidarities and as the ordering of experience. To remember, one needed others. He redefined time from a homogeneous and uniform category to coordinator of social experiences. By pointing the way to an analysis of the

concrete situations of everyday life in their temporality and spatiality with the meanings attached to them, Halbwachs adopted a phenomenological position. On the collective level, his analysis of memory was functional: group memories ensured cohesion and social continuity. They were didactic and effective because they included both concrete and abstract elements, images, and concepts. Space was to be understood in terms of a group's attitudes and intentions toward it, and localizations served as means of legitimation. Besides *Les Cadres sociaux de la mémoire*, Halbwachs developed his theory of collective memory in *La Topographie légendaire des Évangiles en Terre Sainte* (*Legendary Topography of the Gospels in the Holy Land*) (1941) and in *La Mémoire collective* (*The Collective Memory*) (1950), a collection consisting of an article on the collective memory of musicians and of extensive notes found in his papers after his untimely death, indicative of his intention to write another book on the subject of memory. The volume on the legendary topography of the Holy Land illustrates his concern with empirical data through a detailed and systematic examination of the localizations of holy places. Revered by Christians in Palestine, these holy places shifted according to historically significant doctrinal and political changes, thus the spatial framework of memory was continually reshaped by the varying concerns of the living people who did the remembering. Here Halbwachs offered a concrete reinterpretation of the sociology of knowledge, and questioned what images and concepts in a group's past best fulfilled didactic or legitimation purposes. A large collection of Halbwachs's notes and personal letters have recently been archived, and French sociologists are mining them to acquire a more complete sense of his work so tragically interrupted.

Halbwachs's constant focus on concrete facts of everyday life is apparent in his examination of family budgets, of expropriations, of working class budgets, and of memory. This emphasis on the concrete and the familiar differentiates him fundamentally from Durkheim, for he had no general evolutionary social philosophy.

For our postmodern age, Halbwachs's sociological theory of memory with its redefinition of time offers original lines of inquiry and feeds

into modern analyses of ideological forgetting and remembering, while his insights into how values are embodied in material forms provide contributions both to urban sociology and to the sociology of knowledge.

hate crimes

Jack Levin

The term hate crimes has been employed since the mid 1980s to identify criminal acts motivated either entirely or in part by the fact or perception that a victim is different from the perpetrator. The term first appeared in newspaper accounts of a 1986 racial incident in the Howard Beach section of New York City, in which a black man was killed while attempting to flee a violent mob of white teenagers, shouting racial slurs. By the early 1990s the hate crime designation was being applied not only to attacks based on race and religion, but also on sexual orientation, national origin, disability status, and gender.

In legal terms, the groups protected by hate crime laws differ from state to state. By 2003,

45 states had some form of hate crime statute that covered individuals targeted because of race, religion, or ethnicity; 30 also included disability status or sexual orientation; only 27 protected gender (Anti Defamation League 2003).

In some states a separate statute exists which prohibits hate crime behavior, while in other states the hate crime statute is a "penalty enhancement." This means that if an existing crime is committed and it is motivated by bias, the penalty on the existing crime may be increased. Finally, a federal hate crimes statute exists, allowing federal prosecution of crimes based on race, color, religion, or national origin for certain constitutionally protected activities such as voting.

In a sense, the term hate crimes is somewhat misleading in its emphasis on hate as a defining basis for choosing and attacking a particular victim. The level of brutality in certain hate attacks suggests the presence of intense hostility or anger (i.e., hatred) in the motivation of the assailants. In the more typical hate crime, however, perpetrators may be motivated more by a desire for belonging or profit than by hatred for a particular victim. In addition, extreme dislike toward the victim may be present in many hate crimes, even if the primary motivation for the offense turns out to be something other than bias; such crimes can confound efforts to apply a consistent definition of hate crimes.

In terms of offender motivation, hate crimes can be categorized as four major types: thrill, defensive, retaliatory, and mission (Levin & McDevitt 2001). The majority seem to be thrill hate crimes: recreational offenses committed by youngsters – usually males operating in groups – who seek excitement at someone else's expense. Such young offenders get from their attack on a victim "bragging rights" with their friends. Though many of the hate crimes directed against property – acts of desecration and vandalism – can be included in the thrill seeking category, there are also numerous thrill hate offenses that involve intimidations, threats, and brutal assaults.

A second type of hate crime is defensive. That is, the attack is designed to protect an individual's neighborhood, workplace, school, or women from those who are considered to

be outsiders. Defensive hate crimes have often occurred when a family from a different racial group – especially black or Asian – moves into a previously all white neighborhood. Wherever it occurs, a defensive attack is often an act of domestic terrorism because it is designed to send a message to every member of the victim's group.

Retaliatory hate crimes are motivated by an individual's need for revenge as a result of a hate attack directed against his or her own group members. The targets of a retaliatory crime are not necessarily the particular individuals who had perpetrated the initial offense. More than any other type of hate crimes, a series of retaliatory offenses may contain the basis for escalating from individual criminal acts into large scale group conflict.

A final type of hate crime is a mission offense, usually committed by the members of an organized hate group. Actually, no more than 5 percent of all hate crimes nationally are committed by the members of organizations like the Ku Klux Klan or the White Aryan Resistance. Yet organized hate groups continue behind the scenes to support much larger numbers of violent offenses committed by non members who may be unsophisticated with respect to the ideology of hate – racist skinheads, alienated teenagers, or hate filled young men.

Organized hate groups are found not only in our communities, but in our penitentiaries. Established in many states around the country, for example, the Aryan Brotherhood introduces inmates to the theology of the Identity Church, according to which Jews are the children of Satan and blacks are sub human "mud people."

Like other aspects of the Uniform Crime Reports (FBI 2003), hate crime incidents, offenders, and victims are voluntarily reported by local jurisdictions to the FBI. Some 86 percent of the population of the US is now covered in nationally reported hate crime statistics. Of course, there is still reason to believe that hate crimes are vastly underestimated. Whether from ignorance, fear of retaliation, or distrust of the police, many victims of hate attacks simply do not report their victimization to the police.

In 2002 there were only 17 hate motivated murders reported to the FBI. On the other

hand, there were 8,832 hate crimes reported, 68 percent of which were directed against persons. The location of hate crime incidents varied, but they seemed to be concentrated in homes, on the streets, and in schools and colleges. Race was the most common basis for committing a hate offense, with anti black attacks most likely to occur and anti white attacks in second place. Anti gay, anti Jewish, anti Latino, and anti Muslim offenses were also quite prevalent. A wide range of groups were represented among the victims of hate crimes, including people with physical and mental disabilities, Asians, Protestants, Catholics, and American Indians.

Hawthorne Effect

William H. Swatos, Jr.

The Hawthorne Effect is the name that has been given to the possibility that a subject in a research project may change his or her behavior in a positive manner simply as a result of being aware of being studied. This concept takes its name from research studies conducted from 1924 to 1933 at the Western Electric Company's Hawthorne plant near Chicago, Illinois, that ultimately came under the direction of Elton Mayo of Harvard University. The specific research associated with the Hawthorne Effect was the first step among several and was conducted by engineers at the plant from 1924

to 1927, prior to Mayo's entry. This experiment involved increasing the lighting within a work area, using both experimental and control groups. Measuring worker output before and after the change in lighting showed an increase in productivity in *both* the experimental and control groups. Additional experiments with results along these lines led the researchers to conclude that the increased worker output occurred simply because of the increased attention directed toward the workers. It was at this point that Mayo entered the research, and the focus moved from simple variation in illumination to a variety of alterations in actual worker activity. As a whole, the research provided the initial grounding for Mayo to create the human relations movement, particularly in complex organizations.

With respect to research strategies themselves, later research has raised considerable doubts about whether the conclusions drawn across the studies as a whole are supported from the data. Subsequent studies show that the Hawthorne Effect has a variety of limits and may also have been influenced by its novelty at the time. Limits include the relative reasonableness of the alterations, the conduct of the researchers, and the nature of the work and workplace. At the same time, however, the implications associated with the Hawthorne Effect have been extended beyond classical experimental designs, which are relatively rare in sociology, to issues within survey research. Persons who are told that their opinions are valuable may quickly form opinions on topics about which they know very little, or they may modify their actual opinions in ways that they believe will be socially acceptable – either to the interviewer or to members of a group in a group interview setting. These various possibilities underscore the unique character of humans as subjects of research: the ability of humans to construct meaning within research contexts independent of the intentions of the researchers.

At the level of applied sociology in management, however, the Hawthorne studies have been incorporated into consultative approaches to labor management and productivity. That is, designing approaches to output that involve management-labor contact and worker opinion in the manufacturing process can be used as a strategy to improve productivity regardless of

the process itself. Although this tactic is subject to the same limits as occur with respect to research subjects, it nevertheless has become a fairly standard component of worker friendly management styles.

health behavior

William C. Cockerham

Health behavior is defined as the activity undertaken by people for the purpose of maintaining or enhancing their health, preventing health problems, or achieving a positive body image (Cockerham 2000: 159). This definition goes beyond the one provided by Kasel and Cobb (1966), who depicted health behavior solely as the activity of healthy people to prevent illness. This latter definition is too limiting because health behavior does not just consist of healthy people trying to stay that way. While the health behavior of many people is intended to prevent sickness and injury, or to prolong their lives, other people may have other objectives. People with chronic diseases like heart disease and diabetes, for example, also engage in health behavior when they seek to control their disease through diet, exercise, and other forms of health related activity. Some people who are primarily motivated to enhance their bodily appearance and physical fitness through health promoting activities like diet and exercise likewise are engaging in health behavior even if the desire to look and feel good is more important to them than being healthy.

For most people, health behavior consists of actions to maintain, restore, or improve their

health, prevent health problems, increase their life span, or achieve a healthy appearance. These actions include a wide range of activities, including eating healthy foods, not smoking, exercising, brushing one's teeth, taking medication to control blood pressure or reduce cholesterol, getting 7 to 8 hours of sleep a night, and so on. What has brought health behavior to the attention of sociologists is that considerations of health outcomes are increasingly important influences on the daily routines of social life. In past historical periods, a person was either healthy or unhealthy and tended to take this situation more or less for granted. Today, however, this view has changed. In developed societies, good health has become a condition to be achieved and maintained through personal effort. In order to be healthy, people are expected to "work" at it, and believed to risk disease and premature death if they do not. This circumstance has its origins in the public's recognition that medicine cannot cure chronic diseases and the close association of such diseases with unhealthy lifestyles (Crawford 1984). The realization that responsibility for one's own health ultimately falls on one's self, not the medical profession, is viewed as a major reason for the renewed interest in health behavior that originated in the physical fitness movements (e.g., jogging, aerobic exercise) of the 1960s.

One of the first major accounts of health behavior in sociology was provided by the French sociologist Claudine Herzlich (1973; Herzlich & Pierret 1987). Health was described by people in her study as a necessity for both the individual and society, and the means by which a person achieves self realization. Herzlich identified a shift in thinking in French society away from taking health for granted toward a norm of a "duty to be healthy." This norm was strongest in the middle class, but appeared to be spreading, as many lower class people expressed the same orientation. "The right to health," stated Herzlich and Pierret (1987: 231), "implies that every individual must be made responsible for his or her health and must adopt rational behavior in dealing with the pathogenic effects of modern life."

The standard approach to the study of health behavior in public health views such behavior as largely a matter of individual choice and targets the individual to change his or her

harmful health practices largely through education (Gochman 1997). The theoretical models used in such research, like the Health Belief Model and the Stages of Change Model, are typically based on individual psychology. While this research is useful in certain contexts, it neglects the social situations and conditions that may ultimately be responsible for causing the health problem. A sociological perspective allows the researcher to analyze health behavior as a social phenomenon that goes beyond the psychology of the individual. The source of the behavior may be located in the norms, practices, and values of groups, social classes, and society at large that influence the individual. A sociological approach also helps the researcher address macro level conditions like poverty, the stress of economic recessions, and environmental pollution, over which the individual has little or no control but must cope with because of his or her social circumstances. These conditions not only cause unhealthy living situations, but also promote unhealthy behavior when heavy alcohol use, smoking, inattention to diet, and the like are the response.

The focus of research in sociology is not on the health behavior of the individual; rather, it is on the transformation of this behavior into its aggregate or collective form: health life styles. Health lifestyles are collective patterns of health related behavior based on choices from options available to people according to their life chances (Cockerham 2000: 160). Invariably, the better a person's life chances, as typically indicated by his or her class position, the healthier the lifestyle and, conversely, the worse the person's chances in life, the less healthy the person's lifestyle and the higher the probability for a shorter life.

health care delivery systems

Fred Stevens and Jouke van der Zee

A health care delivery system is the organized response of a society to the health problems of its inhabitants. Societies choose from alternative health care delivery models and, in doing so, they organize and set goals and priorities in such a way that the actions of different actors are effective, meaningful, and socially accepted. From a sociological point of view, the analysis of health care delivery systems implies recognition of their distinct history over time, their specific values and value patterns that go beyond technological requirements, and their commitment to a set of normative standards (Parsons 1951; Selznick 1957). The term "system" is used here in a sociological sense (Parsons 1951; Philipsen 1980). Typical system features are functional specificity (operational goals), structural differentiation (the division of labor), goal setting (including effectiveness, efficiency), coordination (of activities, occupations, and facilities by mutual agreement, standards, or hierarchy), and boundary maintaining autonomy (in relation to political, economic, or normative structures). Some health care delivery systems comply more with these system characteristics than others. Where health care delivery systems vary, it is mainly due to long term cultural and structural developments.

Consequently, a health care delivery system is typified by its structure, its relationships between actors and organizations, and its specific pattern of underlying norms, values, and value orientations.

Three factors are significant in understanding the origins of modern health care delivery systems: (1) the socioeconomic level of development of a society, (2) its demographic situation, and (3) the epidemiological state of affairs. As shown in Table 1, modern societies developed from agricultural economies through industrialization to service economies in a *societal transition*. They initially focused on survival and self sustenance of the small landholder and his or her (extended) family, but evolved toward economies creating surpluses (wealth) and added value to products that could be traded. Surpluses were commonly used to institute new roles and occupations that were important but not necessarily productive, such as priests, soldiers, tax collectors, and healers. Surpluses accumulated during long periods, in which stages of prosperity alternated with times of recession, due to war, famine, and

pandemics. As societies further developed and modernized, more structures and institutions came into existence that reduced the risks of daily life.

Table 1 shows that widespread kinship based arrangements to cope with these risks were gradually supplemented and replaced by collective arrangements. This culminated in a *demographic transition* consisting of the reduction of a population's fertility. In modern societies it was no longer imperative to have many children as a provision against old age poverty. At the end of the nineteenth century, at first in Germany, social security systems against loss of income due to accidents and disabilities came into existence. These further developed to include public pension schemes several decades later. In addition to these collective arrangements, financial surpluses were the foundation of economic growth, by extending educational facilities, also creating more services and typical professions, like teachers, health care providers, lawyers, and engineers. In Europe, taxes or fee collection were the primary mechanisms and financial resources for these

Table 1 Societal transitions and the development of health care delivery systems.

<i>Societal transition</i>	AGRICULTURE (rural)	→	INDUSTRY (urban)	→	SERVICES (suburban)
	Multi-generation family		Nuclear family		Individual households
Social tensions, revolutions, war →					
Main health issues	Demographic transition				
	Infectious diseases	→	Declining fertility	Aging population	→ Chronic diseases, diseases of civilization
	Declining mortality			Epidemiological transition	
Focus of care	Hygiene, public health, informal care	→	Emerging curative care, social security, welfare state	→	High tech care, professional home care

collective arrangements. In the course of this modernization process, the *epidemiological transition* took place that reflected a gradual shift from the sheer necessity to overcome infectious diseases (mainly affecting infants) toward dealing with chronic diseases (primarily affecting the late middle aged and elderly). Nowadays, health care delivery systems in modern societies are largely focused on the changing needs and demands of an aging population.

Health care organizations usually lag behind changing patterns of population needs. The reason is that modern, more sophisticated health care delivery systems, characterized by an advanced division of labor, high levels of complexity, and structural means for coordination and planning, require extensive financial resources. Yet only advanced economies are able to put aside sufficient resources for health care. Consequently, the extent to which resources can be generated for health care signifies a nation's stage of economic development. Evidently, on both micro (individual) as well on macro (societal) levels, there is a strong association between health and wealth.

Several conclusions can be drawn. First, the wealth of a society is a major determinant of health. Second, it is more difficult to improve health in affluent societies than in poor ones. Third, in countries with low levels of income (usually typified as developing societies), hygiene, sanitation, vaccination, nutrition, and immunization are the important objectives for health care. Modern societies, with higher average levels of income, largely have to cope with rising costs due to the increasing demand for chronic care, as a consequence of an aging population.

TYPES OF HEALTH CARE DELIVERY SYSTEMS

A simple, traditional market structure consists of bilateral relations between buyers and suppliers. The health care sector differs essentially from such a market structure, as interactions between actors are not organized in bidirectional relations of pairs of producers and consumers and the price of a health care procedure is not the balancing mechanism. Instead, health care delivery systems consist

of five principal actors. These are the consumers (patients), first line providers (usually general practitioners), second line providers (hospitals, institutional facilities), the state, and insurers (Evans 1981). They are organized multidirectionally, as an interacting system. Dependent on organization and system features, consumers (1) have direct access to hospital services; (2) may need a referral from a GP; (3) get their health care expenses reimbursed from an insurer; (4) have total or partial health care insurance coverage and pay taxes or insurance premiums for that reason; or (5) have to pay their bill directly to the provider (like the simple market structure).

Yet in typifying a nation's health system the role of the state in funding is decisive (Evans 1981; Hurst 1992; Marrée & Groenewegen 1997). Ideal typical ways of state funding involvement are:

- *Largely absent:* the state propagates non interventionism, leaving room primarily for private insurance to fill this role. The organization and provision of health care in the US and Switzerland are typical examples.
- *In between:* the state harmonizes the arrangements that developed between groups of citizens (e.g., employers, employees). This is the case in many European countries.
- *Central:* the state controls funding, *with or without* the provision of health care. The former is/was typical of Eastern Europe and Russia; the latter is typical for the National Health Services (NHS) model as found in the UK.

The *free market* model applies when the state conducts a policy of non interventionism and restricts its interference in health care matters to the bare essentials, leaving all other expenses to private funding and corporate provision (HMOs). This is the typical situation in the US, except for Medicaid (indigent) and Medicare (elderly) state interventions. Private insurance fills the gap to some degree, however, leaving about 16 percent of the US population uninsured for health care costs or loss of income due to illness and disability.

The second model is the *social insurance system*, founded in the late nineteenth century in

Germany. Typical for the social insurance system is that patients pay an insurance premium to a sickness fund which has a contract with first line (GP) and second line (hospital and specialist) providers. The role of the state is limited and confined to setting the overall terms of contracts between patients, providers, and insurers. The social insurance system is funded by premiums paid and controlled by employers and labor unions. These, however, have little control over the provision of services. This is left to the professions, specifically to the medical profession and to professionalized care organizations (e.g., home nursing, home help). For people with lower and middle class salaried incomes, collective arrangements are available (sick funds). Founded in Germany, the social security model was almost immediately adopted by Czechoslovakia during Austrian Hungarian rule, Austria, Hungary, and Poland. During World War II it was imposed on the Netherlands (1941) and later adopted by Belgium and France. The social insurance system survived two world wars and National Socialism, and in essence still exists in Germany, the Netherlands, Belgium, France, Austria, Switzerland, Luxembourg, and Japan (Saltman & Figueras 1997).

The third model, typically found in the UK, is the taxed based *National Health Services (NHS) model*. It was first introduced in 1948, is also centralized and is funded by means of taxation, while the state is responsible for the provision of institution based care (hospitals). The medical profession has a rather independent position. Self employed GPs are the gatekeepers in primary health care. Before visiting a hospital or a medical specialist one needs a referral from a GP. The NHS model leaves some room for private medicine. Through processes of diffusion and adaptation, the NHS model was first adopted in Sweden, and then by the other Nordic countries: Denmark, Norway, and Finland. At present, the NHS model applies to the United Kingdom, Ireland, Denmark, Norway, Sweden, Finland, Iceland, and outside Europe by Australia and New Zealand. Four Southern European countries have adopted, or are in the process of adopting, this tax based model. These are Spain, Italy, Portugal, and Greece (Saltman & Figueras 1997).

The fourth, most centralized health care delivery systems model, the *Soviet model*, dates

from 1920. It is characterized by a strong position of the state, guaranteeing full and free access to health care for everyone. This is realized by state ownership of health care facilities, by funding from the state budget (taxes), and by geographical distribution and provision of services throughout the country. Health services are fully hierarchically organized. They are provided by state employees, planned by hierarchical provision, and organized as a hierarchy of hospitals, with outpatient clinics (poly clinics) as lowest levels of entrance. Among the nations that, until recently, had a health care system based on the Soviet model were Russia, Belarus, the Central Asian republics of the former USSR, and some countries in Central and Eastern Europe. Many former Soviet Republics, however, are in a process of transition toward a social insurance based system.

The four models make up a continuum in terms of their "system" character, with state interventionism and centralized health care at one end, and non interventionism at the other. Centralized systems provide best mechanisms for cost control, while absence of state intervention does not appear to be fruitful, as soaring costs in the US evidently show. The four health delivery systems models are to be seen as pure types which can be found in many combinations and varieties. They also reflect stages and outcomes of a historical process. Consequently, system models that came into existence in highly developed economies in the first half of the twentieth century can now still provide useful options to choose from in developing countries or transitional economies like in Eastern European societies.

HEALTH CARE DELIVERY SYSTEMS REFORM

While the models presented reflect the major types that can be found in industrialized countries in Europe, the US, and Asia, none of these countries fully complies with the characteristics of one particular model. In a Weberian sense, they should be seen as ideal types. Through processes of adaptation and diffusion, national health care delivery systems deviate from these models. For example, social insurance based health care delivery systems and the

entrepreneurial system of the US were faced with problems of rising costs in the 1960s and 1970s. The NHS delivery systems and Soviet like delivery systems of Eastern Europe had problems of neglect, underfunding, and extensive bureaucracy in the 1970 and 1980s. In some countries, specifically those with social security based health care systems, this has led to more state regulation to curb the costs of health care. In other countries it resulted in less state intervention, and in the introduction of different forms of managed competition. For example, in Eastern Europe, after the fall of the Berlin Wall, we see the demise of state funding and state provision due to economic deficits. In the countries that have adopted the social insurance model we see more state regulation in order to introduce more planning and to curb the rising costs of health care. One of the consequences has been a stronger position of hospitals. In the UK we have seen a movement towards more decentralization, which was realized by a separation between purchasers (the government) and providers (Saltman & Figueras 1997; Tuohy 1999).

CULTURAL ROOTS AND VALUE ORIENTATIONS

Health care organization is also influenced by cultural circumstances. For example, nations with collective arrangements have more state intervention, a small private sector, a preference for tax rather than insurance funding, and comprehensive coverage with universal entitlement based on the notion of common rights. In contrast, societies steeped in individualism prefer private enterprise and insurance funding with selective coverage and high responsiveness to consumer demand. In societies which have equity as an important root we see explicit attempts to avoid discrimination and to facilitate public participation. In other words, values and value orientations play a role in the structuring of health care delivery systems.

Anthropologists have argued that differences between health care delivery systems are embedded in the values and social structure of the societies involved (Helman 1996). Based on specific histories, traditions, customs, and so on, differences in health care organization reflect the way in which societies define and deal with issues

of health and illness. Health and health care are embedded in value systems which give explanations why and how in specific cultures health problems are dealt with. For example, in some societies health care is considered a collective good for the benefit of all citizens. In other ones, health care is seen more as a "commodity" that can be bought or sold on a free market, or as an individual investment in human capital. As Gallagher (1988) notes: "The concept of health care as a calculable resource is an essential feature in its role as a carrier of modernity." The notion of health care as a commodity, however, has not been accepted everywhere. It seems to be more established in the essentially market oriented organization of health care in the US than it is in Europe or Asia. Nowhere in Europe has it become part of health policy objectives. This is notwithstanding a wide range of health care reforms in recent years introducing market oriented approaches with incentives to introduce more competition between providers and to use resources more economically (Saltman & Figueras 1997). Health care as a collective good for the benefit of all prevails in European health policy and in systems typified as national, social insurance, and so on. Health care as a commodity dominates in the US, although several European countries are moving in a similar direction.

Cultures or nations can vary in value orientations to a considerable degree. For example, values of equity, solidarity, and autonomy may have different health care implications in different societies (Hofstede 1984). Emphasis on hospital care versus home care or care for the elderly, on individual responsibilities versus solidarity between people, reflect a society's general value orientations that have an impact on its health delivery systems model (Stevens & Diederiks 1995; Saltman & Figueras 1997; Philipsen 1980; Hofstede 1984). Or to put this differently, the free market, insurance, and tax based health care delivery models to be found in the US, Germany, and the UK, respectively, are to a certain degree reflections of central values in their societies.

CONVERGENCE AND DIVERGENCE

There is ample evidence that contingencies like increasing health care costs, an aging

population, changing disease patterns, technological developments, growing public demand, and so forth impose a common logic in terms of institutional performance and the structuring of modern health care. In the literature a wide range of convergencies in health policy and health care organization have been listed (Field 1989; Mechanic and Rochefort 1996; Raffel 1997; Saltman & Figueras 1997). These include (1) the concern of governments to control health care costs while at the same time improving the effectiveness and efficiency of the system; (2) the increasing attention for health promotion and healthy lifestyles such as abstinence from substance use (alcohol, smoking, drugs), and healthy behavior; (3) reduction of health care inequalities and differences in access; (4) the stimulation of primary health care while cutting back extensive medical specialization; (5) the promotion of patient involvement in care and treatment and improving patient satisfaction; and (6) the reduction of fragmentation of services and the promotion of continuity of care.

Yet the convergence of modern health care delivery systems is not undisputed. Even if societies are faced with similar contingencies, their societal structures have to be consonant with culturally derived expectations (Lammers & Hickson 1979). Consequently, while there is substantial evidence that modern societies are evolving into the same direction with efficiency equity and utilitarian individualism as core value orientations, differences exist in degree and similarity of these developments. Modern societies still vary considerably in their dealing with issues of health and illness (Anderson et al. 1995). Moreover, while nations may have similar goals, alternative options are available to reach these. National health delivery systems are the outcome of a dialectical tension between universal aspects of technology and medicine on the one hand, and particularistic cultural characteristics of each nation on the other (Field 1989). These particularistic cultural characteristics refer to the historical foundations of health care delivery systems, to the societal and national context, and to specific values and value orientations of societies and health care delivery systems under consideration. Health care institutions are still largely country specific (Pomey & Poullier 1997). Such country specific elements would include social,

economic, institutional, and ideological structures, the dominant belief system, the role of the state versus the market, patterns of health care coverage, and centralization or decentralization of political authority (Saltman & Figueras 1997, 1998).

health and culture

Stella Quah

The cumulative knowledge from nearly a century's worth of studies confirms that the sociological analysis of health and illness would be grossly incomplete without the consideration of culture. Culture is both the context and an important determinant of the behavior, beliefs, and norms of individuals affected by illness and who are making decisions on help seeking, as well as of people and organizations whose role it is to help and to heal.

Many definitions of culture have been offered by scholars over the past century. Those definitions range from Parsons's "patterned system of symbols" to one or more characteristics of a group's or community's way of life, such as philosophical, linguistic, and artistic expressions; their collective norms of behavior; and their ethnic and/or religious customs and beliefs, among other features. Of these components of culture, the most commonly included in sociological studies of health and health related behavior are ethnicity and religion. As Stanley King aptly summarized it in 1962, ethnicity is understood as the combination of a common "language, customs, beliefs, habits and traditions," "racial stock or country of origin," and "a consciousness of kind" in Weber's sense. A group's religion or cosmology – that is, its interpretation of life, birth, and death, of right and wrong – gives shape to a consistent body of health beliefs and practices that are endorsed and implemented by individuals, typically with the tacit or active support and scrutiny of their social networks.

The intellectual context of the study of health and culture has been characterized by multidisciplinary and the presence of a wide range of conceptual frameworks. The early anthropological studies of primitive cultures in the late nineteenth and early twentieth centuries paved the way for the analysis of ethnic differences in illness and health related behavior by sociologists already schooled in the seminal ideas of Durkheim, Weber, Simmel, and Parsons. Parsons himself was influenced by anthropological and psychoanalytical perspectives. By the mid twentieth century, sociologists, social psychologists, and psychologists began collaborating in the analysis of the influence of beliefs and personality upon health related attitudes and behavior. The Health Belief Model was one of the first among several conceptual frameworks generated out of such collaboration. The incorporation of cultural variables in medical sociology research until then was modest and did not follow directly these conceptual developments.

Nearly all theoretical perspectives in sociology concur that ethnicity is socially constructed, is negotiable, and thus has permeable boundaries. However, medical sociology studies (predominantly research on traditional healing

beliefs and practices) confirm Kevin Avruch's crucial reminder (in Stone and Dennis 2003: 72) that while ethnicity is permeable from the perspective of the sociologist observer, from the subjects' perspective their culture is immutable because it "stretches back in an unbroken chain to some primordial antiquity." Indeed, studies of traditional healing systems indicate that people typically cite the perceived ancient authority of their culture as prescribing and sanctioning their traditional healing beliefs and practices (Quah 2003).

Different conceptual perspectives in sociology consider health generally as a state of well being (physical and/or psychological), but theories differ in their interpretation of the social meaning of illness. Some examples will suffice (Gerhardt 1989). Structural functionalism regards illness as "loss of role capacity" and assigns responsibility for one's health to the individual. The symbolic interactionist perspective sees illness in terms of stigmatization and proposes that societal and cultural influences impinge upon individuals' perception of health, self determination, and ability to negotiate their situation. Phenomenology sees the situation as "trouble trust dialectics" (following Garfinkel's approach to trust), where illness as "physical, psychological and role incompetence and incapacities" that break everyday life "trouble trust cycles" may be remedied by "reestablishing trust" in the form of medical treatment. Conflict theory addresses the questions of power and domination and associates illness with a surfacing of the everyday conflict that results from social, "political, and economic inequity" (Gerhardt 1989), an argument also pursued by Marxist and neo Marxist approaches. Of these theoretical frameworks, symbolic interactionism incorporates culture most directly, mainly in the form of socially constructed and subjectively perceived meanings of illness, definitions of illness severity, and labeling.

The two main perspectives that Gerhardt identified in 1989 as representing the major theoretical contention in medical sociology were the illness as deviance perspective and the power domination perspective. These two perspectives have been in confrontation throughout most of the past six decades. Against this backdrop, it is worth pointing out that the inclusion of culture (subjects' values, beliefs, and

customs) in research designs based on either of these main perspectives helps to elucidate their explanatory power. The incorporation of culture in a research design means addressing important questions such as how culture impinges upon people's subjective perception of health, illness, power, and stigma; upon the meaning they attach to illness and health; upon their sense of trust, normality, and deviance; and upon their health behavior. In fact, in the large and rapidly expanding body of biomedical and social science research on health and illness, the serious analysis of culture is a distinguishing feature of medical sociology and medical anthropology.

Increased interest in the cultural dimension of health has been prompted over the past six decades by major sociohistorical events and global upheavals, such as World War II, that motivated the examination of the idea of a sick society (Gerhardt 1989: 353); major movements of populations as the result of forced and free migration (leading to higher rates of ethnic minorities in Europe, North America, Australia, and New Zealand); and epidemics affecting a multitude of culturally diverse communities. The growing attention to the cultural or ethnic dimension of health and illness and the necessity to elucidate the complex web of attitudes, perceptions, and decisions on health risks and health options leading to the spread of epidemics such as HIV/AIDS and outbreaks of infectious diseases like SARS (severe acute respiratory syndrome) have led to a wealth of cross cultural and comparative research involving ethnic communities within countries and across different countries. This research trend has also been propelled by some slow pace but substantial changes in people's lifestyle (e.g., diet, rate of physical activity, leisure activities, long distance travel, exposure to environmental hazards, and high stress levels) and demographic trends, particularly longer life expectancy and the resultant increase in the proportion of older age cohorts and in the incidence of chronic diseases (e.g., cardiovascular diseases).

The wealth of studies of culture and health may be roughly classified into two main dimensions based on the principal unit of inquiry: some studies focus on the subjects affected by illness, while others concentrate on the expected or actual sources of healing. Research on individuals, small groups, and communities

affected by illness includes the sources of illness as well as people's health related behavior, attitudes, and beliefs at all the three main stages of the health-illness trajectory: preventive health behavior, illness behavior, and sick role behavior. Studies dealing with the expected and actual sources of help and healing concentrate on individuals as healers as well as on groups, networks, and organizations whose main objective is healing, or helping the sick, or safe guarding the health of others.

Concerning changes over time, one of the most important developments in the past two decades has been the noticeable increase in cross national and comparative research on cultural determinants of health related behavior involving different ethnic and religious communities. Illustrations of this type of research are studies on attitudes and behavior regarding prevention of and response to HIV/AIDS (e.g., condom use, sexual habits, and stigmatization) and other infectious diseases; and smoking, alcohol drinking, and dietary patterns in connection with cancer and cardiovascular diseases.

Some main trends may be identified in the wide array of current studies on health and culture. As indicated earlier, a continuing feature of medical sociology research on culture and health since the mid twentieth century is the concurrent advancement of theorizing and empirical research. Some critics have argued that theorizing has not moved significantly beyond middle range theories. Although this is true, the slow progress in grand theorizing and the presence of contending conceptual perspectives are common trends across sociology sub fields of inquiry and general sociology. Another current trend is the continued interest in the study of the body, especially within the phenomenological, feminist, and postmodern perspectives. A third trend is that health behavior studies guided by one or more social psychology theories (such as the health belief model, protection motivation theory, self efficacy theory, and the theory of reasoned action) are now paying more attention to cultural variables. The fourth and perhaps one of the most robust and faster growing research areas with the potential to highlight the relevance of culture is the study of the impact of social networks and modes of help seeking on health behavior (Thoits 1995; Levy & Pescosolido 2002). The link between

health and illness and people's ethnic identity, their sense of belonging to a family, network of friends, and community, and the concomitant trust people place in their care and advice in times of distress and illness, are all social phenomena that can be analyzed fruitfully by research on social networks and help seeking.

The methodological challenges confronting medical sociology are found in all other subfields of the discipline. One of the most difficult challenges in studies of health and culture is the refining of methods to ascertain sociocultural and illness related phenomena. For example, while Weber's idea of "a consciousness of kind" has been elegantly discussed as part of the concept "ethnicity," it is difficult to devise a valid method to ascertain a person's consciousness of kind through observation, interaction, or interviews. The same challenge is posed by many other concepts, such as the permeability of a group's culture, stress levels, trust in others, meaning of social support, and a social network's level of cohesiveness and reliability as help provider. The second main challenge is establishing causality. The study of culture and health confront us with the problem of ascertaining causality in many aspects, such as the link between everyday stress and illness. But the question of causality is particularly difficult when trying to establish whether culture is part of the social structure (i.e., the context of agency) within which health attitudes and behavior evolve, or a determinant of health attitudes and behavior, or both.

Future advances in research, theory, and methodology of studies on health and culture need to give serious consideration to three aspects. First, the emphasis on the construction, verification, and improvement of conceptual frameworks is a very valuable feature of this field and must continue to mark the development of medical sociology research on health and culture. Second, the impact of culture as norms shaping attitudes toward health illness and guiding health behavior is an area that requires active consideration by sociologists engaged in social networks and social support research; social networks and help seeking have become very productive research areas in the past decade and will continue to expand. Third, the dearth of authentic cross cultural research needs to be resolved. The bulk of research on health and culture up to the end of the 1990s was

addressed to the majority versus minority contrast (or immigrant versus non immigrant comparisons) within the same country, mostly in the US and in some European countries. This serious limitation needs to be overcome by comparative or cross national studies. Comparative research can provide the basis for more effective understanding of the relative permeability or resilience of cultural boundaries and its effect on health; of the permanent or temporary transformation in belief systems; and of the way cultural beliefs and norms influence accounts of disease incidence and prevalence across communities and countries.

health lifestyles

William C. Cockerham

Health lifestyles are collective patterns of health related behavior based on choices from options available to people according to their life chances (Cockerham 2000). The behaviors that are generated from these choices can have either positive or negative consequences for a person's health status, but nonetheless form an overall pattern of health practices that constitute a health oriented lifestyle. Health lifestyles are becoming an increasingly common form of social behavior given the limits of medicine in treating chronic illnesses like heart disease, cancer, and diabetes and the association of such diseases with unhealthy lifestyles. The recognition that the individual is ultimately responsible for his or her own health often promotes a healthy lifestyle.

The most common health lifestyle practices investigated by researchers are alcohol use, smoking, dietary habits, and exercise. Other practices include drug abuse, personal hygiene, rest and relaxation, automobile seatbelt use, and similar behaviors related to health. Health lifestyle practices also include contact with the medical profession for preventive care and routine checkups, but the majority of activities take place outside the health care delivery system.

Sociological theorizing about health lifestyles generally begins with Max Weber (1978). Weber did not address health practices, but focused on the relationship between lifestyles in general and social status. He found that status groups originate through a sharing of similar lifestyles. The lifestyles of status groups are based not so much on what they and the people within them produce, but on what they consume. This is because the consumption of goods and services conveys a social meaning that displays the status and social identity of the consumer. Weber's work helps us understand that health lifestyles are also a form of consumption in that the health produced is used for something, such as a longer life, work, or enhanced enjoyment of one's physical being (Cockerham 2000). Health lifestyles are also supported by an extensive consumer products industry of goods and services (e.g., running shoes, sports clothing,

diet plans, health foods, club and spa memberships) promoting consumption as an inherent feature of participation.

Weber shows that lifestyles have two major components: life choices (self direction) and life chances (the structural probabilities of realizing one's choices). Weber does not consider life chances to be a matter of pure chance; rather, they are the chances people have in life because of their social circumstances. His overall thesis is that chance is socially determined and social structures are an arrangement of chances. Therefore, lifestyles are not random behaviors unrelated to structure, but typically are deliberate choices influenced by life chances.

Weber's most important contribution to conceptualizing lifestyles is identification of the dialectical interplay of choice and chance in life style determination (Cockerham et al. 1997). Choices and the constraints of life chances work off one another to determine a distinctive life style for individuals and groups. It can be said that individuals have a range of freedom, yet not complete freedom, in choosing a lifestyle; that is, they have the freedom to choose within the social constraints that apply to their situation in life. As Zygmunt Bauman (1999) points out, individual choices in all circumstances are confined by two sets of constraints: (1) choosing from among what is available and (2) social rules or codes telling the individual the rank order and appropriateness of preferences.

Two other theorists, Anthony Giddens and Pierre Bourdieu, are also important in conceptualizing health lifestyles. Through his notion of the duality of structure, Giddens (1991) helps us understand that social structural resources in lifestyle selection can empower choices, not just constrain them. Furthermore, he observes that social situations tend to push people into choosing a particular lifestyle that connects to an orderly pattern of behavior shared with other people. His basic message is that lifestyles not only fulfill utilitarian needs, but also provide a material form to a person's self identity.

Bourdieu (1984) introduces the concept of habitus to lifestyle research that can be described as an individual's organized repertoire of perceptions that guide and evaluate behavioral choices and options. It is a mindset that produces a relatively enduring framework

of dispositions to act in particular ways and originates through socialization and experience consistent with the reality of the person's class circumstances. These dispositions generate stable and consistent lifestyle practices that typically reflect the normative structure of the prevailing social order and/or some group or class in which the individual has been socialized. The habitus produces enduring dispositions toward a lifestyle that becomes routine and when acted out regularly over time, reproduces itself. This suggests that health lifestyle practices are usually habitual modes of behavior strongly influenced by class and other social structural variables, such as age and gender.

The research literature on health lifestyles in sociology began to develop only in the 1980s. The focus in most studies is on determining differences between social classes in health lifestyle participation. Among the earliest and most influential lifestyle studies considering health practices is that of Bourdieu (1984). He constructed a model of stratified lifestyles based on differing cultural tastes in food, art, music, dress, and the like. He found that distinct class differences existed in relation to food and sports preferences and detailed how a class oriented habitus shaped these health lifestyle practices. Another early study was that of William Cockerham and his colleagues (1988), who examined similarities in health lifestyles in the US and Germany and determined how such lifestyles could spread in varying degrees across class boundaries. In Great Britain, however, Mildred Blaxter (1990) found that important differences in health lifestyles persisted between social classes and that living conditions played an important role in determining health practices. A universal finding is that people in the upper and upper middle classes tend to take better care of their health than those in the working class and lower class. Females invariably live healthier lifestyles than males. More recent research in Russia and other former socialist countries in Europe shows that unhealthy lifestyle practices (heavy drinking and smoking, high fat diets, and little or no exercise) are the primary social determinant of the significant increase in male heart disease mortality in the region (Cockerham 1999; Cockerham et al. 2002).

health locus of control

Brian P. Hinote

Health locus of control refers to the degree of control that people believe they possess over their personal health. More generally, locus of control measures indicate the degree of control (internal or external) an individual has over a particular life situation. People reflecting an internal locus of control believe that they can exert control over their environment to bring

about desirable consequences. Consequently, those possessing an internal health locus of control believe that their personal health related outcomes are for the most part determined by their own choices and behaviors. Conversely, people with an external locus of control believe that larger social forces, powerful persons or groups, or plain luck will determine their fate. Those displaying an external health locus of control consider their personal health related outcomes largely a matter of influences extending beyond their own control (Cockerham & Ritchey 1997; McGuigan 1999).

While interest in the notion of health locus of control is seen in medical sociology, the concept was initially derived from Julian Rotter's (1996) social learning theory in psychology. Most early studies investigating this topic used the scale developed by Rotter, the internal external (I/E) scale, to assess locus of control, but researchers have more recently utilized instruments like the Health Locus of Control (HLC) scale, which distinguishes between an internal or external health locus of control. However, behavioral scientists have employed a large number of locus of control scales in research spanning over the past 40–50 years (Wallston & Wallston 1978; Lefcourt 1982; Seeman & Seeman 1983; Cockerham & Ritchey 1997).

Early studies suggesting a significant correlation between locus of control and health first appeared about 40 years ago. More attention, and thus more studies, followed, and over the years investigators uncovered a number of characteristics, behaviors, and outcomes exhibiting correlations with the health locus of control measure. These findings have helped underscore the fact that the widely accepted medical model may not adequately consider the role that one's personal sense of control plays in health and illness behaviors (Seeman & Evans 1962; Seeman & Seeman 1983).

For example, social class often shows a significant correlation with this variable, with persons in lower socioeconomic strata exhibiting the strongest external health locus of control. On the other hand, individuals occupying relatively higher socioeconomic positions tend to show more signs of internal health locus of control. Indeed, such differences in health locus of control manifest themselves in the perception of illness symptoms and the use of physicians, with

the least advantaged seeing physicians more regularly for illness symptoms and the more affluent exercising more control over health and illness (Cockerham et al. 1986). In addition, persons showing higher degrees of internal control tend to express increased mastery of information in their immediate social environment, so much so that patients characterized as "internals" more actively seek out relevant information to learn more about their particular disease or diagnosis (Seeman & Evans 1962).

With regard to mental health, depression is associated with feeling as if outcomes (good, bad, or both) are beyond one's control (external locus of control), and one's sense of control, whether internal or external, reflects the circumstances of a person's social and economic status (Mirowsky & Ross 1990). More destructive health behaviors like smoking also exhibit correlations with this concept. Research suggests that young people who display characteristics consistent with an external health locus of control represent those at greatest risk to start smoking and to become chronic, long term smokers (Clarke et al. 1982). In addition, studies show that demographic characteristics like age can also correlate with health locus of control. Research indicates that between the ages of 18–50 individuals generally tend to show overall high, stable levels of perceived control, but within increasingly older age groups control appears to gradually decrease (Mirowsky 1995).

While findings may show some degree of inconsistency at times, perhaps due to differences in measurement and to interaction effects, the significance of health locus of control within medical sociology appears well established. However, this measure represents only one in a potentially complex constellation of sociological factors influencing health behavior, illness behavior, and outcomes. Regardless, the concept likely possesses a number of implications for both researchers and policymakers. For example, health locus of control measures may be utilized in evaluating health promotion campaigns. That is, developing and fostering attributes of internal control could help such programs become increasingly successful. Perhaps programs aimed at behavioral deterrence should specifically target personality characteristics consistent with externality in order to increase their overall efficacy in real world

applications (Wallston & Wallston 1978; Clarke et al. 1982).

health maintenance organization

Douglas R. Wholey and Lawton R. Burns

A health maintenance organization (HMO) is a managed care organization that integrates health insurance and delivery functions in an effort to contain costs and maximize quality. HMOs differ from indemnity health insurance, where the insurer compensates the consumer for the cost of specified services. On the continuum between indemnity health insurance and HMOs lie organizations such as preferred provider organizations (PPOs) that manage care delivery more than indemnity health insurance yet do not integrate health insurance and services.

There are five HMO types: independent practice associations (IPAs), network, group, staff, and mixed. IPAs contract with physicians in solo or small single specialty group practice. Network and group HMOs are based on physicians in multi specialty group practice: a network HMO contracts with several multi specialty groups, while a group HMO contracts with a primary multi specialty group. Staff HMOs contract with physicians as salaried employees in a multi specialty group. Mixed HMOs include physicians in both solo and multi specialty group practices. In contrast to IPAs, physicians in HMOs based on multi specialty organizations are more integrated, communicate more regularly with medical directors, and are more likely to have a joint governance structure for personnel and practice decisions (Wholey & Burns 1993).

HMOs initially developed in the 1910s and 1920s as prepaid group practices (PGPs) to provide health care services to lumber mill owners and rural farmers' cooperatives in exchange for a monthly premium. Early PGPs encountered active opposition from organized medicine, particularly the AMA. The late 1930s and 1940s saw the formation of HMOs by construction firms (e.g., Kaiser) and consumer cooperatives (Group Health Care) who sought to provide access to care for their members. HMO development at the national level began to accelerate with the passage of the HMO Act of 1973 (amended 1976) which overrode restrictive state

laws that blocked HMOs, provided some funding for start up HMOs, and allowed HMOs to require employers to offer federally qualified HMOs. The late 1980s saw rapid growth of HMOs, with growth continuing at a slower rate through the mid 1990s, and a slight contraction and industry consolidation in the late 1990s. HMO census data show 68 HMOs with 4.5 million enrollees in 1973 (Schlenker et al. 1974), 393 and 18.9 million in 1985, 582 and 53.9 million in 1995, and 424 and 70 million in 2003 (Inter Study 2004). The industry structure also changed, moving from a dominance of non profit network, group and staff HMOs to for profit IPAs.

Two factors driving the growth in HMOs were health care costs and small area variations. Escalating costs, due in part to the Medicare program, led to strong federal interest in cost containment using HMOs. Small area variations (i.e., the large variation in utilization rates between geographic regions) appeared to be due to provider practice style (Wennberg & Gittelsohn 1973). If medicine is indeed evidence based, the magnitude of these variations suggested that health care could be improved while reducing costs.

HMOs manage care by managing either enrollee or physician behavior. Enrollee behavior is managed through panel closure, benefit design, and demand management. Panel closure requires that HMO enrollees obtain services only from physicians contracting with the HMO. By channeling patients to contracted physicians, HMOs increase the dependence of the physician on the HMO, which supports the use of provider management tools. Some HMOs do offer an open ended option (typically for a higher premium and co payment) that allows enrollees to see specialists outside the HMO panel. Benefit design refers to premiums, co payments, deductibles, and covered health services (e.g., medically necessary services covered, experimental services not covered). A key point about benefit design is that the employers purchasing the HMO product, and not the HMO, typically determine what services are covered. Demand management includes activities such as consumer education to promote healthier lifestyles. In the earlier phases of their development, HMOs provided greater coverage than indemnity for well care visits, such as

physicals and immunizations, which enhance preventive care.

Physician behavior is managed in three broad ways: staffing, incentives, and health care management. Staffing refers to the decision on which providers to include on the HMOs panel. HMOs can manage costs and quality by selecting and retaining only providers who meet particular cost and quality standards. Incentives are the methods for compensating providers for providing care. Indemnity insurance pays providers on a fee for service (FFS) basis. HMOs modify this by paying a discounted FFS. Staff HMOs pay physicians on a salary basis. Capitation, perhaps the most controversial method of compensating providers, pays physicians a fixed payment per unit of time to provide a set of services (e.g., all primary care, all primary and specialty care, all primary, specialty, and hospital care) to an enrollee. Capitation shifts risk of utilization to the provider, but allows the provider to substitute nurses or physician assistants for physicians. There is inconclusive evidence whether capitation causes providers to skimp on health care provision to maximize their income.

Health care management refers to tools such as utilization review, profiling, case management, disease management, and education. Utilization review includes prospective review, such as pre-certifying hospital admissions, concurrent review, such as monitoring the progress and length of stay of patients in the hospital, and retrospective review, where patterns of health care use are monitored and profiled. Case management uses a care coordinator for patients with severe, expensive conditions. Disease management identifies patients with a particular condition, such as diabetes or congestive heart failure, and integrates services for that patient based on the evidence based guidelines. A typical goal is to reduce the use of costly services such as hospital admissions by using aggressive preventive care and patient education. Provider education is a key component of profiling and disease management.

Because HMOs seek to contain costs and improve the quality and management of care, they have the potential for adversely affecting health care delivery. A series of reviews show that HMOs and FFS do not differ significantly in quality of care and that HMOs reduce costs

by reducing use of hospitals and expensive resources (Hellinger 1998; Miller & Luft 1994, 2002) and by obtaining discounts from providers (Cutler et al. 2000). Competition among HMOs results in these savings being passed along to consumers as lower premiums (Wholey et al. 1995). However, consumer satisfaction surveys show that HMO enrollees are less satisfied than those not in HMOs with provider access and care delivery processes. Finally, although there is some research that suggests that individuals with chronic conditions may not do worse in HMOs than in other settings, the research results are heterogeneous and inconclusive.

health and medicine

Jeffrey Michael Clair and Jason Wasserman

Medical sociologists embrace a range of sociological concerns indigenous to the human condition – cultural, symbolic, personal, social, ecological, and biological. Medical sociology research can help us develop meaningful ways of thinking about the linkages between health and medicine, which involve a multitude of social factors. Health, medicine, and personhood dynamically interact through patient care. But despite this common insight, there is still much we do not know about the personal health and medicine relationship.

HISTORICAL RELATIONSHIP OF SOCIOLOGY TO HEALTH AND MEDICINE

The seed thoughts for a sociology applicable to health and medicine developed in Europe. The origins can be traced back to German physician Rudolf Virchow, who maintained that medicine was a social science and should be used to improve social conditions (Warbasse 1909, 1935; Walsh 1915; Rosen 1947, 1949, 1962, 1979; Ackerknecht 1953; Hyman 1967). Sixty years ago, medical historian Henry Sigerist (1946: 130) advocated the incorporation of a social science perspective into medical school curricula, arguing that “Social medicine is not so much a technique as rather an attitude and approach to the problems of medicine, one which I have no doubt will some day permeate the entire curriculum. This, however, will require a new type of clinical teacher and new textbooks.” While sociologists have remained underrepresented in this new type of clinical role, sociological insights could increasingly benefit medical practice.

While there is a growing awareness that few, if any, patient care decisions are purely medical, the coming together of social and medical perspectives remains elusive (Kleinman et al. 1978; Eisenberg & Kleinman 1981). Often there seems to be little correspondence between the flow of new social knowledge and its application, despite the fact that social insights and

data clearly can inform the medical clinician’s view of the problem. However, applicable findings tend to remain on the periphery of medical practice with much sociological evidence thought to be too abstract and uncertain to be helpful (Mechanic & Aiken 1986; Clair & Allman 1993).

Straus’s (1957) dichotomy of sociological work “in” and “of” medicine characterizes two approaches to medical sociology. Some sociologists have tended to be critical toward applied sociology “in” medicine work. Research design and data collection structured more to serve medical interests have sometimes not been regarded as true sociological work. As a result, training has focused on sociology “of” medicine and health, where, while still focused on the medical/health arena as a source of data, the overall aim remained committed to contribute to the development of sociological theory.

HEALTH CARE UTILIZATION: HOW PATIENTS APPROACH MEDICINE

Although we know much about the volume and cost of medical care utilization, we still have difficulty explaining cause and variation in health care utilization rates. It is unclear whether service use is based on need or other factors (Cockerham 2005). The relationship between patients’ health and their use of medical services is not necessarily direct, but related to class, race, and all sorts of social variables. Little is known about the decision making process of patients across various social contexts and the ways in which they define a set of health symptoms as requiring medical treatment.

Previous work includes only “users” of health care services when testing health care seeking patterns. This common approach can be seen as inherently problematic because it reduces relevant data and introduces severe sampling bias. It is a fair assumption that those studies focusing on only users of health services are really measuring *frequency of use* rather than the more generic issue of who is using and *not* using health services.

The vast majority of somaticized illnesses are managed almost exclusively outside institutionalized biomedical clinics (Kleinman et al. 1978). It is important to understand why large

segments of the population are seeking alternative forms of health services. We now know that Americans are embracing complementary and alternative medicine (CAM) more than ever before. Sixty eight percent of the adult population will use CAM at some point in their life (Eisenberg et al. 2001). Other studies consistently find that between 40 and 45 million American adults have used CAM within the previous 12 months (Astin 1998; Harris & Rees 2000). In 1997, Americans spent \$27 billion out of pocket on CAM visits, a total dollar amount greater than that spent on conventional care that year (Eisenberg et al. 1998).

This is a phenomenon not limited to the United States. About half the citizens of other industrialized countries also use CAM (Bodeker & Kronenberg 2002). CAM visits are an estimated 49 percent for the French (Fisher & Ward 1994), 48 percent of the Australian population (MacLennan et al. 1996), and the World Health Organization (2003) estimates traditional herbal cures account for 30 to 50 percent of all medicinal consumption in China. If the term alternative medicine is expanded to include traditional (i.e., indigenous) medicine (T/CAM), the figure rises to almost 80 percent in Africa (Bodeker & Kronenberg 2002). Clearly, alternative medicine appears to be a sizable current in the medical stream.

We can see, then, that the decision to go to a doctor with an illness is the result of an interactive process, taking place within the structural parameters of the distribution of available medical services. Factors other than need may be important in health care utilization. To routinely exclude non users (or T/CAM users) from health services utilization analyses is severely problematic.

Explanations of individual determinants of health care utilization are classified into the three major factors of predisposing, enabling, and need (illness) characteristics (Andersen 1968; Andersen & Newman 1973). The model assumes that predisposing, enabling, and illness need characteristics determine the use of health services. The predisposing variables represent individuals' inclinations to seek medical care. Predisposing characteristics exist prior to the incidence of an illness episode, and include subsets of demographic and social structural variables. An important assumption

of this model is that we should observe different patterns of health care utilization among individuals with different demographic and social structural characteristics.

The enabling characteristics reflect persons' access to social and institutional resources. The two levels of means are distinguished as family and community resources. When sufficient family and community resources exist, such as income and access to available medical care, then individuals needing health services are more likely to seek them out.

The illness need characteristics of health care utilization are the third component in the behavioral model. Even when one is predisposed and able to access medical care services, there must be some perceived (individually assessed) or functional (physician assessed) condition serving as an impetus for health care utilization to occur.

Health care utilization is the outcome component of the behavioral model, and can be classified on a continuum between discretionary and non discretionary use (Andersen 1968). At the discretionary end would be medical care use such as a dental visit. Although oral health care is vital to health and longevity, especially among older adults, dental services still tend to be an individual choice, even among those enabled to use them. The non discretionary end of the continuum represents hospitalization, based on decisions made by physicians. In the middle of the continuum would be physician visits, ranging from initial perceived need directed health care visits to more evaluative, physician directed follow up visits (see Andersen 1968; Andersen & Newman 1973; Wolinsky 1990).

Health and illness behaviors are ultimately influenced by how people think about their health. Individuals who place greater value on health potentially have different utilization patterns than those who attach less value. Indeed, individuals who have a greater confidence in their own ability to influence their health and those who are somewhat skeptical of the ability or trustworthiness of medical science are less likely to consult professionals.

There are over 40 million Americans with no health insurance. When we look at utilization research on this segment of the population, a variety of explanations are manifest. First, some

research found a pattern of underusage by the uninsured, prior to the enactment of Medicare/Medicaid programs. Explanation for this pattern suggests that the poor are skeptical of the motives of professional practitioners, lack awareness and knowledge about their symptoms, do not practice preventive care, and tend to delay seeking medical care until symptoms are quite serious. These patterns place the poor at greater risk and result in higher health care costs. This traditional pattern finds the poor underutilizing medical services despite greater need, and attributes underutilization to financial problems, a culture of poverty, and/or systems barriers, both bureaucratic and interpersonal (Clair & Allman 1993).

The alternative pattern of health care seeking behavior by uninsured patients finds that this population tends to utilize professional health services to a much greater extent than insured groups. Research by Cockerham (2005) and colleagues in a series of studies in Illinois, Germany, and the Netherlands shows that less educated, low income patients tend not to discriminate between symptoms on the basis of severity, are more likely to place responsibility for their health on physicians rather than themselves, and are relatively passive recipients of care. When ill, these poor tended to automatically visit physicians, while the more affluent were more likely to engage in self treatment or to recognize minor ailments as self limiting – likely to resolve without treatment. Earlier research in Illinois showed that blacks and the less educated had very positive attitudes about the health care system and believed that visiting doctors was the desirable course of action whenever any symptoms were present.

These two patterns of behavior are clearly influenced by the temporal context of the data. The traditional pattern of non use has tended to be eroded among the poorest poor, those who qualify for Medicaid. Public policy has increased health care access for these groups and research suggests that they now tend to overuse medical care. But the working poor, who do not qualify for Medicaid, but also cannot afford private insurance, may still practice avoidance, thereby underusing medical care. Regardless, a planned intervention could substantially correct for the hypothesized extremes in the care seeking behavior of the lower income

population. The most efficacious provision of health care services must be based on communicating successfully with both those patients who delay too long before seeking help and those who arrive too early.

BIOMEDICAL CAREGIVING: HOW MEDICINE APPROACHES PATIENTS

Knowledge and practice of medicine, and the experience of illness, reveal key aspects of how social systems of meaning and identity are structured. The study of biomedical caregiving is important because a person's health is intimately related to social behavior and has pervasive effects on the performance of social roles and matrices of interpersonal relationships.

Evidence on the effect of social support in alleviating life stress is conceptualized largely in terms of informal support from family and friends. However, the effects of formal social support, such as effective physician communication and guidance, also are important. Examining social support at both informal and formal levels provides insight on how the formal social support network affects the ability of the patient and his or her informal care network to deal with the stressful physiological and psychosocial circumstances of an illness. From this perspective, physicians, representing the health care system, can be seen as providing formal support counseling when caring for patients and their network of caregivers.

The life stress paradigm assumes that external stressors such as life events, role strains, and daily hassles, if unchecked, disrupt an individual's psychosocial equilibrium, induce physiological or psychological responses in the form of distress, and overall, challenge social resources. The premise is that psychosocial resources both alleviate existing distress and prevent or mitigate its occurrence. In addition to directly reducing distress, psychosocial resources play a primary role in mediating the detrimental effects of physiological and social stressors on the distress of both patients and caregivers (Lin et al. 1986; Clair et al. 1995). The concept of psychosocial resources should include not only personal coping and informal family and friendship support but also the *formal* support of professional health care providers.

Research on the mediation effect between life stressors, psychosocial resources, and distress is important. Such a focus can be expressed by the following propositions: (1) the frequency of undesirable life events and the daily pressures for individuals and caregivers are inversely related to social supports and psychological resources; (2) the extent and quality of an individual's informal and formal social supports and psychological resources are related inversely and directly to the extent of burden; and (3) the extent and quality of an individual's informal and formal social supports and psychological resources mediate the effects of undesirable life events and the daily pressures on burden.

Satisfaction with physician services, and the facilitation of services that extend beyond the medical mission of the clinic, are mutable conditions. Actions can be taken to improve physician-patient communication, and to expand a medical facility's domain so that a broader vision of illness and care can reduce burden on patients, family members, and/or primary caregivers.

CURRENT ISSUES AND FUTURE DIRECTIONS

Given a preponderance of health research based on self reported health measures, it would seem advisable for researchers to gain close up, first hand knowledge of issues related to health service utilization by varied subcultural groupings in society, in an effort to determine the extent to which actual health behavior correlates with these self reports. Such studies would then form the basis for generating research questions that are relevant and salient for the populations being studied.

As evidenced by informal health care behavior (e.g., T/CAM), those who utilize formal medical care are not necessarily sicker than those who do not. In fact, these two groups are indistinguishable when one compares the number and type of their symptoms. It would appear, then, that *symbolic* and *cultural* definitions of health are quite salient here. Those who manage their illnesses independent of traditional medicine may do so for a variety of reasons, one of which may entail negative experiences with, and reactions to, the idea of seeking traditional

medical care. Given the growing rate of both uninsured and underinsured persons, it is not hard to envision access to health care services becoming one of the major policy challenges of this century. Addressing issues of health care behavior and use as related to both access and differing symbolic and cultural meanings of health and illness is among the foremost future challenges for sociology.

How health information is being communicated to patients is another important social issue. Information must be presented in a way that takes into account patients' knowledge and values. Ignoring patients' broader social contexts may pose a barrier to adequate health care by creating misunderstandings about recommended treatment and prevention strategies. More importantly, patients may further aggravate their health by failing to adhere to such advice. A fuller understanding of uninsured patients' health values and beliefs, as well as health care seeking behaviors, could yield appropriate intervention data.

Further, we may expect to see increasing use of home health care services as the "baby boomer" generation ages. Efforts should be made to integrate the care regimen across formal and informal structures. For example, home care should be carefully coordinated with clinic and hospital care through centralizing patient records, with a formal health care provider taking responsibility for closely documenting what treatments and services are provided at both loci. Formal-informal service coordination is especially important for caregivers of functionally impaired patients. Home based formal support services may be the critical link to reducing burden, but such services should also enhance informal support services. Formal care providers may have to take responsibilities for what goes on outside the clinic by interjecting themselves into family support systems. For example, a care coordinator from the clinic could call a family meeting to institute a care sharing system among family members. This would reduce burden on the patient, family, and primary caregivers. Current drives for universal health care are based on the premise that traditional biocentric medicine must expand its domain to include health promotion and prevention to be effective. Similarly, the scope of services can be broadened to include meaningful assistance

to caregivers, because the patient's welfare and that of his or her caregivers go hand in hand.

Worldwide increases in the proportion of frail elderly raises a number of important questions regarding the motivations, satisfaction, and coping abilities of caregivers. Studying caregiver social networks and the appropriate responses to their needs is highly important and locating caregiving theoretically and empirically in a matrix of other roles and experiences adds substantially to our understanding of this critically important activity.

Caregivers are an especially important class of social actors in a society with an aging population, expanding health costs, and growing federal debt. Undoubtedly, individuals will be called on to do more caregiving, rather than less, in the near future. Under such circumstances, it is essential that we understand the caregiver distress process. To accomplish this difficult task, greater effort must be made to ground our knowledge of caregiving in more general psychosocial models of distress and to recognize the substantial impact of informal caregiving networks on patient care. Until this is accomplished, we cannot hope to design successful intervention programs for these critical health care providers. Instead we will remain puzzled as to why such programs have borne little fruit.

