that increase the likelihood of collective action. Put more polemically, a political process theorist might argue that to whatever extent strain and breakdown are causally relevant, that relevance is captured in the notion of opportunity structures. What is jettisoned are the negative connotations of traditional strain and breakdown theories. To the extent that opportunity has become a stand in for strain and breakdown, it can be concluded that the latter never really disappeared from social movement theory.

social network analysis

Barry Wellman

Social scientists have used the metaphor of “social network” for a century to connote complex sets of relationships between members of social systems at all scales, from interpersonal to international. Yet not until the 1950s did they start using the term systematically and self-consciously to denote patterns of ties that cut across the concepts traditionally used by social scientists: bounded groups (e.g., tribes, families) and social categories (e.g., gender, ethnicity).

Social network analysis has now moved from being a suggestive metaphor to an analytic approach to a paradigm, with its own theoretical statements, methods, and research findings. It has developed from diverse sources, including anthropological accounts of detribalized urban migrants, surveys of people’s long distance communities, political upheavals, Internet connectivity, and trade relations among nations. The Internet, inherently network like, has so popularized the approach that *Business Week* named social network analysis “the hottest new technology” of 2003, and membership in network analysis’ professional organization has doubled in four years.

Social network analysts reason from whole to part; from structure to relation to individual; from behavior to attitude. They argue that their social structural explanations have more analytic power than individualistic analyses that do not take relational patterns into account and that interpret behavior in terms of the internalized norms of discrete individuals. The structure of a network, the relations among network members, and the location of a member within a network are critical factors in understanding social behavior. Analysts search for regular structures of ties underlying often incoherent surface appearances, and they study how these social structures constrain network members’

behavior. Key concepts include network density, centrality, transitivity, tie strength, clustering, and structural equivalence.

Social networks are formally defined as a set of *nodes* (or *network members*) that are *tied* by one or more specific types of *relations*. In much research, these nodes are individual persons, but they can also be groups, corporations, households, blogs, nation states, or other collectivities. Ties consist of one or more specific relations, such as financial exchange, friendship, hate, trade, web links, or airline routes. Ties vary in *quality* (whether the relation provides emotional aid or companionship), *quantity* (how much emotional aid; how frequent the companionship), *multiplexity* (sometimes called multi-strandedness: ties containing only one relation or several), and *symmetry* (resources flowing in one direction or both). The non-random structure of ties channels resources to specific locations in social systems, fostering inequalities.

Several analytic tendencies distinguish network analysis. First, there is no assumption that groups are the building blocks of society. While social network analytic techniques can discover the empirical existence of groups, the approach is open to studying less bounded social systems. For example, researchers have mapped the structure of the World Wide Web on the Internet, showing how superconnectors shorten distances between websites.

Second, although social network data often include information about the attributes of individuals, such as age, gender, and beliefs, individuals are not treated as discrete units of analysis. Instead, analysis focuses on how the networks affect the individuals and ties embedded in them.

Third, social network analysis contrasts with analyses which assume that socialization into norms determines behavior and social structure. By contrast, network analysis looks to see the extent to which patterns of social relations affect norms and values.

Social network analysts gather data in many ways, such as ethnography, surveys, archives, and simulations. Their data collection emphasizes ties and the problematic nature of boundaries. Although analysts often visualize networks as point and line graphs, they analyze them as matrices that are more amenable to statistical and mathematical manipulation. Specialized

programs, such as UCInet and Pajek, facilitate analyses.

Network analysts often study *whole networks*, all of the ties containing one or a few kinds of relations among the members of a population. These populations can be of different scales, from the members of a small office to Hollywood musicians to the vast blogosphere on the Internet. Multilevel and two mode analyses facilitate the study of *networks of networks*, as when ties between persons also connect organizations. For example, analysts have studied interlocking corporate directorships (who sits on whose boards?) to describe ties among large organizations and to discover the structure of dominant institutions in western societies. Through manipulation of matrices representing who is connected with whom, analysts can discover densely knit clusters of heavily interconnected network members (and thus empirically identify true groups) or discover those network members whose *equivalent* relations show up in *blockmodels* as having similar roles in the social system.

Whole network studies are not always feasible because they require complete lists of all members of a population and all of their ties. Moreover, prior specification of population boundaries may not be appropriate for identifying clandestine networks or studying the diffusion of information, munitions, illicit drugs, and disease. In such situations, their interest is in tracing connections through unbounded networks and discovering clusters of ties.

Some network analysts study *egocentric* (or personal) networks, defined from the standpoints of egos (or *focal individuals*). Analysts typically use survey research to gather information about the networks' *composition* (e.g., percent gender), *structure* (e.g., the density of interconnection among members), and *contents* (e.g., the amount of support provided to egos). This is useful for studying far flung communities, the provision of social support, and the mobilization of social capital.

Social network analysis has blossomed in recent years, with the paradigm appearing throughout the social science. It has a professional association, the International Network for Social Network Analysis, and three specialized journals: *Social Networks*, *Connections*, and the *Journal of Social Structure*. Network

rudimentary Internet software has proliferated, attempting to connect people who know each other directly and indirectly. In addition to sociology, network analyses are often found in management studies (mergers; organizational behavior); anthropology (kinship, urban relocation); geography (dispersion of network members); communication science (virtual community on the Internet); information science (information flows); political science (political mobilization); psychology (small groups; social support); social history (social movements); statistics (multilevel analysis); and mathematics (graph theory).

social network theory

Anne F. Eisenberg and Jeffrey Houser

The idea of social networks is prevalent in everyday vernacular language, ranging from the game "Six Degrees of Kevin Bacon" where players identify how any one actor is linked to the actor Kevin Bacon through no more than six different people, to the way in which people "network" with one another as an avenue through which they gain social capital, to how we describe our computers' ability to "talk" with other computers. The idea of social networks has an equally wide range of applications in sociology, from formal network theory to social network data analysis. The historical development of the sociological use of the idea of social networks originates with Durkheim and Simmel, and its breadth of use is reflected in contemporary theoretical and methodological developments and applications. In its different uses, from the vernacular to its historical development to its current developments, social network theory refers to the ways in which people are connected to one another and how these connections create and define human society on all levels: the individual, the group, and the institutional.

HISTORICAL DEVELOPMENT

The historical development of social networks as a sociologically important idea is represented by two main stages: its origins in the sociological work of Durkheim and Simmel, and its early development in the areas of social psychology. While Durkheim does not use the phrase social networks, it is obvious from his

writings about religion, suicide, and the division of labor that he focused on how changes in the social world, such as those brought about by industrialization and capitalism, affected the connections between people. More to the point, he aptly illustrated how connections between people serve as the basis for human society. For example, in describing the shift from mechanical solidarity to organic solidarity he focused on several criteria, including the quality and quantity of individuals' connections to one another, as expressed by the idea of dynamic density, and by the level of the division of labor. Specifically, Durkheim argued that social relations in a society characterized by mechanical solidarity were meaningfully different from social relations in a society characterized by organic solidarity. He stated that all societies began with small communities of people who are all connected to one another in a familiar fashion. As the number of people within the community grew, social relations changed, leading to more organic forms of solidarity whereby people were connected to larger numbers of other people but in a less intimate way. This shift was also reflected in a change in the level of division of labor, with mechanical forms of solidarity having little to no division of labor and organic forms of solidarity having greater division of labor. Also, in his discussion of suicide, Durkheim focused on the role that integration played in maintaining social order. He defined integration in terms of how it allows for the interchange of ideas and feelings, as well as created shared moral beliefs and goals that prevented the excessive individualism that leads to egoistic suicide. Finally, Durkheim's discussion of religion centered on the role that religion plays in bringing a community of people together through their shared experiences, beliefs, and rituals. It is obvious that for Durkheim it is the meaningful connections between people that allow society to survive and flourish.