Proponents of alternative orientations toward the practice of medicine (and medical sociology) would like to see the emergence of new approaches and broadening conceptualizations of health and medicine, based on both traditional scientific methodology and new ways of knowing. To be sure, "any evaluation of sociology ought to focus not only on the way sociology is produced, but also on how it is consumed" (Merton & Wolfe 1995: 15). Sociology can be at the center of an integrative network of health and illness. However, by failing to make findings more accessible, sociologists enable health care providers to continue to view social factors as being outside their professional concern. Indeed, disciplinary jargons continue to be major obstacles (Freeman & Levine 1989). It will fall on sociologists to find ways of dealing with differences in our conceptual languages in order to infiltrate medicine and other physical and mental health settings, since invitations are not abundantly forthcoming.

health, neighborhood disadvantage

Christopher R. Browning and Kathleen A. Cagney

Although health is often seen as a product of individual or micro level determinants, researchers are increasingly recognizing the role of neighborhood context in influencing a broad range of health outcomes. The concept of "neighborhood" typically refers to a geographically contained residential space the boundaries of which may be defined ecologically (e.g., major streets or railroad tracks), administratively (e.g., census tracts), socially (e.g., with respect to neighbor networks), or symbolically (e.g., shared identification with a local space). Extant research offers evidence of a link between economic disadvantage at the neighborhood level and outcomes such as mortality, morbidity, and functional status. A number of perspectives on the mechanisms linking neighborhood structural characteristics to health have emerged. These approaches emphasize social capital, subcultural orientations, stress, and access to care and other health enhancing resources.

Neighborhood social capital and health. Social capital has been defined as aspects of social structure used by actors to facilitate the achievement of goals (Coleman 1990). We focus here on the role of social network ties and collective efficacy in promoting health at the

community level. First, the increasingly vast literature on the role of informal social network supports in fostering health at the individual or egocentric network level has generated interest in the effects of community level social network characteristics on health. Structurally disadvantaged neighborhoods may be less capable of sustaining viable social networks and may suffer from deficits in local social support and sociability. Berkman (2000) suggests, for example, that networks at the community level influence egocentric connectedness and health enhancing processes such as social support, positive influence, and sociability. Evidence of the positive effects of social support on health is overwhelming and consistent, suggesting that the prevalence of social support activity and social engagement at the neighborhood level may also be relevant for health outcomes.

An additional social capital approach highlights the capacity for action on behalf of community goals as the critical intervening mechanism linking neighborhood structure with health. Robert Sampson and his colleagues (1997) have encapsulated this process in the concept of collective efficacy, which emphasizes mutual trust and solidarity (social cohesion) and shared expectations for prosocial action (informal social control). While acknowledging that local social ties may contribute to these dimensions of community social organization, the collective efficacy approach must be seen as distinct from the neighborhood social support and sociability perspective to the extent that it emphasizes the sense of attachment to community and the willingness of community residents to intervene on each other's behalf regardless of preexisting social ties.

The pathways through which neighborhood collective efficacy may influence health include the social control of health risk behavior, access to services and amenities, the management of neighborhood physical hazards, and psychosocial processes (Browning & Cagney 2003). First, Sampson et al. (1997) have demonstrated the powerful effects of collective efficacy on rates of violence, suggesting that health may be influenced by high levels of collective efficacy through limiting the health damaging consequences of violent victimization. Other forms of problem behavior including illicit substance use, alcohol abuse, child and elder neglect/

abuse, and reckless behavior may also be held in check by high levels of collective social control. Second, collective efficacy may enhance the capacity of communities to attract and maintain high quality health services and amenities such as community health clinics and safe recreational space. Third, collective efficacy may aid in correcting or avoiding the accumulation of neighborhood physical hazards such as decaying infrastructure and housing stock. Communities with the capacity to solicit and secure external resources to correct potentially risky conditions and monitor vulnerable residents (e.g., the elderly) are likely to enhance health. Finally, the effect of widespread trust and neighborhood attachment on factors such as fear and self respect may improve the health and well being of residents – even if they do not benefit from direct network support.

Subcultural transmission and health. Subcultural perspectives on health emphasize the health consequences of emergent alternative or oppositional cultural orientations primarily in economically disadvantaged communities. Fitzpatrick and LaGory (2000) suggest that disadvantaged communities with limited access to extra local mainstream institutions may experience the emergence of “health related subcultures.” Two aspects of these subcultural orientations may have consequences for health: (1) tolerance for risky lifestyles and (2) anomie or detachment from conventional values. First, socially isolated communities are more likely to experience the cultural transmission of problematic behavioral strategies. Some of these behavioral orientations may be adaptive for survival (such as display of a “tough” or violent demeanor). However, modeling of violent and other risky behavior (such as smoking, drinking, risky sexual activity, and poor diet) in these contexts may have serious consequences for health.

Second, structural disadvantage, characterized by widespread poverty, lack of access to employment, and bleak economic prospects, may lead to anomic social conditions (Durkheim 1979 [1897]) in which neighborhood residents question basic normative orientations (e.g., the value of abiding by the law and of employing conventional means such as education and hard work to achieve success). Since the benefits of adherence to basic cultural values are perceived not to accrue to residents of some disadvantaged

neighborhoods, the force of value based prescriptions weakens in these contexts. Possible adaptations to these conditions include the emergence of largely short term, instrumental orientations toward goals marked by little concern for the future. As applied to health, this hypothesis would suggest that anomie induced, short term, “here and now” orientations emphasizing satisfaction of immediate needs will tend to be associated with health compromising behaviors.

Stress based approaches. An additional perspective focuses on the neighborhood context of exposure to stress inducing conditions. Chronic high levels of exposure to stress may tax key systems within the body (e.g., the autonomic nervous system) resulting in diminished health (a condition known as “allostatic load”). Visible signs of community decay may contribute to stress through increased fear of victimization and social withdrawal. Abandoned and boarded up buildings, vacant lots, graffiti, and other physical signs of deterioration combine with indicators of social decline such as public drinking, gang activity, and crime to convey the breakdown of social order and control, particularly among the elderly. Thompson and Krause (2000), for instance, found that neighborhood deterioration, as measured by the condition of neighborhood buildings, roads, and the respondent’s perceived level of safety from crime in the neighborhood, was positively associated with distrust and social isolation and negatively associated with physical health among older adults. Indeed, some elderly urban residents may experience such intense fear of victimization that they live in a state of “self imposed house arrest” (Dowd et al. 1981). Thus, in disadvantaged contexts, the health consequences of fear induced stress may be compounded by limited social support and physical mobility.

Access to care and other health enhancing resources. Finally, in addition to the informal aspects of neighborhood influence on health, the availability and quality of institutions that provide medical care and health relevant resources are likely to vary across the community. Access to medical care depends upon who people are and where they live (Andersen et al. 2002). Research at the interface of sociology and health services has tapped these two dimensions, namely, via research on the behavioral determinants of access to care and variation in

health outcomes across small areas. Variation at the community level may exist due to obvious differences in the number of physicians, clinics, or hospitals. It may also emerge from the community’s ability to attract and maintain health enhancing resources or from factors associated with the organization and training of physicians. For instance, physicians disproportionately practice very near their initial training site, creating “clusters” of clinical norms and practice patterns (Phelps 1992). Variation may also stem from the political level, given care for uninsured persons is driven largely by state and local policy (Cunningham & Kemper 1998). Access to care is critical for health and well being, but may have benefits beyond those to the individual – good hospitals, for instance, may enrich the community apart from the delivery of quality health care.

In summary, neighborhood structural characteristics, particularly economic advantage, may contribute to both formal and informal neighborhood level mechanisms that are consequential for health. To date, the research on the relative significance of these mechanisms – including networks, collective efficacy, social and physical disorder, and access to care – has been limited. However, data collection efforts designed to investigate these mechanisms are generating new insights into the potentially powerful role of neighborhood context in promoting, and diminishing, individual level health status.

health professions and occupations

Elianne Riska

A profession is a prestigious white collar occupation that is based on theoretical and practical knowledge and training in a particular field, such as medicine. The specialized knowledge and the restricted practice is regulated by a central body of the profession to ensure the quality and the ethical conduct of its members. These characteristics separate the profession from an occupation which is a specific type of work done in the market. For example, caring is work done both outside and inside the labor market. In the latter case it is a collective activity organized as various health occupations. Sociologists differ in their views concerning the power of the professions, the character of health occupations, and on the division of labor in medicine.

The theoretical heritage of the sociology of health professions and occupations derives

from a normative approach. Émile Durkheim saw professions as moral occupational communities in the new moral order and division of labor of the urban and industrial society. Based on this notion, Talcott Parsons (1951) defined professions in relation to a specific normative value system: the pattern variables. He viewed professions as occupational groups that had a special autonomy from the emerging bureaucracies of the modern society as depicted by Max Weber.

Special autonomy, knowledge and a service ideal towards clients were the three characteristics which defined the professions, not only as distinct from occupations, but also from the power of bureaucracies. Early research mapped the traits of occupational groups in order to identify to what extent they fitted the criteria of being a profession. This traits approach was considered too static, and a process and a power approach emerged in the 1970s.

Five major theoretical perspectives can be identified in the sociological debate about the character of health professions: the functionalist, the symbolic interactionist, the neo Marxist, the neo Weberian, and the social constructionist and poststructuralist perspectives. According to the functionalist perspective on professions, the physician's tasks are institutionalized as a social role, the function of which is the regulation of the kind of deviance interpreted as based on illness. The institutionalized roles of the physician and the sick person – the so called sick role – contain certain expectations as well as obligations concerning the behavior related to the role. The role of the physician is acquired through a period of professional socialization where both the technical knowledge and the norms guiding professional behavior are taught. The views about the character of this socialization process were covered in a classic text, *The Student Physician* (Merton et al. 1957), which was based on a normative perspective.

The symbolic interactionist perspective on medical work has its earliest representative in a study on the professional socialization of medical students by a group of sociologists at the University of Chicago (Becker et al. 1961) and in Everett Hughes's (1958) collection of essays. For Hughes, the focus of a study of any kind of occupation is the "social drama of work." In his view, most occupations bring

together people in definable roles and it is in their interaction that the content of work and occupational status are defined. An occupation is not *a priori* by means of its expertise and knowledge a profession, but a social status that is socially constructed and negotiated.

Everett Hughes's disciple Erving Goffman focused on the interaction between health professions and patients in a mental hospital and on the power and control function of the medical profession and the routine work of health care personnel. Like Hughes, Goffman (1961) perceived professions not as intrinsically distinct from occupations, but rather as a particular type of personal service occupation based on expertise. Goffman emphasizes the social role of health professions as the basis of their power and he adheres to a Durkheimian approach to deviance. Goffman's complex and often conflicting views on social roles and structure have been pointed out in recent reviews.

A third representative working within the interactionist approach is Eliot Freidson, whose monopolization thesis set the field of sociology of professions on a new path. In contrast to the consensus perspective of the dominant functionalist approach to the study of the medical profession, Freidson (1970) reviewed the pattern variables and their validity for understanding the power of physicians in the division of labor in medicine. Rather than normative consensus, Freidson suggested that, like Hughes's (1958) thesis on the license and mandate of the medical profession, a monopoly of medical knowledge underlay the power of physicians as a profession. A decade later, Freidson (1984) witnessed a change in the character of the American medical profession, but argued that the profession had accommodated to the ongoing corporatization and rationalization of medicine by means of a new internal division of labor. This is Freidson's "restratification" thesis, which states that the medical profession is divided into three groups – the academic elite, administrators, and practicing physicians – in order to maintain its order in the hierarchy of medical work. In more recent work, Freidson (2001) has returned to the issue of professionalism as a special form of occupational control and the character of the market, professions, and bureaucratic and organizational control of work.

Both Parsons's and Freidson's work were focused on the medical profession and had little to say about other health occupations and the larger division of labor in medicine. Other theoretical perspectives not only challenged the narrow focus on the medical profession, but also pointed to the need to look at the broader division of labor within medicine and its basis in the class and gender structure of the larger society.

The neo Marxist perspective relates the power of the profession to the larger underlying economic and political organization of society. According to the neo Marxist perspective on health professions and occupations, the capitalist society determines the superstructure, of which the social organization of health care, the professions, and medicine as a science are but parts (Navarro 1975). The argument here is that the same hierarchy is found in the health sector as in the rest of the capitalist economy.

All the perspectives above perceive the medical profession as united and powerful. The prophecy of a gradual loss of power of the medical profession is attributed to two other sociologists, Marie Haug and John McKinlay, who advanced the deprofessionalization and proletarianization thesis, respectively (see Freidson 1984). For Haug, the knowledge monopoly of the medical profession is challenged both by various female health professionals and clients who have increasing access to medical knowledge through the information industry. Haug's prophecy was that the prerogatives of the medical profession will wither away because professions are rapidly losing their control over their knowledge domain. McKinlay and his colleagues adopted a neo Marxist perspective: medicine is viewed as being taken over by capital intensive and large corporations, a development that will result in physicians working increasingly as salaried employees of such organizations. The "proletarianization" of physicians denotes a process that will gradually result in the loss of the traditional power of the profession. The assumption is that all physicians will lose professional power and autonomy, since the corporatization of medicine is perceived as an ongoing universal process.

According to the neo Weberian perspective, professions are occupational groups that operate in the marketplace and have been successful in demarcating the domain of their work as their

exclusionary right (Larson 1977). The neo Weberian approach to the professions emerged as a reaction to the functionalist and traits perspectives. In focus are the characteristics of medical work and the actions of the occupational group striving for a professional status and defending it through the strategy of closure. Witz (1992) has added a feminist perspective in her analysis of the power of the medical profession, nurses, and midwives in the UK and suggests that professions have always been gendered projects (i.e., the agents are either men or women).

The most recent theoretical perspective that combines the Freidsonian and the neo Weberian views on the power of professions is Andrew Abbott's (1988) systems approach to professions. Here the term "professional jurisdiction" serves as the analytical tool to explain the power of both occupations and professions in the division of labor in knowledge based work in the service sector.

The Foucauldian theory of the power of medicine (Foucault 1975) attracted in the 1990s those who wanted to understand changes taking place in the governance of health care. The conflict perspective on the medical profession presents the profession as a group exerting social control. While the social constructionist tradition viewed the medical profession as a self interested group and patients as passive, the poststructuralist position in the structure agency debate is more complex. The medicalization thesis suggests that the medical profession has crucial power in turning social phenomena into medical problems. The crude version harbors a victimization view of the patient, while the Foucauldian perspective contends that the medical discourse of the medical profession is merely one of many alternative discourses on health and medicine.

In more recent work on health professions, Foucault's notion of governmentality underlies the special role that scientific knowledge and professions have in regulating behavior. For example, a disciplinary regime of self management serves as a "technology of the self" and represents a new kind of professionalism. Self management is an internal normative mechanism whereby not only traditional professions but also new service occupations control their members.

The major theoretical perspectives on health professions have mainly focused on the medical profession. Two aspects have thereby been neglected. First, there is still little research on other health professions, such as nurses and midwives. The rise and struggle of these health professions to achieve professional status and a jurisdiction of their own have been the focus of recent studies (e.g., Witz 1992; De Vries et al. 2001). The theoretical frameworks used in these studies have been neo Weberian or Abbott's systems approach. Second, early works on health professions viewed professions as either gender neutral issues or male dominated groups. In recent research, the gender perspective has been emphasized as a way to reach a broader understanding of the character of nursing and the status of women physicians within the medical profession.

The methodological approaches in the sociology of professions have varied, but can be classified as largely qualitative methods. Aside from statistics on the number of members and their distribution within specialties and sectors in the labor market, mapping of the historical trends and the professionalization process have been based on documents (e.g., organizational records, professional journals, legislation) and interviews with informants recruited from the profession. Recent studies on the job satisfaction or workload of physicians and nurses have used survey research, although a large part of this research has been done within the disciplines of health psychology or public health rather than sociology.

health and race

Leigh A. Willis

Race interacts with health just as it does with other life determining, sociodemographic factors like class, gender, and age. Race is best understood as a shared set of cultural and social experiences common to people of the same skin color. Research has shown that the notion of distinct biological races is misleading because often more genetic variation exists within a defined "race" than between them. Therefore, we all belong to the human race and thus race is a social construction rather than a "true" biological distinction. Even though race is socially constructed (American Sociological Association 2002), the manner in which it influences social relationships suggests that race is a valid construct with "real" repercussions.

Race, for example, is often associated with health, which the World Health Organization defines as a state of physical, mental, and social well being. The relationship is important. By knowing an individual's race, that person's health lifestyle and illness behavior can frequently be predicted. Race and health interact on several levels, as seen in the health effects of racism and discrimination, class differences in health status, access to health care, doctor-patient interaction, health culture, representation in medical professions, and the racial health disparities in the United States and abroad.

There are substantial differences in health status among people of color in America and worldwide. For example, the rate of Hepatitis B is higher among Asians. Hispanics have a higher incidence of certain cancers, such as cancer of the cervix and stomach. Native Americans have high rates of alcoholism and diabetes. African Americans have an average life expectancy that is 7 years less than that of whites. So clearly there are differences in the health status of whites and non whites.

One of the ways race influences health today is through racism and discrimination. All types of racism and discrimination contribute to this problem overtly, institutionally, and covertly. There are many overt ways in which racism affects health, such as through environmental racism, which is racial discrimination in environmental policy making, enforcement of laws, and regulations (Chavis 1993). This causes a disproportionately large number of health and environmental risks for people of color in the communities in which they live. These risks come in the form of housing placed near waste dumps, living in housing with lead based paint, exposure to pesticides, and neighborhoods located in areas with contaminated land, air, and water. Environmental racism has existed for generations like other forms of racism, and is maintained by redlining, zoning, and political decision making. Increased environmental exposure to pollutants in communities of color considerably elevates the risk of its inhabitants for a variety of diseases. Covert discrimination and racism in the medical system also influences health. Even when people of color have equal access and provision for health care services, they are less likely to be treated as aggressively as whites with procedures like chemotherapy

and surgery (Jones 2000). Such treatment decisions ultimately exacerbate the health status of people of color by causing excess and premature mortality.

In order to understand the effects of racism and discrimination on health and how they influence health today, we must take into account its historical antecedents, using the concept of total discrimination. Historically, the institution of medicine was used as a basis of legitimization and justification for the oppression and disenfranchisement that non white "races" have experienced. For instance, medicine was used to justify the enslavement and subjugation of many people of color. Non whites were viewed as subhuman animals, less intelligent, and biologically inferior to whites. More specifically, medical knowledge like virology has been applied to instances of genocide of native peoples. Native Americans receiving smallpox infected blankets from Europeans is an example of these practices. In the same way, enslaved African Americans were used as human guinea pigs for medical procedures and treatments like abortion, hysterectomies, and amputation. Similarly, governments have sanctioned medical experiments on its minority citizens such as the Tuskegee Experiment (African Americans) and the South Dakota Hepatitis A Vaccine Study (Native Americans). Both of these experiments ended relatively recently, in the 1970s and 1991, respectively.

The policies of the past have translated into a pervasive distrust of the medical establishment. This distrust has influenced three outcomes: (1) an underutilization of formal medicine, (2) the utilization of formal medicine in concert with traditional cultural specific alternative means of healing, or (3) lack of participation in clinical trials. Every racial and ethnic group has its own culture specific version of folk and faith healers; among Latinos, it is the *Cuaran* *dermo*/*Cuarandersma*; for African Americans, its root workers; for Asians, its acupuncturists and herbalists; for Native Americans, bonesetters. These healers use rudimentary health practices combined with aspects of religion and mysticism. Folk and faith healers are more effective in improving the patient's mental and spiritual sense of well being than in improving physical health. Still, their contribution is not to be taken lightly given that mental well being is

directly related to immune response. Further more, these healers offer a holistic (treating the body and mind as integrated units) approach to healing that most formal healers lack.

In the same way, the use of faith and folk healers is also due in part to the under representation of people of color in health professions. The paucity of people of color among health care professions is partly due to non whites formerly being prohibited and later discouraged from entering the health professions. This is important because when patients and professionals are of different backgrounds (races) there is a greater potential for racial stereotypes, prejudice, and lack of cultural sensitivity, as well as language barriers affecting the quality of medical encounters. Therefore, some people may decide if they cannot visit a health care professional with a similar racial background, they may avoid contact with formal medicine all together. Simply, many people of color feel more comfortable with health care providers and researchers of similar backgrounds who have an understanding or appreciation of their culture.

The unwitting participation of minorities in medical experiments in which people died or were disabled severely hinders efforts to recruit and enroll people of color in present day clinical trials. Participation in clinical trials is critical to the development of cures, because clinical trials help determine if drugs are effective. Also, by participating in clinical trials participants receive new information about their disease. The under representation in clinical trials also limits the potential for drugs to be designed specifically for people of color.

Access to care is another important factor that must be considered in looking at race and health. People of color are disproportionately poor, unemployed, or employed in jobs that do not provide health insurance. Therefore, they are more likely to be without or have limited access to health care. The costs of office visits, medicines, and therapy are an onerous burden for impoverished people. Also, the location of health care facilities influences access to care when there is closure of hospitals that formerly served non white communities. Typically, non white neighborhoods often do not have adequate medical facilities located within a suitable distance and thus make health care inconvenient

for many. Also, many people of color obtain their health care through the public system of health care rather than the private system. The public system may feature long waiting periods, lack of adequate staff, and limited resources. Thus, it may not be able to provide the necessary treatment options that can impact the quality of care people of color receive. Due to the distrust of medicine, being on the receiving end of poor doctor–patient interaction, and the high cost associated with seeing a health professional, many people of color probably do not seek preventive care, such as routine physicals and screenings. Consequently, they may delay seeing a professional until their disease is in a critical or life threatening stage.

Racism also affects health on a more personal level. A term for experiencing racism is “personally mediated racism.” Personally mediated racism is defined as “prejudice and discrimination, where prejudice means differential assumptions about the abilities, motives, and intentions of others according to their race” (Jones 2000: 1214). Personally mediated racism manifests itself in day to day interactions through devaluation, suspicion, and dehumanization of people of color. Despite a greater utilization of a social support network, racism is a powerful stressor which takes a psychological and physiological toll over time. Psychologically, racism may lead to feelings of helplessness, anxiety, frustration, and nihilism (Clark et al. 1999). Physiologically, stressors like racism negatively impact cardiovascular, immune, and endocrine systems, thus leaving people of color particularly susceptible to a variety of ailments.

Besides racism, racial differences in health also result from patterns of health care utilization, genetics, and health culture. First, differences in health among races may be due to a greater reluctance of non whites to use formal medicine for the reasons specified earlier. Genetics apparently plays some role, in that certain racial groups are predisposed to certain conditions, such as sickle cell anemia among African Americans and significantly higher rates of diabetes among Native Americans.

Health culture among different “races” may also explain differences. As mentioned earlier, people of color are more likely to utilize folk and faith healers from their own culture in concert with traditional medicine. Also, they

are more likely to use a lay referral network, which is the process by which an individual consults lay people such as friends and family members to guide them in interpreting symptoms, deciding whether care is needed, and the type of care they should seek. This process may delay the seeking of professional help. In the same way, different racial groups have innate cultural means of promoting health. Some of these are the stress buffering properties of the extended family network (social support); diet (nutrition); alternative healing practices (e.g., acupuncture); and subcultural emphasis on physical and mental health (e.g., yoga). In contrast, there are aspects of culture that are detrimental to health, such as lack of oral hygiene, internalization of stressors, and lack of disclosure of health status of family, friends, and sometimes the patients themselves.

Recently, racial health disparities between races have begun to receive greater attention in the US and worldwide. In the US efforts are being made to better understand the causes of health disparities. Some areas being examined are access to care and the effects of racism, genetics, diet, and health culture. Internationally, the WHO has been examining many of these issues, such as diseases that disproportionately affect people of color, such as HIV, TB, cholera, substance abuse, and a host of chronic diseases like cardiovascular disease, cancer, and mental illness.

There are methodological issues to be considered when examining the relationship between race and health. First, since race is a social construct, it is not measured consistently across societies. For example, racial categories in health data in America are not standardized. Second, in some situations, “race is not an attribute, but a dynamic characteristic dependent on other social circumstances” (Zuberi 2000: 172). So race is a construct that is defined differently and varies by country. For instance, in Brazil “races” are organized not only by skin color, but by hair type and language. Third, there is the problem of categorizing races. For instance, in some parts of the US, health data are only divided into white and non white categories. This practice is problematic because researchers are unable to uncover key differences and report on the health of Hispanics, Asians, Native Americans, and African Americans. A standardization

of racial categories across the world is needed, though creating a racial taxonomy would be difficult and perhaps cause misunderstanding.

As citizens of the world immigrate and migrate we will see greater diversity in societies as non white populations increase. Thus, all developing and developed nations will have to grapple sooner or later with the issues raised here.

health and religion

Jeffrey Michael Clair

Concepts of health and illness in human society originated from traditional religious views about life and death. One of the first sociologists to study religion was Émile Durkheim, who found that distinctions between ideas

about the sacred and profane were connected to notions of health and illness. Religious views of the sacred body, for example, were equated with health. When someone became ill, it was not because of hygiene, but because of a breach of social norms separating the sacred from the profane. Within this type of belief system, notions of sickness and misfortune generated attempts to justify and explain morally why a particular person was suffering from disease: "Why me?" (Turner 2004).

Fundamental notions of religion and health are apparent in modern everyday life, but as scientific concepts of disease develop, traditional notions of the religious character of illness and disease continue to be challenged. Over time, the social status of biomedicine has increased and the status of traditional healers diminished. During this transformation, we see the introduction of the mind/body dualism. This dualistic focus is responsible for the emergence of mental as well as physical health concerns (Turner 2004).

Contemporary studies show that religion is positively associated with physical and mental health, as well as longevity and mortality (Hummer et al. 1999; Sherkat & Ellison 1999). Religious involvement, measured by attendance at services and feelings of religiosity, is positively associated with physical health, general happiness, and satisfaction, as well as being inversely related to undesirable social psychological states, such as depression. Ellison and Sherkat (1995: 1256) suggest that religious involvement promotes physical and mental health in four ways: (1) shaping health behaviors and lifestyles in ways that reduce unhealthy and risky behavior; (2) by contributing to the individual's social psychological resource support network; (3) by enhancing self-esteem; and (4) by helping produce cognitive coping mechanisms.

Religious institutions and beliefs have long been recognized as control agents that can regulate individual behavior. We see this influence when we talk of religious groups promoting the body as a temple and discouraging negative practices like smoking, alcohol and drug use, and unhealthy diets (Cockerham 2004). Being involved in religious communities also tends to reduce deviant behavior, making an individual accountable for his or her health lifestyles. Some religious values encourage strong marital

relationships, discouraging sexual experimentation. And religious beliefs often promote intergenerational relationships that promote shared meanings about life events and biographical histories (Ellison & Sherkat 1995).

Being involved in religious groups can also be seen as helping integrate individuals into caring social circles (Idler 1995) and therefore add to a person's psychosocial resources that mediate and/or moderate the health consequences associated with social stressors. Here, religious involvement can be seen as not only increasing the size of a person's support network, but also providing regular opportunities to cultivate support (Sherkat & Ellison 1999). Many congregations also provide formal programs for those in need, which enhances opportunities to receive needed information and social support. One result of such opportunities is that they increase an individual's confidence that friends and associates can be counted on to help in time of illness or injury. In general, being involved in such a community can promote aspects of self esteem and efficacy (Ellison & Sherkat 1995). Religion provides not only support, but also structure, stability, and intimacy in dealing with health concerns.

Religious understandings have become "common and effective coping strategies for many individuals dealing with an array of chronic and acute stressors, particularly bereavement and health problems, including physical disability" (Sherkat & Ellison 1999: 374). This is in contrast to the "muscular Christianity" that links good health with the vitality of a nation (Cockerham 2004). Those with disabilities can find religious participation helps them to refocus on aspects of the self "to which a painful, or nonfunctioning, or unattractive physical body is irrelevant" (Idler 1995: 700). Such a refocus allows the individual to find a healthy inner self and emphasize positive emotions such as contentment, love, hope, and optimism as they develop, integrate, and perpetuate their faith into everyday life. In this regard, even private religious activities (e.g., prayer, Bible reading and study) can produce an effect on health by providing meaning, which in turn reduces helplessness and increases optimism (Musick 1996). If religion is viewed as a source of comfort, the increase in individual hope provides a sense of control in a disadvantaged

world, whether that disadvantage is physical health, social, or economic (Ellison et al. 2001).

Many people from a broad spectrum of religious backgrounds hold health and well being as central spiritual concerns. Although there is evidence that spiritual, social psychological, and physical aspects of health are fundamentally interconnected, more research is needed. Post modern developments will continue to challenge the synthesis of health and spirituality. Not only has human action become functionally separated into specialized institutions, but also biomedicine has displayed a predisposition toward differentiation from other institutional spheres, such as religion and the family. And while the general population does not generally disregard the power of medicine's explanations of disease causation, many consider medical explanations to be insufficient, and find themselves embracing complementary and alternative medicine and spiritual healing movements (McGuire 1993).

Future research will need to emphasize religious factors. We know that there is at least some evidence of the physical and mental health benefits of religion among men and women, different age groups, various racial and ethnic groups, and different socioeconomic classes, as well as geographical locations (Ellison et al. 2001). However, there often exist crude measures of religious identification, involvement, and participation. Not only do we find too many single item indicators, but also mostly cross sectional data. For instance, difficult measurement issues include being able to decipher when religious value is collectively produced versus it being a private good with intrinsic value (Ellison et al. 2001). Other suggestions for future work include an analysis of "insider documents" (Ellison & Sherkat 1995: 1265) in order to determine how institutions produce, distribute, and prepare material for religious communities. Because of its multidimensionality, religious involvement displays multiple causal pathways for its effects on physical and mental health. Attention to multidimensional measurement and a commitment to longitudinal data collection are needed. Epidemiological studies of large populations with extensive baseline health assessments and longitudinal follow ups with measures of religious involvement are also required.

health risk behavior

Deborah Lupton

Health risk behavior involves actions and related attitudes and perceptions that contribute to people's propensity to engage in, or

avoid, activities that have been deemed by experts to be hazardous or dangerous to their health. Considerable research in public health and medicine has been devoted to identifying health risks and the behaviors associated with these risks in the attempt to assist people to avoid them.

The juxtaposition of the words "risk" and "behavior" often implies a psychological approach to understanding the processes by which people think about and react to risk. Cognitive science is a major approach within psychology that focuses on risk behaviors, including those related to states of health. From this perspective, people's behaviors are considered very much on an individual level. Research questions revolve around how people process information about risk and what they then do with this information. The "objective facts" of risk, as identified by scientists, medical researchers, and other experts, are considered the standard by which lay understandings are compared, and often found wanting. An individual's propensity to make inaccurate judgments about health risks is seen as based, for the most part, on ignorance, deficiency in self efficacy, or biases.

One example of this perspective is the influential health belief model. People are seen as undergoing a series of cognitive steps when processing the possible threat posed by a health risk, presenting a linear relationship between knowledge, attitudes, and eventual practice. According to this model, risk taking is an irrational and deviant act. Little attention is paid to the symbolic and emotional meanings that are associated with risk perception and risk taking. People are represented as atomized and autonomous, largely removed from the influences of society and culture.

Sociological researchers often take a rather different perspective on health risk behaviors and beliefs. They are interested in exploring the ways in which people recognize phenomena as "health risks," how people identify the relationship between risk and behavior, which kind of risks they consider most threatening, who they see as posing the risks (e.g., are the risks viewed as imposed by outsiders or are they regarded as a product of personal lifestyle choices?), how social and cultural factors such as age, gender, ethnicity, and socioeconomic

status influence health beliefs and behaviors, and what kinds of broader social and cultural meanings and beliefs are associated with health risk beliefs and understandings.

Various theoretical and methodological approaches have been taken by sociologists when researching health risk behavior and beliefs. Sociologists drawing on a critical approach based on Marxist or feminist writings focus their attention on the ways in which health risks are closely associated with social disadvantage and inequality. Rather than draw attention to an individual's personal responsibility for risks, therefore, such researchers emphasize that a person's social location is a major influence on their exposure to health risks and the opportunities they have to avoid them. People in disadvantaged areas both live in environments which are more conducive to health risk exposure, such as a subculture that supports cigarette smoking and a physical environment that is more polluted, and have less access to sources of knowledge and assistance in avoiding health risks than do those from more privileged backgrounds.

One influential sociologist, Ulrich Beck (1992), has written extensively on what he sees as the move to "risk society" in contemporary western societies. Risk society is characterized by a sensibility which is highly aware of, and concerned about, risks, including health risks. Beck is interested in the reasons why certain phenomena are singled out as "risks" and the political uses this serves. Many health risks, he argues, are seen as the result of human action, of modernizing processes that have gone too far: examples include pollution, chemical contamination of food, and epidemics of bacterial infections caused by the inappropriate use of antibiotics. Anthony Giddens's (1991) sociological writings on risk also emphasize these political aspects of risk. He particularly draws attention to lay people's growing loss of trust in experts, and the subsequent confusion they experience in knowing how best to deal with risks.

Researchers working from a social constructionist perspective are interested in the discourses, or organized ways of representing phenomena in language and practice, that surround health risks and give meaning to them. This perspective challenges the "objective facts" of risk themselves. Expert risk knowledge

is viewed as equally subject to the influence of social and cultural processes as lay knowledge. Taking this perspective is not necessarily to challenge the accuracy of expert knowledge, but rather to emphasize that it is constructed in a social and cultural environment that shapes the knowledge in various ways. What phenomena are identified as "health risks," and therefore as hazardous and important for people to avoid, is partly a function of particular social and cultural environments and associated "ways of seeing," for both lay people and experts. Thus, for example, it may be argued that the current emphasis on the risks associated with overweight and obesity in western countries is influenced by a growing anxiety in the last decades of the twentieth century and into the first years of the twenty first century about the shape and size of the body, not only in relation to health but also to physical attractiveness.

Sociologists are also interested in the ways that discourses about health risks serve to encourage people to view themselves and their bodies in certain ways. Thus, for example, the dominant popular and medical discourses surrounding health risks and cigarette smoking represent the smoker's body as vulnerable and open to serious illness, cigarette smoke itself as a contaminating substance, and smokers as ignorant or weak willed, not interested enough in their health to give up the practice. Discourses are mutable, subject to change over time. Compare the positive discourses around cigarette smoking that were evident in the mid twentieth century, which emphasized the glamor and health giving effects of cigarettes, with those described above.

For sociologists, therefore, health risk behavior is not simply an individual's autonomous response to expert advice. Health risk behavior and the beliefs that accompany it are complex products of socialization and acculturation into certain expectations, assumptions, and norms. Behavior and beliefs are intimately associated with people's place in society, and are both political and surrounded by cultural meaning.

health, self-rated

M. Christine Sneed

Self rated health, or self reported health (SRH), is a measure of a respondent's subjective sense of health. The SRH is commonly used to capture a general sense of health from the perspective of the respondent, which is assessed by one simple global question about their overall health. There are many phrasings of this question, including "In general, would you say your health is . . .," "How would you rate your overall health . . .," and "How is your health, compared with others your age?" Response items for these questions are Likert type scales with responses typically scored from 1–5 (excellent, good, fair, poor, very bad) or 1–3 (better, same, worse). Methodologically, the SRH has been found to be both a reliable and valid measure of a respondent's health status (Krause & Jay 1994; Lundberg & Manderbacka 1996; Miilunpalo et al. 1997).

The SRH question is purposely and ambiguously constructed to not specify what is meant by health. While most people tend to think of "health" as physical health, some respondents may use a frame of reference that includes emotional or mental well being. Some researchers place the SRH question at the beginning of a questionnaire so that respondents will not be influenced by later questions. Other investigators, who favor a broad definition of health, deliberately place the SRH at the end of their questionnaire so that responses can be informed by earlier questions. The thinking behind the later placement of the SRH is that if earlier questionnaire items were related to physical, emotional, or social well being, the respondent would utilize this perspective.

The SRH has for decades been used in numerous studies from around the world from many different disciplines. The popularity and wide use of the SRH are based on it being one of the most powerful predictors of health, clinical outcomes, morbidity, and mortality (Idler & Yael 1997; Fayers & Sprangers 2002; Goldman et al. 2004). Most people have an accurate idea of what their health status is and the SRH provides this measure. Therefore, the SRH question is commonly employed in health surveys. It is a common measure, for example, in large scale studies like the Canadian National Population Health Survey, the Danish National Cohort Study (DANCOS), and the US Bureau of the Census's National Health Interview Survey. It has been employed successfully in smaller studies as well (Cockerham et al. 2002; Williams & Umberson 2004).

While the SRH is a powerful and useful measurement, it is not without limitations. It is a "subjective" measure and because of this "subjectivity" there will be differences in interpretations by respondents. The extent and ramifications of differing interpretations of what is meant by health and how respondents answer the SRH are not fully understood. Different social groups may interpret health in different ways. Researchers are currently investigating such issues and there appears to be a growing body of related literature. Gender differences, for example, have been noted in several studies examining SRH as a predictor of mortality. Women tend to rate their health poorer than men, even though they have longer life expectancies (Idler 2003).

Researchers have also noted relationships between other socio demographic characteristics, SRH, and outcomes like mortality trends (Franks et al. 2003), including educational differences (Martinez Sanchez & Regidor 2002) and socioeconomic or income differences. Class differences in particular seem to have strong associations with SRH, but this finding has not been consistent in cross national comparisons (Kneesebeck et al. 2003). A variety of explanations have been used to describe such discrepancies, but there is no consensus as to why these discrepancies occur. There is, however, consensus that health is a multidimensional phenomenon that can be measured in a variety of ways, and that the SRH is a popular and widely used measure.

health and social class

Eero Lahelma

The Black Report on Inequalities in Health (Townsend & Davidson 1982) refers to social class as "segments of populations sharing broadly similar types and levels of resources, with broadly similar styles of living and (for some sociologists) some shared perception of their collective condition." Two main sociological traditions of social class attach people to social structures, emphasizing either their relationships to production, ownership, and material resources (Marx) or their relationships to markets, status, power, and lifestyle (Weber). While in the Marxist tradition class positions between the bourgeoisie and the proletariat tend to be opposite, in the Weberian tradition social classes rather follow a hierarchical stratification. However, these sociological traditions of social class share the idea of unequal distribution of resources and assets in society. Both traditions have influenced the basic medical sociological assumptions that social divisions shape morbidity and mortality, and that poor health is likely to emerge from poor living conditions (Blaxter 1997).

Sociological studies often measure classes by occupations, but education, income, and wealth equally play a part in determining people's social class, or in broader terms, socioeconomic status. Thus, the topic of social class and health encompasses hierarchical inequalities in morbidity and mortality between upper and lower socioeconomic statuses as indicated by occupations and other socioeconomic indicators.

When examining social class differences in morbidity and mortality, it has become habitual to speak about "health inequalities" (Townsend & Davidson 1982). The term inequalities indicates not only neutral health differences between segments of people, but also suggests that most social class inequalities in health are artificial, undesirable, and (in principle) avoidable. Thus, a moral and political dimension of social class and health emerges, suggesting that a large part of health inequalities in modern societies can be regarded as unjust.

INTELLECTUAL AND SOCIAL CONTEXT

The examination of health inequalities dates back to the work of British scholars from the mid seventeenth century, including John Graunt and William Petty, and later Edwin Chadwick and the German scholar Rudolf Virchow (Whitehead 1997). Within this tradition, hygienic as well as social and economic determinants of mortality and morbidity were emphasized. It is by now well known that social class inequalities in health are a universal issue, cutting across all western countries and probably equally developing countries. Health inequalities constitute a major scientific challenge for the sociological study of morbidity and mortality as well as a political challenge for public health.

The Black Report on Inequalities in Health, published in 1982, signaled a new wave of interest in social class inequalities in morbidity and mortality. In this report health inequalities were "re found," since it had been believed that, with social and economic development, "in modern western countries the relationship between social class and the prevalence of illness is certainly decreasing and most probably no longer exists" (Kadushin 1964). Since the publication of the Black Report a large number of studies worldwide have reported on persistent health inequalities.

It is recognized within medical sociology that social class inequalities in health provide keys for understanding major social causes for morbidity and mortality. In addition, the study of health inequalities provides evidence for general sociology on the significance of class and other social structural divisions for people's life chances and their well being. This is challenging evidence, since some sociologists have predicted the "death of class," implying that class divisions would give way to new divisions in society, such as those based on consumption and identity (Lee & Turner 1996). Nevertheless, the study of health inequalities shows that social class divisions continue to shape morbidity and mortality among populations.

Large hierarchical differences in morbidity and mortality between social classes persist in all countries from which evidence is available. This means that the public health challenge posed by health inequalities equally persists.

However, only slowly and in few countries have inequalities in morbidity and mortality been included in the agenda of health and welfare policies (Mackenbach & Bakker 2002). Political and moral reasons for tackling health inequalities have been raised, but successful reduction of health inequalities would not only contribute to equality and justice in society, but also to the overall level of health and life expectancy. For example, in Finland in the early 2000s the difference in life expectancy between upper non manual employees and manual workers is 7 years for men and 3.5 years for women (Valkonen et al. 2000). There are very few equally large health divides as those for social class, and lengthening the life in lower classes provides a large potential to improve the overall public health in society.

MAJOR DIMENSIONS

Social class inequalities in morbidity and mortality exist for occupational class as well as other key socioeconomic indicators, such as educational attainment, individual and household income, and wealth (Lahelma et al. 2004). These inequalities typically follow a hierarchical pattern, called the health inequalities invariance: the lower the social class, the poorer the health. Although occupational class is a key socioeconomic indicator, each socioeconomic indicator reflects partly general and partly particular aspects of the comprehensive concept of social class. Accordingly, there is no a priori paramount social class indicator, and judging from the existing body of research we are unable to say whether social class inequalities in health by one indicator are universally larger than by another. In fact, people's social class is crystallized over the life course: education being achieved first, that contributing to occupational class, and these two together contributing to income. Thus, multiple socioeconomic circumstances jointly shape the overall social class inequalities in health that people will experience.

Inequalities are also found for a broad range of health indicators, and the patterns and magnitude of inequalities may depend on the health indicator employed. Social class inequalities exist for all main causes of death, but deviations

are found, for example, for female and male cancers of the reproductive organs. For violent causes of death, inequalities among men tend to be particularly large (Valkonen et al. 2000). Social class inequalities equally exist for most domains of ill health, including subjective health and functional as well as medically confirmed conditions. For example, large and consistent inequalities are found for self rated health and physical functioning as well as many diseases. Only inequalities in mental health tend to be mixed and even reversed (i.e., mental health being somewhat poorer among upper social classes than lower classes).

A number of factors, such as age, gender, and ethnicity, are likely to modify social class inequalities in health. Inequalities in morbidity and mortality persist over the adult life and relative inequalities tend to be largest among middle aged people. However, for morbidity, there is a period of relative equalization in youth. Whether this is an artifact, or whether a true pattern exists, is not fully clear. Inequalities in morbidity and total mortality tend to be greater among men than women, since men more often die from causes in which inequalities are particularly great, such as accidents and violence, as well as cardiovascular diseases. Gender differences in inequalities in morbidity vary by domains of health, and there is a need for more accurate measurement of women's socioeconomic position. Ethnic background, furthermore, shapes health inequalities and being in a minority position tends to aggravate these inequalities (Krieger et al. 1997).

The patterns and magnitude of social class inequalities in morbidity and mortality vary between countries. According to European comparative evidence, inequalities in morbidity and mortality exist in all countries. For mortality, relative inequalities in the Scandinavian welfare states have appeared among the largest in Western Europe (Mackenbach et al. 2003). This geographic pattern for inequalities in mortality can partly be attributed to the leading cause of death (cardiovascular diseases), for which the decline has been particularly fast in the uppermost social classes. In addition to western countries, very large inequalities in mortality and morbidity among men have been found in the post communist countries, including

Russia and a number of Eastern European countries (Cockerham 1997).

Widening inequalities over time are observed for both morbidity (Kunst et al. 2005) and mortality (Mackenbach et al. 2003), and several Western European countries show widening health inequalities, with no single country showing narrowing inequalities. For morbidity, there was some stabilization in the Nordic welfare states during the 1990s.

CAUSES

So far, much descriptive evidence on social class inequalities in morbidity and mortality has been produced. However, the main intellectual challenge is a better understanding of the causes of health inequalities. Although the Black Report introduced a framework for main types of explanation in the early 1980s, only a small number of subsequent studies have examined causes for inequalities in morbidity and mortality. The explanations have repeatedly been revisited in the aftermath of the Black Report, and the main types include selection and social mobility, early and adult living conditions, health behaviors, and health care (Bartley 2004).

Selection and Social Mobility

Through intergenerational or intragenerational social mobility health directly or indirectly can contribute to social class positions. The natural selection explanation predicts that people are recruited to social classes on the basis of their (inherited) health, and therefore inequalities in morbidity and mortality may not be preventable. The social selection explanation predicts that some social factors, such as parental social class, may contribute both to people's health and their own social class. Social selection may play a role in the production of health inequalities (e.g., as people with disabilities are discriminated against in the labor market and run the risk of drifting down the social ladder). However, explanations other than those related to selection and mobility are causal in nature and predict unequal distributions of the determinants producing health inequalities between social classes.

Early Life Conditions

Unequally distributed circumstances in childhood and early life may have long lasting consequences for later life inequalities in health, either directly or through adult circumstances. For example, material living conditions (e.g., poverty) and psychosocial living conditions (e.g., parental divorce in the childhood family) may contribute to adult health inequalities.

Adult Living Conditions

Equally, in adulthood, unequal distributions of life circumstances and resources are found. Material living conditions, including poor housing and working conditions, provide causes for health inequalities between social classes. Further potential causes include psychosocial living conditions, such as stress and lack of social contacts and support, comprehensively referred to as “social capital” (Szreter & Woolcock 2004).

Health Behaviors

Smoking, excessive drinking, sedentary behavior, and an unhealthy diet all tend to enhance excess health risks among the lower social classes, and thus cause health inequalities. Smoking, in particular, is worldwide a key health compromising behavior which is likely to account for large part of inequalities in morbidity and mortality.

Health Care

Many sociologists tend to hold that health care plays a negligible role in the production of health inequalities. Although little is known about the impacts of health care on health inequalities, there are examples of specific treatments that are unequally distributed among patients, and may thus contribute to health inequalities.

While descriptive mapping of inequalities in morbidity and mortality continues where evidence is still lacking, analytic approaches are increasingly pursued to clarify the causes for health inequalities. Summarizing the existing evidence suggests that the most important groups of factors causing social class inequalities in health include past and present material

and psychosocial living conditions, as well as unhealthy behaviors. Selection and social mobility are likely to provide only limited explanations for health inequalities. Although arguments have been presented for one or another group of factors constituting the key explanation, it is by now clear that the explanations are not mutually exclusive and there is no single “hard” explanation for health inequalities. It has been debated, for example, whether childhood or adulthood, health behaviors or living conditions, material or psychosocial factors, people’s own income or income inequality in society, macro level structural and political processes or individual characteristics, will provide the key explanation. However, inequalities in morbidity and mortality are complex phenomena, and “soft” explanations should be pursued, taking simultaneously into account key groups of explanatory factors. Thus, some studies have sought to find interrelationships and pathways between the key explanatory factors; for example, whether material disadvantage enhances unequal distributions of unhealthy behaviors and these together produce health inequalities, or whether material disadvantage and health behaviors independently produce health inequalities (Laaksonen et al. 2005).

CHANGES OVER TIME

There are a number of further challenges for a better understanding of social class inequalities in morbidity and mortality which future analyses of health inequalities need to take into account.

First, changes over time should be examined more often. While it is known that health inequalities tend to widen over time, the causes for such widening need to be searched for. Second, there is international variation in the magnitude of health inequalities and the factors producing such variation between countries should be examined. Third, there are variations in health inequalities by gender and stage of life course, but the causes for these remain largely unknown. Fourth, a broad range of health outcomes shows inequalities varying in magnitude and in some cases no inequalities are found. It is poorly understood why the magnitude of health inequalities varies from large to

negligible and even to reverse inequalities. Fifth, health inequalities vary by socioeconomic indicator, such as occupational social class, education, income, and wealth. The causes for such variation, too, remain largely unknown. Even more importantly, we know very little about the interrelationships between the various dimensions of socioeconomic status in the production of health inequalities.

The last mentioned complex of issues is a particular challenge for sociologists, since social class is a key structural concept in sociology. The challenges range from postmodernist tendencies to abandon social class, to methodological and measurement issues related to health inequalities. In any case, sociological theory and empirical research on health inequalities need closer links. On the one hand, within the sociology of social class, the medical sociological evidence on persisting social class inequalities in health has played a negligible role only. On the other hand, within medical sociology, the study of social class inequalities in health has been pursued with relatively little theoretical work. Nevertheless, there are examples of Marxist, Weberian, and combined strategies, which have made efforts to apply theoretically based social class schemes in medical sociological studies (Cockerham 1997).

Although a strong current trend within medical sociology, social class inequalities in health are by no means sociologists' property only. In fact, a number of neighboring disciplines are involved, such as psychology, economics, and social epidemiology. The importance of multi-disciplinary examination is evident from the broad range of explanatory factors for inequalities in morbidity and mortality, covering economic, social structural, cultural, psychological, and biological factors. The study of health inequalities can be taken as an example of the advantages of multidisciplinary social research.

METHODOLOGICAL ISSUES

A key methodological issue includes the distinction between absolute and relative inequalities in health. Most studies on health inequalities rely on relative inequalities, indicating the proportion of people with ill health among, for example, manual workers as compared to their

non manual counterparts. Absolute inequalities, in turn, express the difference in the number of people with ill health between the manual class and the non manual class.

In the examination of causes for health inequalities, relative inequalities are preferred, while for efficient egalitarian health policies absolute inequalities are the prime target. It is important to pay more attention to this distinction in order to obtain a better understanding of the unequal patterning of morbidity and mortality. To take an example, among Swedish men, relative social class inequalities in mortality in the 1990s were at a similar level with their Irish counterparts. However, absolute inequalities in mortality between the manual class and non manual class are much smaller in Sweden, because the level of mortality among Swedish manual men is lower than that among Irish non manual men (Lundberg & Lahelma 2001).

TACKLING INEQUALITIES

Inequalities in morbidity and mortality constitute a major public health problem worldwide, and the health inequalities invariance – the lower the social class, the poorer the health – holds true even in the most advanced societies. Health has proven an area where there are no signs of universal social class hierarchies giving way to some other social divisions, and health provides a case showing continuity in social class inequalities. Therefore, health inequalities should have a high priority in the agenda of future medical sociological research, as well as national health and welfare policies.

Reducing social class inequalities in morbidity and mortality still remains largely an open question. As health inequalities are deep rooted, their prevention should start in early life. Promoting equality in society, such as equal opportunities for education, is likely to provide resources also for egalitarian health development. Specific egalitarian health and welfare policies, as well as interventions against health inequalities, have so far been scarce. Nevertheless, in the 1990s such policies and programs have been developed in several countries with the explicit aim of reducing future health inequalities (Mackenbach & Bakker 2002). While we lack compelling evidence showing

which measures would be the most efficient ones, research on the causes for health inequalities suggests a number of potential measures. These include promoting (particularly among the lower classes) better living and working conditions, as well as healthier behaviors, and avoiding discrimination against people with poor health and disabilities.

health and sport

Ivan Waddington

There is widespread acceptance of the idea that "sport is good for health." The ideology linking sport and health has a long history and the promotion and maintenance of the health of schoolchildren has long been an area of concern to physical educators in Europe and America.

The links between physical activity and good health have been endorsed in many official health publications in Britain and North America. In Britain, the Health Education Authority

(1997: 2) suggested "the health benefits of an active lifestyle for adults are well established." In the US, the Surgeon General's report, *Physical Activity and Health* (US Department of Health and Human Services 1996: 10), argued "significant health benefits can be obtained by including a moderate amount of physical activity on most, if not all, days of the week." In Canada, a discussion paper prepared for Health Canada and Active Living Canada (Donnelly & Harvey 1996) noted that a comprehensive examination of Canadian data had similarly identified several significant health benefits of physical activity. Can we conclude, then, that sport is good for one's health? Let us begin by examining the health benefits associated with physical activity.

EXERCISE, SPORT, AND HEALTH

Numerous studies indicate that moderate, rhythmic, and regular exercise has a beneficial impact on health. In the United States, the 1996 report of the US Surgeon General brought together what had been learned about physical activity and health from decades of American research. It concluded that regular physical activity is associated with lower levels of overall mortality for younger and older adults; decreased risk of cardiovascular, and especially coronary, disease; prevention or delay of onset of high blood pressure; reduction of blood pressure in people with hypertension; decreased risk of colon cancer; reduced risk of developing certain forms of diabetes; maintenance of normal muscle strength and joint structure; reduced risk of falling in older adults; lower levels of obesity; and improved mental health.

Five years after the Surgeon General's report, Britain's Department of Health (2001:1) stated there was "compelling evidence that physical activity is important for health" and listed health benefits similar to those identified in the American report. Most recently, the National Center for Chronic Disease Prevention and Health Promotion (2004) pointed out that regular physical activity substantially reduces the risk of dying of coronary heart disease (the leading cause of death in the USA) and has reiterated all the health benefits identified in the earlier reports in the US and Britain.

At first glance, studies like these might seem to indicate that the health based arguments in favor of sport and exercise are overwhelming. Donnelly and Harvey (1996: 5) have noted, tongue in cheek, that the "numerous, almost miraculous claims for the benefits of physical activity lead one to wonder why it has not been patented by an innovative company"; more seriously, they go on to point out that the wide spread nature of these claims should serve as a warning against a too easy and uncritical acceptance, and that the context of the claims needs to be carefully examined. There are indeed some important provisos to be borne in mind when considering studies on the relationship between sport, exercise, and health. In particular, it is important to note that almost all the studies cited to support the idea that sport is good for health refer not to sport, but to physical activity or exercise. Physical activity and sport are not the same thing. Physical activity or exercise might involve lifestyle activities such as walking or cycling to work, dancing, gardening, or walking upstairs instead of taking the elevator. None of these are sport. There are important differences between physical activity and exercise, on the one hand, and sport on the other. Perhaps most importantly, whereas the competitive element is not central to most forms of physical activity, sport, in contrast, is inherently competitive and is becoming increasingly so (Waddington 2000). The increased competitiveness of modern sport, together with the increased emphasis which has come to be placed on winning, mean that, unlike most people who take part in non competitive physical activities, those who play sport are, particularly at the higher levels, frequently subject to strong constraints to "play hurt," that is to continue playing while injured, "for the good of the team," with the associated health risks this behavior entails (Young et al. 1994; Roderick et al. 2000).

It is also important to remember that many sports (not just combat sports) are mock battles in which aggression and the use of physical violence are, to a greater or lesser degree, central characteristics (Dunning 1986: 270). In this context, many sports have, in present day societies, become enclaves for the expression of physical violence, not in the form of unlicensed or uncontrolled violence, but in the form of socially sanctioned violence as expressed in violently

aggressive “body contact”; indeed, in the relatively highly pacified societies of the modern West, sport is probably the main – for many people, the only – activity in which they are regularly involved in aggressive physical contact with others. As Messner (1990: 203) has noted, in the more violent contact sports, “the human body is routinely turned into a weapon to be used against other bodies, resulting in pain, serious injury, and even death.”

The link between sport, aggression, and violence provides a key to understanding why sport is a major context for the inculcation and expression of gender identities and, in particular, for the expression of traditional forms of aggressive masculinity. As Young et al. (1994) have noted, these traditional concepts of masculinity involve the idea that “real” men play sport in an intensely confrontational manner; players are expected to give and to take hard knocks, to hurt and to be hurt and, when injured, to “take it like a man”; injury thus becomes a symbol of virility and courage and, for many players and fans alike, relatively violent sports, precisely because of their violent character, are arenas *par excellence* for young men to demonstrate their masculinity.

Young (1993: 373) has noted that professional sport is a violent and hazardous work place which has its own unique forms of “industrial disease.” He adds: “No other single milieu, including the risky and labor intensive settings of miners, oil drillers, or construction site workers, can compare with the routine injuries of team sports such as football, ice hockey, soccer, rugby and the like.” In this context, one study of injuries in English soccer found that the overall risk of injury to professional footballers is 1,000 times greater than the risk of injury in other occupations normally considered high risk, such as construction and mining (Hawkins & Fuller 1999).

But risks are not confined to elite level sport. There are health costs associated with sports participation even at the mass level.

THE EPIDEMIOLOGY OF SPORTS INJURIES

A leading British research team has commented that there “is a reluctance to recognize that

increased participation in sports and exercise will also result in an increase in exercise related injuries” (Nichol et al. 1995: 232), while Hardman and Stensel (2003: 250) have noted that “the relationship between the benefits and risks associated with physical activity is not well described.”

Research indicates that sports injuries are extremely common and have to be taken into account in any attempt to assess the “health costs” and “benefits” of sport and exercise. Community studies in Europe suggest that every sixth unintentional injury is associated with leisure time physical activity, mainly sports, and that around 50 percent of people participating in team sports sustain one or more injuries over a season (Hardman & Stensel 2003: 226). At one university hospital in the Netherlands, sports injuries comprised about one fifth of all injuries treated over a 7 year period, making these the second highest cause of accidental injuries (Dekker et al. 2000). In the US, a prospective study of a physical activity intervention program (Hootman et al. 2002) found that a quarter of all participants reported at least one musculoskeletal injury, and such injuries were more likely to be reported by those participating in sports than those participating in other forms of physical activities.

Large scale, national studies of sports injuries are relatively rare, but a team from Sheffield University Medical School (Nichol et al. 1993, 1995) estimated that in England and Wales there are 19.3 million new injuries and a further 10.4 million recurrent injuries each year. The direct treatment costs of injuries were estimated at £422 million, with costs of lost production (11.5 million working days a year are lost due to sports injuries) estimated at £575 million (Nichol et al. 1993: 25, 31).

The Sheffield University researchers also sought to ascertain the direct economic costs and benefits of sports and exercise related injuries to the health care system. The health benefits of sport and exercise (e.g., avoidance of costs associated with the management of chronic illnesses) were weighed against the costs of treatment of exercise related injuries. It was found that, while there were economic benefits associated with exercise for adults aged 45 and over, for younger adults (15–44 years old), the costs avoided by the disease prevention effects

of exercise (less than £5 per person per year) were more than offset by the medical costs resulting from participation in sport and exercise (approximately £30 per person per year). Thus, for every 15–44 year old adult who regularly participates in sport, there is a net cost to the British taxpayer of £25 per year. The authors conclude “there are strong economic arguments in favour of exercise in adults aged 45 and over, but *not* in younger adults” (Nichol et al. 1993: 109; emphasis added). A Dutch study that produced similar findings to those of Nicholl et al. noted that this result “contrasts heavily with statements of people who use the supposed health effect of sport as an economic argument to promote sport” (cited in Nichol et al. 1993).

Although the data in these studies relate to injuries from both sport and exercise, the authors did note that injury risks vary markedly from one kind of physical activity to another; unsurprisingly, the highest risks are associated with contact sports and, in line with the analysis presented earlier, the Sheffield study found that the activities with the lowest risks of injury were the non contact, rhythmic (and largely non competitive) activities involved in “keep fit,” swimming, and diving.

CONCLUSION

The relationship between sport and health is by no means simple. Moderate and regular physical activity has a beneficial impact on health. However, as we move from non competitive activity to competitive sport, and from non contact to contact sports, the health costs, in the form of injuries, increase. Similarly, as we move from mass sport to elite sport, the constraints to train more intensively and to continue competing while injured also increase, with a concomitant increase in the health risks. The health related arguments in favor of regular and moderate physical activity are clear, but they are considerably less persuasive in relation to competitive, and especially contact, sport and very much less persuasive in relation to elite or professional sport.

The injury risks associated with competitive sport are increasingly being recognized by public health specialists. Significantly, almost all the examples of physical activity recommended in the 1996 Surgeon General’s report are either

lifestyle activities such as washing a car, gardening, or dancing, or non contact, rhythmic exercises such as water aerobics, jumping rope, or walking. The only competitive sports which figure in the list of recommended examples of moderate activity are playing basketball for 15–20 minutes and playing volleyball for 45 minutes; all the other major competitive sports in the US, with their associated injury risks, are conspicuous by their absence from this list of recommended healthy activities.

healthy life expectancy

Mark D. Hayward

Declining old age mortality has motivated research on the interplay between mortality, chronic disease morbidity, and disability. Do declining mortality rates signal declining morbidity and disability rates? Are the substantial gains in *life expectancy* accompanied by an increase in the expected years in good health, i.e., healthy life expectancy? Investigations of healthy life expectancy are important for anticipating an aging population's demands on health care and evaluating the effects of interventions and policy changes on both the length and quality of life.

A CONCEPTUAL FRAMEWORK

Poor health is a complex concept denoting compromised well being stemming from disability

and disease, and mental, physical, and emotional problems. Health expectancy measures are typically based on the World Health Organization's (WHO) 1980 *International Classification of Impairments, Disabilities, and Handicaps* (ICIDH) and Lois Verbrugge's and Alan Jette's (1994) disablement framework. Disablement typically begins with the onset of a chronic disease that may have a cascading effect resulting in a loss of physical or mental function. Disability results if functional problems make it difficult to perform normal social activities. The pathway is neither unidirectional nor deterministic and death can occur at any point. Changes in the social and ecological environments can alter disablement.

Under the auspices of the WHO, a life table model was developed to integrate and summarize the life cycle morbidity, disability, and mortality experiences of a population. The model allows survivorship to be decomposed into the probability of surviving without morbidity or disability, and the probability of death (see Fig. 1). The vertical axis denotes the probability of surviving to a given age without one of the health problems. The areas under the curves refer to the probability of being in a particular health state at a given age. For example, the area beneath the morbidity curve (A) represents the probability of being free of chronic disease at each age. By definition, the areas describe the person years in a life table cohort spent in each health state. Area C, for example, represents disabled person years while areas of A and B represent disability free person years.

The life table model provides the means to calculate healthy life expectancy, i.e., the expected length of time that an average individual can expect to be healthy (or unhealthy) according to some morbidity or disability criterion. The measure captures the *life cycle* burden of a health condition – i.e., the health related quality of life in relation to the overall length of life. Healthy life expectancy has been used to assess whether declines in mortality lead to a compression of morbidity and/or disability during particular time periods and whether different groups have similar overall survival but differ in terms of life cycle morbidity and disability.

Demographers' use of the life table model has produced a class of specific health expectancy

Figure 1 Hypothetical model of population health.

measures summarizing the life cycle health of a population:

- *Disease free life expectancy*: The expected number of years the average person of a given age would expect to live free of disease (or a specific disease). Although this has not been a focus of demographers, researchers have calculated the number of years lived with heart disease, dementia, and lung cancer.
- *Disability free life expectancy*: The expected number of years free of disability for persons who survived to a given age. Disability free life expectancies have been calculated for a number of countries, for the United States over the past several decades, and for race/ethnic, educational, and gender groups. Socioeconomic differentials in healthy life expectancy typically exceed differentials in life expectancy.
- *Health adjusted life expectancy*: This measure adjusts life expectancy according to weights assigned to health states. The measure is intended to identify the gap between life in perfect health and ill health. The measure has become a policy tool in evaluating the effects of interventions and international differences in disabled years. WHO estimates that disabled life is higher in poorer countries than in developed countries due to injury, blindness, paralysis, and the functional consequences of tropical diseases affecting the younger population.

MEASUREMENT AND METHODOLOGICAL ISSUES

An issue poorly addressed is the meaning of disability change. Disability is the combination of dysfunction (organ system or bodily function) *and* environmental demands on functioning. Changes in disability reports reflect differences in social and environmental support as well as changes in functioning – or adaptation. For example, marital status changes or the addition of technology can result in changes in individuals' reports of getting less help with tasks without improvements in functioning.

This problem points to the need to differentiate functional changes from environmental changes in longitudinal designs to understand how changes in healthy life expectancy occur. For example, a decline in disabled life could be a consequence of reductions in disabling diseases (e.g., cardiovascular disease), the reduction of environmental challenges, and new technology and medications. In the latter case, a reduction in disabled years is not a reflection of changes in functional problems but rather improvements in coping with functional problems.

Assessment of trends and differences in healthy life is also affected by studies' differences in life table modeling approaches. Many studies rely on a prevalence based approach called the Sullivan (1966) method, which weights the person years in a hypothetical life table cohort according to the observed proportion of persons in the population who have a

health (morbidity or disability) problem at a point in time. Prevalence captures current health experience and experiences at younger ages that have stamped the surviving population. An advantage of the Sullivan method is its straightforward data requirements – observed prevalence rates of health conditions and mortality rates for the population. Mortality rates are typically obtained from a country's statistical agency. Prevalence rates are usually obtained from cross sectional health surveys. These surveys are increasingly common internationally, inexpensive to field compared to longitudinal surveys, and yield reliable prevalence estimates.

A potential problem using the Sullivan method for examining trends in healthy life is its insensitivity to dramatic swings in disability and mortality. During periods of rapidly improving survival, the method underestimates improvements in healthy life relative to gains in survivorship.

With the availability of longitudinal data, multistate life tables are being used to model the interactions of morbidity, disability, and mortality. This approach relies on incidence rates rather than prevalence rates to model health changes with age. Incidence rates identify the probability of a change in health status. Unlike prevalence rates, incidence rates document both the onset and recovery from health conditions as well as mortality from each health state. Incidence rates used in multistate models are typically calculated for a relatively short time period (e.g., two years) for a cross section of the population. Multistate models thus produce health expectancies that summarize the years of healthy and unhealthy life for a cohort if current incidence and mortality rates remained unchanged over time.

Health expectancies calculated by the Sullivan method and the multistate model are difficult to compare because of the models' assumptions and the fact that they use different sources of data (e.g., cross sectional surveys versus panel studies). An advantage of the multistate model is that it can be used to assess the causes of changes in healthy life expectancy and the prevalence of health conditions. For example, Eileen Crimmins, Mark Hayward, and Yasuhiko Saito (1994) demonstrated how healthy life expectancy and prevalence respond to changes in the incidence rates governing

declines and improvements in health, as well as changes in health specific mortality.

Although the multistate model has desirable properties, the lack of longitudinal data for lengthy historical periods has limited its use in examining trends. Even if such data were available, the reliability of the incidence rates of health change – the usual inputs for the model – are potentially problematic because of the sparse numbers of health events at certain ages and for some groups. The implications of sample attrition for the incidence rates are also poorly understood.

SOME IMPORTANT LESSONS

Healthy life expectancy research has shown that mortality, morbidity, and disability are related but not isomorphic concepts. An individual may contract a fatal condition but not die from that cause. For some fatal conditions, individuals may live with the disease many years before death. Disability is not necessarily permanent nor does it inevitably precede death. Death is not always the evolutionary outcome of a process wherein individuals contract a fatal condition, the condition induces functional problems and disability, and, when advanced, results in death.

This complexity carries over to understanding group differences in healthy life. For example, sex affects mortality and disability in opposite directions such that women live longer than men, but they also have more disabled years. Men are more likely to die regardless of disability, but men are more likely to recover. Women are also more likely to become disabled. Other studies have documented educational differences in healthy life, showing that poorly educated persons have a higher incidence of disability, as well as higher death rates among persons without disability. Once disability occurs, educational differences in mortality are small. The end result is that education is associated with an increase of both total life and disability free life, and a compression of disabled life.

Models of healthy life are thus important to identify health trajectories consisting of morbidity, disability, and mortality. These models also are important in evaluating group differences in

healthy life and how these differences are tied to differences in morbidity, disability, and mortality. The models, in turn, help the development of theoretical models that articulate with the reasons for the interplay between morbidity, disability, and mortality.

CONCLUSIONS

Concerns about whether longer life signals better health has led to health monitoring systems and an ever expanding body of research. Health expectancy research has clarified that different components of health – disease, disability, and self perceived health – need not move in the same direction at the same time. Some components may rise during periods of falling mortality, a natural part of the epidemiologic transition. Rising disability does not necessarily signal failure of public health policies.

Health expectancy research points to a shift in the United States toward less severe disability accompanying the decline in old age mortality in recent decades. Research has begun to clarify the reasons for subgroup differences in healthy life, and life table models' descriptions of how health problems unfold in groups are useful in refining theoretical arguments underlying health disparities. Within the scientific community, researchers are engaged in debates over health expectancy methods and measures, investigating how different facets of morbidity interact and change over time. These activities are frequently collaborative, involving teams of researchers from multiple disciplines and countries.

Hegel, G. W. F. (1770–1831)

Rob Beamish

Georg Wilhelm Friedrich Hegel rose from within the liberal milieu of Protestant refugees in Württemberg to become Prussia's foremost post-Kantian, idealist philosopher in Berlin (1818–31). Hegel's major philosophical achievements were the *Phenomenology of Spirit* (1804), *Science of Logic* (1812–16), the *Encyclopedia of Philosophy* (1817), and his philosophy of history. Sociologists' interest in Hegel began with the posthumous 1930s publications of Karl Marx's 1840s manuscripts, Alexander Kojève's late 1930s lectures, and Herbert Marcuse's, Karl Löwith's, and Georg Lukács's analyses of Hegel's work.

Hegel's major sociological contributions stem first from the *Phenomenology*. Responding to the Cartesian and Kantian subject/object separation, Hegel argued that through a historical, dialectical subject/object mediation, the apparently unknowable "thing in and of itself" was revealed. Confronting the phenomenal world, consciousness became self-consciousness as mind (*Geist*) dialectically discovered self-reflexivity in the subject/object relation. An increasingly comprehensive intellectual Spirit (*Geist*) followed as a more all-inclusive Reason grasped the complex totality of reality, culminating in an Absolute form of knowledge. Phenomenological sociologists drew upon Hegel's conception of the subjective creation of meaning while Marx replaced "mental labor" with real, material labor as history's prime motive force, to reconceptualize Hegel's emphasis on historical development through conscious human action.

The *Logic*, Hegel's systematic account of dialectical method, was the methodological inspiration for Marx's critique of political economy and remains essential to genuinely understanding his method and overall critique.

Hegel's *Philosophy of Right* addressed the question of social order – now seen under changing historical conditions (placing Hegel among the first modernist, political theorists). Contrary to Rousseau, Hegel did not believe civil society could produce a fusion of individual wills – only the constitutional state, based on the principles of absolute rationality, could create a stable, historically evolving social order. Legislation could create the conditions that would allow freedom to flourish. Inspired by Greek philosophy, the *polis*, and Plato's rather than Aristotle's image of humankind as *zoon politikon* (political animal), Hegel argued that an impartial, philosophically educated civil service would act in the universal interest. Due to its largely eighteenth century traditionalism, the *Philosophy of Right* contained many of the *Republic's* shortcomings.

Hegel's political writings were never totalitarian in orientation although they were elitist; his view of the state guiding civil society was rooted in traditional conceptions of hierarchy, and although the universal grasped the complex totality of reality more comprehensively than the general, Hegel's experiences suggested universal, Absolute Knowledge was only within the grasp of a minority rather than a majority. Democratic outcomes would come from the policies of an educated, impartial, knowledgeable elite, leaving more than Marx's "inversion" of Hegel's idealism separating the two thinkers.

hegemonic masculinity

Donald P. Levy

Developed in the 1980s (Carrigan et al. 1985) to provide a relational and socially constructed conception of men and masculinities, the term hegemonic masculinity describes the hierarchical interaction between multiple masculinities and explains how some men make it appear normal and necessary that they dominate most women and other men (Connell 1987).

Hegemonic masculinity describes a position in the system of gender relations, the system itself, and the current ideology that serves to reproduce masculine domination. In presenting the term, Connell demonstrates the essentialistic, ahistorical, and normative liabilities in previous men's studies scholarship. In the concept of hegemonic masculinity Connell joins the constructivist view of "doing gender" (West & Zimmerman 1987) with insights drawn from feminist scholars who described the ways in which gender relations shape social structures (Hartsock 1983).

Connell seeks to explain how some men succeed in making it appear normal, natural, and necessary for them to enjoy power over other men and most women; why it is that so many men and women participate willingly in their own oppression; and how resistance to hegemonic masculinity can promote gender justice. Connell posits four types of masculinities, more as positions in relation to one another than as personality types: hegemonic, complicit, subordinated, and marginalized. The hegemonic position is the currently accepted male ideal within a particular culture at a particular time. As such, the hegemonic male is an ideal type (Weber 1946). Connell notes that this image changes over time and place, as well as being subject to contestation within a particular culture.

Most men fall within the second, category, complicit. These men accept and participate in the system of hegemonic masculinity so as to enjoy the material, physical, and symbolic benefits of the subordination of women and, through fantasy, experience the sense of hegemony and learn to take pleasure in it, and avoid subordination.

The relations among the four positions are hierarchical. A man in the subordinated position suffers that fate despite appearing to possess the physical attributes necessary to aspire to hegemony. Men run the risk of subordination when they do not practice gender consistent with the hegemonic system and ideology. The clearest examples are men who are openly gay. Gay men are defined in this system as not real men. They lack the legitimacy to aspire to hegemony. The many seemingly innocuous taunts of "Be a man" or "What are you, a fag?" are in reality active gender policing in which the fear of subordination, the loss of legitimacy, and the fall from complicity are actively enacted. Marginalized men are those who cannot even aspire to hegemony – most often, men of color and men with disabilities. Groups can contest marginalization when they seek authorization by making the claim: "I'm a man, too."

The second manner in which Connell uses hegemonic masculinity is to describe the current system of gender relations: current "configurations of practice" organize social relations and structures to the overall benefit of men in relation to women and of some men in relation to other men. Connell stresses that these configurations of practice take place across four dimensions: power, the division of labor, cathexis or emotional relations, and the symbolic. Connell's argument is that hegemonic masculinity as a system becomes built into social institutions so as to make it appear normal and natural for men's superordinate position to be maintained. For example, major societal institutions including government, the economy, and the family are structured so as to reinforce and reproduce male hegemony in ways ranging from structure, credentialing, and even cultural symbolic expressions. Additionally, the hierarchical relations of men with other men are expressed in both social structures as well as cultural expectations in examples such as resistance to gays in the military or the gendering of

occupations, including typically female jobs like librarian, elementary teacher, or nurse.

The third usage of hegemonic masculinity, as an ideology, provides the justification through which patriarchy is legitimated and maintained. As an ideology, hegemonic masculinity structures the manner in which all people experience and thereby know their world, although those experiences vary as both men and women are differentially situated by race, class, and sexuality. This ideology, referred to as hegemonic complicity, can be measured across four dimensions: ideal type masculinity, hierarchical ranking of self and others, subordination of women, and the subordination of woman like behavior (Levy 2005). The first dimension, ideal type masculinity, is the belief that there is a single type of masculinity that is appropriate. Different men or groups of men and women can posit a different ideal type, contesting the definition of that type, but the underlying belief in a single ideal type typifies this dimension.

Hierarchical ranking of oneself and others is perhaps the least studied component of hegemonic masculinity as an ideology. Previous scholars (Lewis 1978) spoke of competition as a restrictive component of masculinity or as a barrier to meaningful interaction. This conceptualization fails to capture the ever present intrapsychic dimension of active hierarchic assessment. Hierarchical ranking is a process in which men compare themselves and others actively and incessantly to their general or contextual ideal type.

Subordination of women and anyone or any trait perceived to be woman like includes overt and covert sexism and homophobia. Although some would argue that both overt sexism and homophobia have been in decline, the lingering or residual effects, often in the form of beliefs about men, women, and sexuality, are quite active.

The three dimensions of hegemonic masculinity as a position, a system, and an ideology can be theoretically separated while their interaction and interconnections are still recognized. Those who criticize the concept of hegemonic masculinity for confusion, reification, or elitism (Lorber 1998; Martin 1998; Whitehead 1999; Demetriou 2001) need to recognize its multiple usages and see that those allegations have merit

only if the critic refuses to consider simultaneously the three understandings of hegemonic masculinity – position, system, and ideology – or to appreciate Connell's continuing dedication to gender justice, a commitment he shares with some feminists often accused of essentialism. Connell calls for forming coalitions among those resisting the subtle but pervasive effects of hegemonic masculinity and feminists opposed to patriarchal and/or class and racial oppressions. Given the ubiquity of hegemonic masculinity as both a system of gender relations and as a justificatory ideology, resistance can be expressed politically or interactionally; that is, rather than contesting the hegemonic position, resistance seeks to alter the configuration of gender practice that reproduces the system of hegemonic masculinity.

hegemony and the media

Dave Harris

Before becoming applied to academic analysis of the media, the term “hegemony” referred more generally to indirect political control, which often replaced the need for constant and direct military or political domination, of the kind exercised by, for example, colonial states over rivals.

The concept takes on more specific implications from its use to explain forms of domination (e.g., by classes, ethnic groups, or genders) within a nation state. Mass media can be seen as having an important role in justifying the rule of dominant groups by supporting their claims to superiority, and in trying to persuade the dominated to consent to this justification. People who specialize in formulating and disseminating ideas (such as journalists, priests, public relations companies, politicians, advisers, and academics) are constantly engaged in interpreting current events and debates so as to fit dominant conceptions and categories (not always conspiratorially). As examples, a violent incident in Iraq is interpreted as further evidence of worldwide terrorist conspiracy; economic crises are blamed on outsiders or seen as inevitable; national sporting successes vindicate political systems.

Scholars associated with the Birmingham Centre for Contemporary Cultural Studies (CCCS) in the UK, and later the Open University Popular Culture Group in the UK, were particularly significant in developing the concept of hegemony as a research tool, although there are also prominent North American writers in the field, such as Giroux, Grossberg, Jhally, and Radway (see their contributions in Grossberg et al. 1992). One aspect of the project was to elaborate the work of Antonio Gramsci, an Italian Marxist working in the 1930s and 1940s. Gramsci had used the term “hegemony” to draw attention to the cultural and political dimensions of class struggle in Italy. Struggle was not only focused on industrial and parliamentary matters, but extended to regional, religious, and local issues as well. One implication he drew from this was that the working class had to unite with other oppressed factions, such as

the remaining peasantry, leading them in a cultural and political struggle with the dominant bourgeoisie, as well as using the usual tactics of industrial strikes and urban demonstrations. A successful socialist or communist revolution would impose the hegemony of the working classes on its rivals and subordinates so that the whole culture would become a socialist one.

Italian fascism combined direct force and cultural, political, and ideological argument and activity and gained mass support. It displayed an impressive flexibility and mobility, reacting quickly to emerging social, cultural, and political events and weaving them into its (underdeveloped) conceptual schemes. Gramsci's attempts to do the same for Marxist theory (but far more rigorously) led to a flexible and impressive set of concepts that departed quite significantly from previous Marxist positions and debates. In particular, the concept seemed to offer a helpful notion of "moving equilibrium" to describe how ideological dominance was continually achieved as part of a process.

A number of specific academic projects were pursued by British Gramscian writers, including analysis of political discourses such as Thatcherism, the local manifestation of the neoconservative turn in European and American politics in the 1980s. Briefly, Thatcherism had gained sufficient mass support at the ballot box thanks to its effective ideological work in knitting together various dissatisfactions, even when they were mutually exclusive – such as anxiety about social change and a promise to modernize British society (Hall & Jacques 1983). More specific analyses soon followed, in which the mass media were seen as a major player in the struggle for hegemony, doing the actual hegemonic work, and explaining emerging events and arguments in popular terms.

One such event was identified as emerging from spectacular youth subcultures in the 1970s and 1980s in Britain. British youth were wearing outlandish clothes, listening to aggressive music, choosing different sorts of recreational drugs, and developing their own distinctive set of tastes. Sometimes, this led them into open conflict, as when rival youth groups fought at seaside resorts. In general, the media (the analysis largely turned on newspapers in the early days) reacted to this challenge by attempting to demonize British youth, by

launching tirades against the "mindlessness" of the activity, or exaggerating its impact on law and order. Perhaps the most extensive analysis of this kind of activity occurs in Hall et al. (1978). Here, black youth are attacked by the press in the guise of a campaign of moral outrage about street crime: the black mugger came to symbolize all that seemed to threaten the stability of Britain in the 1970s – social change, urban unrest, youth unemployment, immigration, etc. Other writers had written about such "moral panics," but Hall et al. politicized their analysis. This particular moral panic took place at a time of a general shift towards an authoritarian solution to the unrest produced by industrial decline and social change: diverting attention towards a visible minority group would offer a popular way to justify the strengthening of the state.

Gramscian analyses of the media peaked with the publication of the Open University course on popular culture (Open University 1982), together with its series of influential textbooks and readers (see Harris 1992). They included attempts to show how current affairs programs on television were also offering a form of hegemonic discourse. Despite their apparent political neutrality, such programs were suggesting in effect that the only legitimate political conflicts took place between recognized political parties working within the dominant system of parliamentary politics. This discourse was often embodied in the physical layout of the studio discussion, with party spokespersons on either side of the set, and a neutral respected commentator in the middle, whose role it was to stress in a concluding summary the underlying virtues of democratic consensus.

Television coverage of the English FA Cup Final (soccer) sought to perform a resolution of national tensions. Particular football clubs symbolize important social divisions, typically those between northern and southern England, for example. They come together on a national occasion as sporting rivals. However, unifying national symbols are also on display in the television coverage: the entire crowd sings traditional hymns, while the commentary team does its best to remind its viewers that football as a whole is the winner, that the English are wonderfully sporting and generous towards losers, that at the end of the day fans of rival

clubs can unite in support of the national team, and so on.

Some more abstract theoretical work supported these specific examples. Hall (1977) discussed how the media produce an "ideology effect" in general. Borrowing from Poulantzas, he argued that social problems can only be described in terms of ideological categories, such as differences of age, region, "race," and so on. Social class in the Marxist sense is never acknowledged, and is hidden by these apparently obvious alternatives. Ideological categories like these then permit the sort of magical resolution discussed above – conflicts can be forgotten as the nation celebrates Christmas, for example, or seen to be reformed away. The whole analysis clearly echoes Marx's own work in exposing the inadequacies and ideological effects of the categories of liberal political economy.

These studies were also criticized. The work on black youth in particular proved controversial: it was not clear whether this work was actually justifying criminal activity as "political," for example (Cohen 1979). Other criticisms turned on the precise relevance of high powered theoretical digressions in the texts: Hall et al. (1978) engage as much in theoretical struggle with Althusserians as they do with the concrete issue of hegemonic moral panics about black crime. Frith (1984) suggests that the theoretical and political interest in spectacular confrontational youth subcultures led to a serious omission: the study of "normal youth."

Media professionals objected strongly to seeing their claims to neutrality questioned. They wanted to suggest that a good deal of creative work went into constructing a television program, and that it was not just a simple matter of using unconscious hegemonic categories. Some work undertaken from within the Open University Popular Culture Group itself expressed similar doubts. Bennett's initial analysis of the James Bond movie (Open University 1982) saw it as structured around some basic hegemonic codes stressing British claims to world importance, the need to subordinate challenging women, and the need to structure and manage desire (in Freudian terms). However, a later ethnographic study of the actual work involved in producing a Bond movie (Bennett & Woollacott 1987) found much more going on as well: attempts to adapt or parody

existing filmic conventions, to make references to other films, to include visual sequences for entertainment, to respond to a global audience, and so on. The role of the active audience was also acknowledged.

The focus on social class in early versions of the analysis led to serious challenge from feminists or black activists, on both political and theoretical grounds. Perhaps the privileged terms of Gramscian analysis were simply not adequate to grasp how sexual or ethnic minorities were depicted on modern television, implying that other concepts from different traditions were also required. Important feminist work critiqued CCCS Marxism (Coward 1977) and developed alternatives, some of them based on the rival Althusserian notion of how the media "positioned" individual subjects as gendered subjects.

The debate indicates a wider theoretical discussion going on about Marxism, and new thinking in poststructuralism and postmodernism. The privileged or "foundational" status of Marxist concepts was much debated following a series of close critical readings of Marx's key works. Perhaps the most devastating of these was delivered by Hindess and Hirst (see Crook 1991), who argued that Marxist concepts were incoherent, not consistently deployed, heavily contaminated with metaphorical reasoning, and usually applied dogmatically. In an allied attack, poststructuralists were tending to refer to Marxism as a discourse, one among many, and refusing to grant it any privileged status as offering unique access to some underlying social reality.

Gramscian notions and concepts, including the notion of hegemony, faced problems from this criticism. The notion of hegemony seemed especially vulnerable to the poststructuralist emphasis on discourse. In a nutshell, ideological conceptions were being analyzed as discourses already, but why was it necessary or desirable to add a particular Marxist political inflection to such analysis? Answers insisting on the necessary reality of underlying struggle seemed to deliver Gramscians back into facing charges of foundationalism. Gramscianism found itself in a very uncomfortable position, having to hold increasingly suspect Marxist conceptions to stave off the possibilities of rival politically undesirable theoretical systems.

Critics have identified a number of dubious maneuvers in the debates that followed. Gramscians sought salvation in incoherent terms such as “relative autonomy” (see the debate between Hirst and Hall in Hunt 1977) or oscillated tactically between the possibilities (Wood 1998). They failed to resolve perhaps the most fundamental problem of all: whether hegemonic struggle is a “real” one located in a concrete social formation, or a discursive one, located exclusively in discourses and their effects (Townshend 2004). The question remains: is the main effect of the media to construct discourses about reality (evidently true but rather trivial and obvious, since what else could they do?), or do they do so as a necessary part of a wider and real political struggle for social control (much more significant, but much less easy to establish)?

help-seeking

Bernice A. Pescosolido

Help seeking refers to efforts or actions designed to assist individuals with physical, mental, or emotional behaviors or manifestations somehow noticed as out of the ordinary. Often, this term is used interchangeably with service utilization, health care decision making, or health/illness behavior. However, a number of factors differentiate the concept of help seeking from the others.

First, help seeking is broader than service utilization, which generally taps formal, scientific medical services. Individuals may seek out lay, scientific, or alternative sources of advice or assistance perceived as potentially useful. Further, help seeking can mean going to a provider of a medical system but, just as readily, can be applied to using the Internet for information, talking to neighbors about their experience with similar conditions, buying over the counter medications, praying, or joining a self help group.

Second, the term is narrower than health/illness behavior because, technically, it refers to an active search by the parties involved. Individuals may, indeed, seek out care; however, it is also likely that individuals will experience legal coercion into the formal medical care

system. The issues of involuntary treatment for mental illness symptoms, contact by public health authorities regarding possible HIV exposure, or employees forced to use physicians for an insurance check up before starting their job, all are likely to result in the use of formal services. Further, and perhaps most troubling to some existing theories attempting to explain illness behavior, individuals may "muddle through" an experience of illness, recounting a story of entry into the formal medical care system that can be described neither as a choice nor as resistance (Pescosolido, Gardner, & Lubell 1998).

Third, help seeking is broader than decision making for medical care, at least in its most usual usage. That is, decision making tends to evoke an image of a single person weighing the costs and benefits of seeking out any of a variety of possible preventive or curative services. However, as Freidson (1970) points out, no small part of the significance of society's influence on the use of services is involved in motivating (encouraging or discouraging) an individual's movement toward assistance and giving them a sense of appropriate cultural solutions. In perceiving symptoms or the risk of a medical problem (for preventive services), or in pushing individuals toward or away from scientific or complementary, alternative services, others around the individual are crucial.

In Talcott Parsons's early, influential theory, help seeking was a non issue since modern societies required acceptance of the sick role (a community based decision) and that an individual seek formal help as part of the obligations inherent in the status. In response, several theories were developed in the 1960s and 1970s that still dominate empirical evaluations at the present time (Pescosolido & Kronenfeld 1995). The only explicit theory of help seeking was developed by David Mechanic (1968). Noting that both the process of definition of illness and the ability to cope with it are socially determined, Mechanic laid out ten determinants of the response to illness. These are: (1) the visibility, recognizability, or perceived salience of symptoms; (2) their frequency, persistence, or recurrence; (3) the perceived severity of symptoms; (4) the individual's or others' tolerance of the symptoms; (5) other belief systems or circumstances that may explain away the

symptoms as "expected" or "normal"; (6) the extent of medical or other cultural knowledge surrounding the individual; (7) other emotions (e.g., fear) that may trigger responses to the symptoms; (8) the extent to which "normal" individual or family routines are disturbed by the symptoms, as well as (9) other role obligations that may facilitate or impede the ability to go to or be taken to services; and (10) issues of access, whether geographical, financial, or logistical.

These factors are reflected in three other models that currently dominate the study of individual or population use of formal services. The Health Belief Model (HBM), targeting health behavior or prevention, was conceived originally by psychologist Irwin Rosenstock and developed further by sociologist Marshall Becker (1974). This model emphasizes perceptions, beliefs, and other social psychological characteristics that influence whether individuals feel at risk for problems and position themselves to change health behaviors and to utilize health care services. The Socio Behavioral Model (SBM), targeting illness behavior and overall use of medical and health care, was developed by sociologist Ronald Andersen (1974) and emphasizes three types of contingencies: enabling characteristics (or access, whether perceived or actual, geographic or fiscal), need (hurt, bother, and worry associated with symptoms), and predisposing characteristics (social and other characteristics like age and gender consistently related to utilization). The Theory of Reasoned Action, developed in psychology by Martin Fishbein (1979), was designed to address behavior more generally, but has been applied to health, illness, and disability issues. Here, the focus is on the factors that influence behavioral intentions because individuals rationally assess information or beliefs about the planned behavior. It is a combination of the individual's own attitudes about the intended behavior as well as the individual's perceptions of social norms that shape the person's subjected probability of "performing" the "target" behavior (for a catalogue of these and another models, see Gochman 1997).

In opposition to these models, which tend to be static in nature, other sociologists and anthropologists have focused on tracing the process of help seeking, calling this approach

the "illness career" perspective. These sociologists, coming primarily from the qualitative tradition, offer a textured recounting of the events and emotions leading up to decisions to use formal services (for a review, see Pescosolido 1991). More recently, the Network Episode Model has been offered as an attempt to bridge the differences between these two approaches, capturing their essential insights and reflecting new realities that face individuals in contemporary societies (e.g., decreasing reliance on tertiary care). The NEM is focused on the "illness or disability career" which marks all of an individual's attempts to cope with the onset of an episode of a health or physical impairment or associated acute illness. It requires charting what individuals do and when they do it through the concepts of patterns and pathways. Patterns of care describe the combination of advisers and/or practices used during the course of coping with a disability or illness episode. Pathways add the element of order; that is, the sequences of advisers and/or practices used to deal with a disability or confront an acute episode of health problems during the disability career.

In the NEM the underlying mechanism is interaction or social influence. The NEM starts with a basic idea: dealing with any health problem or physical disability is a social process that is managed through the contacts (or social networks) that individuals have in the community, the treatment system, and social service agencies (including support groups, churches, community recreation centers, etc.). The experience of illness is embedded in its social life and rhythms, constrained by social structure, and created in negotiation with others. While dominant models have not ignored networks, it is quite different to conceptualize social networks as yet another contingency of choice (e.g., part of normative influence in the HSM and TRA), or to conceptualize social networks as the engine of action in a dynamic model of utilization. Unlike the explicit or implicit rational man assumptions underlying the other dominant models, in the NEM individuals are seen as pragmatic, having commonsense knowledge and cultural routines that they draw from past experience, from proactively talking to others, and from reactively responding to the comments of others when impairments, or other health problems associated with them, occur.

It questions whether every action in coping with a behavior outside the ordinary is the result of the complicated, cost benefit calculus typical of many other models. This view allows for rational choice, forced choice, or even haplessness to explain how individuals try to deal with their problems. But, in general, people face disabilities in the course of their day to day lives by interacting with other people who may recognize (or deny) a problem; send them to (or provide) treatment; and support, cajole, or nag them about appointments, medications, or life style.

Whatever the patterns or pathways, illness careers are not assumed to occur in a vacuum in the NEM. They are embedded in personal lives and changing communities. These community based networks are referred to as "external" networks. Following Freidson (1970), the NEM sees the size of a network as calibrating the potential amount of influence that can be leveraged, and the beliefs and experiences of individuals in social networks guiding them in a particular direction (e.g., toward or away from scientific medical care services). Further, the NEM conceptualizes the medical system itself as a changing set of providers and organizations with which individuals may or may not have contact ("internal" or "inside" networks). Like the community and the disability career, formal treatment systems change over time in response to the problems people have, to the technology and medical knowledge, to health care policies, and to community preferences and demands. These structures determine resource and information flows across systems and organizations, and they influence the behavior of individuals who are connected to or operate within them. These two network systems meet at the interface of the treatment and community system and can work together and cooperate or work in opposition. By seeing interaction in social networks as the underlying mechanism at work, the NEM contextualizes the response to disabilities in everyday life.

Taking a dynamic approach, rooted in the community and its institutions of care, and incorporating ideas from other existing models, poses a number of challenges in understanding help seeking. Such investigations of help seeking require more theoretical, methodological, and analytic work. In addition to

integrating more of the insights of dominant social science models, sociological approaches will have to incorporate new ideas about cognition, biology, psychiatry, and geography, for example, into its models. Moving to a more dynamic approach should bring other concepts from recent developments in the understanding of the life course. Social science methodologists have only begun to consider and develop suitable dynamic tools in the last decade. Further, moving to a more integrated approach will require serious theorizing about linking process and structures. Again, we are only beginning to consider how to integrate results from how one set of social and dynamic processes influences others. However, faced with current failures to explain critical aspects of help seeking, the synthesizing approach of sociology has much to offer in addressing these challenges.

hermeneutics

Wendy Hilton Morrow and Austin Harrington

Hermeneutics is a branch of sociology concerned with human understanding and interpretation. Originally applied solely to texts, sociologists have applied hermeneutics to social events by examining participants' understandings of the events from the standpoint of their specific historical and cultural context. Hermeneutics is opposed to the view that social phenomena can be grasped adequately by reference to invariant laws of cause and effect or statistical regularities, as with positivist and behaviorist approaches and some elements of functionalist theory. Hermeneutics is one among a range of approaches to meaning, symbolization, and representation in social life that includes semiotics, structuralism, deconstruction, and discourse analysis.

The term hermeneutics derives from the Greek verb *hermeneuein* ("to interpret"), thereby relating to the ancient Greek messenger of the gods, Hermes. His role was more complex than that of mere messenger because before Hermes could translate and communicate the words of the gods (which were unintelligible to humans), he first had to interpret and understand their meanings for himself. This complex process is key to theories of hermeneutics, in which texts are understood as intermediaries between writers and audiences. In particular, hermeneutics initially focused on interpreting the Bible in order to understand the word of God.

Among German Protestant writers of the seventeenth and eighteenth centuries, hermeneutics referred to the art of interpreting

scripture in the light of philological evidence. Writing during the early nineteenth century within the Romantic movement, theologian and philosopher Friedrich Schleiermacher favored broadening the focus of hermeneutics, seeking a theory of interpretation that extended beyond religious texts. His writings influenced future work in that he understood the author as creator and the text as an expression of the creative self. Earlier traditions of hermeneutics theorized that a reader would understand intended meanings of a text until encountering incongruous or illogical passages. However, Schleiermacher proposed a radically different position in which understanding was taken as a process in which readers understand the text's context, including the author's creative individuality, the text's particular genre, and its historical circumstances.

Schleiermacher's most lasting contribution to hermeneutics was the concept of the hermeneutic circle, which he understood to operate at every level of interpretation. According to the theory of the hermeneutic circle, a reader can only understand a part within its relation to the larger whole; however, the larger whole can only be understood through its contributing parts. Therefore, readers find themselves oscillating between the part and the whole within this inescapable process of interpretation. For example, readers cannot know the meaning of a word without framing it within the context of the larger sentence. Likewise, they cannot understand the significance of a sentence without the context of the entire work. However, an understanding of the work is based upon its accumulated parts, as well as a context of the author's life and the culture as a whole in which it was created. Therefore, circularity exists across and between all levels of interpretation.

As subsequent theorists applied Schleiermacher's work to other areas of study, hermeneutics flourished in German academia. In modern social thought the first thinker to develop a distinctively hermeneutic program was philosopher and cultural historian Wilhelm Dilthey. Writing in the 1880s, Dilthey extended Schleiermacher's theory of interpretation to the human sciences, which studied all human expressions in disciplines ranging from archeology and history to sociology and anthropology. In an attempt to differentiate between the

natural sciences and the "human sciences," or what he termed the *Geisteswissenschaften*, Dilthey claimed that whereas the natural sciences seek *erklären*, the explanation of phenomena according to laws of regular correspondence between cause and effect, the goal of the human sciences is *verstehen*, the understanding of human action based on intention and context. To interpret a historical event or social process in terms of meaningfully lived experience was itself to account adequately for its occurrence and did not require the support of law like naturalistic generalizations to gain scientific validity. For Weber, Dilthey's ideas underlined the importance of "empathic understanding" and "subjectively intended meanings" and the fallacy of attempts to model social action exclusively on behavioral or psychological laws, such as in the writings of Auguste Comte, J. S. Mill, Herbert Spencer, and the classical political economists.

A second key source for hermeneutics is twentieth century phenomenological and linguistic philosophy. In the 1920s and 1930s Edmund Husserl and Martin Heidegger argued that before human beings come to develop methodical scientific representations of the world, they possess a more primordial existential understanding of the world which they express in everyday life and ordinary communication. These ideas became important notably for Alfred Schütz, who restated Weber's interpretive sociology in the form of a phenomenology of the social world, based on the concepts of intersubjectivity and the lifeworld. Similarly, in the 1950s, drawing on Ludwig Wittgenstein's linguistic philosophy, Peter Winch (1958) argued that social science had the aim of studying social relations in terms of "forms of life" constructed in linguistic rules and "language games" shared between speakers. Conceived of as an attempt to understand the most appropriate way to study human life, hermeneutics became focused largely on method.

German philosopher Hans Georg Gadamer challenged the assumption that understanding was a methodological issue. Gadamer was greatly influenced by philosopher Martin Heidegger's ontological concerns, including his idea that readers bring presuppositions to their understandings of a text. Gadamer hoped to separate the human sciences from prior influences, like

Dilthey and Wittgenstein, that he believed failed to fully reject the scientific presuppositions of positivism. In his 1975 book *Truth and Knowledge* Gadamer proposed that knowledge could never be objective, and, therefore, social theorists were incapable of fully escaping their preexisting prejudices. They can however be brought to a state of reflective awareness by means of what Gadamer calls a “fusion of horizons” between the standpoint of the interpreter and the standpoint of the other culture.

In the 1960s and 1970s Gadamer’s philosophy was criticised by Jürgen Habermas on grounds of failure to address issues of power, ideology, and material conflict in social life. Habermas (1988) argued that hermeneutics raises a false claim to universality when it overlooks the imbrication of linguistic communication with relations of domination. He argued that Gadamer’s and other hermeneutic philosophies need to be emended to incorporate critical assessment of the rationality of social practices in a non relativistic framework. Habermas compared hermeneutics to Marxian ideology critique and Freudian psychoanalysis. He argued that as Marx showed how ideologies can disguise oppressive social class relations, so Freud showed how all psychological interpretation is necessarily guided toward emancipation of the patient from irrational repressions.

Writers such as Ricoeur (1981) and Taylor (1985) have criticized Habermas’s position for ignoring the sense in which both ideology critique and Freudian psychoanalysis are themselves situated in specifically western post Enlightenment contexts of thought and therefore reflect specific pre judgments of their own. In general, however, Habermas’s arguments point to some notable limits around the scope of hermeneutics in social theory. In a similar spirit, other critics such as Roy Bhaskar, Anthony Giddens, and Pierre Bourdieu have argued that hermeneutics is informative only when it does not collapse material, economic, and systemic factors in social life into purely “mental” or “subjective” elements. In this sense, hermeneutics does not obviate the requirements of realist epistemology in social science. It demonstrates that all ideas of social reality depend on interpretation, but it does not show that social reality is reducible to interpretation, or that all causal relations in social life

can be encompassed purely in terms of aspects of meaning or symbolization.

In addition to influencing current sociological thought, the hermeneutic tradition’s attention to textuality and interpretation informs related scholarship in a range of academic disciplines, including philosophy and rhetoric.

heterosexual imaginary

Chrys Ingraham

Culture installs meaning in our lives from the very first moment we enter the social world. Our sexual orientation or sexual identity is defined by the symbolic order of that world through the use of verbal as well as nonverbal language. How we come to understand what it means to be heterosexual is a product of a culture’s symbolic

order and its organizing practices. Heterosexuality as a *social* category is much more than the fact of one's sexual or affectional attractions. What we think of when we talk about heterosexuality or refer to ourselves as heterosexual is a product of a society's meaning making processes. In reality, heterosexuality operates as a highly organized social institution that varies across culture, history, region, religion, ethnicity, nationality, race, lifespan, social class, and ability.

The task of examining this highly pervasive and taken for granted social arrangement requires a conceptual framework capable of revealing how heterosexuality has become institutionalized, naturalized, and normalized. Any attempt to examine the institution of heterosexuality and its incumbent meanings requires a theory and methodology capable of inquiring into its naturalized operation and pervasive social practices (e.g., dating, proms, weddings, Valentine's Day, online dating services, etc.).

French psychoanalyst Jacques Lacan's concept of the imaginary is especially useful for this purpose. According to Lacan, the imaginary is the unmediated contact an infant has to its own image and its connection with its mother. Instead of facing a complicated, conflictual, and contradictory world, the infant experiences the illusion of tranquility, plenitude, and fullness. In other words, infants experience a sense of oneness with their primary caretaker. Louis Althusser, a French philosopher, borrowed Lacan's notion of the imaginary for his neo-Marxist theory of ideology, defining ideology as "the imaginary relationship of individuals to their real conditions of existence" (Althusser 1971: 52). The "imaginary" here does not mean "false" or "pretend" but, rather, an imagined or illusory relationship between an individual and their social world. Applied to a social theory of heterosexuality, the *heterosexual imaginary* is that way of thinking that relies on romantic and sacred notions of heterosexuality in order to create and maintain the illusion of well being and oneness. This romantic view prevents us from seeing how institutionalized heterosexuality actually works to organize gender while preserving racial, class, and sexual hierarchies. The effect of this illusory depiction of reality is that heterosexuality is taken for granted and

unquestioned while gender is understood as something people are socialized into or learn. The heterosexual imaginary naturalizes male to female social relations, rituals, and organized practices and conceals the operation of heterosexuality in structuring gender across race, class, and sexuality. This way of seeing closes off any critical analysis of heterosexuality as an organizing institution and the ends it serves (Ingraham 1994, 1999). By leaving heterosexuality unexamined as an institution we do not explore how it is learned, what it keeps in place, and the interests it serves in the way it is currently practiced. Through the use of the heterosexual imaginary, we hold up the institution of heterosexuality as timeless, devoid of historical variation, and as "just the way it is" while creating social practices that reinforce the illusion that as long as one complies with this prevailing and naturalized structure, all will be right in the world. This illusion is commonly known as romance. Romancing heterosexuality is creating an illusory heterosexuality.

The lived reality of institutionalized heterosexuality is, however, not typically tranquil or safe. The consequences the heterosexual imaginary produces include, for example, marital rape, domestic violence, pay inequities, racism, gay bashing, femicide, and sexual harassment. Institutionalized heterosexuality and its organizing ideology – the heterosexual imaginary – establishes those behaviors we ascribe to men and women – gender – while keeping in place or producing a history of contradictory and unequal social relations. The production of a division of labor that results in unpaid domestic work, inequalities of pay and opportunity, or the privileging of married couples in the dissemination of insurance benefits are examples of this.

Above all, the heterosexual imaginary naturalizes the regulation of sexuality through the institution of marriage and state domestic relations laws. These laws, among others, set the terms for taxation, health care, and housing benefits on the basis of marital status. Rarely challenged – except by nineteenth century marriage reformers and early second wave feminists – laws and public and private sector policies use marriage as the primary requirement for

social and economic benefits and access rather than distributing resources on some other basis, such as citizenship or ability to breathe, for example.

A related concept useful for the study of the heterosexual imaginary and of institutionalized heterosexuality is heteronormativity. This is the view that institutionalized heterosexuality constitutes the standard for legitimate and expected social and sexual relations. Heteronormativity represents one of the main premises underlying the heterosexual imaginary, again ensuring that the organization of heterosexuality in everything from gender to weddings to marital status is held up as both a model and as "normal." Consider, for instance, the ways many surveys or intake questionnaires ask respondents to check off their marital status as either married, divorced, separated, widowed, single, or, in some cases, never married. Not only are these categories presented as significant indices of social identity, they are offered as the only options, implying that the organization of identity in relation to marriage is universal and not in need of explanation.

The sociological importance of the theory of heterosexual imaginary is in its usefulness in researching issues related to gender and sexuality. Integrating this concept into sociological study holds enormous promise for placing a check and balance on a researcher's standpoint, thus ensuring a more objective outcome.

heterosexuality

Stevi Jackson

Before we can even discuss heterosexuality, we need some terminology clarification. The words "sex" and "sexual" can be used to refer to the erotic (e.g., "having sex," "sexual fantasies") or to denote differences between men and women (as in "the two sexes" or "the sexual division of labor"). This semantic confusion reflects some of the taken for granted assumptions underpinning everyday understandings of sexuality: that to be born with a particular set of genitals ("sex organs") defines one as a member of a particular "sex" (male or female) and as destined to be erotically ("sexually") attracted to and to "have sex" with the other "sex." The introduction of the concept of gender, which emphasized the social character of the division between women and men, and the emergence of social constructionist perspectives on sexuality have made it possible to demystify the relationship between genitals, gender, and heterosexuality. Some confusion, however, persists in that some theorists continue to use "sex" to denote what sociologists generally term "gender." In what follows, unless otherwise stated, gender refers to all aspects of the division and distinction between women and men, while the words sex, sexual, and sexuality are reserved for erotic aspects of life.

The term heterosexuality, as it is used in everyday language, denotes sexual attraction to and relationships between differently gendered individuals. In this sense it is a mode of erotic interaction between women and men. From a sociological perspective, however, heterosexuality entails more than merely a sexual practice or preference: it is deeply embedded in wider social relations and practices, institutionalized as the "normal" form of human sexual relationship and as the basis of marriage, family, and kinship relationships. It is recognized by the state through laws and practices governing welfare, taxation, inheritance, and other spheres of governance affecting families. Heterosexuality is inextricably interrelated with gender: it is defined by and helps perpetuate the division of society into two gender categories. Many

aspects of gender division and inequality are associated with heterosexuality. For example, the domestic division of labor and the gap between wages earned by men and women are products of a social order where adults are expected to live in heterosexual couples in which men are the main breadwinners. One of the main foci of studies of heterosexuality, therefore, has been its relationship with gender. The other has been its normative and privileged status, which has marginalized those who do not conform and served to legitimate the stigmatization of gay men and lesbians – historically often with brutal effect.

Heterosexuality might seem to be a human universal, but it is also historically and culturally variable in form. Heterosexual unions can be polygamous or monogamous, based on personal choice or founded on arrangements between kin, and have coexisted at times with socially approved homoerotic and homosocial bonds. Heterosexuality cannot therefore be assumed to have the same meaning or the same place in all societies at all times. Moreover, heterosexuality itself has a history: the concept was coined in the nineteenth century, along with “homosexuality,” in order to differentiate what was deemed “normal” from what was deemed “perverse.”

The term heterosexuality is less often used in everyday language than “homosexuality,” largely because it is simply the taken for granted norm. It is thus an “unmarked” term, one privileged through remaining unsaid. Heterosexual people are generally not expected to identify themselves as such, are rarely called upon to justify or explain their sexuality. Until the last few decades of the twentieth century sociologists largely shared this commonsense view. Thus, while many aspects of heterosexual relations, such as marriage, families, and kinship, had become objects of sociological enquiry, heterosexuality itself was assumed rather than analyzed, taken as given rather than being subjected to critical scrutiny.

During the late 1960s and early 1970s, with changes within sociology and in the wider social and political climate, heterosexual relations began to be questioned. Social constructionism gained ground within sociology, making more critical perspectives on heterosexuality possible. In their classic text, *Sexual Conduct* (1973), John Gagnon and William Simon argued that human

sexuality, far from being ordained by nature, was the product of social scripts. Sociologists working on deviance redefined it as a product of the social rules that defined the boundaries of conventionality and the social processes whereby individuals were labeled deviant. The implications of these perspectives were that heterosexuality was no more natural than homosexuality, the boundary between them was a social construct rather than a natural given, and that heterosexuality was “normal” only by virtue of social definition. A new generation of sociologists, influenced by the rise of gay liberation and second wave feminism, began to draw on these and other radical perspectives to develop critiques of male dominated heterosexual institutions and practices. Gay scholars such as Mike Brake (1976) began to name the heterosexual family as a source of exclusion and oppression, while feminists defined these same family structures as central to women’s subordination. Feminists also began to question the assumption of “natural” differences between men and women and therefore the idea of a natural mutual attraction between “opposite sexes” destined to complement each other in conjugal unions.

From the early 1970s feminist scholars and researchers began documenting sources of women’s discontent within heterosexual relationships, although they did not always identify heterosexuality as the object of critique. Where specifically sexual practices were concerned, feminists challenged the denial of sexual pleasure and agency to women on the one hand and, on the other, sexual coercion and violence. In arguing for women’s sexual autonomy feminists not only attacked the double standard of morality, but also questioned the definition and ordering of “the sex act” itself. Following Anne Koedt’s widely cited article “The Myth of the Vaginal Orgasm” (1972), feminists argued that equating sex with penetrative vaginal intercourse (prioritizing male orgasm while relegating acts producing female orgasm to the status of “foreplay”) constituted a male defined view of sex – though only a few noted that it was equally heterosexually defined. Feminists also paid considerable attention to sexual coercion and violence, making connections between being pressured into unwanted sex, everyday sexual harassment, and rape. Rape was seen as

a reflection of everyday sexual mores, a product of the social construction of male sexuality as an unstoppable force expressed through pursuit and conquest of women. Moreover, fear of rape was identified as a form of social control, limiting women's freedom of movement and legitimating their appropriation by one man in order to protect them from others. Even here, though, heterosexuality per se remained unproblematic. For example, Brownmiller's (1975) classic and encyclopedic analysis of rape never wavered from the assumption of a universally heterosexual world.

At the same time, considerable attention was given to marriage, the linchpin of institutionalized heterosexuality. Through the 1970s and early 1980s a great deal of research accumulated on power and economic dependence within marriage and especially on housework and the domestic division of labor. From the mid 1970s some feminists began to make an explicit connection with heterosexuality. Charlotte Brunch, for example pointed out that "heterosexuality upholds the home, housework, the family as both a personal and economic unit." Most analyses of domestic labor in North America and the UK, however, were oriented to debates on its utility for capitalism, precluding a focus on the heterosexual contract within which this labor took place.

In France, however, a different approach was being elaborated by a group of radical materialist feminists organized around the journal *Questions féministes* who, in the first issue of their journal published in 1979, made explicit the connection between the social construction of the categories "men" and "women" and the divide between heterosexuality and homosexuality. This group included Christine Delphy, who analyzed marriage as a relationship founded on men's appropriation of women's labor, and Colette Guillaumin, who analyzed male domination in terms of the individual and collective appropriation of women's bodies and labor. Drawing on these ideas, Monique Wittig published a series of articles between 1976 and 1981 in which she elaborates on an analysis of the category of sex (the socially constructed division between women and men) as "the product of a heterosexual society in which men appropriate for themselves the reproduction and production of women and their physical persons by means

of ... the marriage contract" (Wittig 1992: 6). She argues that women and men are defined by virtue of their location within the heterosexual contract and likens lesbians, as fugitives from this contract, to runaway slaves and contends that since "woman" has no meaning outside heterosexual systems of thought, lesbians "are not women" (p. 32).

Another founding text of this time was Adrienne Rich's "Compulsory Heterosexuality and Lesbian Existence" (1980). Like Wittig, Rich contested heterosexuality's privileged status as an unquestioned norm. She argued that rather than being natural it was imposed upon women through the erasure of lesbian existence from history and by a range of social practices that constrained women into personal subjection to men. Compulsory heterosexuality thus kept women *in*, within its confines, and kept them *down*, subordinate. Whereas Wittig had argued that lesbians are not women, Rich suggested that all women were potentially lesbians. Rather than emphasizing the differences between lesbian and heterosexual women, Rich argued that all forms of sociality and solidarity among women were part of a lesbian continuum.

Wittig and Rich were both writing at a time when radical or political lesbianism was becoming an increasingly vocal political tendency within feminism on both sides of the Atlantic. Groups such as the New York Radicalesbians and later, in the UK, the Leeds Revolutionary feminists saw lesbianism as a form of resistance to patriarchy and heterosexual feminism as holding back the cause of women's liberation. While Wittig's work was more in tune with this perspective, Rich's was seen as insufficiently radical in allowing heterosexual feminists to consider themselves part of a lesbian continuum while they continued to consort with men (Jeffreys 1990). The concept of compulsory heterosexuality, however, has stood the test of time and continues, alongside some of Wittig's insights, to inform contemporary debates.

During the 1980s feminist discussions of heterosexuality became more muted, as debates shifted to new terrain. Competing perspectives on heterosexuality, however, remained an undercurrent in the heated exchanges between libertarian and anti violence feminists. The former focused on the rigid morality of straight society and thus on heterosexuality's normative

status. Rubin (1984), for example, analyzed the climate of “sex negativity” that resulted in the penalization of all forms of sexuality that lay outside the “charmed circle” of heterosexual monogamy. The latter saw heterosexual relations as a locus of male domination. Thus, Catherine MacKinnon argued that gender was the product of men’s appropriation of women’s sexuality. Two quite separate lines of critique were emerging – of heteronormativity and of heterosexuality’s interrelationship with gender hierarchy – which were to inform the debates of the 1990s.

At the same time, new perspectives on sexuality were emerging following the English publication of the first volume of Michel Foucault’s *The History of Sexuality*. Foucault’s (1979) approach to power as primarily productive rather than repressive and his analytical focus on the discursive constitution of objects of knowledge facilitated a rethinking of the heterosexual/homosexual distinction. From a Foucauldian perspective these concepts did not come into being in order to name preexisting categories; rather, they brought those categories into being. Whereas in previous eras it was particular sexual conduct that was policed, with particular acts condemned or outlawed, in the late nineteenth century categories of sexual persons were created – it became possible, as Foucault said, to *be* a homosexual. A corollary of this is that heterosexuality does not define a pre-given norm, but creates it – that far from being a natural state, heterosexuality is a historical construct, an invention (Katz 1995). Foucault’s arguments were to inform a new perspective that emerged in the 1990s – queer theory – which was also influenced more generally by postmodern thinking and by such writers as Lacan and Derrida.

Queer theory is not easy to define and some contest the utility of the term, but it has become a convenient shorthand for approaches that seek in some way to trouble heterosexuality, to destabilize the boundaries between heterosexuality and homosexuality and to interrogate the binaries of gay/straight and man/woman. Queer theory’s critique of heterosexuality tends to focus on its normative status, but also questions its stability, revealing the ways in which it depends upon its excluded “other” in order to secure its boundaries. Here sexuality is

seen as fluid and contingent and neither heterosexual nor homosexual identities are assumed to be fixed or unitary (Seidman 1997). While queer theory developed from rather different preoccupations from feminism, there was considerable overlap with feminist critique. Both questioned the inevitability and naturalness of heterosexuality and both, to some extent at least, linked the binary divide of gender with that between heterosexuality and homosexuality. This is probably most evident in the early work of Judith Butler, which is often identified as both feminist and queer. The object of her critique is the heterosexual matrix, the regulatory fictions that link sex, gender, and heterosexuality together as a seemingly natural, compulsory order, producing gender as an effect of compulsory heterosexuality. Butler’s radical denaturalization of gender and of the heterosexual/homosexual binary owes much to Wittig’s analysis, but reinterpreted through postmodern theory with the emphasis on bringing gender and sexual identities into question rather than on gender as a form of social inequality. As a result of this emphasis, even feminist variants of queer theory tend to focus on heteronormativity, saying rather little about what goes on *within* heterosexual relations.

Other feminists, however, continued to be concerned with relationships within heterosexuality. The rise of queer theory in the 1990s coincided with a revival of feminist work on heterosexuality, developing and reformulating earlier analyses of its intersection with gender. Rather than treating heterosexuality as a monolithic entity, feminists began to analyze its different facets, considering heterosexuality as institution and identity and in terms of everyday experience and practice (Richardson 1996; Jackson 1999). In so doing they recovered earlier feminist insights, pointing out that heterosexuality was not simply a form of sexual desire and conduct, but of the wider social relations between women and men. In the domestic arena, therefore, heterosexuality was as much about who washed and ironed the sheets as what went on between them (Jackson 1999). Hence, attention was refocused on the gendered character of heterosexuality while, at the same time, making evident the heterosexual character of gender relations. In a key article, “The Heterosexual Imaginary,” Chrys Ingraham argued that

since gender concerns relations between men and women, it is fundamentally ordered by heterosexuality.

These new feminist analyses facilitated a separation of the critique of heterosexuality as an institution from heterosexual identity, experience, and practice. It is now possible to discuss the potential pleasures of heterosexual sex as well as its constraints and to analyze the ways in which heterosexuality is implicated in the perpetuation of a male dominated social order without being critical of individual women for *being* heterosexual. Heterosexual identity can then be analyzed as differing for women and men, but also as often being not an identity as such at all, but a means of validating other aspects of feminine and masculine identities – in asymmetrically gendered ways. For example, first heterosexual is often seen as “making a boy a man,” but not making a girl a woman (Holland et al. 1996). Focusing on actual everyday heterosexual experiences and practices enables sociologists to explore persistent inequalities in heterosexuality, while also taking account of its variability; to consider heterosexual sexuality, but to link it with wider aspects of gendered, heterosexual social relations. For example, recent empirical research has found that despite greater sexual freedom, aspirations towards gender equality, and women’s greater social and economic autonomy, heterosexual sex remains male dominated. Young women, in particular, find it difficult to achieve a sense of sexual agency (Tolman 2002). One group of researchers have suggested that heterosexual sex is not governed by the tensions between masculinity and femininity – it is *masculinity* that regulates the sexuality of both young men and young women (Holland et al. 1998). Such research suggests that, despite the late modern rhetoric of female sexual autonomy and pleasure, women still discipline themselves to conform to an idea of sexuality that prioritizes men’s desires. This parallels other aspects of heterosexual relationship where women continue to do the bulk of the emotional and physical work that maintains the heterosexual couple as a going concern.

The debates of the 1990s have given critical perspectives on heterosexuality a higher profile within social theory and social research. This is

most evident in approaches to sexuality, where studies of heterosexuality can no longer masquerade as studies of sexuality in general. Heterosexuality is routinely named as such, treated as only one form of sexuality, its normative status subject to scrutiny rather than taken as given. In studies of gender, too, heterosexuality is less often merely assumed. Sociologists working on family life are now more likely to be aware of diversity of sexual relations as one of many aspects of family diversity and therefore less likely to take heterosexuality as given. In the wider social and political arena heterosexuality’s privileged status is now more openly contested within debates on gay and lesbian rights, especially with respect to the issue of gay and lesbian marriage or civil partnerships. Yet, in everyday life, despite advances in the rights of lesbians and gays in many countries, heterosexuality’s normative status is rarely questioned.

hidden curriculum

Laura Hamilton and Brian Powell

The hidden curriculum refers to the unofficial rules, routines, and structures of schools through which students learn behaviors, values, beliefs, and attitudes. Elements of the hidden curriculum do not appear in schools' written goals, formal lesson plans, or learning objectives although they may reflect culturally dominant social values and ideas about what schools should teach. Of the three major approaches to the hidden curriculum, the functionalist orientation is most concerned with how hidden curricula reproduce unified societies, the conflict perspective focuses on the reproduction of stratified societies, and symbolic interactionism more fully incorporates interactional context to our understanding of the hidden curriculum.

Because of its focus on education as a tool in maintaining orderly societies and producing appropriately socialized individuals, functionalist works are often collected under the label of consensus theory. Consensus theory depicts schools as benign institutions that rationally sort and order individuals in order to fill high and low status positions, meeting society's need for both experts and low skilled workers. As a concept, the hidden curriculum has its roots in Émile Durkheim's *Education and Sociology* (1922) and *Moral Education* (1925). Durkheim concluded that society could not function without a high degree of homogeneity and that education, as a highly regulated institution, could provide this level of similarity. Drawing upon Durkheim's work, Philip Jackson in *Life in Classrooms* (1968) coined the term "hidden curriculum." Along with other consensualist theorists of that period, he noted that British and American schools teach children to sacrifice autonomy, control, and attention to those with more power, repress their own personal identity and desires, and accept the legitimacy of being treated as a category along with others.

Although the concept of the hidden curriculum originated in the functionalist works of Durkheim, conflict theorists further developed theoretical concepts of the hidden curriculum. In general, conflict theorists argue that education serves to preserve the social class structure. Early challenges to the functionalist approach came from Neo Marxist theorists who suggested that schooling serves the demands of more powerful social institutions and groups. In their influential work *Schooling in Capitalist America*, Samuel Bowles and Herbert Gintis (1976) contended that students are educated in ways that make them suitable for varying levels of ownership, autonomy, and control in the capitalist system. They learn skills, develop a consciousness, and internalize norms that suit their future work. This connection between the social relations of school life and the social relations of production was labeled the correspondence principle. Theories that rely on the correspondence principle are also known as reproduction theories, as they explain how education reproduces social inequalities.

Reproduction theories, however, faced criticism in the early 1980s as some conflict theorists pushed for a less deterministic view of

education's role in maintaining the class system. In *Learning to Labor*, Paul Willis (1981) introduced the concept of resistance to reproduction theories. He found that the working class English boys in his study resisted both the official and hidden curriculums of their secondary schools. Although resistance had the effect of channeling the boys into working class futures, the idea of resistance loosened the rigid theoretical approach to the hidden curriculum. The concept of resistance allowed conflict theorists to see the hidden curriculum as contestable and perhaps malleable.

Similar to the conflict approach, symbolic interactionists who address the hidden curriculum see education as sorting students by their ascribed characteristics into stratified social positions. However, the symbolic interactionist approach shifts the focal point to a micro level, looking at how face to face interactions in the classroom contribute to the creation and maintenance of inequalities. Symbolic interactionists are most concerned with how classroom dynamics create patterned advantages and disadvantages and how academic interactions mold students' personalities, skills, and behaviors.

Early work in the symbolic interactionist tradition noted that certain students are labeled as "good learners" while others are seen as "troublemakers" and that these labels often corresponded to a student's race, class, or gender. Regardless of their previous ability level, negatively labeled students are more likely to perform poorly while positively labeled students are more likely to perform well. The labeling process therefore creates what Merton called the self fulfilling prophecy; students internalize the labels assigned to them and learn to behave in ways that match their labels. More recent work in the symbolic interactionist tradition has extended the focus from labeling to examine other ways in which teachers mold students' bodies, behaviors, and attitudes. They also recognize the importance of peer interactions, the physical environment, and teachers' interactions with each other and the administration.

While the functionalist approach assumes a consensual relationship between schools and societies, both the conflict and symbolic interactionist approaches see educational processes as creating and perpetuating social inequalities. These two approaches illustrate how class, race,

and gender identities are produced and how these markers are used to privilege some students over others. Nevertheless, scholars disagree over the extent to which class, race, and gender differences are intensified as a result of the hidden curriculum. This dissensus is due in part to the variability of hidden curricula over time, place, location, and interaction context and in part to the difficulty of studying and measuring a curriculum that is not explicitly stated.

Some scholars posit that the hidden curricula carry powerful class – based and race – based messages. Pierre Bourdieu and Basil Bernstein, for example, suggest that schools also create social environments that better match with the class backgrounds of middle and upper class students. Through the hidden curriculum, students get the message that middle and upper class cultural values, norms, and attitudes are the standard by which all else is measured. Schools reward conformity to these cultural norms and certify certain methods of learning as the standard. These learning methods are likely to better match middle and upper class styles of interaction and penalize lower or working class students. Physical spaces can also be marked by class, making some students more at home than others. The marking of space is particularly salient at higher levels of schooling: the physical environments in institutions that produce elite members of society such as law or medical schools are often tailored to the cultural norms and tastes of the advantaged.

To the extent that the hidden, and formal, curriculum is geared to the white majority, it is possible that the hidden curriculum inadvertently encourages, in the words of John Ogbu, an "oppositional culture." He argued that racial minorities with a history of enslavement, conquest, or colonization come to see academic achievement and participation in the dominant culture as a threat to group identity and loyalty. Oppositional culture can be considered part of the hidden curriculum as involuntary minorities learn through school that academic success is "acting white." The theory of oppositional culture, however, has been challenged by Douglas Downey and James Ainsworth Darnell among others who find that minorities place just as much if not more value on academic success than do their white peers and that

oppositional culture is a class not race based phenomenon.

Some scholars contend that the hidden curriculum – again in tandem with the formal curriculum – creates and supports gender differentiation. Some scholars have noted that starting in kindergarten, teachers use gender dichotomies that mark and make gender difference salient, using gender groupings to address students, separate them, and create adversarial groups in competitions. There is also some evidence that teachers respond differently to girls and boys. For example, some studies indicate that since boys are often more disruptive than girls in elementary classroom, they are given greater positive and negative attention while girls are left to their own devices. Teacher practices also may affect how girls and boys learn to move in their bodies, teaching girls to take up less space, react passively to threats, regulate movements and speech at higher levels, and place greater value on body adornment than boys. Other scholars have suggested that teachers' beliefs regarding sex differences in math, science, and verbal aptitude may influence their teaching practices and in turn students' performance and interest in different topics. In addition, the content of textbooks and lesson plans in which males are more represented than are females arguably may shape boys and girls' views regarding their own abilities as well as their ambitions.

Research on gender and the hidden curriculum has indicated that peer culture is one of the most influential ways in which gendered behaviors are encouraged and perpetuated. Early on, children also segregate by gender, maintaining cross gender boundaries through romantic teasing. Studies indicate that boys achieve high status in middle and secondary schools on the basis of their athletic ability, coolness, toughness, social skills, and success in cross gender relationships while girls gain popularity because of their parents' socioeconomic status, their own physical appearance, and social skills. These values also may be transmitted through extra curricular activities, most notably the greater financial support typically given to male sports.