Simmel's work can generally be described as examining different aspects of individual lives and individuals' interactions. Similarly to Durkheim, while Simmel never directly used the phrase social networks, his writings focused on how interactions were affected by the way in which people are connected to one another in terms of an individual's social status, as well as the dynamics that occur as different people

engage in interactions with one another. For example, in discussing how group size affected interactions, Simmel examined the qualitative change that occurs in interactions when the dyad becomes a triad. In the dyad, actors are connected by their total interdependence, while in a triad it is possible for a coalition to develop between two of the three actors. Simmel's focus on the different variables that affect our connections to one another is evident in a wide range of his discussions, from exchanges as a form of interactions, to group development, through a series of interactions among people, to the social characteristics (such as whether a person is a stranger) that affect the creation of connections between people.

The second stage in the historical development of social networks as a sociological idea occurs in the early work of sociologists specializing in social psychology. Early social psychologists, similarly to Simmel, discussed exchanges as a form of interactions by building on the ideas of anthropologists such as Frazer, Malinowski, Mauss, and Lévi Strauss, as well as ideas associated with behaviorism in psychology. George Homans highlighted the basic principles of exchange theory, which focused on how connections between people were based on the need for exchanges to occur to fulfill each actor's needs. Peter Blau and Richard Emerson and his colleagues further developed Homans's ideas by explicating the conditions under which exchanges proceed (for the former) and how such exchanges might then create collective action between actors through different types of exchange networks (the latter). While Emerson was the only early social psychologist explicitly using the phrase social networks, it is evident from the work of Homans and Blau that their underlying themes examined the creation and maintenance of connections between people. These themes, and the phrase social networks, are developed further by contemporary theorists and empirical research applications.

CONTEMPORARY DEVELOPMENTS

The idea of social networks is used in a wide range of areas of study in sociology, from economic sociology to social psychology to

political sociology, as well as representing a specific form of data analysis. From its historical development in social psychology, social networks appear in a number of contemporary social psychological theories. Cook and colleagues (1993), among others, extended Emerson's original formulation of exchange theory to examine issues such as the distribution of power in social exchange networks, how bargaining in social networks is affected by power distribution, commitment formation, and coalition formations. Each of these theoretical extensions of Emerson and Blau's work focuses on some aspect of social networks in terms of how connections between actors then affect further interactions and exchanges. Willer and colleagues (2002) developed network exchange theory (NET) to focus on exchange structures and power relations. NET provides explicit predictions about exchanges that may occur based on factors such as whether or not social networks are exclusively connected, the level of hierarchy and mobility that exists in any particular social network, and the order in which exchanges occur. These factors then allow Willer and colleagues to explore how collective action develops among actors in a social network. Finally, social psychologists such as Eisenberg (2002) and Ridgeway and colleagues (1994) interested in groups and group dynamics examine how social networks structure social interactions through social norms as reflected in status characteristics and the resulting group structure.

Network theory is a broader term that represents theoretical developments in all areas of sociology by focusing on the key idea of actors and how they are connected, whereby actors can be individuals or groups or social institutions. In other words, network theory allows us to examine the objective pattern of interactions represented by how actors are connected to one another. By examining how actors are connected to one another, sociologists gain insight into the structure of social interactions on the individual level as well as the structure of groups and institutions. For example, Granovetter (1973) used social networks to explain the importance of weak ties among people and how these types of ties affected exchanges. His work served as the basis for further work in economic sociology, such as explaining organizational survival in

particular economic environments. Uzzi (1996) demonstrated how conformity to specific organizational norms increased an organization's likelihood for survival. Heckathorn (2002) used social networks to explain collective action in social movements by examining how particular networks of people developed into formal movement organizations. Additionally, social networks have been used to explain an array of social phenomena, including job mobility, the structure of groups of scientists, corporate networks, and consumer transactions.

Finally, social network also refers to a specific form of data analysis in which the researcher focuses on the ties among and between social actors. More importantly, social network analysis allows sociologists literally to draw a picture of the actors studied – from the dyad to the triad to the social movement. Social network analysis consists of basic concepts that emphasize how actors are connected to one another. For example, points and nodes identify specific actors (individual, group, organizational, or collectivities) who are then described in terms of their connections to others through either a simple graph figure or through a matrix representing particular ties. Once the social network has been so identified and described, it can then be analyzed in terms of the patterns and configurations of ties. This analysis includes examining the number of ties between any combination of actors, the direction in which resources flow for each set of ties, the strength of the ties, and the density of ties. Computer programs that provide both the descriptive and analytical are now readily available. These programs provide pictures of the social networks being studied, as well as the matrix of connections and calculations representing the patterns and configurations of ties. The reason social network analysis is becoming increasingly important in sociology is that describing and analyzing the social world in terms of objectively measured social connections allows us to avoid qualitative evaluations that lead to subjective, and possibly biased, understanding of specific social phenomena.

social order

Steven P. Dandaneau

Social order is synonymous with both society and social science. People do not regularly live in chaos, even when they are the denizens of postmodern societies that characteristically exacerbate the already chaotic tempo bequeathed by modernity. Regardless of whether it is edifying to accept, ritual and routine, not rebellion and revolution, absorb the lion's share of every day energies. Likewise, apart from whether society is conceived theoretically as organism or system, language game or mode of production, interaction ritual or ethereal spectacle, the essential notion of "society" is scientifically and practically meaningful only when it refers to routinely observable phenomena about which lasting statements are possible. Without social order, social science would dissolve into the ephemeral study of ephemerality.

Probably no figure in the history of sociology more clearly represents the concern for theorizing the practical achievement of social order than Talcott Parsons. Parsons self consciously built an integrated theory of social order through synthesis of previous ambitious attempts to grasp the totality of human society, including via the work of Herbert Spencer, Vilfredo Pareto, Émile Durkheim, Alfred Marshall, and Max Weber. Indeed, the last four are the principal subjects of Parsons's classic *The Structure of Social Action* (1937), which he famously inaugurated with Crane Brinton's question, "Who now reads Spencer?" And not just Spencer, but also Thomas Hobbes, Plato, and so many others. The "problem of order," as Parsons put it, is further systematized in the aptly titled *The Social System* (1951). This book outlined a model of society as a functionally differentiated set of institutions and cultural patterns. In such a society, social order is conceived as the aggregate equilibrium that is achieved when subsystems adapt to meet a priori societal needs. As determinative as this model appears, Parsons emphasized that, for him, social order was always already "precarious" and "problematical," not an "imperative" to be associated with theoretical, much less actual, "fascism."

Parsons's attention to the problem of order brought him many critics, including – as his own use of the fascism word suggests – passionate and politically motivated critics. Among these are Parsons's own students and a striking number of sociology's leading lights. Among the sympathetic critics is his student, Robert K. Merton. While Merton's "middle range" version of "structural functionalism" certainly shares Parsons's concern for social order, it recasts Parsons's theoretical focus on the societal totality in order to render it serviceable for empirical social research. Even such elementary concepts as Durkheim's anomie are in Merton's divining fundamentally revised to focus concern for the maintenance of social order away from the social totality and toward the various mid range problems of social milieu.

Another student is Harold Garfinkel, whose "ethnomethodology" pursues the problem of order, not at the middle range but from the bottom up. Garfinkel advocates empirical analysis of the myriad everyday rules (the ethno methods) that actors themselves use in creating orderly, predictable interactions. While this empirical approach differs fundamentally from that suggested by Parsons, the goal is the same. As Garfinkel stresses, his appropriation of Edmund Husserl's and Alfred Schütz's phenomenological insights is marshaled on behalf of "working out Durkheim's aphorism" that sociology's most fundamental data are concrete social facts. Thus, far from rejecting Parsons's focus on social order, both Merton and Garfinkel aim to render Parsons's problem of order amenable to empirical sociological research, although of significantly different types.

Parsons's more vociferous critics include C. Wright Mills and Alvin W. Gouldner, neither of whom were his students. Mills famously viewed Parsons's attempt to grasp an overarching social order as an instance of "grand theory," a pejorative meant to highlight the theory's ahistorical and empirically disconnected quality as well as call attention to its usefulness as ideological buttress for the specific faults of the mid century United States of America. As immersed in Marx and Weber as was Mills, he could not countenance a social theory in which Marx played virtually no role and Weber appeared as a politically defanged shadow of himself. That is, Mills could not subscribe to a theory of

social order virtually bereft of attention to power, politics, and social domination. Gouldner, for his part, pushed this criticism further, assessing the ideological roots of Parsons's theoretical system from Plato forward and announcing the need for a thorough rethinking of sociology's self conception just as the discipline was in fact, depending on the perspective taken, decomposing through internal fragmentation or liberating itself from Parsons's theoretical straightjacket. Either way, sociology's focus on the problem of social order seemed to dissolve along with the identity of the discipline.

Although not typically conceived as such, Parsons's problem of social order remains an ongoing practical as well as theoretical problem. On the one hand, researchers' plates are full in pursuit of empirical analysis of postmodernity's acceleration, intensification, dispersal, and differentiation of social and cultural life, which may or may not ultimately facilitate the production of social order. Does the World Wide Web integrate globally, or divide humanity into disparate viewers of superficial information? Does the emergence of post Fordist/Keynesian economic systems provide efficiency and facilitate meeting increasingly differentiated consumer demand, or globalize the crisis of overproduction without hope of an equally global Keynesian fix? Does the fact of planetary ecological crisis portend unprecedented forms of international cooperation, or will "the North" use its political, military, and economic power to suppress "the South's" demands for an equitable and democratically coordinated response? Will globalization result in genuinely pluralist societies, or will atavistic and ethnocentric responses undermine civility among culturally diverse populations? Will microtechnologies result in the further medical amelioration of disease and mortality, or will social order be subverted by viral contagions, organic or computer, endemic or laboratory synthesized, unintentionally or by menacing design? Whereas social order in the eighteenth and nineteenth centuries was wracked by such massively disruptive forces as capitalist industrialization, urbanism, liberal democratic revolutions, and European colonialism, and whereas the twentieth century was dominated by such events as two world embracing wars, worldwide ecological degradation, and the threat of nuclear

apocalypse, the twenty first century appears destined to continue to challenge the achievement of social order on terms as particular and general as human experience provides.

Thus, it is perhaps predictable that a leading contemporary social theorist such as Anthony Giddens would deemphasize his concern for social order as articulated in *The Constitution of Society* (1984) in favor of a more historically engaged reflexive modernization theory and pursuit of "third way" and, more recently, post third way politics. Yet, it is also the case that perhaps the most influential contemporary inheritor of the Marxian tradition, Jürgen Habermas, has been profoundly influenced by Parsons and the autopoietic systems theory of another of Parsons's students, Niklas Luhmann. Additional streams of analysis of social order include those that derive from the towering achievement of Michel Foucault and his historical attention to the real world Nietzschean interplay of knowledge and power, and that has resulted in such diverse treatises as Sheila Jasanoff and her colleagues' focus on "the co production of science and social order" and Jackie Orr's "genealogy of panic disorder," the latter, in fact, directly theorizing the historical intersections of Parsons, pills, and patriarchy.

social pathology

Milena Buchs

The concept of social pathology applies the medical metaphor of pathology to describe and explain social problems. From this perspective those individuals and groups who deviate from social norms, or institutions that do not fit with core social norms, are “sick” or pathologic and a risk to the society’s “health.” Social pathology was a very influential model in nineteenth century American and European sociological writings on social problems. The concept is closely related to those of social disorganization and deviance. However, social disorganization focuses on the malfunctioning of social institutions and structures rather than on the individual. The concept of deviance became popular in the 1950s. It was strongly influenced by the concept of anomie (Durkheim, Merton) and is similar to social pathology in that it focuses on

the individual criminal. When the concept of social pathology became famous, many authors using this concept also applied Darwinist and evolutionary models to the analysis of society. They aimed to contribute to social progress and regarded every kind of behavior or social phenomenon that appeared as obstacles to social progress as pathologic and therefore inferior.

The concept of social pathology contains an inherent tension. On the one hand, it emerged at a time when sociologists such as Comte and Spencer sought to establish the field of sociology as a scientific discipline applying objective and scientific methods. This was one of the reasons why concepts from other scientific disciplines such as medicine and biology were employed to study society. On the other hand, social pathology is closely related to a nineteenth century reform movement which applied normative views to the study of social problems. The perspective of social pathology defines social problems as those social phenomena that diverge from present social norms and morals. Social pathologists assumed that norms could be defined in an objective way, for example by setting universal standards of “health” or “normality.”

One can distinguish different versions of the concept social pathology. These versions are also related to the development of the concept over time. Early versions, emerging in the second half of the nineteenth century, were closely related to the socioeconomic context of industrialization and urbanization. Many American social pathologists of that time are regarded as having held relatively moralistic and conservative values deriving from rural forms of social life (Mills 1943). Some authors used a biological or organic version of social pathology. Samuel Smith, for example, used an organic analogy in order to describe different social classes and their relationships. Smith (1911) saw phenomena such as crime and poverty as inherently related to each other and those affected by it as belonging to the “abnormal classes.” Authors such as Lombroso and Ferrero (1895) developed the concept of the deviant person as a “born criminal.” According to this concept, criminal behavior is caused by inherited mental or physical diseases. Another version of the concept regards a lack of socialization as the main reason

for deviant behavior: here the criminal becomes “infected” by the bad morals around him or her. Both versions mainly supported (religious) education and medical treatment as the right methods to “cure” criminals. These early versions of social pathology had their heyday in the period before World War I, after which they declined slowly but steadily.