Social markers such as class, race, and gender are not only salient within the hidden curricula of education systems. They also reflect forms of hierarchy and differentiation that exist

in other societal institutions. In fact, what the orists now see as the hidden curriculum of social control in the United States was once part of the explicit mission of education. This curriculum only became "hidden" as discussion of education shifted to increasingly individualistic terms. Although scholarship of the past few decades has unearthed this hidden curriculum, we still know little about how hidden curricula enter, change, and move out of schools. Moreover, other institutions (e.g., family, medicine, religion, and economy) intersect and shape both the formal and informal curricula of schools. Studying how the hidden curriculum is embedded within these contexts could lead to more informative and potentially transforming scholarship.

hierarchical linear models

J. Kyle Roberts

The history of hierarchical linear modeling (also called multilevel modeling) can be linked to the seminal work of Robinson (1950) in recognizing contextual effects. The theory that

Robinson illustrated is also sometimes referred to as the “frog/pond” theory and bears discussion here. Suppose that a biologist has two frogs lying on an examination table that both weigh 500 grams and are both 1 year old. Consider further that Frog A was drawn from Pond A where it was the largest 1 year old frog in the pond, and Frog B was drawn from Pond B where it was the smallest 1 year old frog in the pond. The possible disregard of the contextual effect of the frogs’ habitat could lead to some erroneous conclusions about frog development if the two frogs were considered outside of the pond from which they were drawn.

Placing this same contextual argument in educational terms, let us suppose that a researcher is interested in monitoring reading proficiency among students within New Mexico’s schools. In testing differences among the schools, the researcher might use an analysis of variance (or ANOVA) to test for differences between mean reading proficiency scores across schools. As was noted with the frog/pond illustration, doing so would neglect the fact that some of the schools closer to the border of Mexico might have a larger number of non English speaking students. Neglecting this structure might lead a researcher to assume that a school is doing poorly in reading education, when in fact that school might be doing a superb job given the make up of students that attend that school.

The strength of the hierarchical linear model (HLM) is that it capitalizes on these contextual effects and models data analysis such that the effect of grouping structures can be included as an integral component of the analysis. Since hierarchical linear modeling may be regarded as an extension of the general linear model (GLM), it subsumes most statistical techniques like ANOVA (see above), analysis of covariance (ANCOVA; comparing group means on a dependent variable after controlling for a covariate), multivariate analysis of variance (MANOVA; comparing group means on multiple dependent variables), regression, and canonical correlation. The advantage of HLM over simple regression or ANOVA is that it allows the researcher to look at hierarchically structured data and interpret results without ignoring these structures.

The structure of data within an HLM design is relatively straightforward. Sometimes referred

to as nesting, the structure of an HLM data set is defined when data at the lowest level of the hierarchy are organized inside higher levels that are considered to determine the context of the lower level responses. Consider the following examples of hierarchical data sets: students nested within classrooms, students nested within schools, students nested within classrooms nested within schools (3 levels), people nested within districts nested within states, measurement occasions nested within subjects (repeated measures), students cross classified by school and neighborhood, students having multiple membership within schools across time (longitudinal data), and children nested inside families. Each of these examples illustrates data that are considered hierarchical in structure. Data derived from such hierarchical designs may be correlated based on the context from which they are drawn, and any subsequent analysis must take this into account.

The structure of a hierarchical linear model looks surprisingly similar to a regression format. Let us suppose that we have a data set in which we are trying to predict the amount of delinquency in children based on student GPAs. If we were to consider this model in a normal regression setting, we would simply place all of our students in a single data set and then make generalities about the relative contribution of GPA in explaining child delinquency. As any good sociologist knows, this model could have surprisingly different outcomes based on the type of school in which the data are collected. Let us use the state of Texas as a test case. In rural west Texas, it would be surprising to find any relationship between GPA and delinquency. With graduating classes sometimes approaching the teens, generally all of the students of the same age in these small rural towns are involved in the same activities and would have similar levels of delinquency (if delinquency can even be measured in these areas). Contrast this school to an inner city low SES school in one of the four large metropolitan areas in Texas. In this school, it may well be that student GPA is a very good predictor of child delinquency. Although this is probably not the most robust of analyses, it does help prove a point: the ability of HLM to consider context could prove paramount in studies where social settings differ between samples.

So just how does HLM do this? Answering this question would take multiple volumes, and is not the point of this entry. However, a quick answer is merited. Conceptually, HLM honors the nesting structure of a data set by simultaneously performing multiple analyses based on the grouping variable. For example, suppose that the above example of GPA and delinquency was performed for 100 students housed in eight different schools. In the first step of HLM we would perform a regression for each school in which we used GPA to predict child delinquency. After this was done, we would have eight slopes and eight intercepts for each of the eight schools. Through maximum likelihood procedures we would then produce a weighted least squares average of the eight intercepts to produce a fixed intercept value (also called the grand estimate for the intercept). Through the same procedures, we would produce a weighted average fixed slope. These estimates can be thought of as the “average” intercept and slope for the combination of the eight schools. We can then use these fixed estimates to go back and reestimate the corrected slopes and intercepts for individual schools based on empirical Bayesian procedures. These are called the random estimates. What we now have are grand estimates that give us information about what is going on in all schools simultaneously, and the random estimates for each school. This can be very helpful, as in the case of delinquency, for examining which schools are performing at different levels from other schools. Furthermore, we have moved beyond asking “Are the schools different?” to “Why are the schools different?”

high school sports

C. Roger Rees

High school sports, arguably the most popular extracurricular activity in American schools, have been inextricably linked to the ideology of modernity. Conventional wisdom has it that participants in interscholastic athletics learn educational skills necessary for success in higher education and positive cultural values upon which they can draw as they develop into productive and well balanced adults. In short, there is widespread public faith that participation in sports “builds character” in the broadest sense of the term. This faith has, for the most part, remained unshaken despite three decades of sociological research from diverse theoretical perspectives that has produced mixed findings about the effects of interscholastic athletic participation.

The belief that sport played a positive role in the character formation of students originated when organized sports were first developed in the private boarding schools of nineteenth century Britain. In these schools a cult of athleticism formed the basis of the muscular Christian movement through which the sons (but not the daughters) of the upper middle class learned “manly” characteristics of leadership, courage, fair play, and patriotism through competitive sports. This movement also developed in the elite boarding schools of New England, which adopted a similar athletic curriculum to their British counterparts, and the value of sports as a socializing agent became “democratized” by the Playground Movement, the Young Men’s Christian Association, and the Public School Athletic League. By the second decade of the twentieth century the belief that school sport could be used to “socialize” students into positive academic and social values was institutionalized.

Contemporary proponents of school sports suggest that athletics is a positive influence on the formal education of students. They claim that participation in sports develops skills such as drive and determination, a positive self concept, and self confidence that are useful in the workplace. Sport increases high school athletes' positive attitudes towards the school, their academic aspirations and achievement, and provides them with opportunities to further their education at college. For less academically inclined students, sport provides the motivation to stay in school and therefore reduces the school dropout rate. Critics of school sport see it as part of a Faustian bargain between teachers and students, particularly students who are not academically motivated, by which sport provides the excitement to compensate for boring and irrelevant classes. Ethnically diverse students from different social strata can find unity in the drive for athletic victory against a common enemy symbolized by other schools. Because of their prominence in this struggle, athletes become the school leaders glorifying masculine values of achievement and aggression, and modeling a simplistic social Darwinist philosophy stressing survival of the fittest (although critics would say survival of the most belligerent) that legitimizes the status quo. Sport helps the school to reproduce the existing status hierarchy in society instead of providing students the skills and motivation to challenge it.

True to historically positivist traditions, research on school sports has examined the success of sport in providing athletes with skills necessary for future success. The relationship between athletics and academic success has been a popular research theme in this endeavor. Believers in the educational value of high school athletics argue that athletes have to practice efficient time management skills because of the time constraints imposed by school athletics, and that the self esteem supposedly gained from sports can transfer to academics. To support such claims they can point to research showing that athletes have similar or higher grade point averages than non athletes, and to more recent results from longitudinal research showing that participation has a small positive effect on grades and on dropout rates. Skeptics suggest that this "athletic effect" is part of a larger selection

process, since athletes tend to come from socio economically advanced backgrounds typical of students with higher grades. Also, they could be graded more leniently than non athletes, could benefit from special tutoring, or take easy courses in order to remain academically eligible to play.

Disagreement over the positive and negative effects of sport has also characterized the research on the relationship between participation and "delinquent" behavior by high school athletes. Approaches based on functionalist theory depict involvement as having a deterrent or reform effect by providing a system of rules and a code of behavior that gives athletes a positive sense of direction and a legitimate means of achieving their goals. Critical perspectives highlight the power of "the sports ethic" to reinforcing "positive deviance" in which athletes attach so much importance to team victory that they will do whatever it takes to win, even if it means taking performance enhancing substances or injuring their opponents on purpose. Longitudinal research has also examined the relationship between participation and the recreational behavior of athletes outside sport, including "risky" behavior such as binge drinking and sexual activity. As before, the results have been mixed. For example, whereas female athletes reported lower rates of sexual experience and fewer partners than did non athletes, the opposite was true for male athletes.

Clearly, the nature of the relationship between academics, delinquency, and school sports remains controversial. Although the longitudinal research has improved on the early cross sectional research designs because it has been able to isolate athletic effects instead of just comparing athlete and non athlete groups, it has not challenged the positivist assumptions that sport can help "fix" social problems such as lack of educational achievement or delinquency. The results of these studies need to be considered in conjunction with research that describes the relative importance of athletics and education in the social and cultural milieu of school life, and which examines sport as part of the "lived experience" of students. These studies tend to highlight the importance of high school sport to the social life of students and to place it at the center of the "hidden curriculum," the unofficial values system that students learn

through informal interaction in extracurricular activities.

The issue of gender identity is a prominent theme here. Feminists have challenged the historically positivist assumptions behind the development of school sports through the assertion that sports have always been linked to the promotion of masculinity. The fear that males were becoming "feminized" led to the origination of school sports and to their contemporary popularity. Some sports are still seen as being suitable only for boys or for girls. For example, the defining characteristics of violence and aggression make football a "male" sport, whereas gymnastics with its emphasis on aesthetics is seen as a "feminine" sport. Such stereotyping supports an "oppositional" view of gender, and has negative repercussions for athletes who risk labels such as "fags" or "dikes" if they play sports that are not "appropriate" for their gender. The male "jock" identity is often constructed around dominant images of masculinity based on victory, physical power, and heterosexuality. The frequent location of male athletes at the top of the status hierarchy of the school and the characterization of them as "cool" by other groups means that boys from less "masculine" cliques sometimes include these macho characteristics in their own self identities. Homophobia is also a common theme in the way male athletes treat females and in the content of hazing rituals by which entry to the team is unofficially "celebrated." It is not clear what effect if any the great increase in girls' participation in high school sport over the past 20 years is having on issues of masculinity and femininity. Critical feminists have argued that this increase has the potential for females to reduce the hypermasculine characteristics of high school athletics, but also that female sports run the risk of being coopted by the "male" model.

Race issues in high school sport are also controversial. Popular mythology sees sports as an ideal avenue for black youth to use their "natural" physical advantage over whites to gain athletic scholarships that allow them access to higher education and the long term benefits of a college degree. However, most sociologists would reject the authenticity of a biological theory of race, and would consider this racial

ideology to be a trap. Excelling at sport in high school is not a "way out of the ghetto" for the vast majority of African American males. Besides reinforcing the stereotype that all African American males live in ghettos in the first place, it marginalizes their academic credentials and encourages them to chase unrealistic "hoop dreams." The myth of genetic black athletic superiority also affects the sporting choices of white males who feel they are at a disadvantage when they compete in sports popular with African Americans. Negative racial ideology is also institutionalized in the naming of many high school mascots. Using caricatures of Native Americans trivializes their cultural heritage. Although the relationship between sports participation and ethnic identity in high school is understudied, current research calls into question the melting pot theory of high school sports. Sport can be used to reinforce ethnic identities, and can also be seen as a form of Anglo hegemony. For example, Doug Foley's (1990) study of Mexicanos in Texas high school football showed that involvement in sport was rejected by some working class Mexicano males, and also that Mexicanos who did participate were generally marginalized. High school football perpetuated Anglo power and privilege in the community.

Given the powerful belief that "sport builds character," research will continue to address the question of whether or to what degree athletics experiences comprise a valuable investment for the future success of youth. However, there is no singular sports experience in American high schools, so research comparing the characteristics of "athletes" to non athletes, or football players to swimmers, is likely to yield conflicting results. The power of sports to influence the life of students can be mediated by factors such as community and school traditions, past success, coaching philosophy, and the existence of an athlete identity. Accepting this reality means that future research should focus on in depth studies of high school athletics interacting with the culture of the school and community and the identity dynamics associated with sport participation. This approach would provide insights into how students view their own racial and ethnic identity in relation to athletic participation and fill a gap in our knowledge, particularly

with regard to female African American students. At the same time, the challenge for applied researchers interested in high school sports still remains how to help sport become more of a compassionate force in the social climate of the school and less of a haven for a jock culture that reinforces athletic elitism, hazing, bullying, and risky health practices such as binge drinking, steroid use, and extreme dieting. However, the excitement and controversy surrounding school sports is also “consumed” by the students and the public. Conceptualizing high school sport as a commodity stripped of functionalist assumptions about positive character development will increase among sociologists as the economics of big time sports (e.g., televising tournaments, naming rights for football fields and gymnasiums, expensive summer camps for elite players) become more prominent in high schools.

highbrow/lowbrow

David Halle

The distinction between “high culture” and “popular culture,” or “highbrow” and “lowbrow,” has underpinned most of the important debates about culture over the last 50 years in the US, Britain, and France especially, but also elsewhere. Theories of culture have tended either to presuppose this distinction or to debate various aspects of it. However, the nature of the debate has changed over time, and in particular the extent to which researchers and commentators are willing to stand by this distinction.

Partly this reflects the spread of higher education. Just after World War II there was a clear gap between an educated elite and the rest (only about 7 percent of the US population had a college degree) and it seemed plausible to talk about an elite of “highbrows” versus the rest. As a college degree became increasingly normal (held by over 25 percent of the US population these days) this education gap has faded, and so has the plausibility of maintaining that there are two radically different cultures, one pitched to an educated elite and the other pitched to the rest of the population. (The term “culture” itself is susceptible to many definitions, broad and narrow. Here I mostly use it in a fairly narrow sense to refer to the arts, namely literature, journalism, film, television, art, architecture, music, dance, and so on; but sometimes in the discussion below “culture” takes on a broader sense to include political beliefs, social attitudes, and religious beliefs.)

Four overall stages can be distinguished in the debates over “high/highbrow” and “popular/mass culture.” In the first stage, which flourished in the 1940s, 1950s, and 1960s, it was held that “highbrow” or “high culture” was unambiguously superior to “lowbrow” or “popular

culture." From this perspective, "highbrow" culture was aesthetically rich and vital while "popular/lowbrow" culture was at best of little merit and at worst was harmful. "Popular/lowbrow" was often depicted as the standardized and homogenized products of large corporations who sold their wares to the unsophisticated "mass public." By contrast, "high/highbrow" culture was the product of the skilled artist or craftsman and was appreciated by an elite, cultured audience. For example, in 1939 Clement Greenberg stressed the superiority of avant garde art over what he dismissed as "kitsch infected" mass art. Theodore Adorno, in the tradition of the Frankfurt School of sociology, berated popular music such as jazz, writing that the culture industry rooted out all deviations and that jazz had achieved musical dictatorship "over the masses." In similar fashion, for about two decades after World War II the movies of Hollywood were typically denigrated by film critics (who were often based in New York City) as the epitome of commercial, mass culture and as the opposite of art, modernism, and New York City which, by contrast, was said to nurture serious, independent, and non commercial filmmaking.

The second stage in the debates over "high" and "popular" culture began in the late 1950s and early 1960s when researchers, especially sociologists, undertook empirical studies of "popular/lowbrow" culture and of the associated audience. These studies often challenged, on empirical grounds, the earlier claims that the products of "popular/lowbrow" culture were of little or no aesthetic value and were experienced by the audience in an uncreative and unimaginative way. While not usually disputing the view that "high/highbrow" culture was aesthetically superior to "popular/lowbrow" culture, these studies typically argued that popular culture was not as bad as its critics had maintained. For example, Herbert Gans, in a classic 1967 account of Levittown, the large suburban housing development in New Jersey, chastised those who denigrated such new tract houses, and the suburban lifestyle of their working class and middle class inhabitants, as dull, homogenized, or lonely. Few of those who lived there experienced Levittown in that way, Gans insisted, although he added that he personally considered that urban life was aesthetically and culturally richer

than that of these suburbs. Seven years later in an influential comparative account of culture, Gans defended popular culture in general against its most dismissive critics.

The third stage of the debates overlapped in time with the research of stage two and took the debates in a more radical turn, upending earlier aesthetic evaluations and arguing that "popular/lowbrow" culture is, in some respects at least, aesthetically superior to "high/highbrow culture." For example, in *Learning from Las Vegas* in 1968, the architects Robert Venturi and Denise Scott Brown insisted that architects could learn much from studying the buildings on the Las Vegas strip, a place that many "highbrow" critics would have dismissed as the epitome of popular, vulgar culture. Venturi and Scott Brown argued that popular Las Vegas architecture was doing exactly what the classical medieval cathedral, a paragon of high culture, did, namely revealing from the shape of the building the function and activities that went on inside. The casinos of Las Vegas were designed so that viewers could recognize, from a considerable distance, not only that the building was a casino but also the nature of the fantasy that customers could experience within. For example, the shimmering black glass pyramid of the Luxor showed that this was a casino decorated in a patina of classical Egypt. Venturi and Scott Brown argued that such architecture was engaging and refreshingly superior to the dreary glass and steel boxes that the "highbrow" School of International Architecture had been building for decades. These anonymous boxes, the design of which dominated the curriculum of elite architecture schools, gave the viewer no inkling of what went on within the building. A similarly radical claim about the merits of popular culture was made by the Pop Art movement of the 1960s and beyond, which celebrated the aesthetic qualities of mass produced modern objects. The success of Pop Art legitimized the status of these objects as art, underlined by the installation of many of its works in the citadels of high culture. Thus, Claes Oldenburg's 10 foot high sculptural representations of a slice of blueberry pie on a scoop of ice cream (installed on the roof of the Museum of Modern Art) and his monumental lipstick sculpture (installed at Yale), and Andy Warhol's depictions of such products as Campbell's soup, forced those who would denigrate

mass culture not only to take a closer look, but to consider the possibility that the products of "mass culture" might in some ways be more interesting than those associated with "high culture."

Also part of this third stage's radical challenge to the established aesthetic hierarchies is the work of the French sociologist Pierre Bourdieu, who argued in his book *Distinction* in 1979 that the driving force of culture had less to do with aesthetics and more to do with struggles for power between social classes. For Bourdieu, the "dominant class" (or classes) use high culture, which is often difficult to understand for those lacking higher education or upbringing in a dominant class family, in order to exclude members of the dominated class(es) from positions of power and privilege. Individuals from the dominated classes, lacking a facility in high culture, which Bourdieu calls "cultural capital," are on that basis kept out of the dominant class cultural rituals of social solidarity (the opera, ballet, etc.) and by that method are kept out of the dominant class even if they have managed to acquire significant economic assets. By arguing that high culture is at base about struggles for power between social classes, Bourdieu undermines its claims to intrinsic aesthetic superiority.

The fourth stage in the debate over "high culture" versus "mass culture" is more radical still, for it questions whether the basic distinction between one category of items that can be assigned as "high/highbrow culture" and another category than can be classified as "popular/lowbrow" is justifiable on any major grounds, not just aesthetic, at least as a basis for social theories that seek to lay out the main contours of modern society. This fourth stage, in short, seeks to dissolve the key terms in the "high culture/mass culture" debate and in so doing to dissolve the debate itself. Beginning in the late 1980s, researchers such as Paul DiMaggio and David Halle point out that surveys reveal that almost everyone, highly educated or not, is involved with at least some of the activities and products often designated as "popular culture." It remains true that some activities associated with "high culture" (e.g., attending the ballet, opera, or classical music concerts) are confined to a smaller group of people, who tend to be very well educated, but these same people for the

most part engage in the popular activities too. Further, any exclusionary function that "high culture" performed in the past has been decreasing for some time, as the institutional world of culture is less and less willing to insist on sharp boundaries between social classes and cultural worlds. Thus, it is noteworthy that contemporary theorists such as George Ritzer, Sharon Zukin, and Terry Clark, who stress the importance of the "consumer/shopping society," the "commercialization of leisure," and the tendency of cities to become "entertainment machines," usually argue that almost everyone is caught up in these phenomena.

Although in the past the analysis of culture has thrived on some version of the distinction between "high/highbrow" and "popular/lowbrow" culture, it increasingly seems as though major cultural theorists will now have to look for their inspiration elsewhere than to this supposed divide. That is not to deny that aesthetic distinctions can be made (though they need to be justified with extreme care), that tastes vary somewhat with such factors as education, or that these distinctions may have more salience and staying power in some societies (e.g., France) than others (e.g., the US). But it is to question whether aesthetic distinctions and taste differences are sufficiently clear cut as to provide the basis on which can be constructed major sociopolitical theories of cultural difference and distinction.

high-speed transportation pollution

Koichi Hasegawa

High speed transportation pollution refers to a type of environmental pollution consisting of high levels of noise, vibration, and air pollution brought about by high speed transportation systems such as the airplane and airport, the “bullet” (super express) train, or the traffic expressway. These disturbances cause damage to daily life such as sleep deprivation or the disturbance of conversation at home, as well as stress related health issues like heart disease or gastrointestinal disease. Bullet trains, jet air planes, and high speed expressways are essential to highly industrialized modern urban life. They are basic conditions for developing efficient modern economies, greatly reducing the time and cost of moving goods and people over large distances. In most countries, high speed transportation pollution is serious along the train line, the expressway, or the area surrounding the airport. It is especially serious in metropolitan areas and in high population density countries like Japan.

In many ways, high speed transportation pollution is quite distinct from industrial pollution. At first glance, the impact on the environment for each flight, bullet train service, or individual

automobile on the expressway looks inconsequential. It comes and goes away very quickly, at most within a few minutes. But an airplane takes off every several minutes at a major airport, and in the case of Japan’s Tokaido line, a bullet train passes through every several minutes. They keep coming every day, including holidays, from early morning to the middle of the night (for the airport and bullet train) or all day and night (for the expressway). The cumulative effect is very great. In fact, as the number of flights and trains rapidly increased in response to growing demand, the pollution from bullet trains and jet planes became serious social problems.

For many years planners, engineers, suppliers, and administrators of the transportation system focused only on the “benefit sphere”: the speed, safety, convenience for passengers or drivers, economy of the system, and economic effect for the surrounding area. They overlooked the “negative” environmental effects for local residents neighboring the transportation system. Effective regulation of the environmental effects only came about with the starting of protest movements and the coming of serious social issues.

In some cases of industrial pollution or daily life pollution, determining cause and effect is not always simple. But in most cases of high speed transportation pollution, the cause is usually obvious: we feel the noise and vibration. Despite the obviousness, planners, suppliers, and passengers tend to miss the negative effects. The principles of remedy or countermeasure are very clear – making the polluter pay (the PPP or polluter pays principle) and fixing the problem at the point where it occurs. These are basic and relatively cheap principles. But in Japan, the government administration and the railway companies tended to reject these principles.

In Japan, during the years of rapid economic growth in the early 1970s, high speed transportation pollution, especially in the high density areas of large metropolises, became a central issue for local residents’ movements. This was because the national government tried to continue high economic growth by constructing many jet airports, bullet train lines, and expressways. This special social background at that time made high speed transportation pollution into a major nationwide social problem.

Representative examples of these protest movements include movements to rectify the Osaka Airport pollution problem; oppose the construction of Narita Airport; rectify the Nagoya bullet train pollution problem; oppose the construction of the Tohoku and Joetsu bullet train lines in Saitama Prefecture and northern Tokyo; and oppose the construction of the Yokohama cargo line. In all of these cases, large groups of residents rapidly and successfully organized a powerful local residents' movement that remained active for a long time.

Each of these cases had a significant impact on subsequent local residents' movements, transportation policy, and the judicial system. The Nagoya bullet train Pollution Response Alliance organized 2,000 households residing within about 7km of the train line. The anti bullet train movement in Urawa demanded that the line be built underground and at its peak could mobilize about 4,000 people to a mass rally (Funabashi et al. 1985, 1988). In other cases, groups of plaintiffs were organized from local residents' movements. For example, litigation over the pollution produced by Osaka Airport and the Nagoya bullet train line sought the suspension or prohibition of airplanes and trains to reduce the environmental damage.

Alongside the litigation over the four major industrial pollution cases, these cases helped to establish a kind of class action lawsuit as an effective strategy for local residents' and citizens' movements, but also exposed the limited capacity of the judicial system to provide relief.

Legal action by local residents' movements seeking redress against industrial pollution principally indicted the interest seeking behavior of private firms, accrediting responsibility to them. In contrast, in the airport and railway cases mentioned above, the movements targeted the Ministry of Transportation and the public bodies in charge of designing and running the national railroads and airports, criticizing them for their refusal to accept responsibility for the harm they were causing or to implement effective policies to prevent noise pollution, and for their continuing defense of their destructive behavior in the name of "the public."

Here, the government actors/perpetrators responded to the residents/victims with

attitudes and tactics that were chillingly similar to the corporations' responses to accusations of industrial pollution. The government and public agencies defined "the public good" according to the social benefit produced by public works and related projects. They used this benefit to justify the behavior of public authorities, to proceed with project construction, and to restrict private rights to reduce (or avoid) the resulting damage and harm.

Residents criticized the authoritarian and oppressive tone of this conceptualization of "the public." They argued that the public good ought to be defined through democratic processes, including a complete prohibition on any violation of fundamental human rights. They demanded, before any large projects proceeded, the informed consent of residents in surrounding areas through direct participation in the decision making processes.

High speed transportation pollution is just one example of the unintended but harmful pollution caused by transportation technology. As mass consumer society becomes increasingly technological, the environmental problems caused by the new technologies extend well beyond noise and vibration into new areas like destruction of the ozone layer by CFCs.

Hinduism

T. N. Madan

Use of the English term “Hinduism” (and its equivalents in various European languages) to designate certain aspects of the cultural traditions of Hindus anywhere is commonplace, but it is relatively recent and not wholly unproblematic. The idea that the Hindus must have a “religion” comparable to Christianity and worthy of study originated with British administrators and scholars in India in the last quarter of the eighteenth century. These scholars, known as the Orientalists, devoted themselves to the study and translation of textual materials, mainly in Sanskrit, some of which they identified as religious and others as secular texts. By the time the British parliament allowed proselytization among the “natives” of India in 1813, the word Hinduism had come into use. Christian missionaries also devoted themselves to the study of religious texts and the observation of religious practices, but unlike the admiring Orientalists their primary aim was to expose the “wickedness” of polytheistic and idolatrous religions and to highlight the “perfection” of Christianity.

The problematic aspect of these studies, often laudable for their reliability and detail, was the basic assumption that the Hindus had a religion which, however, was curiously deficient in significant ways given the absence of most notably, a founder, a single revealed text, and a church-like organization. But that the Hindus were a community of faith, united by a common religion, Hinduism, was considered unquestionable. The widespread use of the Hindu term *dharma* (*dharma* literally means “moral law,” “that which sustains” the social order) in Indian languages, at least from medieval times onward, was deemed sufficient terminological evidence for the historical authenticity of Hinduism. When the first census of the peoples of India under British control was conducted in 1872, classification by religion was considered an obvious objective. The Hindus emerged as the numerically preponderant community. Towards the end of the nineteenth century, when a national movement for some measure of self governance under the British imperium began to take shape,

the notion of India wide religions, respectively claiming the allegiance of millions, was further strengthened, despite some initial skepticism among intellectuals well versed in the Hindu tradition on the ground that the religious–secular dichotomization of areas of life was alien to their way of thinking. Simultaneously with the emergence of the notion of monolithic Hindu and Muslim religious communities, officially enumerated and described, came the idea of mutually exclusive identities and religious nationalisms, that eventually led to the partition of the subcontinent in 1947.

At this point, it may be recalled that the term “Hindu,” like Hinduism, is a foreign coinage from around the middle of the first millennium before the Christian era. The Persians and the Greeks identified the peoples of the plains of northwestern India in the name of the river called Sindhu in Sanskrit. Sindhu became Hindu in Persian and Indos in Greek. The Arabs appeared as conquerors in this area in the eighth century CE and called it al Hind and the peoples thereof, al Hindi. In the course of time a distinction came to be made between the Hindi, an ethno geographical category and the Hindu, a religious category. By further elaboration Hindus were those Indians (and even peoples further east) who remained outside the Islamic fold. By medieval times “Hindu” was established as a term of self designation and Hindu *dharma* also came into use. And, as noted above, Hindu *dharma* became Hinduism in the early nineteenth century.

The roots of Hinduism as we know it now go back to the belief and ritual complex, marked by nature worship, of immigrant Aryan speaking peoples, who were the composers of the body of hymns and instructions on ritual performances collectively known as the *Veda* (“knowledge”). The earliest of these collections of “texts,” transmitted orally, are about 3,200 years old and have over the millennia acquired the status of revealed scriptures. Some elements of Hinduism have been traced further back in time to the Harrappan civilization of 5,000 years ago. As the carriers of the Vedic cults proceeded east and south, a widespread and longlasting process of give and take (called by anthropologists “parochialization” and “universalization”) between them and local communities of faith (“folk religions”) began, producing immense

regional varieties of belief and ritual and generating a vast body of post Vedic texts known as the *Purana* ("legends") from around 300–600 CE. New gods and goddesses and the cults, cosmogonies, and mythologies associated with them proliferated. Mutually hostile sectarian divisions crystallized around some of the new deities (notably Shiva, Vishnu, and the female Devi). These immense diversities rule out any notions of a linear development of Hinduism or of a subcontinentally homogeneous religious community. It must be noted, however, that efforts have also been made for a long time to overcome these diversities. A daring young intellectual and renouncer of South India, Shankara (ca. 788–820), instituted a non sectarian form of domestic worship (*smarta puja*), combining devotion to Shiva, Vishnu, Devi, and other deities, and traveled to the far corners of India to stress the unity and sacredness of the land through pilgrimage and to propagate a monistic philosophy of the oneness of the divine or Absolute and the human in its true essence. This and other philosophies are known as *Vedanta*, the culmination of the Veda, or the ultimate true knowledge. The earliest of the Vedantic texts, concerned with metaphysical issues and known as the *Upanishad* (secret knowledge), are believed to have been composed about the same time as the birth of Buddhism and Jainism (around the middle of the first millennium BCE), which were the first major heresies, so judged by the Brahmans, the teachers and practitioners of the Vedic religion. These ritual specialists were the most privileged of the categories of people who constituted Vedic society.

SOCIAL ORGANIZATIONAL FRAMEWORK

One of the hymns in the *Rig Veda* mentions the birth of four major social categories of human beings, and indeed the whole cosmos, from the self sacrificial dismemberment of the divine "primeval man." From his mouth came the Brahman, knower and teacher of sacred knowledge; the Rajanya (or Kshatriya), warriors, and protectors of the realm, were his arms; the Vaishya, working people, his thighs; and the Shudra, providers of services to the other categories, his feet. Besides the division of labor

that they embodied, the four *varnas*, so called, were ranked, the Brahman downward, in terms of ritual status and social privilege, but in a holistic framework. Over the long duration, the fourfold *varna* order became the caste (from the Dutch *casta*) order comprising numerous *jatis* through a variety of processes including inter *varna* marriages, incorporation of outsiders, and fusion or fission of existing groups. In principle, however, the caste system is based on hereditary membership within a *jati*, endogamy, and the inheritance of occupation and ritual status. Consequently, the caste system is, at least in theory, the most rigid social order conceivable. It is a mirror image, as it were, of the looseness (liberalism) of the belief and ritual complexes that characterize Hinduism in its regional and sectarian diversities. In view of this, some sociologists have suggested that the unity of Hindu society rests not in Hinduism but in its social organization.

Indologists (specialists of classical texts) have long described Hinduism as *varna ashrama dharma*, the morally grounded way of life appropriate to one's *varna* or *jati* and one's *ashrama*. The latter stands for stage of life, of which four are recognized: the preparatory stage of student ship, householdership, retirement, and finally renunciation of all worldly engagements. The renouncers (not all of them may have gone through all the earlier stages) turn their back on caste rules as well as family obligations. In textual Hinduism the three upper *varnas* (referred to as *dvija*, the twice born, in view of the rites of initiation through which everyone must ideally pass) are guided by a grammar of value orientations (*purushartha*). Hierarchically ranked, these values are *dharma* (grounding in moral law), *artha* (rational pursuit of economic and political goals), and *kama* (aesthetic enjoyment and physical pleasure). The fourth value orientation, *moksha* (liberation), is the alternative to the first three taken together. It should be clarified that in a householder's life, being grounded in *dharma* acquires meaning through the pursuit of *artha* and *kama*; but *kama* must not violate the dictates of *artha* and *dharma*, and *artha*, of *dharma*. The renouncers who seek liberation from the web of kinship and other social obligations do not necessarily go out of society altogether: they may return awakened, as the Buddha did, and found new sects, some of which (most notably

Buddhism, Jainism, and Sikhism) blossom in the course of time into full religions. Social involvement and renunciation are not necessarily mutually exclusive: their relationship is dialectical and socially creative. The preoccupation of sociological literature with caste and renunciation, presumably because of their unique character, has led to the grievous neglect of the empirical presence and ideological vigor of the householder as a key bearer of the values and rituals of Hinduism.

The householder, man or woman, is ever engaged in *karma*. In its narrower connotation *karma* is ritual action, but broadly *karma* stands for the full range of legitimate purposive action. *Karma* is the enactment of the triple goals of *purushartha*. Every *karmic* act has consequences (*karma phala*), whether intended or (because of interferences or inadequacies) unintended. A chain of cause and effect is thus constructed; its most significant implication is the belief in reincarnation. *Samsara*, the web of worldly entanglements, is considered a bondage, and *moksha* is the release from it. In practical terms these beliefs do not mean withdrawal from all activity, but rather its pursuit according to *dharma*, so that the secular and the religious make up (at least in principle) one seamless whole, and in a spirit of detachment.

From conception to death and thereafter a Hindu's life is involved in a succession of rites of passage, including the rituals of birth, initiation, marriage, death, and post mortem offerings. These periodic household ceremonies, daily rituals for the well being of the family (steps in a process of moral maturation) and of adoration (*puja*) of one's chosen deities, are a major preoccupation of all households. Pilgrimages to holy places (for example in the high mountains, at the confluence of rivers, or on the seashore) carry Hindus away from home. The precise content of these ritual performances varies from region to region and caste to caste. But there is more commonality in this respect between the upper ("twice born") castes than among the lower, owing to a greater adherence to textual Hinduism in the case of the former and to folk traditions in the case of the latter. Sociological studies of "popular" Hinduism bear witness to its richness and viability; they have also recorded the process named Sanskritization by which lower castes tend to move away from their

folk moorings and attempt to raise their ritual and social status by taking over the religious and secular practices of the upper castes. While such efforts at status enhancement are group based, it is noteworthy that Hinduism is a non congregational religion: its principal agent is the individual and its primary locus is the home. Even in temples and places of pilgrimage, it is the individual or a family who offer worship.

Karma in its various expressions is, then, the way (*marga*) of religion among Hindus. But there are two other equally valid ways, those of *gyan* (knowledge) and *bhakti* (devotion to the chosen deity), and all three are recognized in the scriptural text *Bhagavad Gita* (first century CE), which has gradually emerged as the single most revered "revealed" book of Hinduism. Beginning with the ninth century commentary of Shankara, there has been an unending tradition of commentaries on this text, including in the twentieth century those by the firebrand politician Bal Gangadhar Tilak, the mystic Aurobindo Ghosh, and the pacifist Mahatma Gandhi, each emphasizing a particular mode of interpretation. For Gandhi, the *Bhagavad Gita* is a moral treatise of selfless action (*anasakti*) in the service of humanity, which brings out the futility of violence and the imperative of divine grace in human affairs.

MEDIEVAL SYNTHESIS AND MODERN HINDUISM

Hinduism is not a static tradition. As we have seen, it has grown through dialogic processes involving different levels of articulation from the local (tribal, folk) to the regional and finally the subcontinental, in an increasing order of eclectic complexity. Rightly perhaps, Hinduism has been described as a family of religions. Moreover, internal heterodoxies, some of which have grown into fully fledged independent religions, have also altered the character of the core tradition of Hinduism, one of the best known examples being the value placed upon vegetarianism following the great emphasis on non violence in Buddhism and Jainism.

The arrival of Islam as a proselytizing religion in the eighth century, accompanied by the establishment of pockets of Muslim rule, first of all in the northwest, that by the early seventeenth

century had grown into the subcontinental Mughal empire, opened new possibilities of religious syncretism, particularly at the folk level, but also temporarily and unsuccessfully in the imperial court. Elements of Sufi religiosity blended well with Hindu theistic devotionism (*bhakti*) that had originated in southern India, partly in reaction to the ritualism of Vedism and the atheism of Buddhism. New communities of faith with their distinctive cults, such as the medieval Kabir Panth, were born, providing a “home” to low caste Hindus as well as Muslims, bound together by their ecstatic love of a formless (*nirguna*) divine, unblemished by idolatry and mechanical ritualism. It was in such an ambience that Sikhism took shape as an independent religion in the sixteenth and early seventeenth centuries.

After Islam it was Christianity that provided the new challenge, drawing from the Hindu intelligentsia a variety of creative responses. Bengal was the stage on which these dramas were enacted before they spread elsewhere. Christianity arrived in India early in the Christian era, but it was only in the sixteenth century that, under the aegis of Portuguese and other colonial powers, which gained footholds on Indian shores, that conversions began. Since it was the British who emerged as empire builders in the late eighteenth century, Christianity became a subcontinental presence, particularly after the British parliament lifted restrictions on evangelical activities in 1813. An early response to the new challenge was the search for the best in the Christian gospels – for instance, their ethical precepts – that could be welcomed into Hinduism. Thus the Brahmo Samaj (Society of God) sought to combine the best of Vedanta with the best of Unitarian Christianity, but fared no better than the great Mughal Emperor Akbar’s *Din i Ilahi* (Religion of God) in the late sixteenth century.

As the activities of missionaries (often excessively condemnatory of Hinduism) gathered force, a spirited Hindu response, combining reform and revivalism, virtually burst upon the Indian scene in the closing years of the eighteenth century. Its luminous torch bearer was the Bengali renouncer Vivekananda (1863–1902). Breaking with tradition, he traveled overseas to emerge at the World Parliament of Religions in Chicago in 1893 as one of its most charismatic

participants. Taking his stand on Vedanta, which he claimed contained all the great truths of all religions, he proclaimed that the essence of Vedantic Hinduism was the acknowledgment of religious pluralism. All paths of religious seeking were true, but the tradition that acknowledged this principle, as Vedanta did, was the paradigm of perfection. Lecturing in the US, the UK, and India, he called upon the West to look beyond its materialist riches to the spiritualist treasures of India. To the Indian youth his message was social uplift of the down trodden and the cultivation of rationalism at home and spiritual conquest abroad. Like Shankara, he died young at 39 years of age. Vivekananda was indisputably the founder of global Hinduism.

If Vivekananda’s pluralism was under the umbrella of Vedanta as the essence of true religion, the pluralism of Mohandas Gandhi (1869–1948), known to the world as Mahatma (Great Soul), a name bestowed upon him by the great poet Rabindranath Tagore, was radical and his pluralism was open to the sky. All religions spring from divine inspiration, he said, but are imperfectly articulated because of the limitations of human reason. Things that are only implicit in some religions are explicit in others. Humanity, therefore, needs all religions. In judging each of them, moral sensibility, which he considered innate and universal, provides the yardstick. Whatever is in conflict with it, including ancient texts, must be discarded: the search for truth is unending. The strength of Hinduism, in Gandhi’s view, lies in its inclusivism and willingness to listen and learn from other religious traditions. Indeed, he considered this the true Hindu perspective. That he should have died at the hands of Hindu bigots should therefore not cause any surprise.

Hinduism is today a global religion. By present estimates there are nearly 900 million Hindus spread over six continents. Asia is where most of them live: over 800 million in India, 18 million in Nepal, 14 million in Bangladesh, 3 million in Sri Lanka, and about a million in the US. Migrants and itinerant religious teachers are the principal agents of a globalized Hinduism. Some forms of Hinduism have grown in foreign settings in response to the internal crises of other cultural traditions. The best known case, perhaps, is that of the International Society of Krishna Consciousness (ISKCON) in the US.

In India Hinduism remains a personal spiritual engagement for millions; but those who look upon it as a resource for political mobilization in the pursuit of power are also quite numerous. Their Hinduism is exclusive and often degenerates into communal hate and violence. Gandhi's assassination in 1948 did not bring the conflict between the two Hinduisms to a close.

CONCLUSION

The study of Hinduism in modern times has proceeded along two tracks. On the one hand, there have been the textualists whose studies have presented us with the ideals and norms of Hinduism as a way of life. On the other hand, the contributions of social scientists (particularly social anthropologists) have contributed richly to our understanding of "lived Hinduism" in its immense variety. Methodologically, the truth of Hinduism lies at the confluence of the textual and contextual perspectives. In recent years, both perspectives have become theoretically more sophisticated: structuralism, phenomenology, hermeneutics, cultural analysis, etc. have all been drawn upon with much benefit. As befits an expanding religious tradition, its study also seeks new points of departure and new frameworks of interpretation.

Hirschfeld, Magnus (1868–1935)

Ken Plummer

One of a cluster of early sexologists – like Krafft Ebing, Albert Moll, and Havelock Ellis – who came to prominence in the late nineteenth century, Magnus Hirschfeld was a German physician and sex researcher, as well as a homosexual and a pioneer of homosexual rights. In his early work, he endorsed the idea of Karl Ulrichs's "urning theory," whereby homosexuality was seen as less of a choice and more of a biological "developmental defect." In particular, he argued for a hormonal basis. Much of his work was concerned with "intermediate types." He believed that all human beings were intermediate between male and female – a varying mixture of both. He was also one of the first modern theorists of transgender/transsexualism. He invented the terminology in 1923 and came to be known as "the father of Modern Transsexualism." He produced the film *Anders als die Anden* (*Different from the Others*) (1919), probably the first documentary campaign film about the rights of the homosexual, banned in 1920. Amongst his key publications were *The Transvestites* (1910), *Homosexuality of Men and Women* (1914), *Sexual Pathology* (1917), and *Sexual Science* (the five volume magnum opus published between 1926 and 1930).

Writing initially in the time of the Oscar Wilde trial, Hirschfeld was a reformist and activist until the end of his life. He developed ideas around sexual liberation in general, and on transgenderism and homosexuality in particular. He founded the Scientific Humanitarian Committee (which petitioned the German Parliament for law change in favor of homosexuals, especially the repeal of paragraph 175 of the Penal Code) and the Institute for Sexual Science (in 1919) – seen as a "Child of the Revolution" – which housed major archives, a marriage guidance bureau, and a petition that advocated social change. His work was also very influential on the development of sexual "science" in the UK, leading to the formation of the British Sexological Society in the 1920s.

But his work was also seen as a scandal. Moralists saw much of this work as dangerous to the public, and thought that it should not fall into the hands of ordinary people. Radical feminists were also very critical of his work, both at the time and later. These are not celebrants of sexual diversity, in the ways that many early and subsequent sex researchers have been. In contrast, they suggested that much of early sex research had prioritized men and their power, and had not adequately considered the lack of a woman's right to control her own body and its access. Many contemporary feminists have argued that the situation has become increasingly worse, with the ever and upward rise of so called "sexual freedom" in the twenty first century. In addition, Hirschfeld was the victim of much personal abuse, both as a Jew and as a homosexual. He was forced to leave Germany in 1930, his Institute was burned down by the Nazis in 1933, and he died in France in 1935. The archives, library, and all records, as well as a bust of Hirschfeld, were destroyed. Other homosexuals were subsequently interned in concentration camps and killed.

historical and comparative methods

Ian Varcoe

Among the classical figures, Max Weber stands out from the others in his devotion to comparative historical sociology. His lifelong quest was

to find through the study of "rationalization processes" what sets the West off from the non western civilizations. Concretely, the concern was with modern, rational, or bourgeois capitalism, its origins and development. This series of studies is "macro" and it deals with changes over long stretches of time.

Weber tackles systematic comparative study, whereby, rather than creating data experimentally, the investigator bases comparative analysis on real or natural events, trajectories, and cases. One class of "natural case" is historical sequences in large scale comparative social contexts or units.

Weber is a leading inspiration of comparative historical sociology in the twentieth century. Chief exponents of this are Reinhard Bendix, S. N. Eisenstadt, Theda Skocpol, Charles Tilly, Barrington Moore, Michael Mann, and John A. Hall. Weber came closest among the classical writers to making major use of John Stuart Mill's method of (indirect) difference. Of Mill's two principal procedures, the method of difference is the one that usually features in explicitly comparative research; it is the most powerful of the "logics" he identified and studies usually try to approximate it as closely as possible.

Mill's method of agreement works as follows: (1) several cases are found to have the phenomenon to be explained (y); (2) they also share the hypothesized causal factors (x) (this is the crucial similarity); but (3) in other ways that might seem causally relevant according to alternative hypotheses, they vary (i.e., *overall* there are differences). Mill's method of difference, on the other hand, requires that the investigator take (positive) cases in which the phenomenon to be explained and the hypothesized causes are present ($x - y$); these are then to be contrasted to other (negative) cases in which the phenomenon and the causes are absent (not $x -$ not y). These negative cases are as similar as possible to the positive cases in other respects. Comparative historical sociologists, in particular, can supplement the method of agreement by introducing into their analyses the method of difference; in short, a research design that combines elements of both is possible. Or the method of agreement can be applied twice over so as to approximate the method of difference.

Max Weber did this in his comparative studies of civilizations. Essentially, he conducted two sets of studies, of European societies that developed capitalism and non western ones that did not. Weber thought he could see a number of factors linked to the former which the latter set of societies did not possess. But what if other factors he had not identified were operating? By comparing the two sets of societies, stressing as much as possible their likenesses, Weber was able to strengthen the presumption in favor of his selected factors as the cause of capitalism in the West, their absence as leading to its absence in China and India.

Weber's strategy was to extend an ideal type by developing a subtype effectively containing an implicit explanatory hypothesis concerning difference. Weber's approach to comparative studies was shaped in a fundamental way by his view of causation in the historical and cultural sphere; not general laws but unique constellations of multiple causal factors drew his attention.

In addition to being historical studies, most work by comparative historical sociologists studies one, two, or three cases. Why this tendency to a limited number? The argument for such a limitation is that the cases are intrinsically interesting (they may even exhaust the phenomenon in question) or that they are the most representative. Unraveling complex, compacted causes can only be attempted in a small number of cases treated as wholes. The nomothetic (or generalizing) type of inquiry was held in suspicion by Max Weber as more the province of the natural sciences: opponents of positivism and evolutionism in the social sciences have shared this preference for the idiographic. It is, however, a tendency only, shown in varying degrees by historical sociologists. Studies using a few cases can, and usually do, pose nomothetic or general questions. Both the idiographic and the nomothetic types of studies may seek to explain and the causal forces conceived theoretically may well be the same in both. The import of Weber's methodology for comparative studies is, however, open to interpretation. Being itself a synthesis of conflicting elements, it has proved open to being "read" in different ways – to support more causal analytic and more contrast oriented positions. Comparative historical sociologists draw

methodological inspiration from approaches such as that of Durkheim (and latterly structuralist Marxism).

An interpretation of Weber that sees him as underwriting a highly tentative approach to causal statements is that of Bendix, who offers a sophisticated critique of the traditions of Marxism and structural functionalism. They are, he says, effectively single factor, evolutionary theories confined to proposing a series of "stages." Bendix calls for the kind of comparative concepts that cover some but not all societies. They should allow significant comparison but be less than universal. He argues that these are to be found in the ideal type because such concepts (1) invite specification in historical or developmental terms and (2) provide benchmarks by which historical data can be ordered in a preliminary fashion. The aim of comparative research, for Bendix, is to isolate differences, or explore contrasts, so setting a limit on premature generalizations. Such generalizations are always vulnerable to hidden or unexamined third variables (which may have to be dealt with ad hoc) for which the overly ambitious investigator has not controlled. An ideal type's principal value is to rule out certain possible associations in history by placing limits on the field within which causal imputation is possible, although this does not rule out imputation at some later stage when knowledge is better than it is now, and to give access to complexity unsuspected by "grand" evolutionary theories.

Bendix's modest, self denying strictures against overly generalized research designs are aimed at combatting what he sees as the organic assumptions of classical theory deriving from Marx and Durkheim where societies tend to be seen as bounded entities, the forces for change lying within them. However, if change is exogenous the comparative sociologist needs a way of separating and then relating endogenous and exogenous sources of change. To tackle this question theoretically, Bendix has drawn attention to non bounded societies composed of "layers" of differing degrees of extension beyond permeable borders that predate the unified modern state, and to the phenomenon of what he calls "reference societies" through which influence flows from one society to

another, e.g., with respect to models of industrialization. Concepts such as this sensitize comparative sociologists to the different degrees to which societies are less than self contained units.

Mill's canons of inductive logic say nothing about where the data should come from. They do not stipulate, for example, that they should come from different times and places; nor from how many social systems or units, that is, from one or more than one. The logic of comparative analysis whereby an attempt is made to gain control over suspected causal factors is present in methods that do not necessarily involve a few large units (e.g., nation states, societies, and civilizations). "Deviant cases" may be picked out for study; non existent data randomized, i.e., rendered irrelevant for scientific purposes; and the "imaginary experiment" employed. The aspect of a situation suspected to be crucial in producing a given outcome is "thought away" in an effort to estimate the difference it would have made.

The dilemma of concept formation in comparative research generally is that concepts should be sufficiently abstract to cover the multiple cases such research requires, but not so abstract that it becomes difficult to devise rules for empirical specification of the concepts. Aside from this, the main methodological questions in research concern:

- 1 *Classification.* Placing in the same class means "rendering comparable," i.e., implicitly excluding as causal candidates the respects in which members of the class are alike. Once a definition has been created, a pattern of possible causal relations – of similarities and differences of characteristics – is engendered.
- 2 *Issues of measurement.* Every stage of comparative research – choice of variables, causal inference, the location of indicators and their choice, the selection of units (classification), these last three reflecting implicit causal theories – depends on theoretical ideas. Theory and methods form a seamless unity, although the components of this unity can be separated and analyzed.

In the 1970s a certain momentum was generated for a comparative historical sociology,

to renew the classical tradition of macrosocial inquiry into major transformations of the human condition. Partly this was in reaction to trends like ethnomethodology, and partly the inspiration came from sociologists wishing to continue developing the legacy of Max Weber. But Marxists and neofunctionalists were also drawn in. Major figures were Eisenstadt (neofunctionalism), Bendix (Weber), Perry Anderson (neo Marxism), and Barrington Moore (neo Marxism). Forerunners of this type of sociology were seen to be the French Annales School of Fernand Braudel, who inspired Immanuel Wallerstein's world systems theory, and the historian of the Middle Ages, Marc Bloch. Methodological analysis of the various studies of these scholars suggested that theory influenced research design in various ways. Only one of these was firmly in the camp of macrosocial explanation, using Mill's logical canons in combined ways. Perhaps the most outstanding example of such a study was Barrington Moore's *Social Origins of Dictatorship and Democracy: Lord and Peasant in the Making of the Modern World* (1966). It used eight cases to identify three "paths" to the modern world. It used many independent variables, but principally the nature of class relations – between lord and peasant – in the countryside, to explain the type of emergent polity following industrialization.

Moore was able to establish parallels between countries within his three pathways. But he also made comparisons and contrasts across them. As well as this, he introduced negative cases in his discussion of particular countries. By doing so he approximated the method of difference, shoring up the causal case that he was trying to make.

Comparative historical sociology as a candidate for a preeminent theoretical empirical orientation in sociology has receded since its heyday in the 1980s – it was arguably less a movement or school than a genre. Mainly this is because the agenda of key sociological issues has changed with the end of the Cold War. The coherence of nation states has declined somewhat and issues like industrialization, urbanization, democracy, and revolution have ceded place to others that have flowed from US hegemony, globalization, the resurgence of militant

Islam, human rights, and so forth. None of these seems resolvable in terms of the development of societies as nation states, or is fully understandable with reference to a distinction between a Western European pattern of development and the development of the rest of the world seen as taking place with reference to that pattern. The priority of the West still resonates. However, issues of development are now filtered through the global framework rather than through a direct confrontation with Western Europe and North America. There is no doubt, however, that social change over the very long term is still a vitally important topic. It is historical sociology, but perhaps not *comparative* historical sociology in the analytic sense, that will continue to be practiced and will continue to offer rewarding insights: for example, into “multiple modernities.”

HIV/AIDS and population

Mark VanLandingham and Dominique Meekers

The connections between human immunodeficiency virus (HIV) and population features are vast. While HIV has its largest impacts on population size and structure by increasing mortality among young adults, it also affects and interacts with the other key components of population makeup and change, namely, sexual behavior and fertility, and migration. Impacts on these key components in turn affect the well being of populations in profound ways.

INTELLECTUAL AND SOCIAL CONTEXT

HIV is believed to have infected nearly 60 million persons worldwide, killing more than 20 million of them through the various complications associated with acquired immune deficiency syndrome (AIDS), the disease caused by HIV. The toll has been especially heavy in the developing world, where infection rates are highest and where effective medications are the least available.

The introduction and spread of HIV across the globe is a recent phenomenon and caught public health, population, and other social scientists by surprise. Although it is now thought that the virus probably existed in Africa for a number of years before it emerged within gay male populations in America and Europe, it was not until the early 1980s that this new deadly and infectious disease caught the attention of a scientific community heretofore convinced that the age of epidemics was nearing completion. It is not just the epidemiological transition paradigm that was uprooted by the spread of this new virus and the host of health problems it causes, but also the demographic transition paradigm, which predicted a steady decline of mortality and fertility in the developing world, and a gradual shift from a very young age structure – in which as much as half of the population may be under age 15 – to an older population with a much more evenly distributed age structure.

Instead, we find ourselves almost halfway through a third decade of an epidemic that has reversed decades of progress in increasing life expectancy in several Sub Saharan countries, and has disrupted longstanding patterns of intergenerational relations and exchange, social institutions, and international relations in many others. In terms of numbers of deaths, the HIV/AIDS pandemic is certain to surpass all previously recorded epidemics, and in terms of the disruption it causes, will rival and perhaps even surpass the plagues that ravaged Europe up until the Industrial Revolution and the worldwide influenza epidemic of 90 years ago. Unlike earlier epidemics that spread their misfortune across the age distribution, AIDS affects primarily young adults, at the precise ages when child rearing and economic responsibilities are highest. Indeed, one of the most sinister aspects of AIDS is that in addition to killing those young adults it infects, it also harms in profound ways many in the age groups typically dependent upon those young adults who succumb to the disease.

But if the prevailing paradigms of demography and public health were ill suited for the advent of AIDS, demographers' toolkits for estimating the potential consequences of the epidemic on population structure have proven well suited for the task. Well honed techniques for conducting "what if" scenarios involving changes in age specific mortality rates, even while employing far from ideal data, have facilitated major contributions from population scientists. Even so, there have been new and difficult obstacles to modeling HIV impacts because of poor information regarding the rate of spread of infection (especially related to variability in rates of partner change and partner risk profiles; variability in degree of infectiousness during different stages of the illness; unanticipated changes in behavior, etc.) and variability in the period between infection and death. Changes in such assumptions have very large implications for the results of such models.

It has been much more challenging to investigate the substantive consequences of such impacts. The combination of such high rates of death and the concentration of deaths in the most productive age groups is unprecedented. Also, such deaths affect all other age groups traditionally dependent upon these working

age adults for support, as is society more generally. Sensitivities regarding AIDS and especially its primary modes of transmission make data collection on such topics challenging; and long latency periods and potential delays in the manifestation of consequences after death also make the measurement of long term psychological, social, and economic effects difficult.

DEMOGRAPHIC DIMENSIONS OF AIDS

Demographers have focused much of their attention on the effects of various levels and patterns of AIDS related mortality on the age sex structure and size of future populations. Botswana's population, for example, would most likely have doubled between 1990 and 2025 without AIDS; instead, with AIDS, its actual population will be substantially less than it was in 1990. Worse, the loss of working age adults relative to other age groups will strain traditional support mechanisms for the young and old.

Such projections have proven very useful for illustrating the implications of existing levels of infections for future populations, and also for showing how such dire consequences would be mitigated by lowering rates of new infections. Such efforts have played a major role in inspiring some governments and international organizations to action. Most of this modeling has focused on transmission and subsequent death rates among young adults, but in high prevalence countries where AZT and other drugs that lower mother to child transmission have not yet become widespread, the infection of large numbers of children also implies non trivial decreases in child survival and overall life expectancy.

Conversely, patterns and levels of AIDS related mortality can affect the future spread of the virus. One feature of this relationship that can be readily modeled is the loss of the most susceptible members of a population through early infection, which will, *ceteris paribus*, lead to lower rates of infection and death among those remaining. More difficult to predict and model are changes in sexual practices that occur as a result of increasing AIDS related mortality.

Prevalence of HIV also affects current and future levels of fertility, primarily by increasing

mortality among adults of childbearing age. This results in fewer children than would have been born had these adults lived through these years. Other effects of HIV on fertility are mediated through one or more of the classic proximate determinants of fertility. First, wide spread widowhood will leave many young adult survivors without child producing and child rearing partners. Second, HIV induced morbidity reduces sexual activity among the infected – in proximate determinants parlance, these first and second mechanisms decrease exposure to intercourse. Third, HIV may lead to shifts from contraceptives more effective in preventing pregnancy, such as the pill, to methods less effective in preventing pregnancy but offering new protection against HIV, such as the condom; this third mechanism would affect exposure to conception. Fourth, HIV appears to increase fetal loss among infected women, affecting gestation.

These major mechanisms of HIV on fertility described above are fairly straightforward to incorporate into a projection. But a more difficult mechanism to model is that HIV may change the fertility desires of those infected and/or left behind by widowhood. This could result in either increased fertility among persons living with HIV and AIDS (PHAs) who wish to leave a child behind; or decreased fertility among those who do not want to risk having an infected child and/or a child without his biological parent to raise him.

On the other hand, an increase in fertility – if caused by changes in the frequency or onset of unprotected intercourse for reasons unrelated to HIV – could in principle stimulate subsequent increases in the spread of HIV. However, it is the underlying patterns of sexual practices affecting both fertility and HIV transmission that will have the most important impacts on both.

Migration patterns, too, can be a cause or consequence of HIV transmission. Most attention to this topic in the population sciences has focused on the former. Population scientists studying migration have long speculated that patterns of migration could facilitate the transmission of HIV among migrants, and facilitate the spread of HIV from urban centers to rural communities from which many migrants come. The past few years have seen increasing empirical investigations of this hypothesis. The focus

is most frequently on rural to urban migration because it exposes young adults to new opportunities for sexual experimentation, provides them the discretionary income with which to do so, removes them from the oversight and control of extended kin, and may lead to extended periods of spousal separation among those who are married. Similarly, long distance truckers experience extended periods of spousal separation, which increases the likelihood that they visit sex workers or engage in other types of high risk sexual behavior. Hence, migrants and long distance truckers tend to have above average rates of HIV infection, and may transmit the virus to more permanent partners upon their return. Moreover, many migrants and truckers provide financial support for a large number of family members in their home communities. Consequently, AIDS related morbidity and mortality among migrants and truckers can have a devastating economic impact on their home communities.

Less studied but also important are patterns of migration that result from AIDS. Migration of PHAs who had previously moved to urban areas for work back home to their villages for care taking appears widespread. While the implications for population distribution of such return migrations may not be major, the implications of such widespread moves on intergenerational exchanges (both monetary and in kind) and the welfare of their parental caregivers are likely to be significant.

In addition to interacting with the three traditional components of population growth and structure (mortality, fertility, and migration), HIV also affects other key features of population well being. Mortality aside, the severe morbidity associated with HIV infection severely diminishes the productivity of those infected, and draws away scarce labor and financial resources that would have otherwise been available for family investment or consumption. In high prevalence societies, the loss of highly trained individuals such as teachers, nurses, and physicians to AIDS will affect critical social institutions such as education and health care. Clinics and hospitals may also become overwhelmed with AIDS patients seeking expensive and sophisticated treatments that the staff are ill positioned to provide. And traditional patterns of care for children and the elderly, both of

whom are dependent upon working age adults for their support, are also being disrupted. While the plight of children left behind has been well recognized, the many ways in which older parents have been affected have not. Increasing numbers of households headed by women may face special difficulties related to resource acquisition. Increasing numbers of households with out adult women may face special difficulties related to truncated social networks and a short age of household services that adult women normally provide.

CHANGES OVER TIME IN THE TOPIC AND ITS TREATMENT

Much of the attention given to AIDS by demographers has focused on modeling the impacts of HIV related mortality on future population size and structure, as briefly described above. Impending expansion of antiretroviral drugs to prolong the lives of the infected will soon add a happy complication to modeling efforts aimed at predicting the number of infections and deaths, and their subsequent impacts on population size and structure. Demographers and statisticians have recently also turned their attention to forecasting other future consequences of the epidemic; for example, the number of older persons likely to experience the death of a child before their own deaths. Other models address how features and changes in sexual networks affect the spread of the virus. New sampling strategies, such as the PLACE method and Respondent Driven Sampling, have been developed to access difficult to reach populations, such as sex workers and intravenous drug users, that often play key roles in the spread of the virus throughout the more general populations. Other recent advances in computer assisted analysis of qualitative data have helped make more systematic the investigation of sensitive topics and subtle processes.

Substantive work by population scientists has broadened from a focus on sexual risk taking to analyses of how non infected relatives of PHAs, such as children and, more rarely, older parents, are affected by the epidemic; community reaction and stigma towards PHAs and their families; HIV related domestic violence; and how communities respond to the epidemic.

Population scientists have also played an important role in programmatic research, including developing methodologies to conduct systematic assessments of the relative effectiveness of various types of HIV prevention interventions.

FUTURE DIRECTIONS

As the use of antiretrovirals becomes more widespread in the countries that need them over the next decade, there will be increasing demands for research on access to care, quality of care, and quality of life of PHAs. For example, interactions between nutrition and the progression of the disease are likely to command increasing attention. Although stigma and discrimination appear to diminish over time in most communities, given the sensitivities associated with AIDS and the primary modes of transmission, these are likely to remain central to the research agenda for the foreseeable future.

Hobhouse, L. T. (1864–1929)

Stephen K. Sanderson

Leonard Trelawney Hobhouse was born in 1864 in Cornwall, England. His father was rector of the local parish church, and his grandfather had been a distinguished barrister and public servant (Owen 1974). Educated at Corpus Christi College, Oxford, he became a tutor there in 1887. In 1907 he became the first person to hold the Martin White Chair of Sociology at the University of London. In addition to his academic career, Hobhouse spent time as a journalist, working for the *Manchester Guardian* between 1897 and 1902. Later he spent time as a journalist in London (Owen 1974).

Hobhouse is generally regarded as the first British sociologist. He wrote numerous books, the most important of which dealt with long term social evolution and its meaning for the present and the future. The most important of these books were *Mind in Evolution* (1901), *Morals in Evolution* (1951 [1906]), *The Material Culture and Social Institutions of the Simpler Peoples* (1965 [1915]), and *Development and Purpose* (1927 [1913]).

In *Morals in Evolution*, Hobhouse sketched out the evolution of systems of morality or ethics

as part of a larger process of mental evolution. In this regard, he identified a process of mental evolution that began with the rudimentary and impulse driven thought of early preliterate societies. The first real advance in mental evolution was the protoscience of ancient China, Babylonia, and Egypt. This was followed by a new stage of reflection between the eighth and fifth centuries BCE that was characterized by the rise of the earliest world religions of Judaism, Confucianism, Buddhism, and Hinduism. Then came the first truly critical and systematic secular philosophy of the Greeks, and then finally the rise of modern empirical modes of thinking in Europe beginning in the sixteenth century (Ginsberg 1951).