In the 1960s the concept of social pathology again became more frequently used. Social parameters were quite different and the concept became more popular among liberal social scientists who regarded whole social institutions as pathologic or as causing the pathological behavior of individuals (Rubington & Weinberg 1995). At this time, the concept of social pathology was also used to explain social and political disasters such as the Holocaust by Nazi Germany, the totalitarianism of the Stalin era, and the atomic bombs dropped on Hiroshima and Nagasaki by the US (Rosenberg et al. 1964).

Some authors in the same period also intended to apply the idea of social pathology in a more objective way. This was a response to the critique of social pathology which claimed that the concept in fact supported the culturally specific norms found in rural life such as piety and social stability, but disguised this by the use of pseudo scientific methods (Mills 1943). Therefore, authors such as Kavolis (1968) developed what he called a “universal criterion” for the definition of pathologies. For him, the cross culturally acknowledged criterion of social pathology was “destructive or self destructive behavior” rather than deviance from culturally specific norms. Another difficulty in diagnosing social pathologies arises if one argues from Durkheim’s functionalist point of view that deviance serves a social function and is therefore “normal.”

Since the mid 1980s, constructivist approaches have become prominent in the study of social problems and the notion of social pathology is now rarely used. The constructivist approach does not agree that it is possible to define a cross culturally accepted criterion of “normality.” Rather, from the constructivists’ perspective, social problems are those phenomena that are regarded as problems by the public, political movements, or politicians, all of whom may strive to change the situation by political action.

social policy, welfare state

Franz Xaver Kaufmann

“Welfare state” and “social policy” are generalizing concepts legitimizing political intervention to protect the weaker members of society, to reduce social inequalities, and to promote human capacities for action and self reliance. The contemporary welfare state is the institutional expression of a political system committing itself to human rights, including social rights. Social policy is the generic name for strategies to solve social problems by political intervention, as well as for an academic discipline dealing with such issues.

HISTORY

The idea that the king or the prince was responsible for the “security, welfare, and felicity” of his subjects was already part of

premodern political ideology. In some countries (e.g., Prussia) there existed also a discernible set of policies aimed at promoting welfare (Dorwart 1971). In the UK, the poor laws of Queen Elizabeth I (1599–1601) drafted some basic features of social policy, i.e., the definition of a problem (“poverty”), a classification of recipients and selective treatment (workhouse versus asylum), their entrustment to local officers, and rules of financing. The followers of John Locke, Adam Smith, and Immanuel Kant, however, opposed such a comprehensive political authority. Responsibility for security alone should remain with government or (in continental Europe) the state, whereas individuals should be responsible for their own welfare and happiness.

In the modern sense, social policies and institutions of public welfare emerged in the nineteenth century in reaction to economic liberalism and the pernicious side effects of industrialization and urbanization, with Great Britain and Switzerland being the forerunners. The terms “social policy” and “welfare state” were first coined in Germany: *Social Politik* on the eve of the revolutionary year 1848, and *Wohlfahrtsstaat* by the social reformer Adolph Wagner in 1876. The most perspicacious social scientist in these matters was Lorenz von Stein. Drawing on Hegel’s distinction between “the state” and “civil society” and inspired, like Karl Marx, by French socialists, from 1842 on he developed a dynamic theory of societal transformation leading inevitably to class struggle. But in contrast to Marx, he saw the way out not in revolution but in class compromise, mediated through a “monarchy of social reform” thought to be neutral toward class interests (cf. Stein 1964 [1850]). This class compromise should consist in the constitutional guarantee of private property in favor of the propertied class on the one hand, and in the protection and advancement of the working classes through education, free association, and “social administration” on the other.

In fact, in many European countries, things have evolved along the lines of Stein’s argument, though mostly in a more democratic and corporatist way. Beginning with the September Agreement in Denmark (1899) and followed by Germany (1918), France (1936, 1968), Switzerland (1937), and Sweden (1938), agreements

among employers’ leaders and workers’ associations have been made on a national basis with quite similar content: acceptance by trade unions of private industry and industrial authority on one hand, and acceptance by employers of obligatory collective bargaining and state intervention to protect workers on the other. These agreements proved more or less sustainable, but state intervention regulating labor protection, workers’ rights, and social insurance, i.e., social policies, thus became accepted throughout Europe before World War II.

The welfare state’s heyday came after World War II. The victorious powers were convinced that the ascendancy of fascism and its atrocities was due mainly to the economic and social misery following World War I and the Great Depression. Thus the program for a more peaceful world, originating in the Atlantic Charter issued by Roosevelt and Churchill in 1941 and leading to the Organization of United Nations, included the proposal “to bring about the fullest collaboration between all nations in the economic field with the object of securing, for all, improved labor standards, economic advancement, and social security.”

The ideological shift from social policies for industrial workers to a comprehensive set of welfare policies for all members of a society is documented in the 1944 Declaration of Philadelphia by the International Labor Organization (ILO), which became incorporated into the ILO’s constitution in 1946. In this document is to be found for the first time the conviction that “all human beings . . . have the right to pursue both their material well being and their spiritual development in conditions of freedom and dignity, of economic security, and equal opportunity.” Further, the document defines the major areas of welfare state policies. These ideas are echoed in Article 55 of the Charter of the United Nations Organization. Eventually, the UN’s Universal Declaration of Human Rights in 1948 codified not only civil and political rights, but also economic, social, and cultural rights, to be promoted by national policies and international cooperation. The international implementation of the latter remained quite weak, however. The Economic and Social Council (ECOSOC) has remained a rather ineffective organ of the UN. Yet the plan of a welfare state was internationally established

by these decisions and has taken shape through various regional declarations and covenants.

SCOPE

International comparative research on issues of the welfare state focuses mainly on systems of income maintenance or social security. This is admittedly the most expensive and widespread field of public intervention. But there are two other fields in which sociopolitical intervention is common, namely, labor protection (cf. Hepple 1986) and social services (cf. Alber 1995). From a functionalist perspective, it is thus possible to distinguish social policies in the realm of production (regulating working conditions, wages, labor markets), distribution (social security, taxation), and reproduction (social services: education, health, housing, personal services) (Kaufmann 2001).

In fact, some institutional arrangements providing protection of working conditions, income security, and social services have developed in almost all industrialized countries. But countries differ as to the extent of coverage of the population, the degree of political regulation or self administration, the share of public, semi public, non profit, or private ownership, and financing from the general public budget, by specific but compulsory contributions, or by subsidized market prices. They differ moreover as to the legitimations and specific technologies of administrative intervention. All these features, which form the specific arrangement of public welfare production in a country, depend obviously on more general features of cultural orientations, the political system and the distribution of power, the structure and performance of the economy, and many other factors. So, from a comparative perspective, the object of inquiry is located in both the public and the private sphere, somewhere in between "state" and "civil society." It is much easier to describe "social policy" and "welfare state" from a specific national perspective. But these national self descriptions are far from being convergent in a comparative perspective. Similarities and differences are themselves objects of inquiry.

The welfare state is a focus of research for many disciplines, from political philosophy (Walzer 1983; Goodin 1988) and history

(Baldwin 1990; Ritter 1991) to economics (Atkinson 1983; Sen 1996) and even law. The bulk of research, however, stems from sociology and political science.

SOCIOLOGICAL APPROACHES

In the sociological discussion of the welfare state, the international context is seldom mentioned. This is one reason why concepts of the welfare state often remain rather loose and contested. Sociology mainly focuses on national developments in both national and comparative perspective, and most authors model their concept of the welfare state with respect to their own national or regional tradition. In the present context, only comparative and generalizing research is considered.

There is often an intrinsic correspondence between the choice of method for inquiry and the underlying concept of the welfare state. A widespread and very influential approach to comparative welfare state research operates with national or international statistics (Wilensky 1975). The statistical offices of the OECD and European Union (Eurostat) endeavor to standardize national figures to overcome the intricacies of comparison from heterogeneous national sources. This quantitative approach uses conventional definitions: the welfare state is often equated with social expenditure or its share in GDP. Moreover, all countries with available statistics are often included notwithstanding their institutional and ideological aspects.

A second approach starts from history and compares national developments of a limited number of welfare states in a more or less comprehensive way (Rimlinger 1971). This historical approach is quite flexible and contributes to an intrinsic understanding of various national cases, but it often lacks rigorous comparative dimensions and hence a clear basic concept of the welfare state.

More rigorous comparisons may be attained when the focus remains with particular institutional complexes of the welfare state such as the health system, old age security, or labor protection. Such studies are often quite instructive for a certain field of social policy, but again fail to account for a comprehensive concept of the welfare state. The institutionalist approach may

also focus on the impact of the political machinery upon the emergence of welfare states (Evans et al. 1985).

A thrust to more reflection of comprehensive differences of welfare states has been made by the typological approach. It began with the distinction by Richard Titmuss (1974) of the "institutional redistributive model," the "industrial achievement–performance model," and the "residual model" of social policy. This tripartite distinction is echoed by the welfare regime approach by Gøsta Esping Andersen (1990) which links the institutional differences to the dominance of social democratic or conservative or liberal ideologies. This typology has provoked much debate and has proved fruitful by sensitizing the professional community to the complex character of welfare states and their institutional as well as cultural and ideological differences.

The debate about systematizing differences among welfare states obscured somewhat the question of what they have in common. A convincing answer came from general sociology: the growth and functional differentiation of modern societies erode traditional forms of all embracing solidarity and lead to the emergence of increasingly selective forms of social organization and to growing individualization of life courses. It is therefore necessary to care politically for the inclusion of all individuals within the leading realms of life. This was already the underlying idea of the human rights movement. It was T. H. Marshall (1976 [1964]) who made it a sociological argument, which was then picked up under the heading of "inclusion" by Talcott Parsons and Niklas Luhmann.

This general perspective suggests that the emergence of a welfare state is a necessary concomitant of successful modernization. However, nations and political systems differ markedly in their relation to the economic system. Taking this difference as essential, one might distinguish between "state socialism" (e.g., the USSR), "welfare capitalism" (e.g., the US), and "welfare state," the latter "European model" being characterized by a continuous tension between state intervention and market forces as well as by class compromise (Kaufmann 2003).

The progress of research has not led until now to a dominating paradigm. The subject is complex and multifarious, so substantial

approaches need to define first a specific perspective or, in a more advanced stage, the combination of a defined set of perspectives. Three overarching questions are to be found in comparative sociological and political research: (1) driving factors for the development and retrenchment of the welfare state; (2) functions of the welfare state; (3) evaluation and impact of welfare state provisions.

PROBLEMS

Historically, the emergence of welfare state institutions in Western Europe coincided with post war prosperity and full employment. Between 1945 and 1973, the terms of trade were particularly favorable for Europe, due to the Bretton Woods monetary system linking all currencies to an implicit gold standard expressed by a stable relation to the US dollar. The breakdown of this monetary system and the first oil price shock of 1974 brought to an end these exceptionally favorable circumstances. From then on, the language of "crisis," stemming originally from Marxism, became common in discussions about the welfare state.

The extension of coverage and the creation of new insurances and services in the post war period not only were eased by rapid economic growth, but also profited from the Cold War. There was an overlapping consensus among left and right in Western Europe that in order to survive as an economic system, capitalism had at least to be tamed and, moreover, be restrained to the realm of market economy. People's life chances should no longer be dependent entirely on market forces but should rely on public provision in the event of inability or impossibility of earning one's own living. There remained ample political dissension as to the extent of public protection, but no longer as to the principle of protection itself.

There was furthermore a certain naïve trust in the wholly beneficent character of social policies on the part of their champions. The egalitarian attitude that redistribution is good in itself was backed by Keynesianism, and the strong belief in the problem solving capacities of politics remained unbroken, not only on the left. Doubts about the sustainability of this scenario then came not only from economists, but

also from social scientists. Since the 1980s the deregulation of financial markets has made for intensifying international competition and the increasing bargaining power of capital.

Discourse about the crisis of the welfare state has many issues: crisis of financing, crisis of governability, crisis of legitimation, crisis of efficiency, and crisis of loyalty (cf. Offe 1984). Despite some evidence for particular deficiencies of existing arrangements of public welfare production, the basic idea of a self-enforcing crisis of the welfare state has so far proved to be wrong. There is ample evidence that in most European countries, the institutions of social protection and political responsibility for the basic welfare of all citizens meet sustained acceptance, despite growing economic difficulties.

The "welfare backlash" began with the governments of Margaret Thatcher and Ronald Reagan around 1980. Strong opposition to spending on welfare and social security did not spread throughout the industrialized world, though almost everywhere the tightening of public budgets, growing unemployment, and the perspective of rising demand due to demographic changes made for politics of welfare retrenchment. Empirical evidence shows that the political systems of various nations were coping quite differently with the challenges of unemployment, globalization, and demographic change (Scharpf & Schmidt 2000; Huber & Stephens 2001). By and large, the cutback movement was successful only in slowing down social expenditure, but did not destroy public responsibility for social welfare.

Substantial changes in priorities and methods of welfare provision did take place, however. A general trend is the change of emphasis from a "redistributive state" to an "enabling state" (Gilbert 2002). The class issue loses centrality, while other issues (e.g., regional and generational conflicts) gain in importance. The demographic perspective of aging and decline shifts emphasis from social security to education and family policies (Esping Andersen et al. 2002; Castles 2004). A tradeoff between high standards of labor protection and unemployment is emerging in some countries. Moreover, the focus is switching from state provision of welfare to a mixed system of public, non profit, and market provision ("welfare pluralism").

Though these shifts in emphasis are clearly against the established views of state and class centered welfare policies, it makes sense to preserve the term "welfare state" as long as political commitment to social rights for all and the power of the state with regard to the regulation of social services remain uncontested.

social problems, concept and perspectives

Axel Groenemeyer

“Social problems” have formed a specialized field within sociology, especially in the US, at least since the end of the nineteenth century.

The European context has always been marked by the concept of the “social question,” which was one of the principal sources for the development of sociology as a scientific discipline apart from philosophy, history, political science, and political economy. Unlike US sociology, in the European tradition the concept of social problems was not disseminated in the sociological literature until the end of the 1960s, when it appeared first in books and articles about social work. While the concept today is institutionalized in special sections of sociological associations and in some journals and textbooks, and its use has been spread in public and political discourse, European sociology has always privileged the concept of the social question, with greater emphasis on macrosociological reasoning and theory building. As a consequence, most of the literature using social problems as a theoretical concept is of US origin (Ritzer 2004; for handbooks in German and French, see Albrecht et al. 1999; Dorvil & Mayer 2001).