Hobhouse identified four stages in the evolution of morality. At the lowest stage, people feel obligations toward one another, but these are limited to human relations in very small groups, either the local community or the kin group. Life is regarded as important, but it is only protected through such mechanisms as blood feud, and there is no moral principle that life itself is something sacred. Right moral action means avenging a wrong done to a member of one's own group. A second stage of morality is reached when people conceptualize a duty not merely to avenge a wrong but to protect life and to guard property instead of just retaliating against thieves. Moral obligations have become broader, but they still apply only to the members of one's own group, and there are no general ethical principles. This second stage of morality roughly corresponds to the second stage of mental evolution, and thus makes its appearance for the first time in the earliest civilizations.

In the third stage of morality people formulate moral principles and ideals of character and conduct of a religious nature. Here we find morality and ethics as integral parts of the great world religions; this third moral stage corresponds roughly to the third mental stage. The fourth and highest moral stage is reached when an attempt is made to construct a rational ethical theory that prescribes rights and duties that apply universally. It was the ancient Greeks who first began to grope toward this sort of ethical universalism, which has been extended by philosophers and theologians in more modern times.

In *The Material Culture and Social Institutions of the Simpler Peoples*, written in collaboration with G. C. Wheeler and Morris Ginsberg, the authors classified societies according to their technological inventory. They produced a scheme of seven major “stages of economic culture”: (1) Lower Hunters; (2) Higher Hunters; (3) Incipient Agriculturalists; (4) Middle Agriculturalists; (5) Highest Agriculturalists; (6) Lower Pastoralists; and (7) Higher Pastoralists. There is a rough evolutionary sequence here, except that agriculture and pastoralism stand to each other as subsistence alternatives rather than in an evolutionary relationship.

The authors related these economic stages to other dimensions of social life, especially morality, religion, law, and overall social organization by assembling data on over 400 ethnographically known societies. They found that the higher the economic stage, the more developed and formalized the system of government. In terms of the administration of justice, there was a pronounced trend from private redress of wrongs to public redress by chiefs or tribal councils. The authors also looked at the relationship between their economic stages and various dimensions of marriage and family life. Here the correlations were not always as dramatic or striking. But in the final analyses, which involved variables bearing on social stratification and property ownership, the results were again dramatic. There was a very marked trend from communal to private forms of property ownership and toward greater social and economic inequalities.

Given the emphasis on economic stages as the starting point for the whole book, and the correlations between these stages and other dimensions of social life, one might get the impression that Hobhouse, Wheeler, and Ginsberg were materialists. But this is not the case. Hobhouse was in fact a strong theoretical idealist. This is clear from his *Morals in Evolution*, but even more so from his capstone work, *Development and Purpose*, in which he presents an overall philosophy of evolution. Hobhouse was highly critical of Spencer and the social Darwinists, and claimed that it was the human mind, not the struggle for existence, that was the engine of social evolution. He contended that it was the “slowly wrought out dominance of mind [that] is the

central fact of evolution” (Hobhouse 1951: 637). Even the stages of economic culture themselves are explained ideationally, as the results of the mind accumulating “stocks of knowledge” over the millennia.

Like many early evolutionists, Hobhouse was committed to a doctrine of social progress, even though he recognized that progress is not automatic and social evolution is by no means strictly unilinear. Human progress is erratic, with periods of retrogression interspersed with periods of progression. But on the whole, humankind has been improving itself, gradually moving toward a society based on harmony and a kind of ethical universalism in which all of humanity will eventually form a single social unit.

Hobhouse was a liberal humanitarian and social reformer who was a strong proponent of social harmony and internationalism. He spoke out against imperialism in all of its forms. His interest in practical affairs is clearly indicated by his journalistic activity and his work for many years on various trade boards, where he concerned himself with labor conditions. Several prominent British government officials came under Hobhouse’s influence, either directly or indirectly. These included Harold Laski, Clement Atlee, Hugh Dalton, and Hugh Gaitskell (Owen 1974).

Holocaust

Fred Emil Katz

The stark facts of the Holocaust can be summarized. When Adolf Hitler and his National Socialist Party came to power in Germany in 1933, they initiated measures against Germany's Jews. Before their rise to power the Nazis, under Hitler, had openly and vehemently blamed Jews for all of Germany's ills in the years following the country's loss of World War I (1914–18). After they gained power, the Nazi anti Jewish measures included use of the existing legal machinery of the German state to devise and implement increasingly restrictive measures against Germany's Jewish population. These measures incrementally but inexorably deprived Jews of more and more rights of citizenship and capacity of living their daily lives. The legal measures were augmented by sporadic brutal attacks by organized thugs who molested and terrorized individuals and communities of Jews. The most extreme of these occurred on the night of November 9, 1938, the *Kristallnacht*, where a nationwide attack on Jews took place. Yet all of these eventually turned out to be preliminaries to an active and focused program to actually exterminate all Jews who came within Germany's reach during World War II – the war of 1939 to 1945. During the early years of that war Germany had overrun and conquered most of continental Europe, a land mass that included millions of Jews who had been living in the various countries now under German control. The actual extermination of Jews relied, at first,

on the direct execution of individuals by individual German soldiers and paramilitary functionaries of the state – most notably the SS. Although this took place on a huge scale, the extermination plan was so grandiose that more elaborate systems of mass murder were devised, most notably a system of concentration camps that served as extermination factories, using lethal gas and the burning of bodies on a mass scale never before seen. The Auschwitz concentration camp, located in Poland, was the most notorious but not the only camp of this kind. Murdered at Auschwitz were some 2 million innocent persons, most of them Jews, but also others whom the Nazi ideologues regarded as unworthy of living in their utopian vision of the superstate dominated by pure Nordics. It is estimated that the Nazis managed to murder some 6 million Jews before their rampage was stopped by the victory of the Allies that ended the war. This genocide, this deliberate and systematic murder of 6 million humans beings, is doubtless the largest effort of its kind in all of human history.

Following a period of stunned silence, there has been a flood of responses. Within the academic community these have come from historians (e.g., Hilberg 1967; Bauer 1978), political scientists (e.g., Shirer 1960; Goldhagen 1996), and psychologists (e.g., Adorno et al. 1950; Milgram 1974) and social philosophers (e.g., Arendt 1964, 1968).

Apart from one conspicuous exception (Fein 1979), sociologists have been exceedingly silent in response to the Holocaust. In 1979, a Jewish sociologist said that “there is in essence no sociological literature on the Holocaust” (Dank), and in 1989 another sociologist said that the Holocaust work of sociologists “looks more like a collective exercise in forgetting and eye closing” (Bauman). Bauman's assessment still seems to hold today.

Despite this silence, it seems that sociology can contribute insights about the Holocaust that no other discipline can. And that, in turn, the Holocaust can help us sharpen some of the most venerable sociological insights derived from Max Weber and Émile Durkheim (Katz 1993, 2003, 2004). The first begins from what is perhaps sociology's underlying premise: the need to explain ordinary people's ordinary social lives.

Applied to the Holocaust, a great many ordinary people – not crazy people, not marginal people, not zealous Nazis, but ordinary folks – became active participants in mass horrors. When it comes to monstrous behavior, it is not monsters we need to worry about, but ordinary people; they were active participants and contributors to the terrors we know as the ultimate genocide. It is ordinary people's ordinariness that must provide us with the clues of how genocide is practiced. The Nazis recruited many into becoming mass murderers who did not start out with murderous intentions.

Rudolf Hoess, the commandant of Auschwitz, was the ultimate bureaucrat. From Weber, we learned how the bureaucrat is the functionary who tries to bring rational processes to whatever tasks come his way. Hoess did just that, except that his task was mass murder. He also shows how the distinctive mindset of the bureaucrat enabled him to segregate an ongoing, fairly warm, nurturing home life from deep immersion in a grisly work setting. Weber was resurrected, but applied to a setting of which he could not have dreamed.

Émile Durkheim found an ally in Helen Fein (1979) in her study showing that the degree of Jews' integration into a country influenced the likelihood of becoming victims of the murderous assault. Durkheim's focus on social cohesion – based on what we would now call a group or society's shared culture – is also the focus of the "local moral universe" (Katz 2003, 2004). We humans get our sense of identity and purpose from a moral context, to which we try to contribute. Under such a moral umbrella, we may totally exclude those whom we regard as being on the outside. The result is that, as the Nazis displayed, these people can be treated not only with contempt but also with actual annihilation, and this can be done under the myth of operating on the basis of a high moral purpose and justification. This, Durkheim did not envisage. But his perspective applies and clarifies such a phenomenon.

The distinctive contribution of sociology to clarifying how a genocide operates – using the Nazi Holocaust as a source of insight – is that it can show how ordinary people can be recruited to do the most horrific acts, and do so using our existing social psychological proclivities and

habits. It can show how bureaucratic administrative techniques, so central to modern life, can be hijacked in the service of evil. Furthermore, it can show how the moral umbrellas under which we are accustomed to living, and which serve as instruments for our most humane actions, can also become the instruments for our most inhumane actions. Sociologists can clarify just how these ordinary features of our social makeup actually work. From this knowledge we can not only demystify, but also actually find ways to counter, the evil we have come to call genocide.

Homans, George (1910–89)

Thomas J. Fararo

George Caspar Homans was a major theoretical sociologist whose lucid writings helped to shape numerous developments in basic sociological research. His ideas about theoretical principles in sociology were much debated and often rejected.

Homans entered Harvard College in 1928 with an area of concentration in English and American literature. Among his electives was a course with the philosopher Alfred North Whitehead. Thereafter, in the period from 1934 to 1939, as a Junior Fellow of the newly formed Society of Fellows at Harvard, he interacted with Whitehead and other Harvard luminaries while undertaking independent studies in a variety of subjects, including sociology, mathematics, psychology, and anthropology. He attended a special faculty student seminar on the newly translated general theoretical sociology of Vilfredo Pareto, which led in 1934 to his first published work in sociology, with Charles Curtis, *An Introduction to Pareto: His Sociology*. He also studied historical methods, and began doing original historical research that was published in 1941 as *English Villagers in the Thirteenth Century*. In 1939 he became a Harvard faculty member, a lifelong affiliation in which he taught both sociology and medieval history. By virtue of his later theoretical writings, by the 1960s he had become a major theorist and in 1964 was elected president of the American Sociological Association.

As a theorist, Homans's overall intellectual ambition was to create a more unified social science on a firm theoretical basis. He criticized his colleague Talcott Parsons, notable for a similar ambition, for creating only a conceptual scheme, but not a theory, defined as a deductively organized system of propositions that explain observable phenomena. His own approach to theory developed in two phases. In each phase, there is a presupposition concerning the nature of the subject matter and an associated mode of theorizing.

In his first phase, as presented in *The Human Group* (1950), there is an explicit process philosophical presupposition about reality and a system model for its analysis, reflecting the intellectual influence of Whitehead and Pareto, respectively (Fararo 2001: ch. 3). Echoing Whitehead's stress on events and process, Homans proposes that social reality should be described at three levels: social events, customs, and analytical hypotheses that describe the processes by which customs arise and are maintained or changed. Social relations (e.g., kinship ties) are instances of such customs, defined as recurrent patterns amid the flux of social events.

The conceptual scheme in this first phase consists of three elements of social behavior called interaction, sentiment, and activity, together with emergent norms. Each of these is associated with variables such as frequency of interaction, similarity of activities, intensity of sentiment, and conformity to norms. These behaviors comprise the social system of the group. The system model, reflecting Pareto's influence, employs analogies drawn from physical science, especially thermodynamics. He argues that, like actual thermodynamic systems, social systems vary substantially in their "externals" (apparent differences) but that as in thermodynamics, they possess an underlying similarity described by the hypotheses that interrelate a small number of analytical elements. A year after it was published, Homans's social system theory was formalized by Herbert A. Simon as a system of differential equations, one of the earliest and most influential contributions to mathematical sociology. At the same time, Homans's book set out examples of emergent social structures of groups that have been of continuing interest to social network analysts. The subfield of sociology called "small groups" owes much of its inspiration to Homans.

In this first phase, Homans makes some use of the psychological principle of reinforcement and analyzes social exchange in one particular group. However, he was more attuned to the work of social anthropologists of his time. Chapters that treat theories of ritual, social control, and authority are brilliant forays into the subjects that draw upon and surpass the literature of the day. For instance, in a chapter on kinship, he anticipates

the theory of structural balance in social psychology, as well as his later trenchant critique of functionalist theories of marriage in his 1955 book with David Schneider, *Marriage, Authority, and Final Causes*.

The second phase of Homans's theory program is based on the presupposition that satisfactory explanation in the social sciences must be based upon principles about individual behavior. His "Social Behavior as Exchange" (Homans 1958) proved to be seminal for what came to be known as exchange theory, an important paradigm in sociology. In this article he employed principles from behavioral psychology to explain and synthesize findings from experimental social psychology, and findings from earlier field studies. Social behavior as exchange means that a plurality of individuals form a system of interaction in which the activity of each provides part of the basis for an outcome that has sanction significance (reward or punishment) for each of them. Social approval is a fundamental reward actors can provide one another, functioning at an elementary level of interaction as money does in an advanced economy. He elaborated this approach in his treatise *Social Behavior: Its Elementary Forms*, which appeared first in 1961 and then in a revised edition in 1974, and set out his presuppositions about social science in his 1967 book, *The Nature of Social Science*.

One example of his more specific theoretical contributions concerns distributive justice. In the pioneering 1958 article, Homans had argued that distributive justice is one of the conditions required for "practical equilibrium" in a group. In the *Social Behavior* treatise, Homans elaborated on this theme and suggested the general principle that distributive justice holds in a group when, for any pair of members, the ratio of their rewards (e.g., wages) is equal to the ratio of their contributions or investments (e.g., job responsibilities). These ideas have stimulated a great deal of theoretical and empirical work on justice by social psychologists and sociologists.

In its mature form, Homans's general argument is that fundamental explanatory principles are to be true of individuals as members of the human species, not as members of particular groups or cultures. Furthermore, social psychological propositions (e.g., those pertaining to

interpersonal balance) should be derivable from these principles. Thus, a theory requires two sets of premises: principles of behavioral psychology, and statements applying them to a specific explanatory task. Disciplines differ as to their typical explanatory task. History tries to explain particular social events, economics tries to explain outcomes of one time interactions of individuals, and sociology aims to explain emergent features of recurrent interactions among the same individuals. Hence, sociology is concerned with customs and social structure, but its theoretical aim is to explain these recurrent features in terms of patterns of rewards and punishments that individuals experience through interaction. For instance, status orders and authority relations are two such emergent features of social interaction. Each has a time extended character rather than a transient character. The new presupposition, relative to the first stage, is the idea that a theory must have a deductive structure. Homans is a methodological individualist, but his focus is sociological in the sense that the aim is to explain how processes of interaction generate the generic types of social structural phenomena we observe: social structure as consequence rather than cause. Although structure and culture act back on individuals, they cannot alter the principles of behavior.

Homans's arguments apply to what he calls the subinstitutional level of social life: that which emerges spontaneously from interaction such as informal social ranking. The logical priority of this type of explanation is essential to Homans's research program. Institutions are like the macrolevel enduring objects of fundamental physics: their existence presupposes a level of interactions that accounts for them. In this sense, Homans adopts the reductionist stance inherent in the program of theoretical physics. In terms of the philosophy of social science, his approach is clearly in the tradition of methodological individualism, although in his case it might better be called methodological behaviorism.

Although others called his work exchange theory and treated it as one among a number of ever growing theoretical paradigms in social science, Homans strongly rejected both the label and the multi paradigmatic presupposition that came with it. For Homans, there is only one fundamental theory in social science. That theory is

given by a system of deductive arguments based on the principles of behavioral psychology. The specific task of theoretical sociology is to explain how enduring social relational structures arise out of the interaction of human behavioral organisms (Fararo 2001: ch. 10). A somewhat more general perspective of this sort would apply it also to the explanation of culture, as in *A Theory of Religion* (1987) by Rodney Stark and William Sims Bainbridge, a theoretical work that adopts both the deductive and the behavioral elements of Homans's approach.

Other theories have reflected the influence of Homans's ideas, but in a more critical mode. Some take issue with the behavioral foundation and the scope restriction to elementary processes. For instance, Peter Blau (1964) attempted to create a general theory that starts with face to face interaction but also incorporates explicit macrosocial assumptions. For example, approval of leaders in the small group is paralleled by the legitimation of power at the macrolevel. Although emphasizing exchange processes, Blau adopted neither the deductive nor the behavioral aspects of Homans's approach. In turn, Blau's theory was criticized on the grounds that it lacked a deductive linkage between the micro and macrolevels – a criticism that embodies methodological individualism but not necessarily the behaviorist version favored by Homans. Thus the way was open for a more explicit formulation of a micro macro deductive logic in social theory. Coleman (1990) set out such an approach. It departed from the behaviorist foundation in favor of an approach closer to that of neoclassical economics, grounded in a postulate of rational choice.

Richard Emerson's power dependence theory was closer to Homans's approach. It has led to an experimental research program that, in some versions, retains the behaviorist principles employed by Homans. Power dependence theory has been applied to patterns of exchange between actors in networks. In turn, this development led to a variety of competing research programs that differ in their theoretical assumptions, but that aim to predict outcomes in varying shapes and types of exchange networks defined under laboratory conditions.

Homans's work also remains relevant to various research efforts gaining momentum in the

early twenty first century. Through the use of computer simulation, a number of investigators are developing model building approaches grounded in the idea that the basic task of social theory is to show how the interaction of a set of actors gives rise to emergent social phenomena. These simulations treat actors as knowledgeable agents whose behavior is generated by ever changing knowledge shaped by perceptions of the behaviors of other agents and of the outcomes to which their joint efforts give rise. In this development, the strictly behavioral foundation favored by Homans has been replaced by a more cognitive approach. However, very much in the spirit of Homans, the general theoretical goal is the explanation of spontaneous social order.

homelessness

David A. Snow, Jill Leufgen, and Matthew Cardinale

The sociological conceptualization of homelessness has pivoted on two dimensions: social disaffiliation and residential impermanence. The disaffiliation dimension, associated primarily with research on Skid Row alcoholics of the 1950s, emphasizes the interpersonal and

institutional disconnection of the homeless. Although many homeless individuals lack the affiliative bonds that link most domiciled folks to various institutional structures, not all homeless are socially atomized. Many of them are connected interpersonally to other homeless, some maintain contact with relatives, and most are connected in various degrees to an array of street agencies and programs. Moreover, the majority of homeless individuals are not chronically homeless, as they cycle on and off the street and between street and mainstream agencies and institutions. Because there is considerable variation among the homeless along the atomization continuum, disaffiliation can be best regarded as a variable dimension of homelessness rather than the defining characteristic. Consequently, recent conceptualization emphasizes the residential dimension.

Defined in terms of residence, individuals or families without a permanent place of their own that meets the minimal standards of a residence in their respective cultures are generally thought of as homeless. This would include within the US and much of the developed world not only what Peter Rossi initially termed the “literal” homeless – that is, people living on the streets and/or in shelters – but also institutionalized individuals who have no place of residence upon their release, individuals and families who “double up” with others because they cannot afford a place of their own, and often even those who live in grossly substandard housing. Although this is a very broad conceptualization (referred to as “general” homelessness), it is thought to be too inclusive for research purposes because of the difficulty of reaching agreement, both nationally and cross nationally, as to what constitutes an acceptable level of doubling up and substandard housing. In many large cities throughout the world, for example, the residents of the numerous urban shantytowns, such as Brazil’s favelas, are not typically considered homeless; in the US, by contrast, residents of similar makeshift shelter arrangements (e.g., encampments) are typically counted among the homeless. Because of such complicated issues, most research on homelessness at the end of the past century is based on the “literal” conceptualization, encompassing individuals sleeping in shelters, accommodations paid for by agency vouchers, or in places not intended as dwellings,

such as the streets, abandoned buildings, automobiles, and parks.

HISTORICAL OVERVIEW

Whether viewing homelessness broadly (general homelessness) or more narrowly (literal homelessness), it has been a longstanding feature of the social landscape, particularly since the rise of cities. However, the size and character of homeless populations, and the extent to which they have been regarded as social problems, have varied over time. Homeless beggars and members of “floating populations” were characteristic features of the pre industrial city, wherein the streets were teeming with people because of the blurring of the boundaries between home, work, and leisure. With the exception of a few vilifying pamphlets, such as Martin Luther’s *The Book of Beggars*, the folk tradition of hospitality to beggars and itinerants, and the tendency to idealize poverty as a spiritual virtue, tended to mitigate the stigma of pre industrial homelessness. This changed, however, with the social dislocation caused by industrialization and the breakdown of European agrarian economies, which led to dramatic increases in the numbers of homeless, then referred to derogatorily as vagrants, and to the development of laws and policies to control or eliminate those so labeled, particularly in England and its colonies.

One such law, the Vagrancy Act of 1597, led to the transportation of some number of England’s homeless to its American colonies. These relocated folks, along with other transient poor who moved from community to community because they were denied settlement rights, constituted the first wave of homelessness in what eventually became the United States. A second wave occurred in the 1860s immediately following the Civil War, when large numbers of people were displaced but subsequently absorbed into the western frontier. The era of westward industrial expansion, from the late 1800s to the mid 1920s, called for a transient labor force that gave rise to a third wave of homelessness symbolized by “hoboes” – itinerant, seasonal workers – and the development of “hobohemias” in many large cities, both of which were immortalized in Nels

Anderson's classic sociological study, *The Hobo* (1923). The Great Depression resulted in a fourth surge in homelessness, which lasted until World War II, when many homeless were either absorbed into the expanding workforce or recruited into the armed forces.

The confluence of a number of factors in the wake of World War II – declining Skid Row populations in major US cities, post World War II veterans' programs, the rise of optimistic urban planning programs, and a changing economy – prompted some observers to predict the end of homelessness in First World cities. But the early 1980s ushered in a new wave of homelessness that has persisted into the current century, not only in US cities but also in major, global cities throughout the world, such as Berlin, London, Paris, São Paulo, and Tokyo.

RESEARCH ON THE “NEW WAVE” OF HOMELESSNESS

From the mid 1980s to the turn of the century, homelessness was regarded as one of the most pressing social problems within the US, generating widespread public concern and debate manifested in intense media coverage, Congressional hearings, homeless protests and locality based NIMBY movements seeking to control and contain the homeless, and literally volumes of social scientific research. Nearly all of this research can be classified into three basic genres. The first genre consists of either city specific or national survey based studies focusing on homeless individuals, and particularly on their numbers, demographics, disabilities, and transitions in and out of homelessness (Rossi 1989; Burt 1992; Burt et al. 2001); the second genre includes macrolevel, multivariate studies that assess the relationship among variation in rates of poverty, unemployment, housing affordability, and the like, and variation in rates of homelessness across cities (Ringheim 1990; Burt 1992; Shinn & Gillespie 1994); and the third genre consists of ethnographic field studies that focus primarily on the texture and dynamics of street life and on the adaptive, survival strategies of the homeless (Snow & Anderson 1993; Wright 1997; Duneier 1999).

Estimating the Number of Homeless

Due to the distinction between literal and general homelessness, and the difficulties in counting the “hidden” homeless (sleeping in abandoned buildings, parks, automobiles, etc.) and determining the ratio of street to shelter homeless, estimating the number of homeless city wide or nationally has been a contested enterprise, with agency and advocacy estimates generally being considerably higher (2–3 million) than most research based estimates. Research estimates are generally based on either “point prevalence” or “period prevalence” counts. The former encompasses counts of the number of people who are homeless at a single point in time, usually one day or night, and are typically based on shelter and street counts (Rossi 1989), shelter and soup kitchen counts (Burt 1992), or on counts of homeless in a range of assistance programs (Burt et al. 2001). Since there are no reliable national counts, those derived from a systematically selected sample of cities have been used as the basis for estimating the national homeless population. There have been two such widely cited estimates, both conducted by the Urban Institute and both contested, for the US: close to 700,000 in 1987 (Burt 1992) and around 850,000 for 1996 (Burt et al. 2001). Period prevalence estimates, in contrast, are based on counts of people who have been homeless for some period of time or indicate that they have been in response to a survey, and yield much larger estimates. For example, a 1990 nationwide survey of 1,507 domiciled US adults indicated 3.1 percent (5.7 million) experienced literal homelessness between 1985–90, and 4.6 percent (8.5 million) experienced general homelessness during the same period (Link et al. 1995).

Characteristics of the Homeless

Prior to the 1980s and the fifth wave of homelessness in the US, most homeless individuals were poor, unattached, alcoholic older men (Bahr & Caplow 1973). In the 1980s, as the homeless population grew, their characteristics began to change as well (Rossi 1989; Burt 1992; Burt et al. 2001). The majority of the “new”

homeless were still unattached (single, divorced, separated, or widowed) males, but there were more homeless families and children than in the preceding decades. They were also considerably younger, with a mean age in the late 30s rather than the 50s; they were disproportionately minorities, with black Americans being conspicuously over represented, particularly in large metropolitan areas; and a disproportionately large number were military veterans. As before, alcohol abuse was prevalent among the new homeless, but heavy drug use was more commonplace, spurred in part by the availability of cheap "crack" cocaine during the 1980s. In comparison to the general US population, a disproportionate number of the homeless also experienced a serious mental disability, with most research based estimates ranging from one quarter to one third. A final defining characteristic of the homeless, both the old and the new, is that they are predominantly urbanites. Clearly, the new homeless can be found in all kinds of communities, both rural and urban, but they are most prominent in metropolitan areas, particularly in selected neighborhoods in central cities (Lee & Price Spratlen 2004).

Causes of Homelessness

Historical fluctuations in the incidence of homelessness appear to be precipitated by the occurrence of two dislocating trends or events: large scale structural changes, as in the case of industrialization, and systemic shocks, as associated with wars and depressions. Such changes, particularly of the structural variety, have been identified as the major precipitants of the end of the century increase in homelessness as well. Especially noteworthy is a decline in affordable housing in the context of increasing economic hardship due to such factors as deindustrialization and declining wages. Indeed, the confluence of such trends suggests a general proposition regarding the structural roots of homelessness: it grows in the widening gap between subsistence needs, particularly housing, and the availability of economic resources to meet those needs among increasing numbers of individuals (Ringheim 1990; Shinn & Gillespie 1994; Koegel et al. 1996).

Structural factors alone, however, do not determine who becomes homeless. They designate which groups or classes of individuals are at risk of becoming homeless, but they do not specify which vulnerable individuals are most likely to fall onto the streets. In order to get a handle on this part of the causal equation, researchers have also examined the individual level, biographic correlates of homelessness, such as demographic factors (e.g., race/ethnicity), human capital factors (e.g., educational level), social capital factors (e.g., family attachments), and disabilities (e.g., substance abuse and mental illness). In general, research concludes that the occurrence of homelessness among some individuals rather than others can be best understood by considering the intersection of structural and biographical factors (Snow & Anderson 1993; Koegel et al. 1996).

Survival Strategies

The homeless face specific challenges to survival and must negotiate ways to satisfy their basic human needs. Such challenges include finding food and shelter, establishing social relationships, and even making some subjective sense of their situation. The homeless adopt certain survival strategies that facilitate the satisfaction of these material, interpersonal, and psychological challenges. The strategies employed by the homeless are not uniform, but vary according to the individuals' personal characteristics and length of time on the streets. These survival routines are also embedded in specific organizational, political, and ecological contexts that encourage some strategies while making others less likely (Snow & Anderson 1993; Wright 1997; Duneier 1999).

To satisfy material needs, the homeless often engage in a number of different activities exclusively or in combination. Some homeless individuals receive institutional assistance, some perform wage labor, and some engage in "shadow work," which includes a variety of unconventional work pursued in the shadow of regular work, such as begging and panhandling and collecting and peddling discarded books, magazines, and cans.

The homeless, in general, are not interpersonally atomized and incompetent as often portrayed. However, their interpersonal relationships are often paradoxical in that they can provide security in the form of a non stigmatizing reference group and a source for sharing resources, but they are often fleeting and fragile due to the transient nature of street life.

Like all individuals, the homeless must also make sense of their situation and negotiate meaning in their lives. Research suggests they tend to do so in two main ways: via existential oriented meaning construction, which includes invoking causal accounts, such as "I'm down on my luck," to explain one's situation; and through various forms of identity talk, including distancing one self from negative associations, embracing a positive association, or telling fictive stories to embellish one's status (Snow & Anderson 1993).

Responses to Homelessness

The turn of the century wave of homelessness has elicited a variety of responses by different sets of actors across different geopolitical units, ranging from the local community to the states to the federal government. In terms of doing something about the "problem" of homelessness, the responses have generally been of four kinds. The most pervasive response can be described as "accommodative" in the sense of providing relief that aims to ameliorate the experience of homelessness by expanding, for example, the network of shelters and food providers. This has been the character of response by most governmental units, including the federal government's Stewart B. McKinney Homeless Act of 1987 and its subsequent amendments. Overlapping, yet distinctive, is the "restorative" response, which has sought primarily to repair or remedy chronically disabled homeless individuals through medical and/or religious intervention, as illustrated by the 43rd US president's chronic homeless initiative and faith based charity programs. A third line of response is "preventive" in that the objective is to attack the structural causes of homelessness, such as unaffordable housing, rather than its individual level symptoms. This response is illustrated by the

July 2003 Bring America Home Act (HR 2897) and is championed by most homeless advocacy groups and protest movements. A final general response encompasses various "anti homeless" efforts that seek to control and contain the homeless through sponsoring regulative ordinances and legislation that "criminalize" various subsistence strategies, such as panhandling and sleeping in public places.

Research on the various responses to homelessness has been relatively minuscule in comparison to the volume of research on the scope and causes of homelessness and on the characteristics of the homeless and their survival strategies. Nonetheless, there is increasing scholarly concern with relevant policy issues and with the efforts of advocacy groups and the homeless themselves to mobilize on behalf of homeless interests and rights (Wright 1997; Cress & Snow 2000).

homicide

Leonard Beeghley

Unlike other western nations, thousands of people are murdered in the United States every year. Any large American city displays almost as many homicides as do many western nations (Beeghley 2003). A high rate of homicide – the intentional and illegal killing of another human being – makes the US anomalous.

Historically, homicide rates across Western Europe fell in a ragged but steady way from about 20–30 per 100,000 in the fourteenth century to around 1 per 100,000 in the nineteenth century. Although the data must be pieced together and the use of ranges (for example, 20–30) for past estimates suggests some uncertainty, the long term process is clear (Gurr 1989). The average homicide rate in England and Wales was less than 1 per 100,000 throughout the twentieth century (Beeghley 2003). Other Western European nations exhibit similar rates.

By comparison, the US has always displayed much more violence (Adler 2005). In the

twentieth century, the average US homicide rate was 7.6 per 100,000 (Beeghley 2003). Nationwide, about 16,000 persons were murdered in 2001 – a relatively low number, as homicide rates declined at the end of the century. The US rate in 2001, however, was 5.6 per 100,000, compared to only 1.6 in England and Wales. There were 648 murders in Chicago in 2002, 587 in New York, and 654 in Los Angeles – which were low compared to just a few years ago, and interpreted as showing that these cities are becoming safer places to live. By contrast, there were 858 homicides in all of England in 2002.

One way to understand homicide is to assess people's motives (Akers & Sellers 2004). One might posit, for example, that an individual's frustration and socialization to violence contributed to a homicide. Other factors could be involved as well, of course, but the point is to distinguish individual killers from non killers, to explain one homicide. Although social psychological explanations like these are necessary and valuable, they reveal nothing about the structural factors leading to a high (or low) rate of homicide.

Dealing with that issue requires shifting the level of analysis (Messner & Rosenfeld 2001). Research shows that five structural characteristics make the US unique and combine to produce an anomalous homicide rate: (1) the availability of guns, (2) drug markets, (3) racial discrimination, especially in housing, (4) exposure to violence in the media, at home, in neighborhoods, and from government action, and (5) economic inequality (Beeghley 2003). With one exception, the relationship between each of these factors and the homicide rate is clear and unequivocal. The exception involves guns. This literature has become politicized in the US (but not in other nations, where observers take the relationship as established), which means conclusions must reflect an assessment of the preponderance of the evidence.

The combined impact of these factors is especially important. Scholars writing in each area, however, usually do not refer to works in other areas, which makes it hard to see the interconnections. For example, when studies find a correlation between gun availability and the homicide rate, the authors generally do not

look at drug markets. Yet one reason drug markets are so violent in the US is the presence of so many guns. In addition, one reason economic inequality in the US is related to homicide is that so many people are exposed to so much violence. It is a sociological truism that the parts of society are not only connected, but also that their impact is often mutually reinforcing. No single cause exists in isolation.

We are not helpless. A half century ago, the fatality rate from automobile accidents in the US was much higher than today. Although some argued the problem was the “nut behind the wheel,” design changes in roads and cars reduced auto fatalities – even though “nuts” still drive. In a modern society, that which can be explained can often be changed.

The structural factors identified in the literature suggest some possible directions for policy change. Thus, while people have a right to own guns (at least in the US), under what conditions should this right be exercised? Just as public safety dictates some restrictions on the use of cars, perhaps similar policies ought to be applied to guns. Perhaps the way guns are designed and sold should be modified. Similarly, since zero tolerance policies have not reduced demand for illegal substances in the US, perhaps this tactic should be reconsidered and jail reserved for those we fear, rather than those who anger us. This might mean providing users with treatment to undercut the illegal market and violence it engenders. It might also be useful to consider how to attack housing discrimination, reduce the level of inequality, and limit exposure to violence in the US. In evaluating these possibilities, the trick is to think radically but proceed cautiously, looking out for unintended results (Rosenfeld 2004).

But caution need not be stasis. The experiences of other nations suggest clearly that Americans are not fated to live with so much lethal violence. The US is anomalous for specific reasons that are reflected in public policy. The impact condemns thousands of people to death each year. These policies are not set in stone; they are choices. Choices made can be unmade.

homophobia

James J. Dean

Three important areas of research have emerged on homophobia over the last 30 years. Since Weinberg (1972) first popularized the term homophobia in his book *Society and the Healthy Homosexual*, where he defined it as “the dread of being in close quarters with homosexuals,” we have seen the emergence of sophisticated psychological instruments, a vast array of surveys, qualitative ethnographies, and interview studies that explore the attitudes, feelings, and social practices that constitute homophobia.

While scholars such as Sears and Williams (1997) now define homophobia more broadly as “prejudice, discrimination, harassment, or acts of violence against sexual minorities, including lesbians, gay men, bisexuals and transgendered persons,” psychological instruments have become more adept at detecting differences between homophobic attitudes and feelings. For example, MacDonald and Games’s 30 item instrument Modified Attitudes Toward Homosexuality and Hudson and Rickett’s Index of Homophobia, which uses a scale to measure

reactions to homosexual individuals and situations, have become standard ways to assess homophobic attitudes and feelings in experimental studies. Although these instruments are able to differentiate between attitudes as cognitive beliefs about homosexuals and homosexuality and feelings as deeply seated emotional responses, they are still not able to capture how attitudes and beliefs affect social behavior and practices.

The second and largest area of research on homophobia is the development of a huge variety of surveys on homophobic attitudes among adults. The general findings of these surveys show that the demographic characteristics of those who hold negative attitudes about homosexuals are that they are more likely to live in the Midwest, the South, or small towns and rural areas (Herek 1984; Britton 1990; Bruce et al. 1990). Moreover, negative attitudes are more likely to be held by men who are older and less well educated (Roesse et al. 1992; Herek & Glunt 1993). These surveys also show that men have stronger homophobic attitudes or feelings than women, and that men evidence a stronger dislike for gay male homosexuality than lesbianism (Herek 1988; Gallup 1995).

Other recent research on the relationship between homophobia and the formation of gender and sexual identities has emerged among scholars such as Sanday (1990), Mac An Ghaill (1994), Nayak and Kehily (1997), and Epstein and Johnson (1998). For example, Nayak and Kehily (1997) show through interviews and ethnographic observation how young men in secondary schools use homophobic practices to establish masculine heterosexual identities, emphasizing that masculinities are the basis upon which young men's homophobic practices and heterosexual identities are constructed.

Nayak and Kehily argue that identities are always constructed, and gain their meanings, through cultural oppositions. Hence, masculine identities are constructed through their opposition to feminine ones, gaining their meaning through excluding feminine identities but at the same depending upon them for definition. This understanding, they argue, explains why young men are not necessarily against homosexuality itself, but rather its associations with femininity and the lack of a masculine self identity that it implies. They thus view

homophobia as a practice that establishes boundaries of purity and pollution between pure heterosexual masculine men and polluted non heterosexual feminine ones. They observed several patterns of homophobic practices among young men. For instance, they state that young men avoid intimate conversations with one another, fearing emotional homosocial bonding. That is, talking about feelings could elicit suspicions that an individual might possibly be homosexual. Further, boys avoid other boys who are suspected of being gay in order to maintain clear boundaries between a respected masculine heterosexual status and a denigrated gay one. Moreover, young males use homophobic practices to establish a heterosexual identity through a gendered sign system that categorizes feminine boys as polluted and potentially homosexual. For example, boys who are quiet, studious, well mannered, or do not participate in male bonding practices are often targets of derision, as well as boys who have high voices, a feminine walk, or a scrawny body. By making fun of other boys, deriding them as gay, or even using violence, young men establish a masculine heterosexual identity through excluding and sanctioning other boys.

An even more violent and aggressive heterosexual masculine identity, which depends on homophobia and homosexuality for its constitution, is analyzed by Sanday (1990) in her study of fraternity gang rape. Sanday shows that fraternity brothers promote compulsory heterosexuality in acts of gang rape by using homophobic social sanctions which deride those brothers who do not participate as homosexual or unmanly. At the same time, however, a sublimated homosexuality is expressed by the fact that the frat brothers are having sex with one another through the woman being gang raped. Homosexual desire is expunged out of the act of gang rape through homophobic and compulsory heterosexual discourses that construct masculine heterosexual brothers who "pull train," that is, gang rape a woman, as exclusively heterosexual.

In sum, homophobia has become an important topic in social science research. The growing sophistication of psychological instruments, the increasing number of surveys and qualitative studies analyzing homophobic attitudes, feelings, and practices have helped us to better

understand the phenomenon and its continuing conceptualization as a form of deviance. However, future research on homophobic behavior by both quantitative and qualitative scholars would help to fill in important empirical gaps in the literature, especially on men who consciously and behaviorally identify as heterosexual and commit the largest number of hate crimes against gays and lesbians (Jenness & Broad 1997). Similarly, more research on the most effective strategies for reducing homophobia would be a valuable component in mitigating the pernicious effects of this social problem.

homophobia and heterosexism

Barry D. Adam

Homophobia is perhaps the most widely understood term to refer to anti homosexual attitudes and practices, but comparison of such terms as homophobia, heterosexism, and heteronormativity reveals how these terms rely on different ideas of what homosexual means, and where opposition to same sex relations originates. Homophobia typically denotes, like other phobias, an irrational fear or a set of mistaken ideas held by prejudiced individuals; its alleviation therefore likely comes through therapy or education. Popularized through George Weinberg's 1973 book, *Society and the Healthy Homosexual*, homophobia is a concept with strong roots in psychology. Its use tends to focus attention on individuals, to locate its origins in childhood socialization, and to conceive of it as a prejudice directed against homosexual persons. Heterosexism tends to be used less widely, but it offers a more sociological notion of practices that are embedded in social structures and reinforced by ideology. Use of a term like heterosexism shifts analysis to the ways in which the social institutions of government, workplace, religion, family, and media are organized to exclude or disadvantage same sex relations. Resolving heterosexism implies reforming or reorganizing social institutions in ways that allow and support same sex relationships. Finally, heteronormativity is a term used most often in literary studies, which

see both homosexuality and anti homosexuality as effects of binary distinctions made in language. Textual deconstruction typically seeks to find how and why such distinctions as heterosexual-homosexual arise and are reproduced. If distinctions of this kind were not made at all, or least were of little significance, then presumably anti homosexuality could scarcely come about either. For queer theory, the issue is not one of appealing for tolerance or acceptance for a quasi ethnic, twenty first century urban community of lesbians and gay men, but of shaking up or transgressing the entire heterosexual-homosexual binary that fuels the distinction in the first place.

There are several leading theories that lend credence to each of these conceptions. Gayle Rubin's influential essay on "The Traffic in Women" built on Claude Lévi Strauss's work on kinship systems among hundreds of societies around the world that showed how kinship codes prescribe the exchange of women by male clans, thereby founding and organizing gender systems that order both same sex and cross sex relations. Heterosexuality is recreated each generation through a system of fraternal interest groups that exercise control over women's reproductive power in families. As a consequence, homosexuality among men and among women runs up against different but related difficulties. Homosexuality among men abstains from or transgresses the fundamental social "game plan" of the fraternal interest groups to acquire, control, and trade in the reproductive power of women. Homosexuality in men, according to this scenario, comes to be identified with the betrayal of masculinity and the inability to assert male domination over women. The sexuality of women in such a system is put at the disposal of men; their own sexual preferences are largely precluded. Lesbianism, as Monique Wittig argues in "The Straight Mind," violates the same social order by asserting will and subjectivity among the female gender, intended by patriarchal groups to be objects of exchange. Wittig calls female homosexuality a "revolt of the trade goods" in the "traffic in women." Adrienne Rich (1989) also characterizes lesbianism as an assertion of women's subjectivity and self determination, and a direct challenge to patriarchy. Anti lesbianism, then, for Rich is a variant of misogyny, a means of

enforcing "compulsory heterosexuality," and a system of keeping women subservient to male domination.

Still, it must be noted that anti homosexuality is not the inevitable consequence of kinship organization. In many societies around the world, same sex bonding is accepted and valued by becoming integrated into, and defined by, kinship codes. Same sex connections may take "berdache," "two spirited," or transgendered form in societies with weak fraternal interest groups where gender fluidity, gender mixing, or gender migration appear to be possible for some men and a few women. Where male sexual bonding appears in societies with strong fraternal interest groups, it typically takes the form of hierarchical, military, age graded, and mentor/acolyte relationships, where adult men who exercise control over women's bodies also assume sexual rights over younger, subordinate males.

Gender panic theory focuses particularly on homophobia as an effect of gender. Masculinity, this theory contends, is an achieved and insecure status. Defensiveness against losing male status and privilege generates homophobia. Psychological research shows how homophobia appears to be particularly strong among gender conservatives intent on upholding gender differences, and among adolescent males who feel insecure in their access to masculine status. The queer theory of Judith Butler and Eve Sedgwick relies on, and extends, gender panic theory, contending that heterosexual masculinity builds itself on the simultaneous exploitation and denial of homosexuality. Since heterosexual masculinity can never constitute itself as secure and unassailable, and homosexuality is a default subject location against which heterosexuality defines itself, then homosexual possibilities can never be fully repressed and indeed remain necessary for the masculine self. Through extensive analyses of such cultural artifacts as novels, movies, advertising, and sport, queer theorists reveal how they covertly appeal to (sometimes thinly veiled) homoeroticism at the same time as they overtly deny it. This repetitive denial of homoeroticism in order to shore up the social construct of heterosexual masculinity reproduces heteronormativity. Again, it is noteworthy from a cross cultural perspective that this cultural understanding of gender and masculinity is neither inherent in maleness nor universal.

While gender panic theory offers a strong explanation for homophobia in western and other patriarchal societies, it does not work for societies where same sex bonding is itself regarded as masculine, and makes up a part of the socialization process to masculinize youths.

Sociohistorical theories are particularly interested in the social factors that fuel, or diminish, homophobia. These theories focus on the variability of homophobia by investigating why campaigns of persecution against homosexual relations break out in certain places and times, and among particular social constituencies, while at other times and among other social groups there is acceptance or support of lesbian, gay, bisexual, and transgendered (LGBT) people. Homophobia in western societies is associated with the roles non heterosexual peoples have been assigned in history, meanings attributed to homosexuality by powerful social institutions, and the symbolic value of disenfranchised and "upstart" social groups to dominant forces. In nineteenth and twentieth century Europe and North America, the adherents of anti homosexual worldviews have typically come from a range of social groups disturbed or threatened by modernity – usually traditional elites fearful of change and declining social classes resentful of groups on the rise. Status defense theories note that people with (or threatened with) declining living standards are especially susceptible to a politics of resentment, and have a tendency to strike out against those they see as "undeserving." Anti gay persecution has often run parallel to campaigns of persecution directed against other disenfranchised groups. Perhaps the most egregious example is fascism, which swept up a range of people symbolizing modernity into the Holocaust. Thus gay men came to share the fate of Jews, communists, Roma, and disabled and racialized peoples when Nazism moved to reestablish the dominance of traditionally privileged social groups. Smaller scale and less intense campaigns have mobilized similar constituencies in the United States, from McCarthyism in the 1950s to repeated referendum campaigns to repeal human rights legislation since the 1970s and subsequent electoral strategies on the part of the Republican Party. Sociohistorical theories, then, do not see homophobia as a "given" inherent in gender

and social institutions, but focus on the forces that exacerbate or alleviate it over time.

Despite important gains in human rights legislation protecting the equality rights of LGBT people in many countries, homophobic attitudes and practices remain widespread. High schools appear to be a particular source of anti gay harassment in the English language world. Human Rights Watch found, in a recent investigation of US schools, that LGBT youth frequently find themselves the objects of verbal and physical attacks and that school officials provide them little or no protection or redress. Organizations such as the International Lesbian and Gay Organization, the International Gay and Lesbian Human Rights Commission, and, to a lesser extent, Amnesty International now monitor violence directed against LGBT people around the world. In some countries, state violence flows from laws that continue to criminalize homosexuality, particularly in postcolonial governments of South Asia, Africa, and the Caribbean – many still preserving British laws now abandoned by the United Kingdom itself – and Islamic governments of the Arab world, Southwest Asia, and Malaysia. Some jurisdictions have begun to take steps to curb homophobic violence in the form of hate crimes legislation, as in the United States, or prohibitions against incitement to hatred, as in Northern Europe, Spain, Canada, and Australia, but in many places anti LGBT violence endures.

homosexuality

Gert Hekma

Homosexuality refers to sexual behaviors and desires between males or between females. *Gay* refers to self identification with such practices and desires. Gay and homosexual are both terms mostly used only for men. Lesbian is its female counterpart. Such definitions have run into major problems, and nowadays the concept *queer* is used to indicate the fluency of sexual practices and gender performances.

SOCIAL CONTEXT

Since the 1970s, homosexuality has become the topic of an interdisciplinary specialization variously called gay and lesbian, queer or LGBT studies (Lesbian, Gay, Bisexual, and Transgender, to which sometimes are added QQI: Queer, Questioning, and Intersexual). The field is far removed from traditional sexology that has its base in psychology, medicine, and biology, and is closely linked to what once were called minority (black and women's) studies and now gender studies. Most of the disciplines involved belong to the humanities and social sciences: language and literature, history, cultural and communication studies, sociology, anthropology and political sciences, philosophy. Sociology had a late start, although some of the key figures in the field were sociologists (Mary McIntosh, Ken Plummer, Jeffrey Weeks), but their work was seen as primarily historical. Michel Foucault made a major imprint with the first volume of

his *Histoire de la sexualité* (1976). Other major sociologists contributed to or supported the field, for example Pierre Bourdieu, Michel Maffesoli, and Steven Seidman (1997, 1998). Notwithstanding its important intellectual proponents, the field has a weak base in universities and departments of sociology, where few tenured staff have been nominated anywhere specifically for the field, not even for the sociology of sexuality. Most often, academics started to work on homosexual themes because of personal and social interests. Gay studies has kept a strong interdisciplinary quality, often with close cooperation between sociology, history, anthropology, and cultural studies.

HISTORY

The words homosexual and heterosexual were invented in 1868 and first used in print in 1869 by the Hungarian author Károly Mária Kertbeny (1824–82). In 1864 the German lawyer Karl Heinrich Ulrichs had come up with the words “uranism” and “uranian” to describe a similar social reality, while “philopedia” was created by the French psychiatrist C. F. Michéa in 1849. These words no longer referred to sexual acts that were sins and crimes and were called sodomy, unnatural intercourse, pederasty, and so forth, but to sexual identities and desires that were deeply embedded in persons. Ulrichs and Kertbeny were predecessors of the gay rights movement and wrote mainly against criminalization of sodomy. They spoke largely from personal experiences and historical examples. Most medical authors, who started to use the new terminologies, discussed mainly the causes of such identities and desires and the question whether they were pathological or normal. They set the standards for the search for a biological basis that continues to this day (“gay gene”). Most physicians started to believe that homosexuality is an innate condition (but not the Freudians) and took the position that it is a disease or abnormality that should be healed and prevented. The early research by psychiatrists was mainly based on case histories of what they called “perverts.” They began to discuss not only homosexuality, but other perversions as well that got new names, such as masochism,

sadism, fetishism, exhibitionism, necrophilia, zoophilia, and so forth. The centers of research were on the European continent: Berlin, Paris, Vienna.

The early medical research had several sociological angles. Ulrichs and Magnus Hirschfeld, the founder of the first homosexual rights movement in 1897, came up with the first statistics on the numbers of homosexuals that closely resemble the data of today. While Ulrichs thought his uranians were less than 1 percent of the population, an anonymous Dutch adept of his estimated the figure in 1870 at 2 percent, as Hirschfeld later did. The Dutch physician and homosexual rights activist Lucien von Römer worked with Hirschfeld on sexual statistics. In a survey of 308 Amsterdam students done in 1904, he counted not only the men who identified as homosexual (2 percent) and bisexual (4 percent), but also those who had gay sex during puberty (21 percent) or homosexual fantasies (6 percent). In the first Dutch gay novel that appeared this same year, the author Jacob Israël de Haan told how as a student he made fun of the questions as he answered them. He made clear how unreliable such data often are.

Hirschfeld also did the first urban geography, "Berlin's Third Gender" (1904), in which he described the city's gay subculture of bars and parks and the elaborate world of male prostitution. Mainly German books on the history of sexual morality (*Sittengeschichte*), which often included chapters on homosexuality, preceded and influenced the work of later sociologists and historians like Norbert Elias and Michel Foucault. The work of these psychiatrists who started to give names, definitions, and identities to disease, crime, and perversion made possible the work of sociologists creating stigma and labeling theory. In many ways, this early research paved the way for what would become the sociology of (homo)sexuality. The enormous body of work, available mainly thanks to early, prewar German sexology, was largely forgotten when the main location of sex research after World War II moved to another language, English, and to another country, the US.

Most of the scholarly work on homosexuality remained focused on psychiatry, both in Europe and the US. The major sociological breakthrough came from Alfred Kinsey (1894–1956).

He was a biologist specializing in wasps, but he is generally considered to be the founder of the sociology of (homo)sexuality by means of his two books *Sexual Behavior in the Human Male* (1948) and *Sexual Behavior in the Human Female* (1953). Although these studies have been criticized for methodological weaknesses and the reduction of sexuality to "outlets," this work has been pivotal in putting sexuality on the agenda of the social sciences. Kinsey was the first to come up with more or less reliable statistics on sexual behavior, and placed them in the larger contexts of biology and history. From his research stem ideas that 37 percent of US men have had homosexual experiences and 4 percent exclusively and lifelong. He was a man with a mission who did not hide his political agenda. He stressed time and again that the large majority of citizens would have to go to prison if US laws were applied rigorously, indicating that it was a better idea to change the laws. He did much to normalize taboo acts such as homosexuality, masturbation, premarital sex, adultery, and prostitution. His institute in Bloomington, Indiana, has become one of the world's most important archives and research centers on sexual behavior and culture.

Kinsey offered a sociological instead of a psychological perspective on the topic. In his footsteps and in the wake of the nascent homosexual rights movement in the US and the UK, Edward Sagarin and Michael Schofield began to write on homosexuality from a sociological perspective, using the pseudonyms Donald Webster Cory and Gordon Westwood. Cory's books gave an overview of what was known on the topic, while Westwood interviewed 127 homosexuals on their sexual life. Cory's work in particular had a wide readership among gay men. These works changed the focus from the aberrant homosexual who had gender identity problems or was abused as a boy, to the society that discriminated against homosexuals and largely contributed to their problems (for an overview of early sociological research in the US, see Minton 2001). The Dutch psychiatrist Tolsma, who earlier believed homosexuality was pathological and homosexuals recruited boys to their ranks, did research on its origins and discovered in 1957 that no gay man had become this way through seduction.

In the footsteps of Kinsey and Schofield, more surveys were done among gay men in

the 1970s, in Germany by Martin Dannecker and Reimut Reiche, in France by Michel Bon and Antoine d'Arc, and in the US by Joseph Harry and William De Vall and by Alan Bell and Martin Weinberg of the Kinsey Institute. These surveys provided good pictures of local or national homosexual cultures, but as they could not use representative samples their results are difficult to compare. Frederick Whitam and Robin Mathy surveyed *Male Homosexuality in Four Societies* (1986) and found effeminacy in gay men in all four locations, which suggested, for them, innateness. The homosexual behavior of many non homosexual men in these societies was explained as a secondary sexual outlet. Other de/constructivist perspectives would later change this line of thinking. Surveying quickly developed in the wake of AIDS.

Other centers of research and theorizing took over in the 1950s from the Kinsey Institute and independent gay researchers. The Chicago School of urban sociology started to include sexual variation in its agenda and to study urban gay subcultures. Maurice Leznoff and William A. Westley were the first to write on "The Homosexual Community" in 1956, discussing "a larger Canadian city." The topics range from cliques, their gossip and incest taboos, being secret or overt, and professions (many were hairdressers). The topics are still very close to those of psychiatry. Later work discusses the gay bar in more sophisticated ways. Manuel Castells wrote a landmark study on geographical distribution, community organizing, and political activity of San Francisco gays and lesbians. In 1979 the concept of "gay ghetto" was introduced in the article of the same title by Martin Levine. This was the first article on gay geography and included maps of several gay vicinities that had come into visible existence since the late 1960s. After the queer turn of the 1990s, several books on space and sexuality appeared that were more cultural studies, but still included sociological material, while the field of gay urban histories boomed with George Chauncey's landmark study *Gay New York* (1994) and David Higgs's collection *Queer Sites* (1999). In *Forging Gay Identities* (2002) Elizabeth Armstrong studied gay and lesbian movements in San Francisco that she divided into three stages: the more prudent

homophile movement before 1969, a short interlude of the radical gay movement that connected gay and left interests, and from the early 1970s the identity and one issue gay (and lesbian) movement. The date of the Stonewall rebellion in 1969, when fairies, butch lesbians, and drag queens resisted a police raid in the bar of the same name in New York, is nowadays globally commemorated.

The major concept of the 1970s was stigma. Symbolic interactionism was added to urban sociology. It fit well with the change from psychology to sociology, from pathology to activism. What homosexual men suffered from was not their innate abnormality or viciousness, but social rejection. At the time that activists asked for removal of homosexuality from psychiatric classifications such as DSM, and came out of the closets into the streets, sociologists started to discuss sexual stigma. In a landmark study, Gagnon and Simon (1973) developed the concept of sexual script(ing). Their script was what others later named narrative or story (Plummer 1995). Gagnon and Simon wanted to turn away from biological and Freudian perspectives to a sociological one that combined the social and the individual. Persons become sexual beings in an interaction between both. With many examples, they indicate how the social influences the sexual and vice versa. Theories that focus on instincts and impulses proved to be less helpful to explain erotic experience and variation. Other work engaged with the homosexual "coming out," in which the various stages of this process – sensitivation, resistance, acceptance, integration – were studied and demarcated (Troiden 1988). A budding field was the theme of gay and lesbian youth and their organizations and sexual education. An early and most controversial contribution in the symbolic interactionist tradition was *Tearoom Trade* (1970) by Laud Humphreys, which was about casual homosexual encounters in a public toilet. The debate was both on the topic and on the ethics of the research method. Humphreys had used the vehicle registration plates of the men visiting tearooms to discover additional information without their knowledge. So he came to know that the men often were married and highly conservative.

The major line of research from the late 1970s became historical sociological. In 1967 Mary

McIntosh wrote a promising article ("The Homosexual Role") in this direction, suggesting that such a role had only come into existence in the eighteenth century. The major studies were Michel Foucault's 3 volume *Histoire de la sexualité* (1976, 1984, 1984). The first volume – *La Volonté de savoir* – was the founding work of social constructionism, a term Foucault himself never used. In this work he remarks on the change from the legal concept of sodomy, an act, to the medical one of homosexuality, an identity, that will be insistently researched as part of the politics of the body. His work is a strong critique of the idea of sexual liberation, then prominent on the social agenda through the work of Wilhelm Reich and Herbert Marcuse. He showed how discourses of sexual liberation had been around since the eighteenth century and mainly contributed to normalization and stricter controls of sexuality. His theory of an omnipresent power that used such ideologies to get a firmer grip on sexual practices spurred a new generation to engage with sexual history, also because sexuality was reconceived as something that changed over time and may not in fact have existed as a special social reality before the rise of sexual sciences. Movements of resistance that were included in his theory of power played an ambivalent role, as they largely contributed to the innovation of body politics. Although the work of Foucault deals with sexual culture in general, his leading theme may well be said to have been homosexual pleasures. His studies extended the realm of Gagnon and Simon from the micro to the macro level and gave it a historical twist.

A sociologist who works in the same vein as Foucault is Jeffrey Weeks. He started in 1977 with a book on the development of the homosexual rights movement in England and continued with a general history of sexuality (Weeks 2000). His later work is about sexual ethics (Weeks 1995), while he recently took to researching "non heterosexual" intimate relations (Weeks et al. 2001). The Foucauldian approach came at the same time as the establishment of gay and lesbian studies and inspired the first international conferences. Most new work was based on the idea of *The Making of the Modern Homosexual*, the title of a collection by Ken Plummer. Social constructionism was

opposed to essentialism that sees sexual preferences as innate. Few people in gay and lesbian studies defend that position, while most of the biologists who research gay genes, brain parts, and hormonal systems are unaware of this critique. A main theme became the development of essentialist sexual sciences.

The rise of AIDS stimulated research on several aspects of gay life, especially on sexual and preventive practices. The main aim was to impede risky behaviors. The positive side was that it produced much information on gay sex and created greater openness. But too often the research neglected the social context, once more focusing strongly on sexual outlets of "men having sex with men" (MSM). Many countries saw major surveys on sexual behavior (for the US, see Laumann et al. 1994). The outcome of these surveys surprised the gay movement because the stated numbers of gay men were everywhere lower than those found by Kinsey in the 1940s. The higher numbers of gay men in cities cannot be explained fully by their migration to the more gay friendly towns, as was expected, as cities themselves produce more men identifying as homosexuals.

SPECIAL TOPICS

With the development of gay and lesbian, and later queer studies, the research specialized. Apart from gay bars and urban cultures, particular groups started to receive attention. An early popular issue was male prostitution. These studies discussed the pay and the sexual identity of the hustlers who are often straight, their age and sexual techniques, the locations where they work, their drug use, ethnicity, and class. It is a circuit where the ganymedes, sexually unsure and unprofessional, rob and murder their clients. Later, bisexuals, drag queens, transsexuals, transgenders, intersexuals and s/m ers emerged. A very controversial subject is pedophilia, which is often and unjustly seen as an exclusively gay issue. Anonymous sex on the streets and other places was studied. Other topics varied from gay men in ethnic groups, friendships, and suburban gay lives to violence, suicide, and aging. Masculinity became a topic, sometimes with a focus on the leather scene.

With the start of discussions on homosexuality and the army and same sex marriage these issues arrived on the sociological agenda. The discussion on intimate relations was started by Weston (1991). Later studies showed opposite results. While Weeks et al. (2001) underlined the transgressiveness of same sexual families that were more open to third parties and educated children in various social constellations, Carrington (1999) stated that the couples he researched largely imitated straight codes when it came to the gendered division of labor, household tasks, and financial arrangements. It is likely that these opposite results could be explained by different samples. Other scholars revived the culture of the 1970s, before the times of AIDS, when gay men developed a patchwork of sexual situations, passions, love relations, and friendships that bridged the gap between single and couple. They felt culpable for the epidemic, but with the knowledge of safe sex it is possible to recreate this culture "beyond shame."

With the breakdown of the difference between anthropology and sociology, themes of gay life in a non western and globalized world start to draw more attention. Nowadays a growing number of books discuss same sexual practices and cultures in a great variety of countries, as well as the interconnections between the various parts of the world through migration, tourism, media, the Internet, science, and politics. Globalization created "global gays" and multiethnic queer communities in the major capitals of the world, while global effects got local inflections, or were sometimes resisted by gay and anti gay people (Altman 2001).

METHODOLOGICAL ISSUES

The main question in gay research is the definition of what is the object of study. Most research is dependent on self identification of the interviewees, who may be unwilling to disclose their sexual interests. There are no objective criteria to define the homosexual. Kinsey therefore developed a homo heterosexual scale from 0–6 in which he integrated sexual practices and sexual fantasies. Other authors created layered scales that included more facets or developments

in time as individuals move between sexual identifications during their lives. AIDS research focused on sexual practices, while some opposed this narrow perspective because behaviors are dependent on personal identifications and social contexts.

The confluence of homosexuality with effeminacy and passivity in practice and prejudice offers another challenge. Most biological research is based on the equation of effeminacy and sexual passivity in males with homosexuality, but most modern gay men stress their masculinity and exchange sexual roles with partners. All of these terms can have very different meanings. Transgenders may flaunt their femininity, but can be strong and masculine when they face violent confrontations. Straight men visit male to female transgender prostitutes and often prefer passive roles. Some females in Namibia call themselves "lesbian men" and were intransigent when the local gay and lesbian movement tried to teach them they were really butches – for them, there was a world of difference between the two. The advice to the researcher should be to learn and use the terminologies the respondents themselves use and clarify those instead of attributing names and qualities to them.

Another major stumbling block in research is the absence of representative groups. Most research uses the snowball method. Gay men are invisible, so researchers depend in surveys on self disclosure. Several techniques have been developed to circumvent this problem, for example asking "how often did you have sex with men?" rather than "are you gay?" or embedding questions on sexual behavior in a series that deals with heterosexual experiences. The terminological changes pose another problem, every new generation creating a new word for its same sexual experiences, moving from uranian, homosexual, homophile, and gay to LGTBQQI and queer, while these vocabularies always give different meanings to some times similar, sometimes quite dissimilar practices and desires. Translations into other languages pose specific problems. The use of any concept creates exclusions. The most inclusive word – queer – that is close to non heterosexual is rejected by respectable gay men who consider the term insulting.

FUTURE DIRECTIONS

Some of the research is driven by social developments, so it can be expected that controversial issues such as same sex marriage, homosexuals in the army, violence against LGBT people, or discrimination in various situations such as in offices or sports will remain high on the agenda. The same will apply to sexual education and queer initiation. Specific groups such as elderly, ethnic minority, and questioning young gays will receive more attention. The turn from biology to sociology in gay research means that attention will shift from genes and identities to space and time as context for the development of gay identifications and queer cultures. Urban queer geography will expand, while this will create an interest in suburban and non urban environments of gay men.