DEFINITIONS AND PERSPECTIVES OF SOCIAL PROBLEMS

The term social problem is used in public and political discussions and refers to very different social situations, conditions, and forms of behavior, like crime, racism, drug use, unemployment, poverty, exclusion, alcoholism, sexual abuse, and madness. However, especially in textbooks and journal articles, it also refers to premenstrual syndrome, ecological problems, stalking, exploitation of natural resources, traffic accidents, or even war, terrorism, and genocide. This diversity has been a challenge for sociological definitions and invites the question of identifying the feature that justifies classifying such phenomena under a common topic or theoretical perspective.

As a consequence, the scientific value of having the concept of social problem within sociology is contested, as it seems to be too vague and too broad to be useful for guiding the development of theories. Assessments such as those of Spector and Kitsuse (1987 [1977]) that “there is not and never has been a sociology of social problems” (p. 1) and of Best (2004) that the “social problem has not proved to be a

particularly useful concept for sociological analysis" (p. 15) could find some justification.

The sociological use of the concept of social problems is connected with at least five different perspectives, outlined below.

Textbook eclecticism of social problems. The vagueness of the term is reflected in sociological textbooks and journals on social problems that offer a nearly endless list of various topics. These articles are the product of a vast amount of specialized sociological research on social problems that very often form special fields within (but also apart from) sociology, for example criminology, public health, or the sociology of poverty. In this textbook context, the concept of social problems is used as an umbrella for a wide range of situations and forms of behavior reflecting the public and political meaning of what is problematic within society and what should be treated, ameliorated, or controlled. The problematic character of such phenomena is taken for granted. Definitions of social problems, at least implicitly, follow various kinds of formulations that refer to everything that is defined in public (or by a certain number of people) as social problems: "social problems are what people think they are." This meaning of social problems is closely linked to the production of applied knowledge for public policy.

Sociology of social problems as applied sociology. Since its origin in American reform oriented sociology at the beginning of the twentieth century and its connection to policy, the sociology of social problems is often treated as a field of applied sociology. This perspective is closely tied to the specialized fields of sociology, where the problematic character of social problems is the starting point for the production of knowledge about causes and forms of existing social evils and their social and political control. This is without doubt an important field of research within the sociology of social problems, but there is no common theoretical ground on which a theoretical concept of social problems could be justified. Nevertheless, social problems are the base for political programs, actions, and institutions evoking the fundamental problem of the relation between theory and policy and demanding a discussion of the role of values and normative theory within sociology.

Social problems as social harm and social disorganization. Whereas in these perspectives

the problematic character of social problems is taken for granted or defined by public opinion, there have always been attempts to define the object of the sociology of social problems on the basis of theoretical knowledge about the functioning of society. Social problems are those conditions and forms of behavior that undermine the functioning of important social institutions and cause harm to individuals and social groups. In this perspective – often labeled as "objectivist" – the common character of different social problems is seen in their common social structural sources, defined as social pathology, social disorganization, alienation and exploitation, unequal distribution of resources and power, or anomie. The discrepancy between cultural standards, norms, or values and the actual conditions of social life – Merton's (1976: 7) famous, quite formal definition of social problems – should be identified and analyzed by sociological inquiry, in principle without reference to "what people think" and as a "technical judgment" about the possibility of a better functioning social system.

Social problems as the social question. In the context of European sociology, the concept of social problems has never had a prominent place. Its use is very often limited to problems seen as associated with social inequality and social integration or inclusion. In the European tradition of the social question, social problems are those behaviors and conditions that should be treated by the welfare state through social policy and social work. Unlike the American perspective of social disorganization, the tradition of the analysis of social problems related to the social question privileged a perspective of conflicts rooted in the social structure of modern societies (cf. Castel 2002 [1995]). In this sense the term social problem in the singular was introduced into US sociology in the nineteenth century, but very soon changed its meaning in a plurality of unconnected "social problems."

Social problems as social constructions. While in these perspectives social problems are treated as special objects of sociological inquiry, a constructionist perspective of social problems insists that social problems are not necessarily rooted in harmful social conditions and that the only thing the various phenomena have in common is that they are labeled as social problems. Social problems exist only as cultural

definitions of public activities of grievances and claims (Spector & Kitsuse 1987 [1977]). Social conditions are dismissed as merely "putative," and sociological research focuses on the claims making activities through which social problems become public concerns and political issues. Whereas in sociological research on causes, careers, and control of social problems their problematic character is often taken for granted, the constructionist perspective makes this question its central concern. The sociology of social problems adopts a sociology of knowledge perspective to analyze the strategies and discourses used by collective actors to bring issues onto the public and political agenda. In this perspective, sociology and scientific knowledge in general no longer have special status; their role is reduced to that of one claims maker among others. As a consequence of this radical reformulation and change of paradigm, the "social problems approach" is identified no longer by its research objects but by its theoretical and methodological perspective.

THE EUROPEAN "SOCIAL QUESTION" AND AMERICAN "SOCIAL PROBLEMS"

The history of sociological reasoning has its starting point in the problematization of social conditions linked to the capitalist industrial revolution in Western Europe. In this context, social problems such as poverty, alcohol consumption, disease, and violence were seen as direct indicators of disorder of the social structure and crises of development. The central points of reference were social movements and ideas of social justice to assure national social inclusion and integration of modern societies. Social problems as social crises or social pathologies had been linked directly to questions of social inequality, and sociological reasoning of social problems formed a privileged way to uncover the central mechanisms of functioning and development of modern societies. These ideas are best expounded in the work of the founding fathers of sociology, Marx and Durkheim.

Nevertheless, the "social question" has always been a political question of social reform or social revolution, linked to the three

dominant ideological streams: liberalism, conservatism, and socialism. Based on ideas of social justice, social integration, and social inclusion, national and collective political projects of the welfare state emerged to solve the conflicts of disintegrating capitalist economies.

This European tradition of welfare state orientation still marks an important difference from American sociological reasoning on social problems. Unlike the European tradition, American sociology was not confronted in the same way with fundamental social movements and their ideological orientations. Existing social movements were short lived and concentrated more on single issues without problematizing the social structure as a whole. As a consequence, American sociology at the end of the nineteenth century adopted a reform oriented perspective on isolated social problems (in the plural) and ideas of applied sociology to produce knowledge for treating these problems against the background of pragmatic philosophy.

The adoption of the concept of social problem and its rapid dissemination in European sociology in the 1970s from the US social context reflects a social change after World War II, marked by a rapid and extensive expansion of the welfare state and social services. In this context of economic prosperity, remaining social problems were individualized as deviant behavior to be treated by social work. The social question seemed to be solved and the idea of social problems seemed to be more appropriate for developing specialized sociological and professional knowledge to guide political reforms and interventions.