The development of questioning sexual orientation to a next stage which might be queer has not been touched upon in most theories of coming out, which relied on people with stable homosexual identities, not on those who did not make such a transformation. Too little theorizing has taken place on changes in sexual identifications or object choices. Examples are those men who start with gay and move on to kinky interests, but the reverse rarely happens, from kinky to gay or queer. Many boys who start to have gay interests seek adult partners rather than those of their own age group, while others who begin with their own age group subsequently stay with it, go beyond it, or forget about gay sex. Such changes in identifications and sexual interests have rarely been explored in their social contexts and ramifications.

A major issue concerns the terrains in between homosexual and heterosexual and male and female identifications and their interconnections. Sociological research on self identified bisexuals and transgenders is on the rise, but not on those who identify less along those lines, such as unmasculine men, or those persons who show a preference for intermediate cases. They even lack concepts of identification and can only be circumscribed in descriptive terminologies such as lovers of bisexuals, drag queens, or male to female transgenders.

In most cultures and the western world until about 1900, sexual desire was based on the idea of social distinction: between male and female,

younger and older, higher and lower class. Gay men were effeminate mollies who desired "normal" (straight) men, while others looked over class lines or desired boys or young men. In the literature a classification of homosexualities has been proposed based on gender, age and, less often, class difference (Greenberg 1988). The ideal of sexual connections has become over the last century an absence of social differences. Gay and lesbian relations fit this ideal better than heterosexual ones that still have to deal with a gender difference. But in most cultures connections between same sexual partners continue to be based on gender and age difference. This is the case in most of Latin America, Africa, the Arab world, and Asia. Casual contacts between non homosexual identified males that remain common in those cultures will often express a power difference, or be accompanied by a financial transaction. Many non western urban centers may see the quick expansion of gay cultures where such differences are eliminated, but they are not standard, often even defined as "modern" or "western" in a negative sense. The actual situation with regard to gender and age is rarely researched, not even for the West, while this global and radical innovation from sexual desire based on equality instead of difference has attracted next to no attention. It parallels a similar change of a world that is divided along homosocial lines (separate worlds for men and women) to a heterosocial world in which men and women participate on a basis of equality. This major and remarkable change with its manifold consequences for homosexual desires and worlds has not been a topic of research.

Absent is research on sexual pleasure, both in its individual developments and social locations. Although gay and queer studies often have an implicit liberal or libertine agenda, the sociological aspects of pleasure and desire are rarely discussed or studied. Sex research in the context of AIDS prevention has been weak on this issue, while it has been otherwise largely neglected. Scripting theory would have been a good tool for such work, but has not been used. It could help to study relations between social context and the experience of pleasure or how sexual specialties develop. Important elements of gay culture such as the choreography of cruising and sexual practices have been

regrettably neglected (Bech 1997), or studied from a literary perspective. Sexual subcultures attracted little attention, and their sexual organization remained in obscurity.

The concept of intimate or sexual citizenship (Bell & Binnie 2000; Plummer 2003) has been introduced to highlight the social and political aspects of sexuality. Such aspects were hidden by the traditional relegation of sexuality to the natural and private. This terminology draws attention to the intimate or sexual side of citizenship, next to its economic, religious, cultural, or gendered sides. It is about the body politics of societies that are ruled by straight norms and defined by heteronormativity. These codes pervade all societal institutions, from families and schools to armies and prisons.

Horkheimer, Max (1895–1973)

Markus S. Schulz

Max Horkheimer is best known as the long time director of the Frankfurt School and co author of the *Dialectic of Enlightenment* (with Theodor W. Adorno). In the 1930s Horkheimer defined the Frankfurt School's agenda of interdisciplinary empirical research, guided the Institute through the years of exile, and succeeded in its reestablishment in Frankfurt after World War II.

There is a remarkable continuity in Horkheimer's thought, which some have characterized as a Schopenhauerian Marxism. Although Schopenhauer and Marx had a great impact on Horkheimer, he was also profoundly influenced by Kant, Hegel, Nietzsche, the French Enlightenment philosophers, and three of his contemporaries: lifelong friend and political economist Friedrich Pollock, his university mentor Hans Cornelius, a phenomenologist

philosopher with left Christian leanings, and Theodor W. Adorno, who became his close collaborator.

There were four major stages in Horkheimer's work: (1) formative years from World War I to the late 1920s, in which he sought the conceptual tools for understanding human suffering and exploitation; (2) a brief but ambitious period of setting the agenda for interdisciplinary research during the later years of the Weimar Republic; (3) the years in exile, initially in Switzerland, then in New York and California; and (4) the reestablishment of the Institute in Frankfurt after the Nazi defeat.

Max Horkheimer was born in Stuttgart-Zuffenhausen as the only son of a prosperous German Jewish textile manufacturing family. He wrote his dissertation (1922) and *Habilitationsschrift* (1925) on Kant under the supervision of Hans Cornelius at the University of Frankfurt. In 1931, following the death of Carl Gruenberg, Horkheimer became the second director of the *Institut fuer Sozialforschung* (Institute for Social Research) – later known as the Frankfurt School – and professor at the University of Frankfurt. Horkheimer outlined his vision for the Institute's agenda in his inaugural lecture on "The Present Situation of Social Philosophy and the Tasks of an Institute for Social Research" (in Horkheimer 1993: 1–14). He rejected what he perceived as philosophy's engagement with irrelevant pseudo problems and called for a close collaboration between economics, legal studies, psychology, philosophy, and sociology. The kind of social research and philosophy he envisioned was meant to change social conditions. As director, Horkheimer recruited Erich Fromm, Leo Loewenthal, Herbert Marcuse, Franz Neumann, and Adorno to the Institute. Horkheimer also founded the Institute's *Zeitschrift fuer Sozialforschung* (Journal for Social Research), which published a wide array of scholarly studies. Among the Institute's early empirical projects was a survey on the political attitudes of workers in the Weimar Republic. Although it was never concluded, its informal findings revealed to the Institute members the widespread absence of emancipatory values.

The Nazi rise to power forced the Institute into exile. Horkheimer was dismissed from his post at the university, and the Institute

was closed and its belongings confiscated. Horkheimer had already opened Institute branches in London and Geneva, and so transferred the Institute's endowment to Switzerland. After a brief stay in Switzerland, he moved the Institute to New York, where Columbia University made a building available at Morningside Heights. Horkheimer continued to edit the *Zeitschrift* in German until 1939, when he established its English successor, *Social Studies in Philosophy and Social Science* (1940–2). Among other articles, Horkheimer contributed to the *Zeitschrift* his definitive essay "Traditional and Critical Theory" (in Horkheimer 1972), which set the Institute's stance vis à vis mainstream academic thought. Horkheimer's substantial focus shifted in this period from research on the failure of a liberating revolution to a theory of the misdevelopment of culture. He became chief research consultant for the American Jewish Committee and co organizer of a large scale research project on anti-Semitism, social prejudice, and authoritarianism, the results of which were published in several volumes (with Samuel H. Flowerman, 1949–50) under the series title *Studies in Prejudice*.

In 1940 Horkheimer moved to Pacific Palisades, California, where from 1941–4 he worked with Adorno on a manuscript first circulated in 1944, then published in 1947 as *Dialectics of Enlightenment*. It was a dark assessment of the history of western rationality, surely influenced by the experience of the Nazis' industrial scale barbarism and by deep fears about the mass culture industries in the US. Although collaborative, the title essay and the chapter on de Sade were mainly Horkheimer's. He developed his position further in his major book *Eclipse of Reason*, published in 1947 and based on a series of lectures he had given at Columbia University. The book's later German title *Zur Kritik der instrumentellen Vernunft* (On the Critique of Instrumental Reason) probably reflected better his intent to critique a historically perverted type of reason without giving up reason as such.

In 1949 Horkheimer returned to Germany upon his reappointment as professor at Frankfurt, though he kept his American citizenship and frequently returned to the US as a visiting professor at the University of Chicago (1954–9). He succeeded in reestablishing the *Institut fuer Sozialforschung*, which undertook

research on, among other issues, the political culture in post war Germany. Horkheimer was elected rector of the University of Frankfurt from 1951 to 1953. In the late 1950s he moved to Switzerland and handed over the Institute's directorship to Adorno. Although Horkheimer retired in 1961, he remained active and served increasingly as a public intellectual via the press and radio. He received numerous civic honors. The student movement of the latter 1960s was inspired by Horkheimer's writings, although some distance developed when he later declined to condemn the US involvement in Vietnam. Horkheimer's accommodation with post war Germany and his appreciation of the benefits of liberal democratic institutions seem to have made him uneasy about the extremity of some of his previous positions. Only after years of hesitation did he agree to the German publication of *Eclipse of Reason* (1967). Yet, his posthumously published *Notizen* (Notes) and statements made shortly before his death expressed a profound "yearning for the totally Other" in a "totally administered world." Horkheimer died in Nuremberg and was buried at the Jewish cemetery in Bern Wankdorf, Switzerland.

Horkheimer's relevance cannot be separated from the Frankfurt School. Although not as prolific in his academic publications as his close collaborator Adorno, his sensitivity and vision shaped the Institute's research agenda, and his organizational and leadership skills ensured its survival during the years of exile and beyond. Horkheimer's writings have recently attracted renewed attention not only in Germany but also in the US. Contemporary sociology's growing interests in culture and interdisciplinary studies as well as in public sociology are likely to further fuel debate about Horkheimer's legacy.

hospitals

Sharyn J. Potter

Hospitals are institutions where people in need of medical care receive medical and surgical treatment from trained professionals. The discovery of antiseptics and medical technological advances transformed the American hospital from the death and poor houses of the eighteenth and nineteenth centuries to the cornerstone of today's medical care (Starr 1982). The twenty first century American hospital provides the sick, injured, and healthy with a myriad of diagnostic, medical, and surgical treatment options. The federal government helped solidify the modern hospital as a local institution when the 1945 Hill Burton Act provided federal money for every community to build or expand their existing hospital (Stevens 1989). Hospitals ranging in size from 10–1,000 beds now dot the American landscape. In urban areas hospitals resemble small cities, complete with gourmet restaurants and banking services.

The twentieth century hospital provided families with relief from the disruption of home care by providing medical care for the sick and injured in a manner that was less disruptive for

society as a whole. In recent years hospitals have changed from places of treatment and recuperation to places constrained to treatment. The major payers of hospital care – government and private insurance companies – limit hospital stays by only reimbursing hospitals for the medical or surgical treatment. These payers no longer reimburse hospitals for convalescence care, thereby giving the responsibility of caring for the sick or injured to family or friends. This change in the provision of hospital care can be partially attributed to the passage of the Medicare Prospective Payment System (PPS) legislation in 1983.

With the implementation of the PPS legislation the hospital industry was faced with cost containment legislation for the first time in its history. Previously, hospitals had used their own discretion in pricing hospital services. The PPS legislation eliminated such discretion by authorizing the government to establish uniform prices for all hospital services for Medicare patients. Therefore, hospitals were forced to incur costs lower than the reimbursement amount to make a profit. Many hospitals found that they were able to earn a profit or save money by discharging patients soon after their procedures were complete. “PPS was a fixed payment per case determined in advance ... this approach offered hospitals the rewards of a profit or the penalty of a loss” (Altman & Young 1993: 12). Although this legislation was passed to regulate Medicare spending, the private insurance and managed care companies adopted similar methods of cost containment and initiated similar strategies for reimbursing hospitals in the US.

Three distinct types of hospitals (not for profit, for profit, and public) play an integral role in the US health care industry. Not for profit hospitals comprise the largest hospital sector, accounting for approximately 60 percent of all short term general hospitals. Many not for profit hospitals were opened and operated by various immigrants and fraternal and religious groups as a means to promote group cohesiveness and ensure care for their members. Since 1913 the federal government has formally exempted private and religious not for profit organizations from most revenue and property taxes in exchange for providing some free or below cost medical services (Gray

1986; Roska 1989). This commitment was referred to as the “relief of poverty” requirement (Fox & Schaffer 1991; Stevens 1989). The tax exemption accorded to not for profit hospitals was viewed as an investment of public resources for charitable purposes. Care for millions of uninsured patients was exchanged for the forgiveness of billions of dollars in federal, state, and local taxes.

The “relief of poverty” requirement remained in effect until 1969, when the Internal Revenue Service (IRS) modified the language and replaced it with the more general requirement that such hospitals provide “community benefit” (Roska 1989; Fox & Schaffer 1991; Seay 1992). The language in the 1969 IRS ruling resulted in considerable confusion about the interpretation of community benefit and a transformation in how hospitals began to define it. Because the rhetoric in the ruling was ambiguous and community benefit was not explicitly defined, not for profit hospitals explored alternative ways to meet this newly named requirement (Fox & Schaffer 1991). While some not for profit hospitals continued to maintain their tax exempt status in the traditional manner by providing medical care for underserved populations (Seay & Sigmond 1989; Seay 1992; Fox & Schaffer 1991; Gamm 1996), other NFP hospitals established their exemption status through more creative and non traditional methods. Some NFP hospitals began to invest in high tech equipment and new hospital and office buildings for the sake of the community (Fox & Schaffer 1991). Other hospitals developed a myriad of wellness and community education programs, that some suggest would more appropriately be called patient recruitment tools (Buchmueller & Feldstein 1996). As a result, it has been argued that the change in IRS requirements has enabled hospitals to provide “outreach activities focusing on the special health problems of the underserved” (Gamm 1996: 80; Seay & Sigmond 1989) and not necessarily on meeting the greatest needs in the community.

This conflict between charity care and community benefit continues (Kane & Wubbenhorst 2000: 186), and some believe the 1969 IRS ruling has blurred the distinction between services for the underserved and services that increase hospital visibility and revenues (Tuckman & Chang 1991; Buchmueller & Feldstein 1996). In an

effort to ensure that NFP hospitals are earning their tax exemptions, some communities now require NFP hospitals to quantify and report the community benefit services they provide (Kane & Wubbenhorst 2000). Other communities are pursuing the revocation of their hospitals' tax exempt status, believing that the increased tax revenue will give them needed funds for other projects.

Not for profit hospitals can earn profits; they are prohibited from distributing these profits. Instead, profits must be reinvested in the hospital. The major distinction between not for profit and for profit hospitals involves the distribution of profits. For profit hospitals can distribute their profits to their owners or shareholders. Therefore, stockholders demand that for profit hospitals behave in a manner that results in healthy financial statements. Gray (1991) argues that profitability is the key indicator for evaluating the success of a for profit hospital and poor financial performance can cost managers their position.

In the early 1900s many for profit hospitals were operated by physicians in rural areas where other types of hospitals were non existent. In urban areas, eminent surgeons opened for profit hospitals for patients who preferred not to seek treatment at not for profit hospitals. In 1910, for profit hospitals accounted for approximately 50 percent of all hospitals (Stevens 1989). Thereafter, the number of proprietary hospitals steadily decreased as "community hospitals opened their staffs to wider membership and doctors found that they were able to have the public provide the capital for hospitals and maximize their incomes through professional fees" (Starr 1982: 219). By 1928, according to Paul Starr, proprietary hospitals accounted for only 36 percent of all hospitals. The number of proprietary hospitals subsequently declined further to 27 percent and then 18 percent of all hospitals, in 1938 and 1946, respectively (Stevens 1989).

Today, for profit hospitals account for 13 percent of all short term general hospitals. For profit hospitals choose to locate in affluent areas, purposely avoiding the provision of expensive charitable care that detracts from potential hospital profits. These well defined profit goals are the most appropriate justification for policies that tend to exclude poor patients (Homer et al. 1984). Over the years some for profit hospital

stocks have earned record returns for their investors. Critics indicate, however, that these record returns are not always gains for their communities. Potential stockholders do not base their purchasing decisions on how well the hospitals are meeting community needs (Rushing 1976).

The presence of public hospitals in a community influences the strategies of the other hospitals, both for profit and private not for profit. Research indicates that public hospitals often care for patients that other hospitals consider undesirable. A disproportionate number of their patients are poor, uninsured, or Medicaid recipients (Brown 1983).

Since the 1700s, public hospitals have played a vivid role in the history of American hospitals. Many big city public hospitals began as alms houses, including Bellevue in New York City, Charity in New Orleans, and Cook County in Chicago. In 1902 public hospitals were described as grim and barracks like; they typically had wards for patients with syphilis, tuberculosis, and mental disorders, and for unmarried pregnant women (Stevens 1989). Policymakers predicted the closure of many government not for profit hospitals following passage of the 1965 Medicare and Medicaid legislation, which gave the poor the means to pay for hospital care (Fox & Schaffer 1991). In theory, all patients now were paying patients and were entitled to private care. This prediction did not come true, and a mass closing of government not for profit hospitals never occurred. Public hospitals currently account for 26 percent of all US acute care hospitals.

Some researchers question whether the care at public hospitals is comparable to care at their private not for profit and for profit counterparts. For example, researchers who recently compared the records of patients suffering from ischemic heart disease at the three types of hospitals found that patients at public hospitals received less extensive services than patients at for profit and private not for profit hospitals. Likewise, other researchers find that patients at public hospitals received fewer diagnostic tests, fewer surgeries, and fewer follow up visits.

Twenty first century hospitals face a number of challenges. As cost pressures and medical technology facilitate the movement of many procedures away from the hospital to physician offices and less expensive free standing

facilities, hospitals will have to develop strategies to meet these challenges. Furthermore, many smaller communities struggle to support their hospitals and mergers occur on a regular basis, removing hospital access from local communities.

households

Graham Allan

When people discuss family life there is often a confusion between family as kinship and family as household. The two ideas are so much part of commonsense understandings of "family" that they are elided together. Though less common in sociology, a similar lack of clarity over what aspect of "family" is being examined sometimes arises. In principle, the distinction is clear cut. Family as kin are all those people who are linked to you genealogically or who you otherwise define as kin (Schneider 1968; Silva & Smart 1999). Typically, they remain kin whether or not they live with you, though the boundaries of inclusion and exclusion drawn around "my family" may alter across the life course. Households, on the other hand, are essentially those people who share a home with you. In this sense "my family" are those with whom I live and with whom I participate in a domestic economy. The membership of an individual's household will certainly change over time, and may for significant periods include people who are clearly not regarded as family.

Defining who belongs to a household appears relatively straightforward and for many people it is. There is a clear cut group of individuals who

normally eat together, share a common house keeping, and sleep in the same dwelling. These are the essential criteria used for defining a household, criteria which in different combinations are utilized in official government practices, records, and statistics. However, both in the past and currently, these issues are not quite so simple for all. At times, for example, some people may eat many of their meals in one household but sleep in another. Thus, one or more children in large sibling sets may sleep at a grandparent's house where there is more room, but otherwise live with their parents. Or a daughter or son with an elderly, infirm parent may regularly sleep at the parent's house in order to provide care at night.

Contemporary demographic patterns are also making the boundaries of households more diffuse than they were. For example, increasing numbers of people are spending different times of the week in different houses, usually as a result of conflicts between employment and domestic demands. Thus, some people do weekly commutes to work, living in one household during the week – possibly a small apartment or shared house – while living in the “family home” at weekends. A growing number of couples are also now “living apart together,” sometimes through choice rather than employment demands. Here each partner maintains their own home, but they also regularly spend time together in one or other of their homes. Whether the individuals involved in these arrangements are defined as living in one or two households, or as having a multiple household, is a moot point, as in some cases may be the question of whether they are “family” to one another. The central issue though is that the living arrangements people construct are flexible and variable and consequently cannot always be characterized as fitting neatly into a single household.

Other demographic changes have also had an impact on the composition of households. The rise in divorce, for instance, has clearly contributed to the higher numbers of lone parent households there now are, as well as to the increased proportions of people living alone for periods in midlife. So too the rise in separation and divorce has resulted in an increasing number of children whose parents share care of them in separate households. In terms of

their own household experience, these children belong to more than one household, alternating between each parent's household for whatever periods of time have been agreed. Other demographic shifts that have affected household composition include changes in life expectancy resulting in longer periods spent without dependent children in the household and later marriage age. This latter has had consequences for both the number of single person households and for the rise of non familial shared households consisting of unrelated friends and others living together (Heath & Cleaver 2003).

Generally, these demographic shifts have contributed to a greater degree of household diversity and mobility. In the early phases of adulthood particularly, people's “household careers” are often less “ordered” than they were, with changes in living arrangements being quite common. As well as the growth of shared housing as a living arrangement, young people are also now more likely than previously to be involved in relatively temporary cohabiting relationships of different durations. Equally, at least in Britain and other European countries, there has been a marked tendency for the process of leaving the parental home to be less clear cut than it was for previous generations (Holdsworth & Morgan 2005). That is, not only are adult children living for longer periods in the parental home, but there is also a noticeable trend for them to return to the parental home as circumstances in their lives – changing employment, relationship breakup, financial pressures – alter.

As a result of these different trends, overall patterns of household composition have been changing quite significantly in most western countries over the last 30 years. Taking Britain as an example, household size has continued to reduce, from nearly 3 people per household in 1970 to 2.3 in 2002 (National Statistics 2005). Currently, only a fifth (21 percent) of households consist of what used to be conceptualized as the “standard” family households of two adults and dependent children, compared to 31 percent at the end of the 1970s. And of course this number now includes increasing numbers of cohabiting unions and stepfamilies, as well as first time marriages. Significantly, nearly a third of all households (31 percent) are single person households (compared with

21 percent in 1978), though the routes into these single person households and the length of time spent in them varies significantly. A further third of households (34 percent) now consists of couples living alone, either married or cohabiting; some have not had children and others have children who are no longer dependent. The remaining households generally comprise lone parent households (8 percent) and those where people are living with friends/unrelated others (4 percent). Importantly, as discussed above, just as household composition has been altering, so too there is even greater flux over time in the personnel involved in each category as people's domestic circumstances and partnership status alter.

While these figures are about Britain, broadly similar trends are found in other western countries as a result of shifting family demography under the global processes of late modernity (Buzan et al. 2005). As noted, the growth of cohabitation, divorce, and separation and the lack of clarity over the processes of children leaving home are having an impact throughout the developed world. Clearly, though, the extent to which they occur and the impact they have depend in part on the social, fiscal, and urban policies impacting on family and household organization in the different societies. One significant element within this is the operation of the housing market. The availability of different forms of housing to different sections of the population, the costs and quality of such housing, and the alternatives which are considered acceptable all have an impact on the choices people make and the pattern of households they construct. To take one example, at a macro level, increased separation and divorce are likely to generate provision of more single person housing, but in turn people's decisions about whether or not to remain in a particular partnership will be influenced to some degree by their perception of the housing that will be available to them. Similarly, decisions about leaving the parental home will be based on alternative housing options as well as ideas of appropriate independence.

Howard, George Elliott (1849–1928)

Michael R. Hill

George Elliott Howard, a distinguished social scientist trained initially in history, rose to the presidency of the American Sociological Society in 1917. Howard earned the A.B. in 1876 at the University of Nebraska. Following two years of advanced study in Germany, Howard joined the Nebraska faculty in 1879. Howard's most prominent Nebraska student from this period, Amos Griswold Warner, later wrote *American Charities* (1894) – a standard classic in the field. Howard was named to the prestigious "First Faculty" of Stanford University in 1891.

At Stanford, when sociologist Edward Alsworth Ross was summarily fired in 1900 by university president David Star Jordan, Howard immediately defended Ross's right to free speech. Jordan demanded Howard's apology – or his resignation. Howard resigned, as did other Stanford faculty members in sequence. Instantly, Ross was hired by chancellor E. Benjamin Andrews to teach sociology at the University of Nebraska. The so called "Ross

affair” at Stanford resulted ultimately in the founding of the American Association of University Professors and the establishment of academic tenure in American universities.

After a series of brief appointments, including the University of Chicago (1903–4), Howard returned in 1904 to the University of Nebraska, where his colleagues included Edward A. Ross and Roscoe Pound. In 1906, with Ross’s departure for the University of Wisconsin, Howard was named head of Nebraska’s newly reorganized Department of Political Science and Sociology. Howard was an egalitarian, activist, and humane sociologist who championed women’s suffrage, encouraged racial tolerance, and advocated prohibition. An exacting scholar, Howard’s elaborate published syllabi on *General Sociology* (1907), *Social Psychology* (1910), *Present Political Questions* (1913), *Marriage and Family* (1914), and other topics remain extraordinary models of rigorous instructional guidance. Howard’s later Nebraska protégée, Hattie Plum Williams, earned her PhD in 1915, and in 1923 – with Howard’s encouragement and endorsement – became, at Nebraska, the first woman in the world to chair a co educational doctoral degree granting department of sociology. Howard retired in 1924.

The author of scholarly books and dozens of professional articles, Howard is best known today for his massive *History of Matrimonial Institutions Chiefly in England and the United States* (University of Chicago Press, 1904). A quintessential study in the sociology of institutions (Howard claimed for himself the invention of “institutional history” as a category of study), *Matrimonial Institutions* merited critical appraisal from Émile Durkheim and provided the intellectual foundations for the 1906 National Congress on Uniform Divorce Laws.

human genome and the science of life

Anne Kerr

Although the double helix structure of DNA was discovered in 1953 by James Watson, Francis Crick, Maurice Wilkins, and Rosalind Franklin, it was not until the 1980s that powerful sequencing and information technologies were developed that enabled scientists to identify particular genes associated with hereditary diseases and to begin to map all of the genes in human DNA: the so called human genome. The human genome project was a massive international mapping exercise which began in the 1990s and culminated in the publication of a draft sequence by the International Human Genome Sequencing Consortium of the entire human genome in 2001, which is freely available on the Internet.

In the same period a broader range of biomedical knowledge was also developing, particularly in the fields of assisted conception. More recently, research into stem cells and tissue engineering, alongside the so called “postgenomic sciences” of pharmacogenomics and proteomics, has also developed. This “science of life” involves detailed understanding of the basic cellular mechanisms involved in human

development, as well as a focus upon copying and ultimately manipulating these processes in the laboratory. This is linked to a number of biomedical developments in the diagnosis and treatment of disease, particularly the move towards more targeted individualized treatments tailored to individuals' particular genetic makeup, and perhaps, in the future, utilizing cells and tissues taken from people's own bodies to develop treatments for them.

The use of embryos is a particularly contentious aspect of the science of life and human genomics. The dangers of surveillance and discrimination against a "genetic underclass" have also been raised, as have concerns about "designer babies." More generally, the optimism about these new developments has been criticized for being a form of hype which sustains the pharmaceutical, bioscience, and infertility industries, but will do little to tackle the major causes of ill health that the majority of the world's citizens face: poverty. In the UK the government has responded to these public and professional concerns by establishing a number of oversight bodies, notably the Human Fertilization and Embryology Authority, which enforced strict limits on the type of research that can be conducted upon human embryos. Across the world there are a range of similar bodies and more or less restrictive laws, but in some countries the science of life is largely unregulated, notably China and North Korea, where stem cell research is developing apace. In the US regulation is uneven. Although assisted conception is largely unregulated, there are stringent controls on federally funded biomedical research to prevent the use of human embryos.

Sociological work on these developments covers a wide remit. The early days of the human genome project saw sociologists, in common with their colleagues in the ethical and legal disciplines, exploring the implications of greater knowledge about individuals' genetic makeup, particularly the dangers of eugenics and genetic determinism. Others focused upon the political economy of the project, especially patenting (notably, indigenous people's DNA) and access to genetic information by the state (primarily with respect to large scale genetic databases). As Waldby (2002) noted, this was part of a growing trend of "biovalue" in which bodily parts and processes were commodified. However, these

developments have not gone unchallenged. John Moore challenged the patenting of his own DNA by researchers at Johns Hopkins University. Although he lost his case, the ownership of DNA was politicized in the process. Indigenous peoples have also resisted so called bioprospecting, where researchers take DNA samples from them to patent in the West, and this has resulted in a number of international treaties and legal claims which reassert the rights of ownership of individuals and communities over indigenous natural resources.

The lay-expert divide is also being breached in other respects where genomics and the science of life are concerned. Many patients with hereditary diseases have considerable expertise about their condition, which can lead them to challenge costly treatments and research. A range of oppositional groups such as the disability rights movement have also challenged the biologization of illness and disability. An unlikely alliance of feminists and anti abortion groups has attacked the commodification of women's bodies in assisted conception in particular, challenging, for example, reproductive tourism where rich western women travel to eastern countries to purchase eggs from local women for their assisted conception treatment. These criticisms are often focused upon the political and economic aspects of biomedical research and treatment within the context of late capitalism, and unpack widespread cultural assumptions about the nature of disability and infertility. Yet they can also perpetuate conservative notions of reproduction, where the sanctity of life is paramount. Nor is medical authority necessarily challenged in the process. Patient support groups often share with clinicians a discourse of objectivity and support for medical progress. And many of the people who become active in such organizations have a medical or scientific background. There are clearly a range of complex and sometimes contradictory views being expressed by particular groups and individuals in this area, which means that simple categories of "patient," "clinician," or indeed "activist" are largely unhelpful.

From an ethnographic perspective scholars have also spent considerable time exploring the practices of gene sequencing in the laboratory and tracking their utilization in the clinic. As Rapp (1999) and Sarah Franklin have shown, as

the uncertainties of diagnosis are profound, clinicians' and clients' choices can be very difficult. Although foregrounded, the individual is not necessarily privileged as a result of these new insights into reproductive and genetic futures. Although some patients might welcome an insight into the human face of science which an ambivalent clinician might present, others struggle to find categorical meanings to match the categorical actions that they are ultimately obliged to take about reproduction, diagnosis, and treatment: you either act or you do not.

The complexity of molecular genetic and other new forms of biological information is often highlighted by Foucauldian scholars, particularly Nikolas Rose, who explicitly contrasts it with the crude genetics of the past, particularly in its eugenic guise. This fits with a wider theoretical emphasis upon complexity and messy systems in late modernity. Echoing the risk society thesis, the main argument here is that as biomedical science has evolved so too has its risks and uncertainties. The bureaucratic edifice of the twentieth century was unable to control and tame these risks by centralized rational means, and faith in expertise weakened to the extent that the authority of biomedicine itself came into question. At the same time, the individual became more important than the collective, and a cultural emphasis upon personal rights and choices emerged. Science has therefore evolved to develop more complex, decentred interpretations of life, where flexibility and contingency are key. Genomics and the science of life, alongside developments in information and computer technologies, are at the forefront of these complex sciences, particularly the trend towards individualization of treatment, and a move away from "one size fits all" drugs and procedures.

However, others argue that the transformative potential and complex underpinnings of contemporary biomedicine and genetics in particular have been overemphasized. As scholars such as Diane Paul (1998) have shown, the so called "old eugenics" had myriad links to established scholars of genetics, and their understandings of human disease were far from monological or crude. Other studies, such as Kerr's work on cystic fibrosis, have shown that genetics has a history of multifunctional complex paradigms, which have often coexisted alongside other more determinist understandings of disease. This

suggests that complexity is not unique to the contemporary science of life, nor is it primarily a *response* to risk. Instead, it is an enduring feature of biological science.

The extent to which genetic tests and other diagnostic and screening services give patients informed choice about whether or not to participate have also been queried in a wide range of psychosocial, ethical, and sociological empirical studies. Theresa Marteau and colleagues have comprehensively demonstrated that the context in which pregnant women make decisions about antenatal screening is often one where information and interactions are subtly cued towards compliance. On the other hand, studies of familial testing for diseases such as Huntington's disease show how relationships with close relatives, wider family, and the community as a whole, as well as the very fact that these disorders are often untreatable, shape people's decisions about presymptomatic testing in such a way that it is often declined. Individuals who come from affected families also have complex responses to antenatal testing. For many, this is also fraught with difficulties and contradictions, as the potential to avert the birth of an affected child is weighted against the implicit denigration of affected individuals. The danger of too much information about one's future health being generated by these tests has also been discussed at length.

This work is often mobilized in debates about the extent and meaning of "geneticization," a term coined by Abby Lippman to stress the pernicious reach of genetic explanations for disease and behavior. Yet evidence about the uptake of genetic diagnosis and its effects upon attitudes to disabled people and social misfits is mixed. There is no comprehensive genetic paradigm being enforced by the biomedical establishment, yet it is not possible to say that the more widespread emphasis upon biological reasons for disease of which genetics is a part has no effects upon how people account for citizens' rights and responsibilities for health care in particular.

In any case, Lippman's term was always meant to be focused upon a broader trend towards reductionist notions of the genetic determinants of identity, disease, and anti social behavior. Other critics such as Dorothy Nelkin have made similar arguments about the

simplicity of much of the popular presentation of genetics, as well as the limited analysis of burgeoning fields such as evolutionary biology. Although some sociologists have called for a deeper engagement with these sciences and an end to the nature versus nurture debate, many remain committed to challenging the reductionism and circularity of this new form of biological determinism. Others, such as Peter Conrad and Alan Petersen, have focused their attention upon the popular presentation of genetic determinism in media accounts in particular, but policy documentation can also be subjected to similar analysis to show the prevailing emphasis upon "genes for ..." stories alongside an underlying positive focus upon technological progress, individual choice, and personal responsibility. At the same time, new technologies of visualization have emerged to move our understanding of life from the now relatively humble ultrasound of the disembodied fetus to laser scanning of internal cellular dynamics, bringing with them discourses of mastery and control alongside those of complexity and uncertainty.

A considerable corpus of work has also been built up into the public understanding of genetics, exploring and unpacking people's understandings and ambivalent responses to genetic knowledge and its application. Media messages notwithstanding, this work shows that the public are far from ignorant about new developments. Although their technical proficiency is often wanting, their wider social intelligence about the institutional politics of science and their experiences of raising children and mixing with a range of social groups can generate sophisticated questioning of the hype around the science of life and profound concerns about commodification in particular. Just as with the analysis of the various interest groups involved in more public debates about these new technologies, the study of more general public discourse shows that it not possible to box people into particular categories of "right to life" or "patient advocate" when their arguments and experiences overlap in myriad ways. It is also clear from a range of studies of the ethics of genomics and the science of life that professionals share many of the so called public's concerns, but that their ambivalence is often suppressed in more public spaces.

A further feature of sociological inquiry into genomics and the science of life concerns the emergence of new forms of ethics, primarily located in new institutional forms such as the HFEA. The perception of increasing public anxiety and newfound uncertainties of the science itself, particularly its application in the clinic and beyond, has meant that ethicists have moved out of academia into policy communities at a national and international level. This has been intensified by the globalization of biomedical research, signaled most clearly by the worldwide efforts of the HGP, but continued in the more routine arrangements of trade in information and bodily commodities which sustain the research networks in this field. Ethics has also been institutionalized in local research ethics committees which vet research applications from scientists and sociologists alike. A particular issue here is informed consent. This is a reflection of the rights based culture in which we live, but also a response to a range of scandals about biomedical research where subjects' and/or their families' consent had not been obtained prior to the performance of dangerous and/or distressing procedures. This holds science to account in a more public way than ever before, but in a fairly limited and (some would argue) limiting way. In contrast, ethics writ large is often focused upon pushing the boundaries of appropriate practice in this area, and is dominated by a number of high profile libertarians such as John Harris and Julian Savulescu, who make compelling arguments in favor of everything from genetic enhancement to reproductive cloning.

Once again, it is not possible to interpret the rise of bioethics as uniformly supportive or restrictive towards the science of life. It would also be wrong to see it as a response to particular aspects of the science or the technology itself, as it flows from a range of complex sociopolitical developments which have happened alongside the scientific discoveries and developments. Although a greater range of voices is now included in ethical reflection and debate than perhaps was the case in the past, ethical reflection in the public sphere is not unique to the contemporary period, and ethical restrictions on medical and scientific practice have long operated at various levels of formality and informality as a matter of course. And although the new institutional forms have developed a complex

infrastructure of surveillance to control medical practice, it is still the case that in the clinical context where consent is sought for diagnosis, treatment, or donations to research, the complexities of consent forms and the interpersonal dynamics between provider and client can and often do engender consent, just like the paternalism of the past.

Other sociologists, such as Nik Brown, have tracked the evolution of the human genome into post genomic and related areas of the life sciences, exploring the public presentation and interpretation of these developments, and the construction of expectations in particular. This involves innovators in packaging particular disorders and technical interventions in a way that emphasizes their relevancy and social usefulness while also generating and attempting to sustain an optimistic politics of hope in the face of profound uncertainty about medical and biological futures. The ethics of such hype has been questioned by scientists as well as sociologists, yet its place in the pharmacological armory seems fundamental. Profit drives innovation so the emphasis upon the future consumer of biomedical enhancement becomes necessary to the success of the industry, although the everyday practices of health services on the ground suggest that the ultimate operationalization of the “science of life” is more mirage than reality.

human–non-human interaction

Clinton R. Sanders

Human interaction with non human animals is a central feature of contemporary social life. The majority of households include at least one companion animal, more people visit zoos each year than attend professional sporting events, people are more likely to carry photographs of their pets than of their children, married women report that their pets are more important sources of affection than are their husbands or children, and more money is spent on pet food than on baby food (Arluke 2003). Despite the fact that human interactions with animals are so commonplace, they have, until fairly recently, been virtually ignored within

sociology. This prosaic disregard of human-animal exchanges is based on a variety of core assumptions. Sociology is conventionally seen as the study of *human* social structures and relationships. Sociologists also hold to the Cartesian liguacentic assumption that because animals lack the ability to employ spoken language they are consequently mindless and selfless. And, as Arluke (2003) has observed, sociologists who specialize in the investigation of inequality and oppression tend to be suspicious of the study of non human animals because it may be seen as trivializing their focal concerns.

Although anthropologists traditionally have attended to the cultural role of domestic animals in simple societies, sociologists have only fairly recently begun to systematically examine the relationships and interactions between people and the animals with whom they share their everyday lives. For example, sociologists working in such varied substantive areas as social movements, the sociology of the family, work and occupations, criminology and deviance, and sociological psychology have turned their attention to human-animal issues. In tandem with the growth of interest in human-animal relationships within sociology, a wide variety of social scientific disciplines (geography, history, feminist studies, political science, and consumer research, among others) have also begun examining the phenomenon. Evidence of the burgeoning interest in what is now commonly referred to as human-animal studies is seen in the publication of special issues of established journals and book series established by academic presses devoted to the topic. The disciplinary legitimacy of human-animal studies was affirmed in 2002 when the American Sociological Association officially recognized the Animals and Society section.

The few early discussions of people's interactions with animals were relatively unsystematic and unempirical. For example, in 1865 Harriet Martineau (a pioneer in observational methods) wrote about the problems presented by feral dogs, while in an 1872 issue of the *Quarterly Review* Frances Power Cobbe speculated about the impact of dogs' physical characteristics upon their consciousness. In a little known but significant paper entitled "The Culture of Canines," Read Bain (1929) criticized the anthropocentrism of sociology and advocated the

development of "animal sociology." In his discussion of the "culture of canines" Bain stated: "Just as animal intelligent and emotional behavior, anatomical and physiological structure and function, and group life, have their correlates in human behavior, so the dividing line between animal and human culture is likewise vague and arbitrary."

Bain's contemporary, George Herbert Mead, frequently discussed non human animals in his writing. He employed descriptions of the *behavior* of animals as the backdrop against which he juxtaposed his model of human *action*. Mead maintained that, while animals are social beings, their interactions involve only a primitive and instinctual "conversation of gestures" (the dog's growl or the cat's hiss, for example). From Mead's perspective, animals lack the ability to employ significant symbols and are therefore unable to negotiate meaning and take the role of cointeractants. Their behavior is directed toward achieving simple goals such as acquiring food or defending territory but, unable to use language, their behavior is devoid of meaning. They are mindless, selfless, and emotionless. Mead's perspective reflected the anthropocentric, rationalist views of Descartes; non human animals could not think, therefore they were not worthy of serious analytic attention. This orientation laid the groundwork for the conventional discounting of animals and lack of attention to their interactions with humans that dominated interactionist social psychology (and sociology in general) until the last quarter of the twentieth century.

A significant turning point occurred in 1979 when *Social Forces* published an article by Clifton Bryant in which he advocated the importance of sociologists attending to the "zoological connection" evident in so many areas of social life. Soon, a few pioneering sociologists were beginning to investigate settings in which human-animal interaction was a central feature and to overtly call into question the Cartesian orthodoxy that held sway within sociology.

The major focus of this early work was on occupational settings in which workers routinely interacted with non human animals. Some of the earliest sociological work on this topic was done by C. Eddie Palmer on animal control officers and game wardens, D. Lawrence Wieder (1980) on researchers working with

chimpanzees, and William Thompson on slaughterhouse workers.

Arnold Arluke later emerged as the major figure in this topical area when his 1988 article based on the ethnographic research he conducted in biomedical laboratories was published in the interdisciplinary journal *Anthrozoos* (the sole academic journal devoted to human–animal studies at that time). Arluke's paper, and the various other related works he produced, laid the groundwork for a theme that became central to the substantive field: the dichotomy between defining animals as "pets" or functional objects and the impact of this determination on how animals are treated. Arluke expanded on this theme in his later writings, emphasizing the job related ambivalence experienced by animal shelter workers, veterinary students, and researchers in primate labs (Arluke & Sanders 1996). The number of studies focused on animal related occupations grew: Carole Case studied race track workers, Clinton Sanders (1999) wrote about veterinarians and guide dog trainers, and Mary Phillips discussed laboratory workers' perceptions of animal pain and emphasized the importance of whether or not laboratory animals were given names.

Arguably, the richest focus of systematic attention within sociological human–animal studies has been on the everyday interactions between people and their companion animals. This work has been done primarily by scholars working within the perspective of symbolic interactionism and centers on a direct critique of Mead's anthropocentric discounting of animal abilities. Key recent examples are Sanders' (1999) research with dog owners, Gene Myers' (1998) study of the interactions between children and animals in a preschool program, and Janet and Steven Alger's (2003) book on a cat shelter. These writers examine the intersubjectivity that emerges when people routinely interact with animals; the process by which people construct an understanding of the individuality, mindedness, emotionality, and identity of animal others and, in turn, how association with animals shapes the identities of human actors. Leslie Irvine's (2004) book, centering on her participation in an animal shelter, builds upon and extends this intersubjective focus by presenting a case for animals possessing a self. Basing her analysis on the work of William

James and studies of prelingual infants, Irvine makes the case for the animal self as being constituted by a sense of agency (being the author of one's action), a sense of coherence (understanding one's physical self as the locus of agency), a sense of affectivity (experiencing feelings associated with the self), and a sense of self history (maintaining an understanding of continuity in the midst of change). Irvine concludes that the self is "a system of goals, which we pursue through relationships and experiences, which involves the ways in which we respond to and order the worlds around us . . . [A]nimals, like people, manifest evidence of selfhood . . . as they manifest agency, affectivity, history, and coherence, as well as the capacity for intersubjectivity" (pp. 172–3).

Three additional main foci in the extant sociological work on human–animal interactions deserve mention. Grounded primarily in the insights of Erving Goffman, some writers have explored the impact of how being with a companion animal in public facilitates and/or impedes human to human social interaction. Non human animals have also emerged as the focus of criminological discussion, most notably in the works of Piers Beirne and Gertrude Cazaux, both of whom attend to situations in which animals are cast as violators of the criminal law and the relationship of animal abuse to people's violence toward other humans. This latter relationship has become a major focus of attention, since it incorporates broader issues of social inequality and is seen by some as offering insights into elements of a person's movement into and through a violent career. It should be noted that the predictive value of abusing animals with regard to eventual involvement in human to human violence is an issue of considerable controversy.

The third major focus is based within the traditional literature on social movements. While some writers do not see their work as overtly situated in human–animal studies (e.g., James Jasper and Dorothy Nelkin), investigations of the animal rights movement do speak directly to how social definitions of animals are constructed and are employed to establish principles governing "appropriate" and "inappropriate" interaction with, or treatment of, non human animals. David Nibert (2002), a sociologist who overtly identifies with human–animal studies,

combines an orientation based on principles of the animal rights movement, sociological perspectives on inequality, and critical theory to make the case for the oppression of non human animals – like that of women, racial minorities, and other members of disvalued human groups – as being directly related to the political and economic structure of contemporary society.

Sociologists employ a variety of methods in their investigations of human–animal relationships and interactions. Some conduct surveys to ascertain people’s perceptions of both domestic and wild animals. Others use photographs of people with animals in order to explore the impact of being in the company of animals on social and personal identity. Content analysis of advertisements, films, greetings cards, and other graphic depictions of animals have also been used to assess cultural definitions of animals. However, the most common approaches employed within sociological human–animal studies are ethnography and its variant autoethnography (the systematic recording of the researcher’s personal experience). Ethnographic techniques have proven to be the source of the richest, most detailed, and theoretically sophisticated portrayals of human–animal interaction in both public and private social settings.

As a relatively new substantive area within sociology, the study of human–animal interaction offers a wide variety of alternatives for future research. Since most of the extant discussions are focused on people’s everyday relationships with cats and dogs (the animals most commonly incorporated into households), studies of relationships with “exotic” animals such as ferrets, potbelly pigs, reptiles, insects, and rabbits would be new and instructive. There are also a number of unexplored animal related occupations (e.g., the work of veterinary technicians, wildlife rehabilitators, zoo keepers, professional dog handlers, animal behavior consultants, circus personnel, and K 9 police) available for fruitful investigation. Finally, as Arluke (2003) has observed, sociologists have now amassed sufficient basic understanding of human–animal interaction to begin to apply this knowledge in an attempt to deal effectively with problems in urban human–animal relations, veterinary medicine, animal control activities, and other settings and exchanges that

constitute the “dark side” of this key form of social interaction.

human resource management

John Hogan and Miguel Martínez Lucio

Human resource management (HRM) has various definitions, but in the main there are two general approaches. The first descriptive approach states that HRM is the managing of employees and human assets at work and within the organization in an integrated and coherent

manner. The second approach elaborates this further by stating that HRM is distinct to previous forms of personnel administration in being proactive and therefore strategic: it concerns itself with soliciting higher forms of employee commitment and motivation. It is therefore both a relationship with organizations and a dedicated field of academic enquiry that has developed under this heading since the early 1980s.

Intellectually, HRM draws from various academic disciplines and subdisciplines, which in turn vary according to its distinct national contexts. Firstly, HRM derives from both traditional personnel management and labor/industrial relations as an area concerned with the question of employee control, cooperation, and commitment. It has, however, managed to constitute itself as something distinct to these two dimensions, with key proponents arguing it is more individualistic, strategic, and performance driven in orientation and not "reactive" or collectively underpinned. Hence, the role of occupational psychology has dovetailed into discussions on HRM regarding leadership and motivation, for example, and even matters of occupational health. Secondly, there is an economics tradition within HRM studies which is very much drawn from labor economics and concerns itself with matters concerning the relation between HRM processes and outcomes, as well as the subject of changing (flexible) labor markets and their relation with the HRM strategies of firms. Thirdly, there is a sociological trajectory which concerns itself with employment matters and management–employee–trade union relations within the workplace, and the broader composition of the workforce.

HRM is therefore a multidisciplinary area of analysis in terms of its academic context. It is a highly "populated" subject in terms of academic researchers, in the main due to the prevalence of business schools within the academy during the past two decades. There has also been an increasing demand from a practitioner perspective for information and guidance. This demand has come from organizations seeking greater flexibility in their workplaces, greater employee commitment, and developments in the capabilities of employees (e.g., the move from technical skills to communication and social skills). These demands have been driven

by a range of changes in product markets, competitive strategies, the structure of the firm, the competitive challenge through the globalization of economies, social changes and employee demands, and the changing context of regulation.

The topic is based on a growing belief that competitive success increasingly depends on securing more from employees in terms of commitment and resources rather than passive compliance to managerial instruction. The topics that have emerged were best described by Walton (1985), who argued that future competitive success required the eliciting of commitment rather than the imposing of control. There were five "pillars" to this:

- 1 High commitment or high involvement management: hence the increasing interest in forms of involvement and participation at work of a direct nature through team briefings and not just intermediaries such as trade unions.
- 2 Employee development: the emergence of the human resource development field with its interest in new forms of skills such as communication and interactive skills – seen as essential for service delivery in a service economy.
- 3 An emphasis on the individual employee: this dovetails with the manner in which reward and performance management systems begin to constitute the employee more as an individual and less as part of a collective.
- 4 An emphasis on leadership both at the senior and workplace levels: the changing nature of leadership through the proliferation of coaching and communication skills.
- 5 An adoption of a more "strategic approach" to HRM, which can take two forms in terms of (1) "internal fit" (i.e., that there is a consistent link and planned approach to the way elements outlined above are tied together around a "vision") and in terms of (2) "external fit" (which has this strategy linked to the needs and demands of the product market and external environment in a more responsive manner).

There emerged approaches that referenced such developments in terms such as "hard"

and “soft” HRM. Normally, these were equated with the work of such American schools of HRM as Michigan (“hard”) and Harvard (“soft”). The first approach is more drawn to questions of control and direction (e.g., the role of cultural imposition of values and surveillance) and the second to a more negotiated approach based on involving stakeholders in the elaboration of strategy. These approaches have been nourished by the development of total quality management, with its emphasis on performance management on the one hand and employee involvement in matters related to service quality on the other.

HRM has expanded as an area of study in part due to the manner in which it is seen as being less a department or management identity/profession, and more a feature of all managerial functions. It remains an integral feature of core management education at various levels, although it has not always been able to rival the strategic popularity of areas such “change management,” and especially marketing, within the confines of the business school tradition.

There are two schools of thought and practice. One sees HRM as a series of techniques and practices which are transferable across time: the much feted emergence of the Japanese model of HRM during the 1980s and early 1990s with its emphasis on teamworking, employee commitment, and performance management, has been integrated by an Anglo Saxon model which prioritizes employment flexibility, financial control, and greater customer awareness. Both these models were seen as being transferable to other contexts in their attempts to develop competitive economies through labor management policies. The second school of thought is increasingly concerned with context – both regulatory and, to a greater extent, cultural. Hence the idea of prescribing models and strategies is increasingly being confronted with an emergent interest in environmental/regulatory constraint and mediation. Thus, questions of convergence are being discussed in relation to questions of divergence/contingency/context.

This is being mirrored in the debate on organizational culture and the emergent interest in the historical narratives of the firm. Not only are external national, economic, and cultural perspectives a focus of analysis; internal cultural and organizational specificities and

identities have also emerged as a source of study and intrigue which mediate the nature and content of HRM.

There are traditions within the study of HRM in recent years that also draw attention to the way management strategies are constrained and even mediated by the question of employee rights. The issue of diversity has begun to impact on the HRM debate as the tradition of equal opportunities and legal intervention has been complemented by the organizational utilization of employees and their socially diverse characteristics in the form of the discourse of “managing diversity.” HRM debates have placed great store on the fact that such issues as gender and ethnicity rights can be enhanced for social and economic gain, leading to the building of a business case for a diverse workforce. This business case is also apparent in the question of partnership, and a renewed interest in a form of cooperation between management and unions/employees based on the mutual gains both “sides” can achieve through a dialogue which removes traditional forms of adversarialism of a class nature and replaces it with a common alliance and strategy. Such developments, in the terms of representation and rights within HRM, are hotly disputed due to their slow progress, the concern with real gains for employees, and the nature of employer motives regarding social and representational issues (Kochan & Osterman 1994; Martínez Lucio 2004).

Current work is broad and research is expanding rapidly in the area due to the sheer scale of researchers within business schools and the dominance of consultancy practices. There are very broad sets of developments: the main ones are as follows. Firstly, there is growing interest in taking the question of “fit” discussed above and modeling it and studying it through quantitative research methods. This is known as the “bundles” approach, which aims to establish the ingredients that ensure effective HRM strategies and which allow for a match between product market pressures and HRM “recipes.” This has its own political dynamics as a feature of HRM in that there are concerns about the extent to which employee involvement and trade unions are part of such recipes in leading edge firms. There are various firm specific approaches and national/geographical

studies aimed at substantiating such links. Hence, a more qualitative approach to this subject in the form of the mutual gains approach (Kochan & Ostermann 1994) attempts to establish the role of labor – collectively and individually – as a key factor in ensuring greater quality and contentment at work and in terms of production.

Another departure is the question of meaning (i.e., the meaning of HRM in terms of its rhetoric, its contingent qualities, and its tendency to be more of a cultural and political veil than a measurable reality in terms of increasing levels of skill formation and involvement). In this respect there are studies and overviews aimed at revealing the rhetorical and political qualities of HRM (Legge 2004), its tendency to be driven by an imperative for control as suggested by the increasing levels of surveillance at work (which has drawn interest from Marxist and postmodernist accounts), and, with regards to postmodernism, the way HRM strategies have attempted to construct employees ideologically in a variety of manipulative ways. In turn, studies are showing that such strategies often lead to new forms of contestation and resistance – and even misbehavior (Ackroyd & Thompson 2000). Hence, there is a growing preoccupation with issues of employee dignity and work–life balance due to the pressure brought by HRM strategies.

There are fundamental tensions in the study of change and HRM, especially in relation to research methodology. The first is the tension between prescriptive studies of HRM which are common in the managerialist and guru/fad literature, with its recommendations as to what managers and organizations should do with regards to issues such as commitment, and the more descriptive and explanatory literature (Huczynski 1993). This tension is played out in terms of the practitioner dimension of the discipline and the academic end, with the former tending to reproduce itself in business schools, especially when there is no critical dimension or tradition present among HRM staff. The second tension revolves around quantitative and qualitative approaches. Increasingly, the dominance of North American academic paradigms means that organizational change and the evolution of HRM is understood through a quantitative prism and the concern with strategic and

organizational factors regarding issues of “fit” – both internal and external. Whereas qualitative research has focused on the more contradictory and contingent nature of change; it has also drawn attention, increasingly, to the distinct meanings of management processes and practices. Moreover, there are severe disputes between the sociological and economic perspectives on the one hand, with their interest in social relations and regulation, and psychological perspectives on the other, with their emphasis on distinct methodological concerns and research questions based on the individual.

The comparative agenda is the main challenge to the future research on HRM. Models of analysis still default to cultural perspectives or regulatory traditions of analysis. Mapping varieties of HRM at the macro and micro level is a major development, in part driven by the concern with efficient and “better” models of people management and by a cartographic desire to see if there are common features emerging in the way people are managed.

This is paralleled by a broad diffusion of interest in the changing nature of the firm as a space within which HRM strategies are elaborated. Firstly, with regards to spatial boundaries, there is the increasing internationalization of the firm. The development of transnational corporations brings the question of “fit” and employee management across boundaries up against the question of national regulatory and cultural context. Secondly, the firm’s boundaries are changing in organizational terms: the impact of decentralization, subcontracting, and ICT means that the jurisdiction of management is mediated and influenced by a broader set of sub actors. This has led to a growing interest in the role of social and corporate networks in the study of the firm, and inevitably to questions of social capital, transaction costs, and organizational coordination. There is also a third feature to this boundary issue in terms of the relation between HRM and other areas such as marketing, with its interest in communication/branding/ethics, and information management, for example, calling on academics to appreciate the interactive nature of management processes in an age of IT and image.

Finally, regardless of the initial talk of a break from traditional stakeholders and forms of organization there is an ongoing concern

with (1) the sociological characteristics of management and employees (e.g., in terms of gender and ethnicity), (2) the challenge of cooperation and involvement, and (3) the ethical framework of the firm. The ethical dimension in terms of the role of corporate social responsibility within the firm is a major aspect of current concern.

human rights

Susanne Karstedt

"Human rights are those liberties, immunities, and benefits which, by accepted contemporary values, all human beings should be able to claim 'as of right' of the society in which they live" (*Encyclopedia of Public International Law* 1995: 886). Virtually all states embrace and support the idea of human rights, and they have indicated some general agreement as to their objectives and contents. This definition which casts human rights in legal terms barely mirrors the expectations that individuals,

groups, and peoples have attached to them. When on December 10, 1948 the United Nations General Assembly adopted the Universal Declaration of Human Rights (UDHR), the Declaration was hailed as "an international Magna Carta of all mankind" that could set up a common standard of achievement (Risse & Sikkink 1999: 1). Five decades later, human rights are seen as "offering a framework for debate over basic values and conceptions of a good society" (Charlesworth & Chinkin 2000: 210), and as social claims made by individuals and groups against organized power for the purpose of enhancing human dignity. Human rights are a powerful discourse on the *moral nature* of society and individuals that is simultaneously a *legal discourse* on rights, obligations, and accountability.

Human rights discourse provides a normative legal basis that is obligatory, not optional for states. Human rights are entry points for individuals and collectivities into the sphere of international law and international relations. They require active and effective remedies in the international arena, and accountability in national and domestic arenas. Perhaps more than ever they are a constant source of hope for empowerment, identity, and self-determination for individuals, groups, and peoples who are invisible and suffer from exclusion, discrimination, and human rights abuses (Charlesworth & Chinkin 2000).

After a slow start, human rights discourse gained momentum in particular during the last decades of the twentieth century. Roughly between 1970 and 1990 the international social structure of human rights norms and institutions was built, including transnational human rights NGOs and advocacy networks. During this period major covenants came into effect, new international institutions emerged, bilateral and multilateral human rights policies were developed, and regional institutional structures were established in Europe, Latin America, and Africa. Since then and concomitantly with the third wave of democratization that took hold first in Latin America and then Eastern Europe, a process of genuine international "norms cascade" began as the influence of human rights norms and discourse spread rapidly around the globe. This norms cascade has promoted the "internationalization" of human rights norms

in the international community and given them a taken for granted quality (Risse & Sikkink 1999). If its momentum can be sustained human rights will be increasingly accepted and embedded in national norms and justice systems. The extensive human rights discourse, however, also revealed basic controversies and paradoxes that are innate to the paradigm of human rights, to its institutions and history. Three of these are presently most widely debated: first, the paradox of “international accountability for the domestic practice of sovereign states” (An Na’Im 2004); second and related to this, the controversy about the claim for universality of human rights against cultural relativism; and third, the claim for social and economic rights, in particular for the right to development.

Human rights have historical roots that reach far back into history. In particular those human rights that guarantee due process or security can be traced to ancient societies, Roman civil law, and the common law of Anglo Saxon countries (Ishay 2004a). Tolerance was and is embedded in many religions throughout the world, and states entered into treaties which acknowledged tolerance for heterodox religious worship. Through many centuries communities existed where at least some of what are now considered fundamental human rights were well protected by bodies of law, institutions, and customary law. However, the modern paradigm of human rights emerged in and is part of the Enlightenment tradition in Europe and the US. It came out of the struggles against the modern state that was accumulating more power than ever before, the bitter religious wars that had haunted the continent for nearly two centuries, and the claim for independence made by a colonial people. The first of these were the Petition of Right in 1628 and the Bill of Rights in 1689 in Britain, followed by the more encompassing declarations of the American and French revolutionaries: the American Declaration of Independence (1776), the French Declaration of the Rights of Man and of the Citizen (1789), and the American Bill of Rights (1791).

They were designed to empower individuals as human beings and because of their moral identity, thus ensuring individuals as moral personalities. These early declarations of human rights also made the state responsible

for guaranteeing these rights. The legacy of Enlightenment philosophy was twofold in this respect: it introduced the notion of individual autonomy and liberty, and simultaneously the notion – based on contract theories – that the state existed to secure the universal rights of all its inhabitants. This legacy entailed a lasting paradox for the role of the state in human rights regimes, “as both the guardian of basic rights and as the behemoth against which one’s rights need to be defended” (Ishay 2004b), a paradox that has been meanwhile transported to the supranational level and international humanitarian intervention. In the course of the nineteenth and twentieth centuries bills of rights were adopted or otherwise incorporated into constitutions on the entire continent of Europe, and the movement spread to the Americas, Asia, and Africa. The declarations of human rights further inspired and entailed other bilateral and multilateral international agreements and treaties that later were incorporated into the present paradigm of human rights. A prohibition on slavery and slave trade became customary international law in the nineteenth century and was later codified in widely accepted treaties. Further, humanitarian international laws that prohibited particularly cruel weapons and protected prisoners of war and civilians during wars were developed before World War I.

It was only in the wake of World War II and the barbarous acts committed in its course that the members of the international community, the United Nations, finally pledged themselves in the UN Charter to “take joint and separate action” for the promotion “of universal respect for, and observance of, human rights and fundamental freedoms for all without distinction as to race, sex, language, or religion” (Article 55 of the UN Charter). This led to the successive development and adoption of what is today known as the International Bill of Rights, which comprises a declaration, covenants, and measures of implementation. The International Bill of Rights can be termed as a major achievement and breakthrough in international law as it established individuals and groups as subject and legitimate preoccupation of international law besides sovereign states. The four “instruments” of the International Bill of Rights are the Universal Declaration of Human Rights

(UDHR) of 1948, the International Covenant on Civil and Political Rights (ICCPR), the Optional Protocol to the International Covenant on Civil and Political Rights (ICCPR OP), and the International Covenant on Economic, Social, and Cultural Rights (ICESCR), all adopted in 1966. The International Bill of Rights is enshrined in regional conventions that specify human rights obligations and norms for the member states of supranational regional organizations. The European Convention on Human Rights that entered into force in 1953, and in particular the establishment of the European Court of Human Rights, have been a model for other regions and the development of legal institutions to monitor the observance of human rights. In 1986 the African Charter on Human and Peoples' Rights was adopted, and in 1993 the Managua Declaration of the Organization of American States stated explicitly the obligation of its member states to promote and safeguard human rights. Other instruments mainly in the form of conventions cover specific violations of human rights (e.g., racial discrimination, forced labor, genocide, and torture) or address and protect the rights of specific groups like children, women, and migrant workers. The continuous development of these instruments over the decades in fact demonstrates the norms cascade of human rights.

The International Bill of Rights and its four instruments comprise 39 rights (or freedoms) (Condé 1999). It differs however in two important respects from the predecessors on which it is based. While these focused on individual autonomy, the UDHR and the ensuing Covenants are based on the notion of the "inherent dignity" of human beings, thus acknowledging the social and cultural embeddedness of human nature. While it was important for the Declarations of the Enlightenment era to establish the right to private property, thus promoting a free market economy, the UDHR and both Covenants do not include this right and thus abstain from defining the economic order of member states. The rights are often, though controversially, described in terms of first, second, and third "generation" rights reflecting on their historical legacy. The UDHR invokes in its 30 articles all generations of universal rights, which are then detailed and supplemented

in the Covenants. The first generation rights consist of civil and political rights and liberties as they were conceptualized during the Enlightenment. They protect against arbitrary interference and deprivation of life, liberty, and security by the state, and make the state obey the principle of the rule of law. The first generation's major document is the ICCPR. The ICESCR details the second generation of human rights, such as those to health, housing, and education. In contrast to the first generation these require active intervention by the state to ensure their protection. Individuals and groups can claim from their governments to secure their subsistence which is necessary to lead a life in dignity. Both Covenants further include third generation rights comprising peoples' or collective rights. Most prominent among these is the right to self-determination that was absent in UDHR. Third generation rights further include the right to development and peace. Claims can be made against the international community and nation states, and benefits will flow to individuals and the respective group. Third generation rights are more often than not contained in the "soft" law instruments like UN General Assembly declarations and resolutions, with the African Charter of Human and Peoples' Rights a notable exception.

While there is agreement on the justiciability of first generation human rights laws, the implementation and enforcement of second and third generation social, economic, and cultural human rights have raised debates about the general accountability of states for securing these rights for their citizens, and the actions necessary to achieve this. The Declaration on the Right of Development adopted by the UN General Assembly in 1986 epitomizes these controversies, as it links human rights language with international economic issues in a highly ambiguous way. Notwithstanding its symbolic significance in the UN system, it has also contributed to the sense that first generation liberal values and rights have a permanence and solidity that second and third generation rights do not possess (Charlesworth & Chinkin 2000: 207). However, these also have come under intense criticism. First, the right of states to international humanitarian intervention, and the legitimacy of such interventions, is debated (An Na'im 2004). Second, the claim of human

rights to universality has recently emerged as a most contentious issue (Ishay 2004a, 2004b; An Na'Im 2004). This concerns the popular, social, and cultural acceptability of human rights norms within specific social and cultural contexts. Since human rights are without doubt the product of a specific culture but nonetheless claim universality, a given set of human rights norms (in particular those based on individual autonomy and liberal values) can be perceived as alien and unacceptable in other cultures (e.g., rights for women). Further, human rights norms might not only be alien in some cultural and social contexts, but endanger those who they are supposed to benefit, by unraveling the social fabric which supported these groups. While western countries support the claims for universal rights, but are more reluctant in their endorsement of collective rights, Islamic and Asian cultures prioritize collectivistic over individual rights. It is important to address these issues in the effective and practical implementation of human rights.