On the one hand, cultural pluralization and the development of new social movements in the 1960s and 1970s could explain the popularity of cultural relativism expressed by radical constructivist and postmodern perspectives in Europe. On the other hand, processes of globalization and internationalization, economic crises, and the spread of new poverty and growing social inequality from the 1980s on, together with an expansion of migration processes, brought back questions of social integration and exclusion to the sociological research agenda and strengthened the idea of a "new social question" as new challenges for the welfare state (Bourdieu 1993; Castel 2002 [1995]).

THEORETICAL ISSUES

Despite marked differences between the sociological traditions of understanding social problems, there are common theoretical and conceptual perspectives and problems (for an overview, see Rubington & Weinberg 1995). While typologies of theoretical positions are arbitrary and misleading, very often there can be found a differentiation between “objective” or “realist” approaches and “constructionist” perspectives. These labels are misleading because, on the one hand, they involve the danger of misinterpreting constructions of social problems as not being real social problems, and, on the other hand, they lead to the misinterpretation of “objectivist” approaches in assuming that there is still a methodological position of naïve objectivism in sociology.

Social Problems as Social Harm and Social Disorder

An early version of describing social problems as harm and social disorder is *social pathology*. This perspective, still very common in political and popular discourse, is based on the idea of society as an organism. Social problems are indicators of a pathological state of society and/or are caused by pathological individuals. This idea found its roots in nineteenth century sociology, where the success of medical treatment and hygiene formed the model for sociology as a medical profession of society. In this analogy, social problems are seen as deviance from a normal and healthily functioning society, in which there is harmonious coordination between specialized subsystems. The identification of social problems is not a problem, because the criteria underlying society as a well functioning organism are seen as evident and based on common sense normative and moral ideas (fundamentally criticized as a backward conservatism by Mills 1943). However, the central arguments against the idea of social pathology are that values and norms in society are changing and have to be different for different groups in differentiated societies. Beyond this it is clear that many social conditions that mark “social health” in one field of society automatically cause harm to other fields, which also means that the pathological

functioning of one sector has to be analyzed as the condition for the healthy functioning of another sector (Rosenquist 1995).

Nevertheless, the sociology of social problems is always confronted by the question of how to analyze values and norms that inevitably form the base for constructing and identifying social problems in public as well as in sociology. Inasmuch as the sociology of social problems takes existing definitions from public and political definitions of social harm as its starting point, it runs the risk of being normative. In a vast proportion of research in special fields of the sociology of social problems, the problematic character of the issue in this sense is taken for granted. This position very often corresponds with a perspective of applied sociology, where the problematic character of the issue has to be the starting point from which to develop and analyze political programs and interventions of social control.

A similar critique confronts the perspective of *social disorganization*, which was developed in the context of the Chicago School for analyzing deviant behavior and its spatial distribution in cities. Social problems are seen as indicators of, or as a result of, a breakdown of rules and social control in poor neighborhoods, caused mainly by processes of migration and rapid social change. Beyond criticisms of its normative base, the social disorganization perspective has been criticized for failing to specify the difference between deviance and social disorganization. Very often deviance is not a sign of disorganized neighborhoods or of a breakdown of norms and social control but is a result of a *cultural conflict* between local subcultures and the values of a majority society able to define common norms and values for the whole society. Within this perspective also, the problem of separating “normal” or even necessary and disorganizing social change is not solved.

The general form of argumentation with social disorganization also forms the base for the concept of anomie, developed by Durkheim (1902 [1893]). Here the disintegrating consequences of division of work and social differentiation in the processes of modernization result in “pathological” consequences, indicated by an extraordinarily high level of crime or suicides in modern societies. These perspectives of social disorganization and anomie experienced

a renaissance after the 1980s in European sociology, especially for analyzing conflicts and social problems in relation to processes of migration and growing social inequality.

With the supremacy of *structural functionalism*, the idea of anomic developments became one of the leading sociological perspectives on social problems in US sociology in the 1950s and 1960s. Social problems are seen as functional disturbances of social systems and as a problem of social disintegration. The functioning of social systems and their stable reproduction became the central point of reference for identifying social problems. In Merton's (1971, 1976) classic formulation of this program, this identification is seen as a "technical" analysis of the possibility of a better functioning of a social system and not one of a political or normative judgment. In principle, social problems could be identified by sociological research without depending on their public or political definitions. This allows criticisms of existing public definitions of issues and claims as being ideological misconceptions of what in effect does not result in social harm, or diagnosing social developments as resulting in "latent social problems" not yet defined as social problems in public. The separation of problematic social conditions and of publicly recognized social problems thus defines, in principle, a critical program for a sociology of social problems, even if the idea of a "technical judgment" of social dysfunctions seems to present a perspective oriented by an organic view of a normally harmonious and well functioning society already criticized in the approach of social pathology.

The differentiation of social problems as "social disorganization" and "deviant behavior" as different types of social problems has been developed in this context (Merton 1976). Social disorganization refers to the malfunctioning of the internal organization of a social system in providing stable role orientations, statuses, rules, and valid norms for the participant actors; it refers to the diagnosis of an absence or a breakdown of norms, whereas deviant behavior depends on the existence of a stable and accepted system of social norms and of actors motivated to obey them (Cohen 1959).

In the functional perspective, social disorganization is a consequence of rapid social change caused by technological, demographic,

or cultural change to which some social systems react more easily than others. It could be interpreted as a cause of deviant behavior if a state of normlessness, contradictory, or conflicting expectations in a social system results in strain for individuals. But deviant behavior could also lead to social disorganization if mechanisms of social control and exclusion fail to reestablish social order. Very often social contexts described as disorganized have developed subcultural systems of values and norms that provide members with stable orientations, but are interpreted as deviant in relation to the social environment and the dominant system of values and norms in the society. In these cases, social systems could not be interpreted as disorganized; in a functional perspective, they could be described as disintegrated since subcultural social systems result in dysfunctional conflict for the system as a whole.

This concept seems to be too vague since it has not been able to provide "technical" criteria for the healthy functioning of a social system without reference to values, interests, and power apart from the absence of conflict, faulty socialization, and deviant behavior. As a consequence, this perspective has been criticized for failing to provide criteria to judge conflicts in pluralistic societies as disorganizing or as leading to necessary social change. The idea of social disorganization follows a utopian view of a society in harmonious balance. Implicit in this view is the misconception of social problems as being conditions that could and should be solved. Obviously, societies survive quite well even if they leave unsolved their major social problems, and typically the treatment or solution of one social problem means the creation of social problems in other fields of modern societies. Beyond this, Durkheim is known for his functional argumentation of social problems. Social problems and deviant behavior fulfill important functions for societies inasmuch as they provide sources of solidarity, mark limits of morality, symbolize examples of misconduct, or indicate necessary social change.

Whereas in perspectives based on the diagnostic of social harm the difference between social disorganization and deviant behavior is often interpreted as a difference between "structurally" and "behaviorally" caused social problems, it seems appropriate to interpret them as

different kinds of social problem definition. For example, unemployment could be defined as a social problem related to the malfunctioning of the labor market, but it is also very widely seen as the malfunctioning of individuals who are either unwilling or unable to integrate into the labor market.