Human rights law is constantly challenged, and though most states formally accept human rights regimes they undermine such commitment by use of extensive reservations, thus widening the gap between human rights promises and practices; further, many states are responsible for numerous human rights violations. The process of democratization and the development of full liberal democracy reduce the gap between promise and practice and generally the level of human rights violations. The implementation of human rights further requires processes of socialization that incorporate human rights regimes into the political identity of citizens and nations. Risse and Ropp (1999) identify three processes on the international and national level: adaptation and bargaining, moral consciousness raising, "shaming," and persuasion, and institutionalization and habitualization. The density and strength of international institutions and "advocacy coalitions" of NGOs on the international and national level both coalesce into the "world time" and norms cascade of human rights regimes. Their "spiral model" of five stages towards enduring change of human rights regimes reflects the importance of interaction between advocacy networks, national movements, and international support.

Notwithstanding the numerous problems of implementation and enforcement, human rights law has an expanding role in the international community as a statement "of the elements of humanity" (Galtung 1994). It is perhaps the most important development in international law during the last century, with its norms cascade reaching into and defining the twenty first century. It has destroyed the myth that the way in which states treat their citizens is not the concern of anyone else. In the era of globalization human rights abuses are becoming the concern of everyone else.

Humanism

Joseph Scimecca

Humanism, a philosophical movement that affirms the dignity of the human being, originated in Italy in the second half of the fourteenth century. While the twelfth and thirteenth centuries had been dominated by the philosophical school of Scholasticism (philosophy taught by the “schoolmen” of medieval universities who tried to reconcile the philosophy of the ancient classical philosophers with medieval Christian theology), by the fourteenth century, Scholasticism was more and more seen by thinkers outside the church and the universities as irrelevant to everyday life. This view of Scholasticism, along with the growth of cities and greater contact with the East and its differing views and customs, led thinkers such as Francesco Petrarch (1304–74) and Desiderius Erasmus (1466–1536) to view the world differently than had the Scholastics. Although, the early Humanists were still Christians who believed that God ruled the world, it was a world which they saw as in need of change, change that could be brought about by human reason. For the Humanists, human beings possessed free will and the ability to use their reasoning power to bring about a humane world.

Humanism spread throughout Europe over the next few centuries, finally culminating in the Enlightenment, and it was out of the Enlightenment that the fundamental underpinnings of the birth of social science and eventually sociology sprang forth. It was a group of Scottish and French Enlightenment philosophers (or *philosophes*, as they are collectively known) who laid the foundation of what Auguste Comte (1798–1857) would later call “sociology.” The *philosophes* – John Locke (1632–1704), Baron de Montesquieu (1689–1755), Jean Jacques Rousseau (1712–78), Adam Smith (1723–90) – called for a fusion of morals and science, for a social science that sought to liberate the human spirit and ensure the fullest development of the person. Whereas these traditions of moral philosophy and empiricism are now seen by modern sociologists as separate, they were for the Enlightenment *philosophes* intertwined. And it was this emphasis on both moral philosophy

and empiricism, as modified by German Idealism and more recently by the American philosophical tradition of pragmatism, that constitutes the foundations of Humanism in sociology today.

THE *PHILOSOPHES* AND SOCIOLOGICAL HUMANISM

Although the Enlightenment *philosophes* initiated the discipline of sociology through their call for the application of scientific principles to the study of human behavior (Rossides 1998), it should not be forgotten that the *philosophes* were first and foremost moral philosophers. Science and morality were to be fused, not separated; the “is” and the “ought” were to be merged into a moral science, a science to be used for the betterment of humankind. Rousseau, with his arguments against inequality and for the dignity of the person, can be seen as an exemplar of this moral science tradition. Rousseau (1985) started with the fundamental assumption that all people are created equal but “everywhere they are in chains.” Rousseau was wedded to the idea that individual liberty and freedom prospered only under conditions of minimal external constraint – that the “chains” had to be broken. For Rousseau and the *philosophes*, this could only be accomplished through a fusion of morals and science, by a social science that sought to liberate the human spirit and bring about the fullest development of the person.

This tradition of a “moral science” is overlooked by the majority of contemporary sociologists, who instead focus on the empiricism of the *philosophes*, which though it played a huge role in the rise of social science, is only one part of what the *philosophes* advocated (Goodwin & Scimecca 2005). By their dismissal of the “moral science” tradition and by almost unquestioningly embracing the positivism that Comte, Spencer, Durkheim, and the other early founders of sociology advocated, sociology as it began in France, England, and later in the US strayed from its humanist roots. Sociology, however, developed differently in Germany, and it is through German philosophy and social science that the tradition of Humanism in sociology was kept alive.

GERMAN IDEALISM

German social science (unlike its English, French, and later American counterparts) was much more influenced by idealism than by empiricism – an influence due to two giants of philosophy: Immanuel Kant (1724–1804) and Georg William Freidrich Hegel (1770–1831). Like the medieval Humanists, Kant (1965) was concerned with the basic question of how autonomy and free will were possible in a deterministic Newtonian universe. Kant's answer lay in moral philosophy and the basis of moral philosophy was to be found in the human mind; moral law was located *a priori* in the mind and could be deduced rationally.

Kant's explanation was that objects of scientific investigation were not simply discovered in the world, but were constituted and synthesized *a priori* in the human mind. The external world which human beings experience is not a copy of reality, but something that can only be experienced and understood in light of *a priori* forms and categories. According to Kant, these forms and categories determine the form but not the content of external reality. Morally right action, too, was located in the mind. Going back to Rousseau and before him to the medieval Humanists, Kant (1949) focused on the dignity of the human being, postulating the notion of the categorical imperative – that each person be treated as an end and never as a means. This solidified the importance of the person as the cornerstone of philosophical inquiry and of Humanism. Moral values come from human consciousness, but lacking a viable theory of consciousness Kant could only go so far. It would be Hegel who subsequently made further progress toward the development of a humanistic orientation in sociology.

Although Hegel (1967) held that Kant's epistemology was successful in explaining how scientific knowledge was possible, he differed with Kant by rejecting his belief that the categories were innate and therefore ahistorical. For Hegel, the human mind had to be understood in the context of human history. Human reason was the product of collective action and as such was constantly evolving toward an ultimate understanding of its own consciousness. Hegel is very close to modern sociology in numerous aspects of his thought and it is unfortunate that he is so

often dismissed because of his ultimate reliance on the metaphysical assumption that total understanding would only come with the realization of the absolute spirit in human history, along with his conservative political views which some have seen as justifying a totalitarian system. Such interpretations overlook that Hegel was the first modern theorist to develop an anti positivist, critical approach to society. Hegel rejected positivism because of its over reliance on empiricism. As was Kant's philosophy, Hegel's philosophy was Humanist at its core.

Given the times in which they lived, neither Kant nor Hegel had a fully blown conception of self in society. It would be up to the American pragmatists to provide an active view of the self, laying the groundwork for contemporary Humanist sociology.

PRAGMATISM AND HUMANISM

Pragmatism assumes an active epistemology which undergirds an active theory of the mind, one which challenges the positivistic behaviorism of the time made popular by the likes of John B. Watson. For the pragmatists, how the mind comes to know cannot be separated from how the mind actually develops.

Mead (1974) exemplifies the pragmatists' view concerning the development of mind. Consciousness and will arise from problems. Human beings are capable of reflexive behavior, that is, they can turn back and think about their experiences. The individual is not a passive agent who merely reacts to external constraints as positivism holds, but someone who actively chooses among alternative courses of action. Individuals interpret data furnished to them in social situations. Choices of potential solutions are only limited by the given facts of the individual's presence in the larger network of society. This ability to choose among alternatives makes individuals both determined and determiners (Meltzer et al. 1977).

The individual is engaged in an active confrontation with the world; mind and self develop in a social process. Mead and the pragmatists provided an epistemological justification for freedom (*the* basic tenet of Humanism). The mind develops in a social context and comes to know as it comes into being. Any restriction

on the freedom of the mind to inquire and know implies a restriction on the mind to fully develop.

Pragmatism, by joining epistemology and freedom via the social development of mind, also provided a solution for the seeming incompatibility between an instrumental and an intrinsic approach to values. The value of freedom is instrumental in that it is created in action (the action of the developing mind); but it is also intrinsic in that the mind cannot fully develop without the creation of an environment which ensures freedom (Scimecca 1995).

Pragmatism, however, did not go far enough in its assumption of freedom of choice. Choice among alternatives is always limited. It is in pointing out these limitations in the form of power relations and vested interests behind social structures that Humanist sociology built upon pragmatism and thereby confronted the basic sociological criticism of pragmatism – that it lacked a viable notion of social structure. Humanist sociology seeks to fashion a full blown vision of the free individual within a society based on the principle of human freedom.

HUMANIST SOCIOLOGY TODAY

Humanist sociology has moved beyond pragmatism with its attempt to spell out the social structural conditions for the maximization of freedom. Humanist sociology is explicitly based on moral precepts – the foremost of which is that of freedom, “the maximization of alternatives” (Scimecca 1995: 1). This is assumed to be the most desirable state for human beings – and the goal of sociology is to work toward the realization of conditions that can guarantee this freedom. Given its Meadian theory of self (an active theory of self that chooses between alternatives), Humanist sociology is concerned with what type of society best ensures that the freedom of the individual is not thwarted by the institutions of the society. For the Humanist sociologist, there is one basic purpose: to develop a society where the dignity, interests, and values of human beings are always given the highest priority (Goodwin & Scimecca 2005).

hybridity

Jan Nederveen Pieterse

Cut 'n' mix experiences in consumer behavior, lifestyles, and identities are common and every day, for example in food and menus. Hybridity refers to the mixture of phenomena that are held to be different, separate. Hybridization is defined as “the ways in which forms become separated from existing practices and recombine with new forms in new practices” (Rowe & Schelling 1991: 231).

The theme of hybridity matches a world of intensive intercultural communication, everyday multiculturalism, growing migration and diaspora lives, and the erosion of boundaries, at least in some spheres. Hence, hybridity has become a prominent theme in cultural studies. New hybrid forms are indicators of profound changes that are taking place as a consequence of mobility, migration, and multiculturalism. However, hybridity thinking also concerns existing or, so to speak, old hybridity, and thus involves different ways of looking at historical and existing cultural and institutional arrangements. This suggests not only that things are no

longer the way they used to be, but were never really the way they used to be, or used to be viewed.

Anthropologists studying the travel of customs and foodstuffs show that our foundations are profoundly mixed, and it could not be other wise. Mixing is intrinsic to the evolution of the species. History is a collage. We can think of hybridity as *layered* in history, including precolonial, colonial, and postcolonial layers, each with distinct sets of hybridity, as a function of the boundaries that were prominent at the time and their pathos of difference. Superimposed upon the deep strata of mixing in evolutionary time are historical episodes of long distance cross cultural trade, conquest, and empire and episodes such as transatlantic slavery and the triangular trade. Within and across these episodes we can distinguish further hybrid configurations. Taking a political economy approach we can identify several general types of hybridity in history. Hybridity across modes of production gives rise to mixed social formations and combinations of hunting/gathering and cultivation or pastoralism, agriculture and industry, craft and industry, etc. Semi feudalism and feudal capitalism are other instances of mixed political economies; modes of production did not simply succeed one another but coexisted in time. Hybrid modes of economic regulation include the social market in Europe and Scandinavia and market socialism in China, which organize economies by combining diverse principles. The mixed economy and the social economy of cooperative and nonprofit organizations are hybrid economic formations. Social capital, civic entrepreneurship, and corporate citizenship – prominent themes of our times – are also hybrid in character.

Hybridization as a process is as old as history, but the pace of mixing accelerates and its scope widens in the wake of major structural changes, such as new technologies that enable new forms of intercultural contact. Contemporary accelerated globalization is such a new phase. However, if practices of mixing are as old as the hills, the thematization of mixing as a perspective is fairly new and dates from the 1980s. In a wider sense it includes the idea of *bricolage* in culture and art. Dada made mixing objects and perspectives its hallmark and inspired the collage. Surrealism moved further

along these lines and so do conceptual and installation art. Psychoanalysis brought together widely diverse phenomena – dreams, jokes, Freudian slips and symbols – under new headings relevant to psychological diagnosis.

While hybridity may be unremarkable in itself, the critical contribution of hybridity as a theme is that it questions boundaries that are taken for granted. Thus, hybridity is noteworthy from the point of view of boundaries that are considered essential or insurmountable. Hybridity is an important theme also in that it represents one of three major approaches to globalization and culture. One is the idea that global culture is becoming increasingly standardized and uniform (as in McDonaldization); second is the idea that globalization involves a “clash of civilizations”; and third is globalization as hybridization or the notion that globalization produces new combinations and mixtures. The hybridity view holds that cultural experiences past and present have not been simply moving in the direction of cultural synchronization. Cultural synchronization does take place, for instance in relation to technological change, but counter currents include the impact non western cultures have on the West and the influence non western cultures exercise on one another. The cultural convergence view ignores the local reception of western culture, the indigenization of western elements, and the significance of crossover culture and “third cultures” such as world music. It overrates the homogeneity of western culture and overlooks that many of the cultural traits exported by the West are themselves of culturally mixed character if we examine their lineages. Centuries of East–West cultural osmosis have resulted in intercontinental cross over culture, and European and western culture are part of this global *mélange*. For a long time Europe was on the receiving end of cultural influences from the Orient and the dominance of the West dates only from 1800 onward (Frank 1998).

The term hybridity originates in pastoralism, agriculture, and horticulture. Hybridization refers to developing new combinations by grafting one plant or fruit onto another. A further application is genetics. When belief in “race” played a dominant part, “race mixture” was a prominent notion. Now hybridity also refers

to cyborgs (cybernetic organisms): combinations of humans or animals with new technology (e.g., pets carrying chips for identification, biogenetic engineering).

Hybridity first entered social science via anthropology of religion and the theme of syncretism. Bastide (1970) defined syncretism as "uniting pieces of the mythical history of two different traditions in one that continued to be ordered by a single system." Creole languages and creolization in linguistics was the next field to engage social science interest. Creolization came to describe the interplay of cultures and cultural forms (Hannerz 1992). In the Caribbean and North America creolization stands for the mixture of African and European elements (as in the Creole cuisine of New Orleans), while in Latin America *criollo* originally denotes those of European descent born in the continent. The appeal of creolization is that it goes against the grain of nineteenth century racism and the accompanying abhorrence of *métissage* as miscegenation, as in the view that race mixture leads to decadence and decay, for in every mixture the lower element would be bound to predominate. The cult of racial purity involves the fear of and disdain for the half caste. By foregrounding the *mestizo*, the mixed and in between, creolization highlights what has been hidden and values boundary crossing. The Latin American term *mestizaje* also refers to boundary crossing mixture. Since the early 1900s, however, this served as an élite ideology of "whitening" or Europeanization; through the gradual "whitening" of the population and culture Latin America was supposed to achieve modernity. In the US, crossover culture denotes the adoption of black cultural characteristics by European Americans and of white elements by African Americans. A limitation of these terms is that they are confined to the experience of the post sixteenth century Americas and typically focus on "racial" mixing. A different perspective is the "orientalization of the world" and easternization, in contrast to westernization. This concerns the influence of Japan and the rise of East Asia, China, and India and the twenty first century as an "Asian century." Each of these terms – creolization, *mestizaje*, crossover, and orientalization – opens a different window onto the global mélange and global intercultural osmosis.

Hybrid regions straddle geographic and cultural zones, such as the Sudanic belt in Africa. Southeast Asia combines Indo Chinese and Malay features. The Malay world, Indo China, Central and South Asia, Middle Eastern, North African, and Balkan societies are all ancient *mélange* cultures. Global cities and ethnic *mélange* neighborhoods within them (such as Jackson Heights in Queens, New York) are other hybrid spaces in the global landscape.

What hybridity means varies not only over time but also in different cultures. In Asia it carries a different ring than in Latin America. In Asia the general feeling has been upbeat, as in East–West fusion culture. Hybridity tends to be experienced as chosen, willed, although there are plenty of sites of conflict. In Latin America the feeling has long been one of fracture, and fragmentation and hybridity were experienced as a fateful condition that was inflicted rather than willed. The Latin American notion of mixed times (*tiempos mixtos*) refers to the coexistence and interspersions of premodernity, modernity, and postmodernity. In recent times Latin America's hybrid legacies have been revalued as part of its cultural creativity.

The domains in which hybridity plays a part have been proliferating over time, as in the hybrid car (combining gas and electricity), hybridity in organizations, and diverse cultural influences in management. Interdisciplinarity in science gives rise to new hybrids such as ecological economics.

The prominence of hybridity has given rise to a debate in which hybridity is being criticized as an élite perspective (Friedman 1999). A brief account of arguments against and in favor of hybridity is as follows (see Nederveen Pieterse 2004). Critics argue that asserting that all cultures and languages are mixed is trivial; a rejoinder is that claims of purity have long been dominant. Critics hold that hybridity is meaningful only as a critique of essentialism; which is true, but there is lots of essentialism to go around. Some question whether colonial times were really so essentialist; a rejoinder is that they were essentialist enough for hybrids to be widely despised. Critics object that hybridity is a dependent notion; but so are boundaries. Some critics argue that hybridity matters only to the extent that people identify themselves as mixed; but the existing classification categories hinder

hybrid self identification. Critics claim that cultural mixing is mainly for élites; but arguably cross border knowledge is survival knowledge also or particularly for poor migrants. Critics hold that hybridity talk is for a new cultural class of cosmopolitans; but would this qualify an old cultural class policing boundaries? If critics ask what the point of hybridity is, a riposte is what is the significance of boundaries? Boundaries and borders can be matters of life or death and the failure to acknowledge hybridity is a political point whose ramifications can be measured in lives.

A next step is to unpack hybridity and to distinguish *patterns* of hybridity. The most conspicuous shortcoming of hybridity thinking is that it does not address questions of power and inequality: "hybridity is not parity" (Shohat & Stam 1994). This is undeniably true; but boundaries do not usually help either. In notions such as global *mélange* what is missing is acknowledgment of the actual unevenness, asymmetry, and inequality in global relations. What are not clarified are the *terms* under which cultural interplay and crossover take place. Relations of power and hegemony are reproduced *within* hybridity, for wherever we look closely enough we find the traces of asymmetry in culture, place, and descent. Hence, hybridity raises, rather than erases, the question of the terms and conditions of mixing. Meanwhile, it is also important to note the ways in which relations of power are not merely reproduced, but refigured in the process of hybridization.

Thus, according to the context and the relative power and status of elements in the mixture, hybridity can be asymmetric or symmetric. For instance, colonial society is asymmetric. We can think of types of hybridity along a continuum with, on one end, a hybridity that affirms the center of power, adopts the canon, and mimics hegemony and hegemonic styles, and, at the other end, mixtures that blur the lines of power, destabilize the canon, and subvert the center. The novels of V. S. Naipaul are an example of the former and Salman Rushdie's novels often match the latter. Menus that mix cuisines and health care practices that combine diverse methods may offer examples of the symmetric end of the hybridity continuum, but completely free floating mixtures are rare, for even at a carnival the components carry different values.

hyperconsumption/ overconsumption

Jeremy Schulz

Social critics and social scientists, on observing the transformations of American and Western European societies throughout the twentieth century, have relied on terms such as "overconsumption," "consumptionism," "new consumerism," and "hyperconsumption" to convey the increasingly central role played by the acquisition and consumption of goods and services in the lives of individuals, the shaping of cultural forms, and the dynamics of social organization.

This family of terms has a long history in the American context, where "consumptionism" entered the popular lexicon in a 1924 article by journalist Samuel Strauss. Like many other social critics of his time, Strauss sought to expose the ethical bankruptcy of a society in which a concern for the standard of living dominated all other aspects of national and individual welfare. Decades later, in *The Affluent Society* (1958), the economist John Kenneth Galbraith savaged the "overconsumption" fueled by the growth of mass markets and American merchandisers' insatiable appetites for huge sales volumes.

The term "overconsumption" also figured prominently in the critiques of the American lifestyle formulated by social critics and social scientists during the 1970s and early 1980s. Moving beyond earlier critiques, these treatments took aim not only at the ethical consequences of overconsumption, but at the effects of consumption oriented lifestyles on physical health, psychological well being, and social functioning. Scitovsky (1976) and Wachtel (1989), for example, argue that ever increasing quantities of goods and services do not ensure gains in satisfaction at the individual or collective level. In such a society, individuals accustomed to more and more inevitably adapt their consumer expectations to their new circumstances. Consumers will constantly revise their consumption standards upwards, conceiving a whole new set of "must haves" as general consumption standards rise. Other writers from this period address the theme of overconsumption from a less psychological standpoint. Hirsch (1976) considers the perverse social consequences of American society's extreme emphasis on private goods at the expense of public amenities. The profusion of private goods and services and the starvation of the public sector make it necessary for each consumer to meet their needs individually through market channels. In Hirsch's view, when all goods and services are supplied and consumed in this way, social and individual well being suffers.

Combining the themes which preoccupied the critics of the 1970s with the concerns for status and emulation which inspired Veblen at the turn of the century, Frank (1999) focuses

on the competition over status and social position in the consumerist America of the 1990s. Frank relates the "upscaling" of expectations about what constitutes a desirable wristwatch, suit, or car during the 1990s to the desire American consumers have for "positional goods" (Hirsch 1976) which assist people in creating the "invidious distinctions" Veblen mentioned in his writings on conspicuous consumption (Veblen 1967). Because they represent membership in certain reference groups to which they aspire, today's status seeking consumers treat socially sanctioned "high end" products, brand name clothes, cars, and "trophy homes" as necessities. For the status driven American consumer, a serviceable \$50 wristwatch suddenly becomes inadequate when \$1,000 wristwatches start appearing on the arms of well off neighbors, successful co workers, and even media celebrities. Frank's concern with adaptation and status seeking surfaces in many journalistic accounts of overconsumption in the contemporary US. During the late 1990s, articles about expensive and oversized "trophy homes" and "McMansions" appeared frequently in the pages of the nation's newspapers.

Several recent works on overconsumption have shifted the focus somewhat away from the proliferation of luxury goods and the upscaling of consumer norms among the affluent. The predicament of the middle class overconsumer who depends entirely on earned income and consumer credit to finance his acquisition of goods and services is now a central theme in writings about overconsumption. In her influential book *The Overspent American* (1998), the economist Juliet Schor examines the new wave of middle class consumerism supported by earned income and consumer credit. In Schor's view, middle class purchasing of status goods and services has exploded because of the visibility and transparency of the lifestyles associated with middle class reference groups such as celebrities. The status insecurities of middle class Americans who fear sliding down the social ladder add to this emulationist pressure and stimulates even more consumerist behavior.

For the status conscious members of the middle class, the acquisition, ownership, and display of "socially visible" goods such as cars, houses,

and clothing have become essential means of proving to themselves and others that they belong in the “really made it” and “doing very well” groups which have come to play the reference group role for more and more Americans. Today’s middle class overconsumers live in a social world where one cannot validate and affirm one’s claims to membership in the “made it class” without owning and flaunting the cars, clothes, houses, and computers which are recognized as essential components of upper middle class living. Indeed, George Ritzer (2001) remarks it is the very inconspicuousness of contemporary brand name overconsumption which differentiates it from the kind of overconsumption characteristic of Veblen’s elites. Consumerist individuals who want to be seen driving certain cars and wearing certain clothes are at once proclaiming their conformity to a particular generalized type and their distinctiveness as “individuals” (Baudrillard 1998).

A new interest in the institutional and infrastructural conditions of overconsumption has surfaced in the works of sociologists studying consumerist practices at the beginning of the twenty first century. The American sociologist George Ritzer coined the term “hyperconsumption” (Ritzer 1999, 2001) to capture the vastly expanded scope and scale of mass consumption supported by the organizational and logistical innovations of the last quarter century. Ritzer has written extensively about the physical and virtual settings and contexts where the contemporary consumer interacts with producers and sellers of consumer goods. In his view, the emergent “cathedrals” and “landscapes” of hyperconsumption offer an irresistible combination of abundance, enchantment, and predictability. They lend ordinary acts of purchase a magical aura, while at the same time removing all obstacles and barriers to the pleasurable and efficient acquisition of goods and services.

Ritzer (1999) reminds us that American consumers encounter a more and more rationalized and “McDonaldized” set of organizations and practices on the supply side of today’s consumer oriented American economy, an economy where consumer spending now accounts, either directly or indirectly, for a constantly rising

proportion of US GDP (now around 70 percent) and some 60 percent of all domestic employment (Toossi 2002). At the same time, the demand side of the American economy has been increasingly reorganized to support ever growing levels of consumption. Equity based credit cards and other innovations in the “means of consumption” (Ritzer 1999, 2001) give ordinary American consumers the capacity to spend far beyond their current means.

It is possible to distinguish three strands in recent empirical research into contemporary trends in overconsumption and consumerism. British and American ethnographers tend to concentrate on the experiential dimensions of shopping, whether at luxury stores or the large volume discount stores so prevalent in the US (Zukin 2004). More theoretically and structurally oriented researchers have dealt with the markets and organizations which supply the means – such as consumer credit (Calder 1999) – and the opportunities (Ritzer 1999) for overconsumption.

Emergent lines of research include, at the behavioral level, studies of individuals’ use of and relationship with goods such as large homes and luxury cars and services, particularly leisure and entertainment services such as cruises, casinos, hotels, and restaurants. At the structural and institutional level, researchers are turning their attention to the orchestration of consumer credit services, the structuring of large scale discount retailing/small scale luxury retailing, and the diffusion of American models of retailing and credit provision in Europe, Asia, and other parts of the world. Finally, theoretically oriented researchers are rethinking the category of consumer. Zygmunt Bauman, for example, argues that in contemporary neo liberal societies the empowered consumer now wields a kind of agency inaccessible to the comparatively disempowered worker employee who must cope with an ever more rationalized workplace. For this reason, individuals and households who lack purchasing power because of their low incomes or status as unemployed members of society find themselves stripped of consumer sovereignty. The loss of consumer choice casts the poor and unemployed further into the social abyss and further into the ranks of the “repressed” (Bauman 1998).

hyperreality

Michael T. Ryan

The capitalist mode of production has gone through some significant changes in the twentieth century (according to Henri Lefebvre, a mutation). A number of French social theorists inspired by Marx have attempted to grasp this process with new concepts and theories, especially in relation to new cultural forms and processes (e.g., media technologies) that are no longer treated as epiphenomenal superstructures that are reducible to the economic substructure of capitalism as orthodox Marxists have traditionally conceptualized this relation. Cultural phenomena have become critical forces in the moments of distribution, exchange, and consumption of commodities in late capitalism. The heroic age of the revolutionary bourgeoisie ended around 1910 with the decline of all of the referentials of classic capitalism: clock time, the vanishing point in art, the work ethic and productive values, history, proletarian revolution, etc. Class strategy has shifted from the organization of production to the bureaucratic organization of consumption and everyday life. The age of simulation begins with the liquidation of referentials, according to Jean Baudrillard. Signs and signifiers have become detached from their referents, from reality, and now only refer to each other. For example, according to Mark Gottdiener, Las Vegas casinos have a variety of themes and constitute a structure of differences that have nothing to do with the gambling and profit taking that goes on in them. What is the social and historical relation between a simulated

pyramid and the gambling, entertainment, and profit taking that takes place there? If fantasies connected to ancient Egypt do not do anything for the consumer, there are a number of other fantasies with which to play (e.g., tropical paradise, the Wild West, simulated urban environments, etc.). For Umberto Eco, in themed environments like wax museums "[absolute] unreality is offered as real presence . . . The sign aims to be the thing, to abolish the distinction of the reference." For Baudrillard, hyperreality "is the generation by models of a real without origin or reality." The production and reproduction of the real or the hyperreal is what material production is all about in our postmodern society. Simulations, signs, and codes now structure social relations and social practices rather than the capital/labor production relations of classical capitalism. Modern men and women have been set adrift in a sea of signifiers and simulations.

While commodification, industrialization, and market relations were seen as elements of an explosive process in early capitalism, Baudrillard, following Marshall McLuhan, sees an implosion of all binary distinctions and boundaries in late capitalism: high and low culture, past and present, good and evil, capital and labor, male and female, white and non white, developed and underdeveloped nations, appearance and reality, urban and rural representation and reality, true and false, etc. The poles of every opposition have been absorbed into one another and have become undecidable. Although he is not explicit about this, one could trace this process of implosion as Lefebvre does to the failure of the working class to become an agent of revolutionary transformation, an agent that was supposed to explode all of the contradictions that had accumulated in the capitalist mode of production and to transcend all of the premodern and bourgeois institutions to create a new socialist mode of production and urban society. While Lefebvre sees the implosion of this over organized society as a dystopic possibility, Baudrillard sees it as an accomplished fact and only offers us one alternative possibility: a return to symbolic exchange that structured tribal cultures and, along with the challenge (i.e., warfare as a mode of appropriating economic surpluses as well as martial sports, the

ancient Greek Olympics or medieval jousting matches that maintained warrior skills and discipline), structured agrarian societies as well. Simulation begins when the poles of all of these oppositions collapse. Indifference and neutralization of all of these formerly dialectical oppositions is the consequence. The media provide models for lived experience and interactions in everyday life (e.g., sex manuals, manuals for parenting, advice columns, radio and television call in shows, etc.).

Hyperreality is seen by most of these social theorists as a constituent element and a structural tendency in the development of the consumer society and late capitalism. While most of these theorists connect this process to the political economy of the capitalist mode of production, Baudrillard sees postmodern society as a fundamental break from modern capitalism. We move from a society organized around production to a society organized by semiurgy. Capital is simply one sign among a multitude of signs that structure social experience and practices in everyday life. Many of Baudrillard's readers have recognized the importance of his early critical work, see it as an enrichment of Marxist theory, and incorporate it in their critical analyses of late capitalism. But as Douglas Kellner sees it, Baudrillard abandons a social scientific perspective for a metaphysical philosophical perspective in his later works after *The Mirror of Production*.

While hyperreality is a useful concept to grasp the effects of the media in late capitalism, there are a number of problems with Baudrillard's later works. First, unlike Lefebvre who situates linguistic phenomena and consumerism within the process of the reproduction of the capitalist relations of production, Baudrillard sees the hyperreal as taking on a life of its own disconnected from the capitalist mode of production. He has reduced our understanding of this society to a single form and process (i.e., formalism or technological reductionism). He has failed to lay out the mediations to political and economic forms and processes, and he has failed to situate this tendency in history and in the possibilities for social change.

Second, his analysis is abstracted from any notion of agency. Which agents have brought this situation into existence? Which agents can

take up the task of transcending this closed system that apparently can only break down in a catastrophic manner? The only resistance is the passivity of the silent majority, which are the objects of his contempt. This often happens to radicals who live through a period of social movements that contest the powers that be and then fail, as happened in the 1960s/1970s. With social change unlikely in his lifetime, he abandoned these social movements to embrace some very reactionary political positions.

Third, his analysis is abstracted from the content of everyday life, the lived experience of consumers who are even more alienated than the workers of Marx's era. Does this postmodern society integrate all of its elements? Does this consumer society take care of all of our needs, especially social needs and services? Will the earth sustain a global consumer society? Are we not in the process of committing *terricide* as Lefebvre suggests?

Fourth, while Baudrillard is long on theory, he has failed to put together a research agenda, and in Kellner's judgment he has even failed to fully develop his theory. His concept of code is never satisfactorily defined. His work is often metaphorical; the logic of the metaphor displaces the logic of social processes (i.e., his use of DNA as a master code). For hyperreality to become a more useful concept, the students of Baudrillard will have to answer his critics.

hypersegregation

Nancy A. Denton

Hypersegregation occurs when a race/ethnic group is highly segregated in multiple ways, no matter how segregation is conceptualized or measured. It is an explicit recognition of the fact that residential segregation by race is a complex phenomenon that is multidimensional in nature. First used in 1989 in an article by Massey and Denton about patterns of black-white segregation in large US metropolitan areas in 1980, the term now occurs in both the academic and popular literature to describe the extremely high residential segregation experienced by African Americans in the US. Though residential segregation has generally declined in recent decades for African Americans, hypersegregation was still documented for African Americans in both 1990 and 2000. For the first time in 2000, Hispanics are hypersegregated in two places as well. No other group experiences hypersegregation in US metropolitan areas.

The complex, multidimensional nature of segregation reflects the historical causes of racial residential segregation, which include prejudice, discrimination, the behavior of realtors and mortgage and insurance agents, as well as the FHA and the development of the suburbs. Associated with the Chicago School, segregation is used to gauge the spatial assimilation of diverse groups into US society, beginning with comparisons of the residential patterns of European immigrant groups to native born whites and blacks. The theory was that as groups became more similar to native born Americans in terms of language, education, income, and occupations, they would also reside in similar areas. The study of segregation is also linked to the development of long term amortized mortgages for housing purchase. Though these enabled many people to own their own homes, the mortgages necessitated that the lender have some way of knowing that the home would still be valuable decades hence, and the future value was linked to characteristics of the neighborhoods where houses were located, including the race of the neighborhood residents. The tremendous post World War II housing boom, combined with the baby boom and suburban development, resulted

in urban landscapes that some described as “chocolate city, vanilla suburbs.” In recent decades, residential segregation of blacks has been linked to the development of underclass areas where the spatial concentration of poverty also concentrates other social ills such as crime, joblessness, single parenthood, low levels of educational attainment, etc. Even for the non poor, the linkage between housing appreciation and neighborhood and their exclusion from such neighborhoods, combined with denial of mortgages and higher rates of interest, has been estimated to have cost the current generation of blacks almost \$95 billion in lost assets (Oliver & Shapiro 1995). This brief history of residential segregation serves to illustrate the complexity of it. Throughout all of these studies the segregation of African Americans always stood out because it was so consistently high across cities and over time. The concept of hypersegregation was developed as a way of measuring and describing this uniqueness.

Conceptually, hypersegregation occurs when a group has high segregation scores on four or five different dimensions of segregation. The first dimension is evenness: the extent to which all the neighborhoods in a metropolitan area show the same distribution of groups as the total area. Thus, if an area is 20 percent black and 80 percent white, there would be no segregation if each neighborhood had that racial distribution as well. Evenness is measured by the Index of Dissimilarity (D), the most commonly used measure of segregation. The next dimension is isolation: the extent to which a group shares its neighborhoods with only members of its own group. While evenness looks at distributions *across* all neighborhoods in a city or metropolitan area, isolation provides the view from *within* neighborhoods. A group may live in only a subset of the neighborhoods in a city, but if those neighborhoods are relatively integrated the group has contacts outside their group and their segregation is not as severe as when their neighborhoods are occupied only by their own group. The third dimension, concentration, refers to the relative proportion of the total land area a group occupies, relative to the group's size. This dimension addresses the issues of crowding, population density, and the advantages associated with housing on spacious suburban lots. Centralization, the fourth

dimension, measures how close to the central business district a group resides. In the past, the central business district was not a desirable place to live because of the presence of factories, and in more recent years it reflects the disadvantage associated with not living in the suburbs, where many jobs are now located. The last dimension of segregation, clustering, looks at whether the neighborhoods where a group lives are themselves clustered into one large area or are scattered throughout the metropolitan area. It addresses the aspect of whether a group member, regardless of the composition of their neighborhood of residence, interacts with non group members if they leave their neighborhood. In hypersegregated metropolitan areas, black neighborhoods tend to form large contiguous ghettos.

The five dimensions used to measure hypersegregation were identified through a factor analysis of 20 different segregation indices, computed for blacks, Hispanics, and Asians in 60 metropolitan areas in 1980 (the 50 largest plus ten others with large Hispanic populations) (Massey & Denton 1988). After selecting a single index for each dimension, a group was defined as hypersegregated when their segregation was above a cutoff on four or five of the dimensions. The original criteria for defining hypersegregation were 0.6 for indices of evenness and clustering, 0.7 for isolation and concentration, and 0.8 for clustering (Massey & Denton 1988), though in later work (Massey & Denton 1993) the cutoff was simplified to 0.6 for all dimensions. The choice of a cutoff reflects the fact that in the literature segregation above 0.6 is usually considered high when indices range between 0 and 1. In a reanalysis of the dimensions of segregation for the same metropolitan areas using data from 1990, Massey, White, and Phua (1996) found that the clustering dimension was not as clearly defined in 1990. These researchers also analyzed all 318 metropolitan areas and found that the original five dimensions of segregation identified in 1980 were clearly observable in 1990, indicating that the structure of segregation had changed somewhat in the largest metropolitan areas, possibly because of the increased presence of Hispanics and Asians in these places, but that segregation could clearly be defined as comprising five dimensions in 1990 as in 1980. In terms

of which index best represented each dimension, however, the choice was not as clear for clustering and concentration.

In summary, to define hypersegregation requires three decisions: first, which index will be used to measure each of the five dimensions; second, what value of each index will be considered "high"; and third, on how many of the five dimensions must a group be highly segregated to be called hypersegregated. Choices on each of these are made based on both the extant literature and the judgment of the researchers: in short, there is no absolutely correct choice, and changes will yield different lists of hypersegregated places and groups. While this may at first seem to imply that hypersegregation is an arbitrary idea, what it really reflects is that segregation is a continuous variable. Furthermore, as will be seen when specific hypersegregated places are discussed below, varying these choices does not dramatically change the overall pattern of results.

Where does hypersegregation occur and does its location change over time? Using data from the 1980 US Census, ten metropolitan areas were originally identified as hypersegregated: Baltimore, Chicago, Cleveland, Detroit, Milwaukee, and Philadelphia on all five dimensions, and Gary, Los Angeles, Newark, and St. Louis on four dimensions (Massey & Denton 1989). As noted above, these were selected by examining the 50 largest metropolitan areas in 1980, as well as ten others with large Hispanic populations. In 1993 an additional six areas were added to the list as a result of modifying the criteria for defining hypersegregation to be 0.6 for all indices: Atlanta, Buffalo, Dallas, Indianapolis, Kansas City, and New York. Thus, in 1980 hypersegregation was most often found in larger, formerly industrial cities of the Northeast and Midwest that had large African American populations. A decade later, looking at the same 60 metropolitan areas originally used, Denton (1994) found that African Americans in all of these metropolitan areas remained hypersegregated except those in Atlanta and Dallas. In addition, examination of black segregation in the remaining metropolitan areas revealed hypersegregation of African Americans in an additional 15 metropolitan areas. While eight are smaller metropolitan areas located in the South (Albany, GA, Baton Rouge, LA,

Beaumont Port Arthur, TX, Monroe, LA, and Savannah GA) or Midwest (Benton Harbor, MI, Flint, MI, and Saginaw Bay City Midland, MI), the other seven are large metro areas, implying substantial black populations living in hypersegregated conditions: Birmingham, AL, Cincinnati, OH, Miami Hialeah, FL, New Orleans, LA, Oakland, CA, Trenton, NJ, Washington, DC.

Research using data from the 2000 census reveals the continuance of hypersegregation for African Americans, as well as the emergence of hypersegregation for Hispanics. Wilkes and Iceland (2004) identify 29 metropolitan areas with black-white hypersegregation in 2000: Chicago, Cleveland, Detroit, Milwaukee, Newark, and Philadelphia on all five dimensions, and Albany, GA, Atlanta, Baltimore, Baton Rouge, Beaumont Port Arthur, Birmingham, Buffalo Niagara Falls, Dayton Springfield, Flint, Gary, Houston, Jackson, Kankakee, IL, Los Angeles Long Beach, Miami, Memphis, Mobile, Monroe, LA, New Orleans, New York, Saginaw Bay City, MI, St. Louis, and Washington, DC on four dimensions. While most of these were also hypersegregated in 1990, Wilkes and Iceland used a different index to measure concentration than the one recommended by Massey and Denton. If a consistent set of indices is used across the three censuses, then nine metropolitan areas drop off the list of those hypersegregated in 2000 (Benton Harbor, Cincinnati, Indianapolis, Kansas City, Miami, New Orleans, Oakland, Savannah, and Trenton), though they remain highly segregated. However, three areas (Atlanta, Dayton, and Mobile) became hypersegregated in 2000. In addition, Hispanics in Los Angeles and New York are found to be hypersegregated in 2000.

Why is hypersegregation important? The multidimensional layers of segregation implied by hypersegregation mean that to the extent that blacks living in these places are denied access to the spatial resources in terms of schools, jobs, safety, and housing value appreciation that whites experience, then hypersegregation is a factor supporting the disadvantaged status of blacks in metropolitan America. It is of particular importance that Hispanics in New York and Los Angeles are now experiencing hypersegregation as well, for there is little reason to expect that it will not have similar effects

for them as it has had for African Americans. Future research on hypersegregation will have to confront the fact that, currently, hypersegregation is defined relative to non Hispanic whites. While this group is the most socioeconomically privileged, controls the opportunity structure in most metropolitan areas, and is usually the largest group numerically, metropolitan areas are increasingly diverse. Future studies of hypersegregation will have to include more groups and use multiple group indices such as the Theil Index, which is just beginning to be used in segregation studies (Fischer 2003; Fischer et al. 2004). In addition, increasing heterogeneity within groups, in both income and suburban location, implies that future work may show that some members of a group live in hypersegregated conditions while others do not (Alba et al. 2000; Fischer 2003).

hypotheses

Ivan Y. Sun

Hypotheses are predictions that specify the relationships among the variables. The role of hypotheses in scientific research is to provide explanations for certain phenomena and to guide the investigation of related others. The development of scientific knowledge hinges ultimately upon the results from hypothesis testing. For malized hypotheses consist of two types of variables: the independent and dependent variables. The former is the cause and the latter is the outcome. A good and well worded hypothesis should (1) indicate the specific relationship between the dependent and independent variables to be examined; (2) suggest the nature of the relationship; and (3) imply the nature of the research design (Cone & Foster 1993).

Hypotheses, which are derived directly from a theory or theories, have to be testable. The hypothesis testing process generally involves three steps. The first step is to formulate two hypothesis statements: a null hypothesis (often symbolized as H_0) that predicts no relationship between the variables in the population (e.g., H_0 : Social class is unrelated to deviant behavior) and an alternative hypothesis (H_1) that predicts a relationship between the variables (e.g., H_1 : Social class is related to deviant behavior). The null hypothesis should be mutually exclusive of the alternative hypothesis, meaning that there is no overlap between the two hypotheses. They are also exhaustive, representing all possible outcomes in reality. If the null hypothesis is not correct or rejected, then the alternative hypothesis may be correct or accepted.

The second step is to select the level of significance. In order to decide whether to reject or

fail to reject the null hypothesis, researchers must select a significance level (i.e., the α level) for the null hypothesis, which is typically at .05 or .01. If the alternative hypothesis specifies a direction of the relationship between the variables (e.g., H_1 : Social class is negatively related to deviant behavior), then the test is called a one tailed or directional hypothesis test of significance, which looks for either the increase or decrease of the dependent variable. If the alternative hypothesis does not specify a direction of the relationship (H_1 : Social class is related to deviant behavior), then the test is called a two tailed or non directional hypothesis test of significance, which examines any change in the dependent variable.

A final step is to calculate the value of test statistic and compare the statistic to a critical value obtained from distribution tables (e.g., Distribution of t or Chi Square or F) based upon the α level. If the test statistic falls beyond the critical value, then the null hypothesis is rejected and the finding is significant (e.g., People with high and low social class differ significantly in their deviant behavior). If the test statistic does not exceed the critical

value, then the null hypothesis cannot be rejected and the finding is not significant (e.g., People with high and low social class do not differ significantly in their deviant behavior), meaning that the difference in deviant behavior between people with high and low social class only occurs by random chance.

ideal type

Stewart Clegg

The notion of an ideal type is best known to sociologists through the work of Max Weber, although it was a term in common usage in nineteenth century German historical social sciences. It was designed to solve the problem of comparison. A historical event cannot be described without reference to the persons involved and to the place and date of its occurrence. Thus, all historical events were unique and one could only tell specific local stories. Forcing these into some overall framework would usually prove, at worst, ideological and, at best, would do violence to the integrity of local detail.

What an ideal type captures is meaning: what counts for history is always the meaning of the people concerned in its production and interpretation. As Leopold von Mises (1976: 60) argued in his *Epistemological Problems of Economics*:

An ideal type cannot be defined: it must be characterized by an enumeration of those features whose presence by and large decides whether in a concrete instance we are or are not faced with a specimen belonging to the ideal type in question. It is peculiar to the ideal type that not all its characteristics need to be present in any one example. Whether or not the absence of some characteristics prevents the inclusion of a concrete specimen in the ideal type in question, depends on a relevance judgment by understanding. The ideal type itself is an outcome of an understanding of the motives, ideas, and aims of the acting individuals and of the means they apply.

As Weber conceived them, ideal types were hypothetical and a reference not to something that is normatively ideal but to an ideational

type, which serves as a mental model that can be widely shared and used because analysts agree that it captures some essential features of a phenomenon. The ideal type does not correspond to reality but seeks to condense essential features of it in the model so that one can better recognize its real characteristics when it is met. It is not an embodiment of one side or aspect but the synthetic ideational representation of complex phenomena from reality.

For instance, Weber's analysis took emergent terms and ideas that were current in actual bureaucracies at the time that he was writing and used them as the basis for theoretical construction of an ideal type of bureaucracy. They were a reconstruction of ordinary language in use into the ideal type. Now a certain normative slippage occurs in this process, because he is using ordinary language terms, as defined by members of organizations, to describe what it is that these members do. The members were those of the Prussian and German bureaucracies of the state and military. They were bounded by a ferociously strong sense of duty and conformance.

Schütz (1967) took issue with one aspect of Weber's approach to ideal types: were they a construct by the analysts, or were they the analysts' account of the constructs in use by the members of the research setting in question? For Schütz it was not clear whether Weber's ideal types, in their basis in social action, were a member's category or one that belonged to analysts. By this he meant that their construction out of the concepts of everyday life should ensure that they were grounded in the members' usage. However, once they were refined by an analyst, they become somewhat dissociated from everyday usage.

An example of how slippage could occur is evident in the history of the concept of bureaucracy. Weber's synthesis of its ideal type

meaning became the basis for a narrow focus on “bureaucracy,” which became, ultimately, much more compatible with an instrumental concern with “efficiency” overshadowing the cultural, historical, institutional, political, and economic analysis of the market which Weber (1978) pioneered. Bureaucracy had been identified with elite constructions of organization; these, in turn, were now taken to be the literal depiction of the phenomenon. Rationality in the empirical world became identified with top managerial prerogatives defining what the bureaucracy should be and irrationality became identified with deviations from it.

Some sociologists made a similar error: because the ideal type was a construct from a highly specific place and time, it would have been odd for later and different realities to correspond to it. When writers such as Gouldner (1954) investigated organizations, they compared the realities they found with the type that they had inherited. However, since the type was always an imaginary and synthetic construct from a specific place and time, this is not an immediately sensible activity. It ends up privileging the subjectivities of those members whose everyday usage first grounded the construct and neglects that in different circumstances other members might have constructed quite other usages, which should surely provide the material for constructions of other ideal types. What can happen, instead, is that the type becomes reified. It takes on a life of its own. The analysts’ casting of the ideal type sets it in concrete and it is employed long past its use by date. For example, once again this seems to be what happened with Weber’s famous ideal type of bureaucracy. It was widely used in the 1950s and 1960s as the basis for both case studies, such as Gouldner (1954), and for the development of what were heralded as taxonomic approaches to organizations (Pugh & Hickson 1976). The latter saw the ideal type elements abstracted by Weber with respect to nineteenth century German bureaucracy become the definitive features of a functionalist conception of organization structure as an essential form determined in its particular patterns by specific local contingencies, such as size or technology. Analysis then became caught in a historical cul de sac of ever diminishing returns as scholars sought to defend the essential structure against all comers (Donaldson 1996).

Meanwhile, the members of actual organizations were, in practice, using quite different everyday concepts to construct their realities (supply chains, outsourcing, virtual organizations, etc.), which could not be captured adequately in the abstractions of the reified form. As Martindale (1960: 383) suggested, we should “compare different empirical configurations, not empirical configurations and types,” as any specific type is always historically bounded and “destined to be scrapped.”

identity control theory

Peter J. Burke

Identity control theory (ICT) focuses on the nature of persons’ identities (who they are) and the relationship between the persons’ identities and their behavior within the context of the social structure within which the identities are embedded. ICT grows out of identity

theory (Stryker 1994; Stryker & Burke 2000) and structural symbolic interaction theory more generally (Stryker 1980). Central to all of these theories, including the symbolic interaction perspective, is the idea that behavior is premised on a named and classified world and that people in society name each other and themselves in terms of the positions they occupy. Further, these positional labels or names and the expectations attached to them become internalized as the identities that make up the self. These self labels thus define persons in terms of positions in society and these positions carry the shared behavioral expectations. Further, these positions, conventionally labeled roles and groups, are relational in the sense that they tie individuals together. For example, with respect to roles, father is tied to son or daughter; with respect to groups, the in group is related to the out group and in group members are related to other in group members. This is reflective of William James's (1890) notion that people have as many selves as they have relationships to others. Thus, through their identities, people are intimately tied to the social structure.

The social structure, in this view, is not fixed or static. Fluidity of the structure of social relations is conceptually brought about by introducing Turner's (1962) concept of "role making," which takes place situationally as persons interact and negotiate common meanings that may reshape, reinterpret, and otherwise change the situation. However, this is variable. Some structures (open) are more open to role making, negotiation, and change than others (closed). In the more open structures, names and classes as well as possibilities for interaction may be modified through negotiation and interaction. In closed structures, such modifications are made only with difficulty.

MEANING

Central to ICT is the concept of meaning around which identities are formed. What does it *mean* to be "father," or "son"? What does it *mean* to be an "American"? An identity is a set of meanings applied to the self in a social role or as a member of a social group that define who one is (Burke & Tully 1977). Identity control theory takes the definition of meaning

from the work of Osgood et al. (1957), which in somewhat simplified terms is a response that a person has to a stimulus; meaning is a response. From Mead, a symbol is a stimulus to which people share a common response. Thinking about myself as a father (the stimulus) calls up in me a set of responses (set of meanings) similar to those called up in others. These responses define for a person what it means to be a father, e.g., being strong, being caring, or being the breadwinner. These common responses lead to common expectations and understandings about what a father is and what a father does, as well as shared understandings about the relation of father to son or daughter and the position of father in the family.

CONTROL OF PERCEPTIONS

Each identity is viewed as a control system with four components (Burke 1991). The set of meanings for a given identity is held in what identity control theory terms the *identity standard* – one of the components of an identity. In addition to the identity standard containing the self defining meanings, an identity contains *perceptions* of meanings in the situation that are relevant to our identity (most of which come from the feedback from others about how we are coming across in the situation), a *comparator* that functions to compare the perceived meanings with the meanings in the identity standard, and an output function of the comparison, sometimes called an *error* or *discrepancy* that represents the difference between perceptions and the identity standard. Finally, as a function of the error or discrepancy, there is meaningful behavior enacted in the situation that conveys meanings about our identity.

If, in an interactive setting, people perceive their identity relevant meanings to be congruent with the meanings in their identity standard, that is, the discrepancy is zero, people continue to do what they have been doing. If the discrepancy is not zero, people change their behavior in such a way as to counteract the disturbance and reduce the discrepancy back toward zero. By changing their behavior, people change meanings in the situation. These altered meanings are perceived and again compared to the meanings in the identity standard. Thus, each

identity is a control system that acts to control perceptions (of meanings relevant to their identity) by bringing them into congruency with the meanings in their identity standards, thus reducing toward zero any discrepancy or error caused by a disturbance.

This process of controlling perceptions of identity relevant meanings to make them congruent with the meanings in the identity standard is the process of identity verification. Thus, people act to verify or confirm their identities, and in so doing, they bring about a situation in which relevant (perceived) meanings are consistent with their identity standard. The meanings in the identity standard represent goals or the way the situation is "supposed to be." If the identity is a role identity, then the behavior that brings about the changes in the situational meanings to make them consistent with the identity standard is appropriate role behavior. If the identity is a group- or category-based identity, the behavior which verifies the identity is the behavior that maintains group boundaries and divisions in the social structure. Thus, by verifying identities, people create and maintain the social structure in which the identities are embedded.

Note that by controlling perceived situational meanings, role players and group members are bringing about and maintaining certain conditions or states of affairs by whatever behaviors accomplish that. They are not engaging in particular behaviors except insofar as those behaviors bring about the condition of meanings that are perceived to be the way things are "supposed to be." It is the outcome that is important; an outcome that is accomplished by various means in spite of various unpredictable disturbances. For this reason, the meanings in the identity standard may also be conceptualized as goals to be achieved or realized by having perceptions that match the outcomes indicated in the identity standard.

As discussed above, identities control perceived meanings to bring them into alignment with meanings held in the identity standard. Meanings, also discussed above, are responses to stimuli. Identity control theory distinguishes between two types of meanings: *symbolic* meanings and *sign* meanings (Lindesmith & Strauss 1956). Symbolic meanings are responses to stimuli that are shared with others. These stimuli

are symbols. The meaning of the symbol "pen" is understood and shared by persons in the same culture. When one person talks about a "pen," others understand. Signs, however, are stimuli whose meanings are not necessarily shared with others, but which help us manipulate resources in the situation (Freese & Burke 1994). Using a pen to take notes, a person feels how the pen fits into her hand, how it flows along the surface of a sheet of paper, and how it makes marks with ink that are controlled to form writing. The responses that she has to the pen in its use are sign meanings. Sign meanings allow us to control resources present in the situation.

RESOURCES

Resources within identity control theory are processes that sustain persons, groups, or interaction (Freese & Burke 1994). This is a functional definition in which resources are defined by what they do rather than what they are. Resources are of two types: *actual* and *potential* (Freese & Burke 1994). Actual resources are resources in the situation that are in use in the sense of currently sustaining persons, groups, and interaction (e.g., the pen that is writing, the chair that is supporting an individual, the idea that solves a problem). Potential resources are resources that are not being used, but have the potential for use at a future time (e.g., the pen or chair that is not in use, food in the pantry, oil in the pipeline). Sign meanings allow us to control actual resources. Symbolic meanings allow us to control potential resources through thinking, planning, and action. When an identity controls meanings relevant to the identity in the situation, it controls both sign and symbolic meanings, and through them it controls actual and potential resources.

As described at the beginning, identities are primarily defined in terms of the named categories and positions of the general social structure. Further, the identity's position in the social structure, i.e., in a group or network, governs its access to the actual and potential resources either directly or through network ties. In this way, the resources controlled by identities are those that sustain the social structure by sustaining the groups, the roles, the individuals, and the interaction that defines

these. To understand identity functioning in an empirical sense then, one must understand the location of the identity in the social structure.

THE BASES OF IDENTITY

ICT distinguishes between three bases of identities. These are *role identities*, what it means to be in a role such as father, *social identities*, what it means to be in a group or category such as American, and *person identities*, or what it means to be the unique biological being that one is. Identities based on each of the different bases operate in the same way, wherein people seek to verify the identity or make the relevant situational meanings (both signs and symbols) match the meanings held in the identity standard by counteracting any disturbances. Analytically, each of these bases differs in the resources that are controlled through the control of meanings. For a role identity, control of meanings results in control of resources that sustain the role and the group within which it operates. For a social identity, control is of the resources that help sustain the group and maintain its boundaries. For a person identity, control is of the resources that sustain the individual as a unique biological being. Analytically, these differences are clear, although in practice and empirically, it is often difficult to know which resources go with which since we are often all of these at once: a biological being who is a group member in a role.

People have many identities, one for each of the many persons they claim to be, roles they have, and groups and categories to which they belong. This complexity of the self with its many identities reflects the complexity of society (Stryker 1980). In ICT, the multiple identities are arranged into a hierarchy of control systems in which some identities are higher than others in the sense that the outputs of those identities at the higher level are the standards of those identities at a lower level (Tsushima & Burke 1999). Higher level identities have their own perceptions, standard, and comparator just as the lower level identities.

While the output of the comparator of the lower level identities leads to behavior that maintains (when there is no discrepancy) or alters (when there is a discrepancy) meanings in the situation, the output of the comparator

of the higher level identities acts to alter the standards (identity meanings) for lower level identities. In this way, higher level identities act as general principles that guide the programs of lower level identities. Higher level identities include such master statuses as one's gender, race, or class, and many person identities, the control systems of which are used across situations, roles, and groups. One may, for example, be not just a friend but a female friend; one may be not just an American but a black American; one may be not just a professor but a diligent professor. In each case, the master status of gender or race, or the person identity as diligent, acts to change the manner in which friend, American, or professor is played out.

IDENTITY CHANGE

The most obvious outcome of a discrepancy between the perceived identity relevant meanings and the meanings held in the identity standard is behavior that counteracts any disturbance to the perceived meanings and quickly brings them back into alignment with the identity standard. At the same time, however, ICT recognizes the less obvious outcome that identities change: i.e., the identity standard slowly changes in the direction of the situational meanings. Both outcomes occur simultaneously, but at much different speeds. If the disturbed situational meanings are restored quickly, any change to the identity standard may not be noticed. If the discrepancy persists, however, because the person cannot change the situational meanings for one reason or another, the slowly changing identity standard will continue to move toward agreement with the situational meanings and the person will come to see herself as consistent with the situational meanings. The discrepancy has been removed not by changing the situational meanings to be in agreement with the identity standard, but by changing the identity standard to be in agreement with the situational meanings, although this generally takes a long time and most people would leave the situation rather than endure such changes to who they are.

Nevertheless, in persons who have been prisoners of war, in persons who are brought into cults, and in persons who are abducted and kept for a long period of time with their abductors, we

see the changes in the identities that are brought about. In each case, these powerless persons are unable to verify their (former) identities by changing perceived meanings in the situation. These persons with their lack of power and status are unable to change their perceptions and their identity standards slowly change to match the perceptions. This result was shown in research that examined identity verification among status unequals (Cast et al. 1999). The identities of persons with less power or status came to be more in alignment with the perceptions of meanings provided by more powerful others. The reverse was not true. Of course, children have very little power and their identity standards are strongly set by their parents who have the power.

EMOTIONS

In ICT, the verification process of identities is tied to emotional outcomes that help guide the process (Burke 1991). When the discrepancy between identity relevant perceptions and the identity standard is small or decreasing, people feel good. When the discrepancy is large or increasing, people feel bad or distressed. These consequences have been shown in research by Burke and Harrod (2005), who found that persons become distressed, angry, and depressed when their spouse's view of them is different (better or worse) than their self view or identity standard. Current work in ICT examines the role of identity verification in the production of self worth, self efficacy, and feelings of authenticity (Cast & Burke 2002) and is developing predictions about the specific emotions that may be felt when identities are verified or not verified (Stets & Burke 2005).

FUTURE RESEARCH

Because ICT is part of a continuing research program, new developments and additions to the theory are always being made; the theory is not fixed. A few areas that new research is exploring include: (1) how identities change in response to external events and the other identities an individual holds; (2) how the multiple different identities an individual has relate to one another; (3) how the social context in

which identities are or are not verified influences the variety of emotions felt; (4) how identity verification is related to the health and well being of individuals; (5) how the identities of persons in interacting groups influence interaction and group processes; and (6) how ICT relates to other developing theories in social psychology such as justice theory, exchange theory, expectation states theory, and status characteristics theory. It is clear that much work remains for the future development of this theory (Stryker & Burke 2000; Burke 2004).

identity, deviant

Patricia A. Adler and Peter Adler

Identities refer to the way people think of themselves. This is important in the field of deviance because people's perceptions and interpretations of situations and themselves are likely to affect their behavior. If people conceive of themselves as deviant, they are more likely to engage in further deviant behavior than if they have a non deviant identity. The study of deviant identities has focused on how people develop and manage non normative self conceptions. This processual approach has been fostered by the special interest in deviant identity taken by symbolic interactionists, with their rich heritage from labeling theory to dramaturgy. Central themes in the study of deviant identities include the ways that they develop, factors that foster their development, and consequences of having them.

Some structuralist scholars consider definitions of deviance rooted in absolutist elements intrinsic to people's attitudes, behavior, conditions, or social statuses. This approach sees unchanging, universal sources such as God or nature as responsible for differentiating between the deviant and the normative. Structuralists would likely view certain acts as so inherently abhorrent that these would be banned by all societies. Relativist scholars, such as Howard Becker, however, view deviance as the product of people's reactions to events, which are situationally variable by the era in which they occur, the relative social power of the perpetrator and victim, and the consequences that arise from them. Relativists believe that the likelihood of

an act becoming defined as deviant (and the punishment that accompanies it) depends on who commits it, who suffers from it, and who knows about it. This partly explains the higher likelihood that individuals of color who commit crimes against white people (or lower class people who commit crimes against rich people) will be arrested, charged with a crime, and prosecuted, since such victims generally have high social power and the perpetrators' social power is relatively low. Relativists note that definitions of deviance have significantly evolved over time and continue to do so. Most conceptions of deviant identity follow this latter approach, recognizing that people are most likely to develop deviant identities when they experience situational factors where such self conceptions are pressed upon them. In fact, Becker (1963) suggested that many people go through a range of experiences as "secret deviants," violating norms but doing so inconspicuously. As long as no others are aware of their transgressions, he suggests that people are unlikely to think of themselves as seriously outside of the norm.

The process of acquiring a deviant identity unfolds processually as a "deviant" (Becker 1963) or "moral" (Goffman 1963) career, with people passing through stages that move them out of their innocent identities towards one labeled as "different" by society. "Deviant identity careers" develop through seven stages. The point of departure, as Becker (1963) suggested, is getting caught and publicly identified. People commit deviant acts, such as theft; if they are apprehended, news of this spreads. Second, others begin to think of them differently. In light of this new information, others may engage in what Kitsuse (1962) called "retrospective reinterpretation," reflecting back onto individuals' pasts to see if their current and earlier behavior can be recast. For instance, people may wonder how someone now caught for college cheating got such good grades without studying much, and decide that he or she was probably cheating all along. Third, as this news spreads, either informally or through official agencies of social control, individuals develop "spoiled identities" (Goffman 1963), where their reputations become tarnished. Erikson (1966) noted that news about deviance is of high interest in a community, commanding intense focus from a wide audience. Deviant labeling is hard to reverse, he

suggested, and once people's identities are spoiled they are hard to socially rehabilitate. He discussed "commitment ceremonies," such as trials or psychiatric hearings, where individuals are officially labeled as deviant. Few corresponding ceremonies exist, he remarked, to mark the cleansing of people's identities and welcome them back into the normative fold. Individuals may thus find it hard to recover from the lasting effect of such identity labeling, and despite their best efforts they often find that society expects them to commit further deviance. Merton (1968) referred to this as the "self fulfilling prophecy," where people tend to enact the labels placed upon them, despite possible intentions otherwise.

Fourth, Lemert (1951) noted that the dynamics of exclusion then set in, where certain groups of people, organizations, employers, and others may not want to associate with the newly labeled deviants, who become ostracized from participation and membership with them. They may be cast out of honors societies, professional associations, relationships, or jobs. Fifth, Lemert highlighted the corollary to this point, discussing the dynamics of inclusion, which make people labeled as deviant more attractive to others. Their very acts may lead fellow deviants or would be deviants interested or engaged in similar forms of deviance to seek them out. Thus, individuals may find that as they move down the pathway of their deviant careers that they shift friendship circles, being pushed away from the company of some, while being simultaneously welcomed into the company of others.

Sixth, others usually begin to treat those defined as deviant differently, indicating through their actions that their feelings and attitudes towards the newly deviant have shifted, often in a negative sense. They may not accord people the same level of credibility they previously had, and they may tighten the margin of social allowance they allot them. Seventh, and finally, people react to this treatment using what Charles Horton Cooley referred to as their "looking glass selves." In the culminating stage of the identity career, they internalize the deviant label and come to think of themselves differently. This is likely to affect their future behavior. Although not all people who get caught in deviance progress completely through this full set of stages, Becker (1963) described this process as the effects of labeling.

Degher and Hughes (1991) have suggested that along the way to identity change people may be nudged out of their normative self identities and into deviant ones by active and passive "status cues." Active status cues are communicated through interaction, such as when people make remarks that let their friends know that they appear different, or that they ought to reconsider something about themselves. Passive status cues derive from the environment, such as when people discover that they are no longer capable of doing something or appearing a certain way. While active status cues are direct, people may encounter passive status cues for a long time without recognizing them, and often require some sensitization to perceive and accept these as pointing towards themselves. These cues serve to press on individuals the realization that their conventional identity no longer fits, and to move them through the identity change process.

While we all juggle a range of identities and social selves, Hughes (1945) asserted that a known deviant identity often assumes the position of a "master status," taking precedence over all others. Many social statuses fade in and out of relevance as people move through various situations, but a master status accompanies people into all their contexts, forming the key identity through which others see them. Deviant attributes such as a minority race, heroin addiction, and homosexuality are prime examples of such master statuses. Others, then, may think of an actor, for example, as a Hispanic actor, a heroin addicted actor, or as a gay actor, with the individual's occupation coming as secondary to his or her deviant attribute. Hughes noted that master statuses are linked in society to auxiliary traits, the common social preconceptions that people associate with these. Self injurers, for example, may be widely assumed to be adolescent white women from either middle class backgrounds or disadvantaged youth whose lives are unhappy. They may be thought of as lacking impulse control, seeking attention, possibly abuse survivors, mentally unstable, or as people who seek to inject control into their lives. The relationship between master statuses and their auxiliary traits in society is reciprocal. When people learn that others have a certain deviant master status, they may impute the associated auxiliary

traits onto them. Inversely, when people begin to recognize a few traits that they can put together to form the pattern of auxiliary traits associated with a particular deviant master status, they are likely to attribute that master status to others. For example, if parents notice that their children are staying out late with their friends, wearing "alternative" clothing styles, growing dreadlocks in their hair, dropping out of after school activities, and hanging out with a "druggie" crowd of friends, they may suspect them of using drugs.

Lemert (1967) asserted another processual depiction of the deviant identity career with his concepts of primary and secondary deviance. Primary deviance refers to a stage when individuals commit deviant acts, but their deviance goes unrecognized. As a result, others do not cast the deviant label onto them, and they neither assume it nor perform a deviant role. Their self conceptions are free of this image. Some people remain at the primary deviance stage throughout their commission of deviance, never advancing further. Yet a percentage of them do progress to secondary deviance. The seven stages of the identity career, described above, move people from primary to secondary deviance; their infractions become discovered, others identify them as deviant, and the labeling process ensues, with all of its identity consequences. Others come to regard them as deviant, and they do as well. As they move into secondary deviance, individuals initially deny the label, but eventually come to accept it reluctantly as it becomes increasingly pressed upon them. They recognize their own deviance as they are forced to interact through this stigma with others. Sometimes this internalization comes as a justification or social defense to the problems associated with their deviant label, as individuals use it to take the offensive. At any rate, it becomes an identity that significantly affects their role performance. Some people may compartmentalize their deviant identity, but others exhibit "role engulfment" (Schur 1971), becoming totally caught up in this master status.

Most individuals who progress to secondary deviance advance no further, but a subset of them moves on to what Kitsuse (1980) called tertiary deviance. In contrast to primary deviants who engage in deviance denial, and secondary deviants who engage in deviance

acceptance, Kitsuse sees tertiary deviants as those who engage in role embracement. These are people who decide that their deviance is not a bad thing. They may adopt a relativist perspective and decide that their deviant label is socially constructed by society, not intrinsic to their behavior, such as individuals with learning differences who consider themselves more creative than "typical" people. Or they may hold to an essentialist perspective and embrace their deviant category as intrinsically real, such as gays who "discover" their underlying homosexuality and accept it as natural. They therefore strongly identify with their deviance and fight, usually with the organized help of like others, to combat the deviant label that is applied to them. They may engage in "identity politics" and speak publicly, protest, rally, pursue civil disobedience, educate, raise funds, lobby, and practice various other forms of political advocacy to change society's view of their deviance. Examples of this include people who fight to destigmatize labels such as obesity, prostitution, and race/ethnicity.

All of these identity career concepts encompass a progression through several stages. They begin with the commission of the deviance and lead to individuals' apprehension and public identification. They move through the changing expectations of others towards them, marked by shifting social acceptance or rejection by their friends and acquaintances. The breadth, seriousness, and longevity of the deviant identity label are significantly more profound when individuals undergo official labeling processes than when they are merely informally labeled. With their internalization of the deviant label, adoption of the self identity, and public interaction through it, they ultimately move into groups of differential deviant associates and commit further acts of deviance.

Exiting a deviant identity is considerably more problematic than assuming one in the first place. Our society has many types of what Erikson (1966) has called "commitment ceremonies," where people are stripped of their respectable status and marked with a negative one. Such moral passages are more noteworthy than returns to the normative fold, and garner considerably more public attention. Institutions of social control thrive on processing deviants, and have vested interests in holding individuals within their domain. Members of society also

tend to reinforce people's continued deviance by their social expectations that they will not become rehabilitated. Finally, avenues of opportunity often close for those negatively marked, making normative movement difficult from a practical standpoint. The route out of deviance, then, is often more gradual than precipitous, more solitary than social, more ascetic than pleasurable. Individuals seeking to exit deviant identity careers often have to hit bottom before they are willing to make the sacrifices necessary to regain the mundane everyday status that they once disdained.

identity: the management of meaning

Christine Coupland

This description is an attempt to provide an informed understanding of classical and contemporary approaches to identity. Studies of identities aim to understand the ways we socially constitute ourselves while considering the link between society and self identity. The term "identity" was relatively unheard of in sociology and social psychology prior to 1940. Since then it has become the focus of vast amounts of research. Its theoretical, cultural, and empirical development has continued as academics apply, dispute, and discuss the concept. Precursors to the concept of identity developed in the disciplines of sociology, anthropology, and psychology. Importance was given within these early developments to self, character, and personality.

Identity is a broad term incorporating notions of the individual in interaction with other individuals and with social structures. There is a long tradition of research on identity from within many diverse areas (e.g., anthropology, organizational theory, philosophy, psychology, and sociology), each bringing particular frames of philosophical inquiries and methodologies. The resulting heterogeneity of the field has been further developed over time due to movements across the social sciences which affect how the individual is considered to be constituted in social relationships and the implications this has for the study of identities. These movements have challenged the assumptions that characterize modernity which underpin dominant understandings of the modern world. Criticisms have been raised on many fronts, political (Hall & Jacques 1989), from feminist perspectives (Luke & Gore 1992), through conceptions of reality (Baudrillard 1989) and claims to truth and knowledge (Lyotard 1984; Rorty 1989).

During these movements, identity has been theorized in three different ways. First, that of a knowing and conscious subject, second as a product or outcome of social relationships, and finally as both outcome and resource in interaction between the self and others. Definitions of identity thus vary according to different

philosophical assumptions; from an essentialist, mainstream view there has been a tendency to represent the "self" as a unified construct, thus leading to definitions that suggest personal identity is defined as the distinct personality of an individual regarded as a persisting entity, or the individual characteristics by which a thing or person is recognized or known. From a social relationship perspective attention has tended to focus on societal or cultural influences on identities, and from a dialectic or discursive approach it is acknowledged that identity is a contentious concept, subject to ongoing dispute rather than one with ontological reality which can be easily seen and defined. This illustrates its socially constructed nature rather than an objectively defined one. Hence, more contemporary definitions of identity suggest that it is emergent, always in flux, and that it is a perception that each person develops about who he or she is in relation to others. This definition requires us to understand the concepts and resources on which social actors draw to structure their relationships and is concerned with issues surrounding power, conformity, deviance, and difference.

There may be many reasons for this shift in perspective on what identity is and how it may be examined, but one major reconceptualization of identity and views of the self surround a critique of a neutral representation of the person by instead highlighting identity claims and descriptions as doing important work in constructing and transforming individuals and the social world.

MAINSTREAM APPROACHES TO IDENTITY

The notion that an individual has an essential inner self, which is carried around and can behave appropriately, dominates the western concept of people in social situations. This view, as a historically bound notion, may be seen in the rise of individualism for which most would credit the Enlightenment as the birth place of our contemporary beliefs about the self. Although social theorists from different stand points have questioned the universality of the contemporary western concept of the person, this remains the dominant notion of the self. In support for this argument, studies of other

cultures have shown their people as depersonalized from a western point of view, which implies its cultural specificity.

Underlying traditional or mainstream approaches to understanding identity is the assumption that identity is something an individual or society has. From this perspective, the questions asked in traditional studies of identity include: What criteria distinguish identities from one another? Or, what part do identities play in society? One aim of the studies is to use identity as a predictive variable. Working from the assumption that identities (e.g., middle class) correspond to an existing social structure, and are not just externally attributed but internalized through socialization, attempts have been made to link individuals with the social structure through this process. Two of the traditional or mainstream theories that attend to the individual/social structure/socialization process are role identity theory (e.g., Goffman 1959) and social identity theory (Tajfel 1978).

Role Theory

Role theorists propose that society is made up of roles which are internalized as identities that people take on. Goffman (1959) equated social interaction with dramaturgical performance. His work suggested that identity is a performance and that the actor's skills enable the management of impressions left on others, the audience. Although influential in terms of understanding work identities in particular, this theory has been criticized because it places the person in the position of "social dope" where the self comprises a "true" self and a "social" self. The view that individuals are actors performing roles provided by society has been further critiqued as a "calculating" and "intellectual" view of the self (Bruner 1990). Finally, other critics of role theory argue that the notion of a script from within this dramaturgical perspective implies that the words are already decided. This underestimates the creative potential of interaction for the construction of the self.

Social Identity Theory

Social identity theorists suggest that social identities have a reality in relation to social groups.

This approach developed from a concern within social psychology to include a relationship, theoretically and empirically, between individual psychological functioning and the wider social processes that both shape this functioning and are shaped by it (Tajfel 1978). Individuals become aware of group membership and their preference for particular groups. In this way, the structure of society is reflected in the structure of the self as category memberships are internalized.

Its close relation, self categorization theory (Tajfel & Turner 1979), although concerned with people's categorizations of themselves, assumed them to be psychological, subjective, mental processes. They proposed that social identity is based on individual need to enhance self esteem through social comparison processes and differentiation. These influential theories have been interpreted, modified, developed, challenged, and expanded in numerous studies since their inception, which is an indication of the author's contribution. However, one of the criticisms of the work was that language was simply not considered to be an issue. If discussed at all, it was in terms of a psychological process along with motivation. This reflected the orthodox view of the time embodied in psycholinguistics from within a structuralist framework.

These and other traditional or mainstream approaches to identity have theorized largely at the intra individual level, regarding categorization as a cognitive process. With reference to understanding group identity, the question being asked from the mainstream approach has focused around how people identify with groups and what the consequences are of such identification. Finally, traditional or mainstream approaches share a view that language is a transparent medium or conduit onto some hidden, internal process and therefore they ignore the constitutive nature of the interaction.

CONTEMPORARY APPROACHES TO IDENTITY

Contemporary perspectives on understanding identity have been largely connected to a discursive approach. However, there were earlier writers in the field who considered how identity was

a linguistic construction, for example Cooley (1902). More recent approaches focus on inter individual explanations where categories and groups are considered to be discursive resources. Perspectives from within this broad description share skepticism of many mainstream assumptions and explanations of the self and instead regard identity as a process, rather than a product, evolving subject to historical and cultural influences. Identity formation is both active and context relevant. From within the contemporary approaches to identity two major schools of thought differ in terms of how identity may be constructed. For simplicity's sake these are labeled the poststructuralist and the interpretive schools. There are some distinct differences between the poststructuralist and interpretive approaches which are outlined briefly here, but this represents an oversimplification as there are also several similarities. For example, there is a shared proposal for a move from considering the self as an entity to considering the self as a construct (Gergen 1985), specifically in order to consider how the self is talked about.

Poststructuralist Approaches to Identity

The term "poststructuralist" is applied to those writers who presume that discourse operates as an organizing factor through which identities are produced. From this approach subjects are "interpellated," or called to identity relevant positions. This version of positioning began with Althusser's (1971) argument that ideologies in institutions (e.g., church, school) mean that people are trained to recognize themselves in a particular way. The focus of the poststructuralist approaches' study of identity has largely been on the relationship between power and discourse in that we are all claiming and resisting identities from within prevailing discourses. Poststructuralist writers argue that living under prevailing ideologies creates the illusion that we have chosen our way of life. Poststructural theories emphasize the nature of discourses in terms of how they constrain and enable ways of being, identities, in the social world. One criticism, however, of the poststructuralist view of language is that it disregards language's constitution through argument, while focusing on how it operates to obliterate argument in the interests of domination (Billig 1996).

Interpretive Approaches to Identity

Writers who adopt an interpretive approach propose that identities are constructed "online," are situated in ongoing interactions, and are constructed to perform accounting or explanatory work in talk. Many share an ethnomethodological concern with people's own displays of understanding and pay attention to the micro detail of talk in order to explore the "online" construction of plausible, persuasive identities. Members of a work community, for example, draw on, deploy, and reconstruct resources, which are available in that context and the broader context in which the workplace is situated. In this way, identity is viewed as a situated self which is set within a wider system of possible identities. Interpretive scholars have been criticized for treating "discourses" as cultural or social resources, as if one could construct self at whim. This would also imply some leaning toward a "calculating" view of the self, if it were not for the "structures" of plausibility, authenticity, and reasonableness in the talk. To disregard these in interaction would be to risk being thought mad or at least being misunderstood. To attend to how these function in talk makes visible commonsense, hidden ideologies surrounding how we are able to talk about the self today. From this perspective, a salient identity is a local, occasioned matter where members construct categories and draw on their rights and obligations in talk.

FUTURE DIRECTIONS

It is clear that the widespread acceptance and use of the term identity does not suggest agreement upon or even a clear understanding of its many meanings. Furthermore, the emergent trends in theorizing about identity should not be regarded as enduring but rather as historically and culturally located concepts which are enmeshed with emergent trends in the social sciences more broadly. This is not to suggest that scholars are gradually refining their understanding of what identity is and how it should be examined; rather, the trends are indicative of, shaped by, and subsequently shape understandings and social practices surrounding identities. Theories abound regarding identity,

sharing a focus upon understanding the ways that we socially constitute ourselves while considering or exploring the link between society and self identity. Future approaches will need to become aware of and analyze the transformations in nature and meanings of identity under conditions of modernity, late modernity, and beyond.

identity politics/ relational politics

Leslie Wasson

Human society is no stranger to exercises of interpersonal power and identity politics. The annals of political history are replete with descriptions of these exercises. Power is the ability to get what you want with or without the consent or cooperation of others. Effects of deployed power are observable at the structural and institutional levels of society, and in face to face interactions. A discussion of identity politics (sometimes also called relational politics) may focus on either the class or group level or the level of personal interactions. The subject of interpersonal politics rests within a set of related concepts, such as the distribution of social power, social location and status, and a stratified system in which these interpersonal resources may be valued and utilized for purposes of individual or group advantage over other individuals or groups.

Groups in a stratified system, that is, a social system with a ranked structure of positions, may contend for advantage among themselves. Each group may seek to utilize group level resources in addition to individual characteristics to secure a better or stronger position vis à vis the members of other groups in the social tapestry. This may not be a result of actual conspiracy: often, people acting in their own perceived self interest serve the mutual desires of others in a similar social position.

In the struggle for relative advantage, winning groups succeed in marketing the notion that their group has characteristics that mark them collectively as the legitimate holders of a higher social position than members of other social groups. One example from recent American history was the successful claim by

men that group characteristics associated with maleness and masculinity were more valuable to society and thereby more deserving of monetary compensation for paid labor than the group attributes of females in equivalent positions. This is represented today in the tendency for women to earn between 65–70 percent on average of the amount men earn for similar work.

Members of different ethnic or cultural groups may also work collectively to deploy their ethnic and cultural capital to best advantage. Examples of research on this phenomenon include Bayard de Volo (2001), who examines gender politics in Nicaragua between 1979 and 1999; Finlay (2005) on the use of altercasting a group identity with negative connotations as a strategy in political conflict; House (2002), whose study of cultural continuity and language among the Navajo posits language shift as an indicator of identity politics; and Howard (2006), on the construction of Irish identity in the British 2001 census.

Kiely et al. (2005) suggest that perhaps new conceptual tools are needed to effectively analyze identity politics from a civil/territorial perspective rather than a more traditional ethnic or cultural approach, since their research indicates that some contemporary identities are more complex as a result of transience or competing political considerations.

While some identity politics plays out at the level of the political order and public discourse, individuals also engage in identity politics in face to face encounters. Goffman (1959) notes: “an individual may find himself [*sic*] making a claim or an assumption which he knows the audience may well reject ... when the unguarded request is refused to the individual’s face, he suffers what is called humiliation.” Later, Goffman (1963) calls the resulting damage to identity a “stigma” that is then managed well or poorly by the individual in succeeding interactions. Blumer (1986) describes how these patterned social interactions are real to their participants and result in mutual expectations for behavior in wider contexts.

Goffman (1970) also contributes the concept of strategic interaction. In strategic interaction, the individual manages self presentation and social resources to maximize personal advantage

in the situation vis à vis other participants. Using the Japanese concept of “face” or the social perception of the individual by others in the situation, Goffman is able to integrate ideas about impression management, saving and losing face, and the potential for emotional manipulation, which contribute to politics at the interpersonal level of interaction.

Scheff (1988) suggests an interactionist perspective rooted in emotion for the individual level of identity politics. For Scheff, individual self concept is influenced by basic emotions of pride or shame. Individuals are therefore subject to manipulation on the basis of these emotions, which results in the acknowledgment of status hierarchy among them and deference to others as a result of that hierarchy.

One set of themes in the academic literature regarding identity politics involves the practices of identity claiming on the one hand, and altercasting, on the other. In identity claiming, an individual seeks to portray herself or himself as a certain kind of person, which portrayal may or may not be met with agreement from others. Altercasting occurs when another or others attempt to impute an identity to an individual, which the individual may or may not embrace. These processes may also operate with groups.

A second theme in research and theory about identity politics is the ongoing debate between essentialist models of identity and social constructionism, also referred to as anti essentialist positions. This is particularly noticeable in the debates about gender and identity. Debating whether group level characteristics are innate (essential) or socially constructed obscures a basic misunderstanding about the difference between diversity and inequality. Over time, identity politics has shifted somewhat from demands for equality of opportunity toward demands for recognition of and structural access for persons and groups of diverse views and practices.

A third theme that may be observed in the literature on identity and relational politics is the relationship between individual experience, personal status, or social roles and political stance. For example, one might examine the expectation that part of being gay is being political, or that only members of oppressed minorities can legitimately “belong” in their movements for equality, such as an African American rights group that only accepts

European American members in “auxiliary” roles.

For recent summaries of these themes, one might consult Bernstein (2005) for an overview of the topic or Warnke (2005) for an examination of race, gender, and pluralistic or anti integrationist identity politics.

identity: social psychological aspects

Kevin D. Vryan

Sociological social psychologists conceive of identities as social constructs – culturally and interactionally defined meanings and expectations – and as aspects of self processes and structures that represent who or what a person or set of persons is believed to be. Identities define people in social terms; they depend upon shared meanings and situate their bearers within variously structured and enduring sets of social relations. If a person is believed to belong to particular categories of persons, the meanings and expectations attached to those categories are presumed to be relevant to the person. Identities affect self conceptions and other intrapsychic structures and processes of the person believed to embody the identity as well as their actions, and affect how others will interpret, feel, and act in relation to the identified individual. The meanings of an identity draw upon sociocultural constructs attached to an identity type and may relate to relatively enduring positions within social structures, but they are actively and creatively presented, interpreted, and modified across different social contexts and over time. Identities are both reflections of socially structured sets of relations and are emergent and negotiable by social actors. As such, they can recreate and reinforce existing sets of social relations as well as alter them.

While the notion of identity is often used without further specification, it is useful to differentiate between several forms of identity (Vryan et al. 2003). The focus on *social identities*, *role identities*, constitutes much of sociologists' empirical study and theorizing on identity. A social identity defines a person or set of persons in terms of the meanings and expectations associated with a socially constructed group or category of people, and locates a person within socially structured sets of relations. Social identities define persons as members of particular groups or sets of people and hence not others (e.g., a Jew may define herself as Jewish and as therefore different than Christians and Muslims). They lead to expectations about

how the identified person – whether self or other – is likely to think, feel, and act. At the same time, social identities represent how a person fits within various interactional, network level, and sociocultural structures. Social identities commonly studied include those related to sex/gender, family, race and ethnicity, nationality, religion, occupation, sexuality, age, and voluntary subcultural memberships, but social identities may be based on any distinction socially constructed or interactionally defined as significant. An individual may possess many social identities, but those identities will vary in their importance, centrality, or salience within different contexts, in turn affecting behavior differentially.

A *situational identity* is defined in terms of the emergent structure of a localized, shared definition of a particular interactional situation. While social identities tend to be enduring as long as a person's relations within webs of social relations endure and are often considered to be essential aspects of their bearers, situational identities are facets of particular interactional episodes and are not usually considered to be enduring or essential to those who enact them. In any interaction, participants must define the situation and the other participants in order to determine their own courses of action and to know how to interpret others' talk and other behaviors. While various social identities may also be defined as relevant to a situation by interactants and affect behaviors and interpretive activities, situational identity enactments and negotiations are specific to a given type of social situation. For example, the situational identities of "student/audience member" and "teacher/lecturer" are defined as essential to the structure of a classroom lecture, while "salesperson" and "customer" are defined as essential to the structure of the situation of shopping in a retail store. Were someone to ask a lecturer if returns require a receipt, or to ask a salesperson if the price was going to be on the next exam, the lack of appropriate self and other attributions of situational identities would significantly problematize the interactions. While the particular situational identities that are deemed appropriate and the content of those identities may be indicated in sociocultural constructs (e.g., general social definitions of classroom and shopping situations, including the identities considered relevant and

appropriate), they are actively interpreted, adapted, presented, and mutually negotiated during interaction. Much research on situational identities focuses on their emergence, creative presentation, and negotiation in interaction and how people manage potential and actual problematizations of them (e.g., Goffman 1963; Snow & Anderson 1987).

A *personal identity* is a set of meanings and expectations specific to a given individual. Personal identity is associated with a personal name, a body and appearance (e.g., a clothing style), a biography and personal history (e.g., within a particular family network), a unique constellation of social identities, and a set of personality characteristics and traits (Goffman 1963; Shibutani 1964). Of the three forms of identity discussed here, personal identity is considered the most enduring and essential representation of a person, although its content may be presented differently to different audiences and may be redefined over time. Whereas social and situational identities focus on people as members of categories of persons – as similar to other members – a personal identity identifies the individual as unique. No two people are likely to share the exact same set of social identities, much less the same personal history and personality. But as with other forms of identity, personal identity functions to situate individuals within socially structured worlds, such as by specifying the identified person's various social identities and embeddedness within a particular family. Personal identity has been much less studied and theorized than social and situational identity.

Sociological social psychological work on identity followed an early symbolic interactionist focus on the related concept of *self*. Early symbolic interactionists and those who influenced them (e.g., William James, George Herbert Mead, Charles Horton Cooley, W. I. Thomas, Herbert Blumer) did not explicitly theorize and study identity as much as the related notion of self, but their conceptualizations significantly shaped work that was to focus directly on identity. Identity emerged as a concept of growing interest to both psychological and sociological social psychologists in the wake of immigration and disrupted national and ethnic identities following World War II, developing alongside and influenced by subsequent social changes and identity movements of

the 1950s (e.g., the Civil Rights Movement), 1960s (countercultural rejection of traditional role identities), and 1970s (Women's Movement) in the US. The relevance and importance of identity in academic work paralleled a growing modernization characterized by geographic and cultural mobility, rapid social changes in social roles and the meanings and expectations attached to identities, and personal and cultural "identity crises."

Sociologists applied the interactionist emphasis on the importance of meaning and its emergence in interaction to their conceptualizations of identities – or meanings applied to people – as key aspects of any self and interaction and as important in understanding human behavior. As people's actions and interpretive activities both constitute society and are shaped by it in an iterative process, identities are seen as constituted by and within particular cultures and social situations that specify certain meanings, expectations, rights, and constraints for those who are seen to possess them, and also as actively created and managed by people.

Among the first to argue for the importance of identity to sociology, Nelson Foote (1951) explained that identity was vital to understanding motivation and hence behavior. Humans know and act toward objects – including themselves and others – in relation to the symbols (meanings, especially as represented in language) that they attribute to those social objects. Our identities inform us as to how to act and not act, producing motivations and social action. More broadly, Foote and other interactionists argued that identity is an important way to conceive of how individuals relate to each other and to society at large. Anselm Strauss (1959) was also quite influential in shaping treatments of identity. As did other interactionists, he challenged psychological models and viewed identity formations and transformations as lifelong, socially determined (rather than determined by essential and universal human developmental trajectories), and actively negotiated processes. Strauss emphasized the significance of language and meaning (as socially constructed and negotiated) – an emphasis pervading sociological treatments of identity. In a line of thinking receiving increasing attention presently, Strauss linked identity with self narratives; we construct and reconstruct our various selves and identities

by naming them, thus assigning meanings to them. Linking social structure to identity transformations, Strauss discussed “turning points” as signals to institutionalized identity transformations, such as those experienced when getting married, graduating school, or becoming a parent. As socially structured realities change, so do the identities of the people embedded within them. And as identities change, so do social structures. While Strauss’s primary focus was, at least initially, on identity processes in face to face interactions, he attended to the cultural, intergenerational, and historical realities that affect such situations (1995). Other recent work builds on these foci, infusing recent theoretical and methodological developments associated with a “cultural turn” in sociology (e.g., Holstein & Gubrium 2000).

Gregory P. Stone (1981) called attention to the significance of appearances in the process of identification. Initially, it is appearance (e.g., clothing, nonverbal behaviors such as gestures, location) that leads us to an identification of the other, which precedes taking the role of the other; we must identify a person before having the ability to conduct that fundamental social process. Our selves as well as our behaviors in interaction are shaped by our identifications of ourselves and others, whether those identifications confirm or challenge a given identity that is presented or attributed. When there is congruence between the presentation of an identity and attribution by others, then a socially meaningful identity emerges. Erving Goffman (1963) was the first to explicate the complexities and intricacies of how it is that people create and manage identities as they go about their everyday lives, calling attention to the many problems that can arise as people go about defining themselves, others, and their social worlds. He also explained how people work collectively and continuously to manage their own and others’ identities, engaging in teamwork that seeks to protect or restore the identities of participants. Identities are understood as social accomplishments rather than properties of individuals, and ongoing behavior – even if it has other purposes and goals as well – is seen as a collective enterprise of identity management. In studying identities considered to be deviant in *Stigma*, Goffman (1963) showed how problematic identity management

can be, and how creative and resourceful people are in accomplishing their self conceptions and social interactions.

In addition to the situationally focused work of those discussed above – sometimes referred to as Chicago School symbolic interactionism – some sociologists pursued approaches known as structural, Iowa School, and Indiana School interactionism. Their work focused less on the situational and interactional emergence of identity and its management, and more on its enduring and socially anchored qualities, infusing reference group and role theories into their versions of interactionism (Stryker 1980). They saw identity in terms of intrapsychic self structures and in more clear relation to larger and more enduring social structures, developing models intended to enable the prediction of self and behavioral outcomes and to be testable via quantitative data analysis techniques consistent with traditional positivistic scientific practices. Key figures working along these lines include Manford H. Kuhn (Kuhn & McPartland 1954), Sheldon Stryker (1980), George J. McCall (McCall & Simmons 1978), and Peter Burke (Burke & Reitzes 1981).

Structural interactionists conceived of identities in terms of self structures, with enduring social identities being most significant to individuals’ self conceptions. More important than situationally emerging and renegotiable identities, the social identities seen as key to self concept and behavior tie people to particular reference groups and social structural arrangements. Complex societies characterized by multiplicity and complexity are seen as resulting in a multiplicity and complexity of selves and identities; when people hold many different social statuses they possess many different identities. Self structures include multiple identities arranged according to their salience, or the likelihood of a given identity affecting behavior rather than another. Structural interactionists explain that social arrangements and statuses affect salience hierarchies and, in turn, salience affects behavior, such as is modeled in Stryker’s version of identity theory. Others home in on intrapsychic identity processes and structures that operate to affect behavior, as in Burke’s version of identity theory that applies a cybernetic control model (Stryker & Burke 2000).

Many lines of research and theoretical specifications have emerged from the theoretical approaches and methodological techniques sociologists have applied in their studies of identity. Those following the more situationalist approach explain with increasing depth how, and identify generic social processes according to which, identities are taken on as aspects of self and are presented and managed in interaction. They most often apply qualitative methods such as ethnography within localized, naturally occurring social contexts and in depth interviewing among people sharing a particular identity in order to discover how people collectively accomplish "identity work" in their everyday lives and how identities are constructed via self and group narratives. Structural interactionist research models how it is that social arrangements writ large affect individuals via identification with the meanings associated with categories of people that are defined by their social locations within those structures, seeking to explain and predict self structures as a function of social positions, and behavior as a function of identification in terms of those positions. They most often apply quantitative methods such as survey research and laboratory experimentation suited to their goals of theory testing, replicability, and prediction of intrapsychic self structures and resulting behavior. Lines of research not explicitly or directly symbolic interactionist – such as expectation states theory and various psychological approaches – also inform our understandings of identity, although sociological treatments of the topic nearly universally share the interactionist emphases on identities as sets of meanings emerging and made meaningful only within social contexts.

Some scholarship theorizes identity generally, such as self verification theories that posit that people will select interactions and relationships that confirm their self identifications regardless of what the identity is. Other research and theories focus on particular identities or types of identities. Most often, these are social identities based upon socially constructed and structured distinctions such as sex/gender, race, ethnicity, and minority status (e.g., Porter & Washington 1993), occupation (or other statuses within occupational and educational systems), deviance/normativity, age, and national or other

collective identities. Lines of research also pursue particular behaviors as functions of identification, such as social movement participation (Stryker et al. 2000). In addition to these lines of research that more deeply flesh out social realities related to particular identities, identity types, or contexts that shape identity structures and processes, there is increasing attention being paid in recent years to the multiplicities of identity, with theory and empirical research attending to the ways that multiple identities are organized and managed within self structures and interactional and sociocultural contexts, as well as how they intersect. This can be seen, for example, in recent emphases on multiracial identity and in a tendency to study the intersections of a greater number of distinct types of identities such as those based upon gender, class, race, and sexuality. Scholars are increasingly attending to the importance of emotions, the body, and embodiment in their work on identity, as well as mental and physical health (e.g., Charmaz 1995). In addition to continuing these recent emphases, future research on identity is likely to explore more thoroughly how identity is affected within mass and computer mediated contexts, as well as other new forms of social organization and interaction that relate to new ways of defining, presenting, and managing identities (e.g., Holstein & Gubrium 2000).

identity, sport and

Chris Stevenson

Identity is a rather loose concept which has various degrees of currency in a number of different disciplines. For example, Bosma et al. (1994) have argued that there is little consensus in the field of psychology about the phenomena to which the term identity might refer. They go on to suggest that, as a result, different definitions of identity not only have led to the development of different schools within psychology, each with its own theoretical and empirical traditions, but that scholars appear to know little about, or prefer to ignore, what is happening beyond the boundaries of their own school.

There is not quite the same situation within sociology, where considerable theoretical and methodological developments of the concept of identity have occurred primarily in the sociological tradition of symbolic interactionism, in both the Chicago and Iowa schools, and where, according to Weigert et al. (1986), the notion of identity has also had some limited currency in the sociological traditions of structural functionalism, critical theory, interpretive sociology, and the sociology of knowledge.

The sociological concept of identity is broadly understood to include notions of “social identity,” “personal identity,” and “ego identity.” *Social identities* are those identities which tend to refer to the individual’s position(s) in a social structure, understanding that various cultural and social factors influence the extent to which the individual is pressured into fitting into available identity “molds” (Côté & Levine 2002). They are identities which are either seen as providing some social value and are therefore claimed by the actor, or imputed or attributed to others in order to place or situate them as social objects. *Personal identities* are the self designations and self attributions which an individual brings into play or asserts during the course of interaction, and are essentially the meanings the individual attributes to the “self” (Snow & Anderson 1987). “Personal identity,” then, is a concept which places the focus on the specific individualities that are peculiar to each of us, which arise as a result of the accommodations between the

definitions of our social identities and the uniqueness and peculiarities of our actual lived experience (Côté & Levine 2002). The term “ego identity” refers to the sense of sameness or continuity in the “self” (or personality) which individuals experience over long periods of their life. Bosma et al. (1994) use the illustration of a tree, which, although it experiences great changes over the seasons, still remains the same tree. Similarly, although a person experiences tremendous changes between the times of her conception and death, she remains the same, unique individual.

Two major interests have been apparent in sociology’s focus on identity: (1) the process(es) through which adult identity is formed and (2) the process(es) by which that identity is maintained once it is formed. Identity formation is a process through which, particularly in modern societies, individuals are able to choose from an array of potential self definitions and personal meanings, and then may work to develop those identities in interaction with others (e.g., see Goffman’s 1959 work on impression management). Modern societies, it is argued, provide many more models of social and personal identity and offer much more freedom to choose from among these models. The notion of identity maintenance picks up on the idea, associated with late modernity, of the increasingly transient and unstable nature of social identities, with the consequence that the sustained validation of such social identities by others constantly requires work (Côté & Levine 2002: 6). This approach to the management of identities suggests that, first, the individual is required to act in a manner that is appropriate to the identity/ies which he or she is claiming, and second, that the individual must gain a confirmation of the performed identity/ies from the responses and reactions of appropriate significant others.

These ideas about identity are clearly centered on such assumptions as: (1) individuals are able to choose their identities; that is, they have an array of potential identity options available to them; (2) they are active players in the interactions which lead to the creation, assumption or appropriation, and development of an individual identity; that is, individuals have agency; and (3) it is through the validations of others in social interaction with the individual that such identities are maintained; that is, one

must work at securing these validations and confirmations.

Various literatures within the field of sport sociology have focused on the role that “sport” (broadly understood to include the many forms of participation in a wide range of types of physical activity, considerations of the physical body in movement, and the many forms of secondary consumption of sporting activities) may play in the processes of identity formation generally, and of particular identities specifically, and in the processes through which individuals strive to sustain such identities. This work has examined the role of sport (1) in the formation of an identity as an “athlete”; (2) in the formation of identities specific to particular sports; and (3) in the formation of more generic identities, such as gender identity, racial/ethnic identity, or national identity. It has also examined the consequences of successfully claiming an athletic identity on the individual’s future options for seeking alternative identities and career paths.

The generic identity of “athlete” has considerable saliency in many social settings and in many of the countries of the world – although the specific characteristics associated with this identity vary from sport context to sport context and from country to country. Nevertheless, such an identity is clearly valued and may provide many social benefits to the individuals who are able to successfully claim it – whether this occurs at an elementary school age, at high school or college, as a member of a professional or national team, or even as a masters athlete in his nineties. The success of such identity claims rests on, first, the individual’s ability to satisfactorily or authentically present the main characteristics of this identity, and second, the validation of the identity claim provided by primarily non athlete, significant others – one’s peers, family, community, and so on.

There are also many, more specific, sporting identities that are available in a wide range of different sporting activities, and in these cases the sport sociology literature has focused on the processes of identity formation and maintenance of such identities. An excellent example of this focus is provided by the work of Donnelly and Young (1988), who show how identity claims are made in the context of existing sport groups, and that successfully claiming an

identity as an athlete in a particular sport is an interactive process that occurs in social and cultural contexts in which social definitions and meanings serve as influencing factors.

Using their ethnographic work on the sporting subcultures of rugby and rock climbing, Donnelly and Young illustrate the various ways in which neophytes to these two sporting activities deliberately strive to take on and claim – in Donnelly and Young's words, "construct" – the social identity of "rugby player" or "rock climber." They describe how, upon entering the social context, these neophytes often have a limited or even erroneous understanding of the behaviors, values, and attitudes typically associated with the sporting identities they are attempting to claim. If they are to be successful in these identity claims, therefore, the "rookies" need to realign their public presentations of these identities to meet the expectations of the subcultural insiders, the "veterans." It is through an interactive process in which the rookies "try on" the potential identities and attempt to manage impressions that they become more "accurate" in and more comfortable with the presentations of these identities. More often than not, however, they make mistakes, misinterpreting the meanings and the significance of certain behaviors, expressions, and narratives from within the subculture. It is here that the role of subcultural insiders is critical in this interactive process, as Donnelly and Young demonstrate, as the insiders test the newcomers in order to validate the identity claims that they are making, particularly about the skills, abilities, and experiences they are claiming as part of the identity – such as having climbed certain routes which have an established level of difficulty, or about having played in certain positions in rugby or at certain levels of expertise in countries recognized as rugby powers. The result is that these insiders act to either support and confirm or refute the claimed identity.

The formation and maintenance of more societally generic identities through personal participation in sports as well as through watching sports has been another focus of the sport sociology literature. Sports are believed to be particularly efficacious in such identity processes because of their enormous popularity, the passion they can engender in both participant and spectator, and their potential to present

effective modeling of the different identities. For example, sociologists have explored the ways in which a wide variety of sports can be used to create and to reinforce gender identity, such as a "masculine" identity through participation in such sports as soccer, North American football, rugby, and ice hockey (e.g., see Burgess et al. 2003). Alternatively, scholars have also shown how participation in sport can be used to create and sustain gender identities which challenge traditional meanings and definitions – for example, gay athletes who challenge hegemonic definitions of masculinity (see Anderson 2002). Similarly, scholars have examined the role of sports in the construction of various racial and ethnic identities, such as baseball and the Latino identity, basketball, football, and athletics and the African American identity, and rugby and the Maori identity (e.g., see King 2004). And, of course, sociologists have investigated the role of soccer worldwide in the construction and reinforcement of various national identities, from Ireland and Scotland to Israel, Liberia, and Brazil (e.g., see Bairner 2003).

Finally, some literature in sport sociology has examined the consequences of successfully claiming and maintaining sporting identities on an individual's future options for seeking alternative identities and career paths. This literature has looked at the ways in which such successfully claimed sporting identities, while on the one hand encouraging the deepening of the individual's commitment and "embeddedness" in sporting involvements, may, on the other hand, also act to constrain the individual's immediate and future life choices. For example, Stevenson's (1990) examination of the careers of elite athletes illustrates how many of these individuals were often recognized early (but not always) in their lives as potentially excellent "rugby players" or "field hockey players" by a number of significant others (including their peers and their community, their parents and siblings, and such significant adults as teachers and coaches). The initial consequences of being attributed such desirable identities were generally very positive, in that these individuals received considerable attention and praise, and were held in high esteem by their immediate social group. Such consequences served to heighten the commitment of these individuals to these identities and to their sporting activities,

increasing the time, energy, and resources which they committed to them, while also simultaneously reducing the perceived value of pursuing alternative identities and other types of careers. So, as they enjoyed these benefits over their careers as athletes, they also found that their options to be “other than a rugby player” or “other than a field hockey player” became constrained. As the costs of their identities as successful athletes began to mount – injuries, the intrusion on other aspects of their lives, including their relationships with others, the constraints on their ability to create other career and identity possibilities outside of the sporting context – the resultant difficulties in maintaining their identities as athletes became increasingly acute, until their athletic careers came to an inevitable end or became transformed into associated identities, such as coach, administrator, or media commentator.

identity theory

Michael J. Carter

Identity theory is a social psychological theory based on the tenets of structural symbolic interactionism (Stryker 1980). Similar to other work that has emerged within this type of symbolic interactionism, identity theory treats society as stable rather than erratic – the result of repeated, patterned behaviors of individuals. The theory examines how the self is created and how actors attach meanings to the multiple roles which they play; research within this theoretical framework addresses how identities emerge within social structures. Macro level structures are continually replicated through interactions between actors in a reflexive process; identity theory examines how micro level processes serve to create and maintain the meanings actors have for themselves as well as others, and how these meanings perpetuate themselves over time. This perspective sees the self as emergent from social interaction and portrayed to others through identities that are appropriate in specific situations.

The term “identity” is used in various ways in sociological literature, and usually concerns one of the following contexts (Stryker & Burke 2000). First, identity is sometimes used in reference to *culture*, where distinctions between identity and ethnicity are often blurred or disregarded altogether. Second, identity is also used to refer to common identification within *collectivities* or *social categories*. Identity here

focuses on how phenomena (such as social movements) serve to create a common unity among individuals. Third, and unique to those who work specifically within identity theory, identity is seen as a component of the self. Identities in this context provide meanings that actors apply to various roles which are played out through social interaction. This orientation is aligned with the work of G. H. Mead concerning the self and others, and the reflexive relationship between the two. As part of structural symbolic interactionism, identity theory examines the embeddedness of the actor in society and how the self is organized around identity structures and identity meanings.

Identity theory begins by addressing the ways in which the self is comprised of multiple identities. These identities determine how an actor behaves when alone, while engaged in a role, or when in a group. Thus, there are different types of identities for different social dynamics: *role identities*, *social identities*, and *person identities* (Burke 2004). Role identities (e.g., student, worker, father) are defined by the meanings an actor attributes to the self while performing roles. These meanings emerge from socialization and through culture, as well as by the unique, individual assessment of what the role means for the actor. Role identities are a combination of *shared* and *idiosyncratic* meanings which are negotiated by an actor during interactions (Stets 2006). Social identities describe how actors identify with groups or categories (e.g., Republican, Christian). Actors' social identities operate as an in group/out group dynamic, with others being categorized as either *similar* or *different*. Social identities allow actors to create a sense of unity with other in group members and share common bonds, and provide mutual reinforcement to act in various ways. Person identities refer to the self meanings that allow an actor to realize a sense of individuality. Person identities are self meanings such as being competitive or passive, moral or immoral. These identities are frequently activated because they are not generally unique to any specific circumstance; they rather apply across many situations. All three types of identities can operate simultaneously, and in many situations an actor can have multiple identities activated – including role, social, and personal identities.

Contemporary work within identity theory generally has two emphases. One emphasis examines how social structures influence identity and behavior, and how actors' many role identities are organized in a *salience hierarchy* (Stryker 1980). The other addresses the ways in which internal dynamics within the self influence how individuals behave (Burke & Cast 1997; Burke & Stets 1999). An additional area within identity theory specifically emphasizes role identities (McCall & Simmons 1978). While all three emphases add to the general understanding of identity within structural symbolic interactionism, most current research is aligned with the first two areas, following the work of Stryker and Burke.

SALIENCE AND COMMITMENT

Stryker's hierarchical approach to identity seeks to explain how a social actor will behave in a situation based on how often and strongly identities are invoked. Behavior is a function of how salient and committed identities are for actors as they interact with others in the social structure (Owens 2003). Identity salience refers to the probability that an identity will be invoked by the self or others in social situations; identity commitment refers to the degree to which actors' relationships to others depend on specific roles and identities. A salient identity is an identity that is likely to be activated frequently in various contexts. The more salient an identity, the more likely a person will perform roles that are consistent with role expectations associated with the identity, perceive a situation as an opportunity to enact an identity, and seek out situations that provide an opportunity to enact the identity (Stets 2006).

One's commitment identifies the number of actors that one has connection to through an identity and how strongly one is attached to others based on the identity. When an actor is more committed to an identity, the identity is seen as high in the salience hierarchy. The structural aspect to identity is important here: identities that have strong commitment are the identities that are invoked most often across situations. Research that addresses these aspects

of identity examines such themes as religion and how salient religious identities are for individuals. For example, studies have shown that actors committed to relationships based on religion have highly religious identities; these identities are a function of the amount of time people spend doing religious activities (Stryker & Serpe 1982). Stryker's work emphasizes how the salience hierarchy for identities is crucial in determining human behavior because one's identity level directly influences choice and action – the higher an identity in the hierarchy, the higher the probability the identity will be activated (Owens 2003).

INTERNAL DYNAMICS

Burke et al.'s work in identity theory addresses the internal dynamics within the self that influence behavior (Burke & Tully 1977; Burke & Reitzes 1991; Burke 2004). Early work within this emphasis focused on how identity and behavior are linked to common meanings – by identifying what meanings actors apply to identities, one can predict the meanings associated with individuals' actions. Recent research that examines how internal processes affect behavior reveals the connection between identity and behavior, showing that the internal process for invoked identities is a perpetual control system (Burke 1991). Here the internal dynamics of the self are highlighted and identities serve as standards that influence behavior; identities are sets of meanings attached to the self – these meanings provide references that guide behavior. The perpetual control system is a circular process and mechanism that explains how an actor's self defined identity meanings are reflexively attached to experiences in the social environment. Basically, when an identity is activated in a situation, a feedback loop emerges. As the feedback loop operates across situations, actors act to verify their identities and identify both who they believe they are and who others believe them to be. Work within this emphasis of identity theory furthers the idea that behavior is guided by situations or internal meanings by revealing that behavior results from the relationship between situations and self meanings.

ROLE IDENTITIES

The third emphasis examines role identities – an actor's subjective interpretation of him/her self as an occupant of a social position (McCall & Simmons 1978). Role identities have two dimensions: conventional and idiosyncratic. Conventional dimensions of role identities refer to expectations and self meanings actors internalize concerning social positions within the greater social structure. Idiosyncratic dimensions regard the unique interpretations actors have for their specific roles. McCall and Simmons (1978) understand identity similarly with Stryker in terms of identities being arranged hierarchically, but give more emphasis to a prominence hierarchy of identities. A prominence hierarchy reflects how individuals see themselves according to what ideals and desires the individual has, as well as what is considered important to the individual. An identity's location in the prominence hierarchy depends on three things: the degree of support an individual obtains from others for an identity, the degree of investment or commitment an individual has for an identity, and the rewards one receives by invoking an identity. The prominence hierarchy basically represents how actors' sense of priority affects their behavior in situations; it represents one's *ideal self*. McCall and Simmons also identify a salience hierarchy, as do Stryker and his colleagues. A salience hierarchy here reflects more the situational self rather than the ideal self. An identity's location in the salience hierarchy is a function of the identity's prominence, need for support, and actor's need for the kinds and amounts of intrinsic and extrinsic rewards achieved by the identity, and the perceived degree of opportunity for its profitable enactment in the situation (Stryker 1980; Stets 2006). Actors negotiate their identities by considering who they encounter and the context in which the interaction occurs – identities are in relation to counteridentities that exist in interactions with others. For example, the role of "doctor" is dependent on another's role of "patient"; the role of "employee" is dependent on the role of "boss." Actors have expectations for their roles as well as the roles of others; when interaction changes go smoothly (i.e., both actors act

within one another's expectations for each role), relationships are maintained and prominence hierarchies are supported.

RESEARCH METHODOLOGIES

Research within identity theory incorporates multiple methodologies, both quantitative and qualitative. Past research has used surveys and interviews to examine self definitions of identity, identity commitment and salience, and how identities provide meanings for actors in specific situations. For example, surveys created to measure identity salience and commitment have asked participants questions such as "how often do you see yourself as a student?" and "which people are you more likely to discuss a sensitive issue with?" Such methods allow researchers to measure how salient and committed identities are for participants by finding what importance a participant places on an identity and by identifying the amount and type of people a participant is connected to through an identity. Other methods have used survey instruments to examine what it means to *be* a specific identity by measuring how often a participant plays a particular role – for example, how often a person sees herself as a student or spouse. Recent methodologies within identity theory (specifically, identity control theory) have used a combination of surveys and laboratory experiments to measure identity processes and identity verification. Contemporary research designs also use surveys and laboratory experiments to measure undeveloped facets of identities, such as how individuals act in groups when they are not committed to a situational identity and how identities are invoked when actors are amidst unfamiliar others (Stets 2006).

Identity theory continues to be an influential subfield for the general study of self, identity, and symbolic interactionism. The theory continues to grow in terms of its theoretical development, methodological innovations, and research areas that address the dynamics of the self within greater society (Stets 2006). Scholars of identity theory attempt to reveal how individuals attach meanings to themselves and others, and continually strive to identify the mechanisms that explain how social structures affect and constrain individuals, as well as how individuals

create and maintain social structures. The prevalent emphases within identity theory differ in degree more than kind, and the corpus of work produced by scholars from all areas of the theory has furthered the understanding of both micro and macro level phenomena, within both sociological social psychology and sociology in general.

ideological hegemony

Matthew C. Mahutga and Judith Stepan Norris

Ideological hegemony theorizes the way in which relationships of domination and exploitation are embedded in the dominant ideas of society. To the extent that dominant ideas are internalized, they induce consent to these relationships on the part of the dominated and exploited. Consistent with the interconnected world in which we live, there are as many levels of ideological hegemony as there are levels of society.

The concept of ideological hegemony has deep historical and theoretical roots in the development of Marxist thought during the twentieth century. At the beginning of the twentieth century, Marxist theorists and parties were faced with the absence or failure of worldwide communist revolutions. The concept sought to explain why workers were not gaining control of their states.

One of the earliest theorists to develop these ideas and use the phraseology of bourgeois hegemony explicitly was Georg Lukács (1885–1971). Lukács was active in the Hungarian Communist Party after World War I. He remained loyal to the Communist Party throughout his lifetime, but became increasingly critical of it toward the end of his life. Lukács's most important contribution was arguably *History and Class Consciousness*, published in 1923. Though greatly influenced by the writing of V. I. Lenin, Lukács unequivocally claimed to have been producing an exposition of Marx's theory as "Marx understood it." In this work, Lukács drew a distinction between what he calls *objective* and *subjective* class consciousness. Objective class consciousness consists of the material interests facing the working class at any given historical moment. Subjective class consciousness, on the other hand, consists of the actual ideas and attitudes that the working class may have. Thus, "false consciousness" is the gap between the working class's objective class interests and their awareness of them.

Drawing the distinction between objective and subjective class consciousness moves away from the "pure economism" that dominated Marxist thought during this time, which suggested that communism was inevitable due

to the inherent contradictions in capitalism. In addition to the notion of false consciousness, Lukács suggested that social classes that were not "purely" proletarian (i.e., the petty bourgeois, peasantry, or semi wage earners) were unable to attain a revolutionary consciousness because their consciousness was limited by their objective interests within society, which were not driven toward the dissolution of capitalism. Thus, Lukács presents two mutually reinforcing explanations for why the working class failed to gain control of the state across Europe and the United States: either the working class's objective and subjective class consciousness failed to coincide, or the working class simply failed politically because they could not gain the allegiance of classes that were neither proletarian nor capitalist. Either way, the source of these failures was the "hegemony of the bourgeoisie," which not only dominated economically, politically, and militarily, but also naturalized capitalist social relations through the development of a theory of economics, politics, and society that dominated the intellectual milieu.

The most often cited author in connection with ideological hegemony is Antonio Gramsci (1891–1937). While in prison in Fascist Italy between 1927 and 1935, Antonio Gramsci developed the notion of ideological hegemony. His writings, in particular his conception of ideological hegemony in *The Prison Notebooks*, were directed at the Marxists of the Second International, who emphasized the primacy of science and materialist forces, and anticipated that working classes in advanced industrialized nations would vote out the representatives of the capitalist classes once they obtained the right to vote. Gramsci, in contrast, argued that perceptions and other mediations come between material forces and the meanings connected to them. The realm of ideas, or what Marx called the "superstructure" (religion, legal structures, the family, etc.), is affected by the interests of the ruling class such that they incorporate those interests without the appearance of doing so. Exploited people unwittingly adopt ideas and ways of life that are consistent with the continuation of their exploitation (Boggs 1978).

To get a grasp on how this process operates, Gramsci distinguished between different levels of the superstructure. "Civil society" represents all that we consider private, and

“political society” refers to the state. In civil society, the dominant group exercises hegemony, whereas it utilizes the state for direct domination.

According to Gramsci, ideological hegemony is a project that the ruling class must accomplish. Therefore, the level of ideological hegemony varies between societies. Where it is strong, capitalists need not rule mainly by physical coercion, but instead rely on popular consensus. Here, power relations are mystified. Where it is weak, that is, where traditional social and authority relations have been undermined, where bourgeois culture and lifestyles have lost their appeal, physical coercion becomes more necessary. In the latter case, workers’ revolutionary potential is higher. Still, workers need not only throw off the old, but must also develop counterhegemonies to successfully accomplish their revolutionary potential. The development of a counterhegemony is the main political task of the socialist movement (Boggs 1978).

Gramsci’s development of the notion of hegemony and counterhegemony goes beyond theorizing to the realm of politics. Gramsci distinguished between a “war of position” and a “war of maneuver” as necessary parts of the socialist/communist movement’s counterhegemonic project. The war of position entails a battle for the hearts and minds of individuals within civil society. The war of maneuver involves a violent “frontal attack” on the state with the purpose of total political victory. Gramsci brings the role of “organic intellectuals” to center stage, arguing that only this group of thinkers, who are intimately connected with the day to day lives of the working classes, can construct an alternative vision acceptable to civil society. According to Gramsci, the role of organic intellectuals flows from their position in civil society, which unifies their subjective and objective class consciousness through the philosophy of praxis. Through praxis – practical/critical activity – the working classes can win the allegiance of all workers as well as other classes. Finally, a victorious war of position makes a victorious war of maneuver possible.

Around the same period as both Lukács and Gramsci, the Institute of Social Research was founded at the University of Frankfurt. The

Institute became known as the Frankfurt School and continued the development of Marxist ideas. One of the most influential members of the Frankfurt School was Herbert Marcuse. By the 1960s, Marcuse was one of the most influential scholars of the New Left. This same period witnessed the popularization and proliferation of the writings of Antonio Gramsci, as the New Left became disillusioned with the Soviet Union and sought an explanation for the brutality of Stalinism. Though Marcuse never used the word hegemony explicitly, his ideas can be viewed as an extension and explication of ideological hegemony to the highly developed nature of advanced capitalism.

In *One Dimensional Man* (1964), Marcuse criticized both capitalist society and the Soviet Union. He moved his analysis of the failures of radical politics from the impediments of a revolutionary “class consciousness” to the impediments of an oppositional consciousness of any kind. To the modes of hegemony articulated by Gramsci, Marcuse added the advertising industry, industrial management, and the very act of consumption. The diffusion of mass consumption wedded the lower classes to an exploitative system through the act of consuming, which mitigates oppositional behavior and critical thinking. This analysis became the cornerstone of much of the New Left’s critique of capitalist society for the implication that it creates false needs in human beings, which reproduces, unnecessarily, relationships of exploitation and domination.

The legacy of Gramsci, Lukács, and the ideas subsumed under the notion of ideological hegemony can be clearly seen in current writings of critical theorists. Perhaps the most influential of these is Jürgen Habermas, the last of the Frankfurt School writers. Though Habermas’s range of subject matter is quite large, he is concerned with the very basic notion that a socialist society is possible, but that there are systemic impediments to its emergence. For Habermas, “advanced capitalism” has evolved past the pure wage labor/capital dichotomy outlined by Marx and has proved able to avert (at least temporarily) a terminal economic crisis. Advanced capitalism instead produces a series of distinct but connected crises leading ultimately to

a legitimation crisis (Habermas 1973), in which the system might cease to produce the motivation for the masses to consent. Though space considerations preclude a further discussion of the evolution of the notion of hegemony, suffice it to say that the whole field of critical theory owes an undying legacy to the development of Marxist theory in general, and ideological hegemony in particular.

The notion that hegemony must be achieved by convincing people to accept its terms in civil society implies that capitalists dominate the cultural sphere. When not achieved, hegemonic groups must exercise control through state violence. Thus, the maintenance of hegemony hinges on the ruling class's monopolization of cultural transmission in civil society. Cultural institutions, broadly defined to include the media, educational system, religious institutions, and so on, become the media through which "legitimate" discourse is defined. As evidence for the notion that elites have disproportionate access to media of cultural dissemination, many empirical studies have shown that the highest levels of corporate, political, and cultural arenas are occupied by interlocking directorates (Domhoff 2002). The empirical findings of dense and exclusive elite networks that unite the highest echelons of political, economic, and cultural institutions provide evidence that a dominant class has the ability to both construct and disseminate an ideology that legitimates their interests.

Many scholars who do research on or use the concept of hegemony focus on the mechanisms through which consent is achieved on different levels. Special attention is given to demonstrating the reproduction of hegemony through interpersonal interaction. For example, on the level of production processes, scholars have shown how submission to relationships of domination and exploitation on the shop floor is embedded in the act of work itself. Michael Burawoy (1979) has shown that piece rates induce a proclivity toward competition and manipulation between workers, and thereby solidify workers' commitment to the status quo on the shop floor.

Research in the area of media studies has focused on the means by which popular culture, as expressed on television or through the film

industry, projects consistent images of society that mitigate critical thinking. For example, the very format of television creates a reified view of reality impervious to radical change by proposing character themes that are fixed rather than developing in nature. Furthermore, the very act of consuming mainstream cultural transmission via television precludes public discourse and encourages passive absorption of dominant ideologies. Finally, critical media scholars also point to the profit logic driving media dissemination as creating a contradictory consciousness. Here the idea is that views toward profit create appetites for sensationalism in media, which at best distracts consumers from the redress of everyday problems.

The theory of ideological hegemony explicitly implies that there are real limits to hegemony. Because of the strong link between the economic/political structure of society and the ideology it produces, as well as the fact that the economic/political structure of society is constantly in a state of change, hegemonic ideology must always change in order to naturalize evolving social relations. Todd Gitlin has argued that television in the 1950s was able to exclude voices of dissent because of the relatively calm era of smooth economic expansion. By the 1970s, however, themes dealing with racism, sexism, and poverty were increasingly pushing their way into the mainstream. Thus, what emerged in mainstream television culture was an attempt to domesticate ideas of feminist and ethnic resistance by delegitimizing "radical" views in favor of those that were easily co-opted. One study of American labor during its height of effectiveness in the industrial heartland showed that the presence of a progressive union can not only mitigate hegemonic ideology in the workplace, but also initiate *counterhegemonic* orientations (Stepan Norris & Zeitlin 2003).

Because of the historical legacy of Marxist theory on the development of the concept of ideological hegemony, it oftentimes assumes a Marxist epistemology. Even when ideological hegemony is used in explicitly non Marxist ways, it still relies on the distinction developed by Lukács between objective interests and subjective consciousness to imply that there is an objective reality of domination/exploitation that

people in power obfuscate. To the extent that whether or not social relationships are exploitative remains an empirical question, studies of hegemony run the risk of tautology. Consequently, sometimes studies of ideological hegemony lapse into a “reinterpretation” of a given phenomenon with the language of a critical perspective, rather than conducting empirical investigations into whether or not such a reality exists to be covered up. In the end, however, if relationships of exploitation/domination have been shown to exist, the concept of ideological hegemony always provides a language to decode them and explicate the mechanisms through which subordinate groups consent to both the relationships and their outcomes.

ideology

Christoph Henning

An ideology is a system of shared beliefs that is relevant for social action, integration, and social stability, though it is not necessarily true. Ideologies are very important for sociology: if there was no ideology, we would not need sociology. Because people's opinions of how society works differ from how society actually works, a science of society is necessary in the first place. It is not necessary for society to function that people have true beliefs about society. Rather, every social group holds its own beliefs to be true. If one group of people believes another group of people's set of beliefs to be false, they will call this belief system an ideology. Implicit in this denunciation is the claim of the first group to possess a more accurate theory of society. But such claims have become rare nowadays – at least, the term ideology is hardly used any more. After the cultural turn, this term lost its former prominence, for a simple reason: today, the claim to possess the one and only “true” theory of society is highly discredited. It was replaced by postmodernist pluralism. Here you can only investigate different discourses, without claiming that they are false. All of them are part of a certain culture, whether we like them or not. Nevertheless, in current public discourse there are many sentiments that could very well be called ideological from a sociological point of view.

The term ideology in its modern sense was first used in 1796 by Destutt de Tracy in the context of the French Revolution. He intended a descriptive *science des idées* in the tradition of the Enlightenment, but with an almost positivistic approach. The “ideologues” became an influential school of thought in early nineteenth century France. Yet the term was soon to be used much more polemically. Napoleon criticized the pure reason of the “ideologues” that abstracted from pragmatic political necessities and the “knowledge of the human heart,” meaning the human need for pleasant illusion. This was the birth of ideological criticism, which mainly contains an accusation of a detachment of theory from reality (abstractification). It was later taken up by Marx and Engels's use of the

term ideology, which they developed in their seminal, but long unpublished, book, *The German Ideology*.

The Marxian use of the term ideology has the following implications. First of all, like mythology, it refers to self conceptions of a whole society. But the societies Marx has in mind are modern societies. This means two things: first, they employ a social division of labor, resulting in a class society or, as later sociology would call it, a “functional differentiation.” Secondly, one of these classes dominates the others, mainly through control over the means of production. Resulting from the division of labor is a fundamental opacity of the way society functions (estrangement), which calls for easy explanations to reduce this complexity cognitively and symbolically. This leads to “false consciousness,” to false ideas and pictures about the way society functions. Here, ideologies develop and spread without anybody intending it. Resulting from the dominance of the ruling classes, on the other hand, is an imposition of their worldview on all members of society. “The ruling ideas are the ideas of the ruling classes” (Marx). This later process can include consciously intended actions in order to obtain such hegemony – not necessarily, but possibly. Later Marxist writers (e.g., Gramsci, Lukács, and Adorno) investigated how capitalism, or specific parts of the bourgeoisie, managed to uphold an ideology of “just” capitalism in spite of its partly and seemingly catastrophic consequences. One of these ideologies, Marxists would claim, was nationalism and fascism, another one was Keynesianism and the welfare state, and the most recent one is neoliberalism with its meritocratic master narrative.

Large parts of leftist twentieth century sociology were engaged in a criticism of ideology, most importantly Critical Theory. Yet even before the cultural turn there were two serious challenges. First, by the middle of the century Daniel Bell and others proclaimed an “end of ideology,” resulting from the weakened class conflict and increased sociological knowledge that allowed for more planning (technocracy). This was a rather old claim: ideologies never declare themselves openly, they always try to sell themselves as “truths.” And this was the case with Bell’s narrative, as well. After some decades, it has become obvious that ideology is still alive, as

writers like Žižek, Hall, and Bourdieu have shown. The “end of ideology” thesis was nothing less than yet another ideology. It depends on the social standpoint of the spectator whether something appears as ideology or as “truth.” This irony of Marx’s was in many cases missed by his critics.