One central problem in the definition of social problems proposed by Merton is the identification of a “substantial discrepancy between widely shared social standards and actual conditions” (Merton 1971: 799). Even if Merton insists on identifying social problems on the basis of a “technical judgment” about the functioning of social systems, the identification of “social standards” and the diagnostic of a “substantial discrepancy” are finally based on the empirical registration of public opinion (Manis 1974). This could result in the problematic consequence of being unable to identify a social problem sociologically, for instance, if racial discrimination is found in a racist society, since in this case there is no “substantial discrepancy” between the shared racist standards and the actual racist conditions. We face the problem of having no standard beyond empirically measured public opinion to decide whether shared values in society are in fact ideological manifestations. This problem could only be resolved by stating the validity of a system of values – for instance, human rights – independently of publicly (and politically) shared social standards (Manis 1974). On this basis, the identification of “latent social problems” and the sociological critique of existing definitions of social problems remain important questions for the sociology of social problems.

This approach loses much of its power of persuasion when we ask why certain social harms or discriminations last over a long period without being identified as social problems by the public, or why definitions or interpretations of social problems change over time even if the social conditions remain nearly unchanged. Beyond this, the guidance of public interpretations of and attention to social problems fulfills important political functions and could be used as a means of achieving success in elections or to attract resources for public agencies or professional institutions. In this sense, social problems do not always have their origins in

social developments but are rooted in political strategies of symbolic policy (Edelman 1977).

Social Problems as Social Construction

The “cultural turn” in sociology of the 1970s was caused at least partly by the adoption of ideas of symbolic interactionism and other microsociological approaches as criticisms of structural functionalism. This first happened in the field of sociology of deviance and social problems in the 1960s with the development of perspectives insisting on the idea that deviance and social problems in general are not qualities of social conditions or specific forms of behavior, but instead have to be analyzed as results of interactive processes of social definition and labeling. This idea was then radicalized in constructionist approaches based on the idea that social problems exist only as public “activities of individuals or groups making assertions of grievances and claims with respect to some putative conditions” (Spector & Kitsuse 1987 [1977]: 75). This has been a radical reformulation of the problem of defining and analyzing social problems.

Whereas sociological perspectives that define and analyze social problems as social harm insist on the fact that social structures and developments could result in problematic life conditions and behavior, for constructionist perspectives these social conditions are merely “putative” and a more or less rhetorical means of “claims making activities”: social problems are constructions that successfully attract public and political attention. As a consequence, the main questions to be analyzed are no longer about causes and social conditions that might explain the existence and affection of specific groups, but concern the processes of how social problems are successful in attracting public attention and become public issues with a special quality.

The approaches that follow ideas of social structure and social change as analytical bases for defining social problems – now labeled as “objectivist” – always had to face the problem of justifying a general concept of social problems that could unify very different social phenomena. With the new formulation of

constructionist perspectives, this problem was solved in that different phenomena labeled as social problems could analytically be unified under the common question of what (and who) made them problematic and how they became public issues. The sociology of social problems consists in the reconstruction of activities and processes that explain the public mobilization for specific definitions of issues and themes within society and the establishment of social problem discourses. Social problems are specific forms of collective behavior which explain the significance given to the analysis of media representations, moral entrepreneurs, and social movements.

Whereas in so called "objective" approaches scientific, especially sociological, knowledge has given an outstanding position to the analysis of social problems and their developments, in constructionist approaches this role is limited to that of one "claims maker" among others. Constructionist perspectives insist that the role of sociology cannot be seen as criticizing existing constructions and their forms of public definition. Its role is reduced to that of a reconstruction of the processes by which such constructions became convincing for the public, and not to analyze their structural and social historical bases. In its radical form, this approach is limited to the analysis of rhetoric and counter rhetoric on public issues.

Today, especially in the US context, the sociology of social problems is identified with the constructionist perspective, and a vast amount of social problem research is devoted to case studies of many different issues that at one time or another attracted public attention (see, e.g., Best 1989, 2001; Loseke & Best 2003). But, while it is very often identified as the only valuable perspective and forms the mainstream of social problem analysis, the constructionist perspective has its critics.

The most important criticisms from within constructionism have been developed by Woolgar and Pawluch (1985). In reconstructing constructionist case studies on social problems, they argue that the underlying argumentation of these analyses is marked by a contradictory use of the perspective of social construction. In framing their question, these case studies assume that the social conditions or the behavior

in question remained more or less unchanged, while the social constructions of the problem in public have been changed. On the one hand they insist on the idea that social problems are social constructions, while on the other they base their argumentation on some "true" social conditions, what Woolgar and Pawluch criticize as "ontological gerrymandering."

Since then constructionist approaches have become highly differentiated (Holstein & Miller 2003; Loseke & Best 2003), but at the same time the idea of constructivism has become less clear and is very often reduced to the perspective that social problems are the result of the active behavior of interested groups and collective actors, who define and produce certain issues in a specific form. This is nowadays common sense within sociology; the main point of discussion is whether these "productions" are based on cultural and social resources that are rooted in social structures and embedded in social change in modern societies. But even if social problems are social constructions – as actually all objects of sociological research are – they are no less real in their consequences and effects; it makes no sense to talk about social problems as social constructions in opposition to "real" social problems. In this sense, the opposition of "objectivist" and "constructivist" approaches within the sociology of social problems is misleading, as it assumes that "objectivist" approaches are not able to analyze social problems as processes of cultural production.

As a reaction to the sociological hegemony of structural functionalism in the 1950s and 1960s, the constructionist perspective has been developed on the microsociological grounds of symbolic interactionism, ethnomethodology, and phenomenology. The European tradition of the social question as sociopolitical and macro sociological projects concerning social conditions and processes of social integration and social inclusion seems to have been completely dismissed from the American sociology of social problems.

Axel Groenemeyer

SOCIAL PROBLEMS AND THE POLITICAL SYSTEM

In the sociology of social problems, surprisingly little attention has been paid to the state and the political system. Given the central importance of social problems as public issues and claims for political action and public policy, and their role in shaping social and political change, this neglect seems all the more surprising. Especially in newer US versions of constructing social problems – very often seen as the only valuable sociological perspective on social problems – they have been defined either as “claims making activities” of collective social actors (Spector & Kitsuse 1987 [1977]) or as public discourses and rhetoric narratives (Ibarra & Kitsuse 1993). If the struggle for social problems were merely cognitive and symbolic, then the conflicts about their definition would have to be understood only as a system of contested narratives that result in new narratives. In these perspectives, references to power and conflict and to the political functioning of public issues and collective

actors have attracted only little attention. But if the construction of social problems is based in the interests and values of collective actors, we have to ask how the struggle for public attention relates to the distribution of material, political, and symbolic resources. In this perspective, already the social construction of social problems by collective actors in society has to be analyzed as a social conflict, and in this sense as a fundamental political issue.

Not only in Western European democratic welfare states but also in all modern societies with a state centered political system in general, the state has the legitimate monopoly on the means of violence and is the main target of "claims making activities." Even if the treatment or claims of solutions for social problems sometimes are addressed to public associations or by private enterprises, the political system and the state are the ultimate arbiters of allocating valued goods and resources. The political system and the state are constituted by a system of organizations and institutions that shape public issues and social problems by providing opportunities for claims, by selecting and establishing administrative categories as quasi official definitions of social problems, and by giving them the cultural power or by actively producing and promoting some definitions of social problems for political means and according to criteria of political strategies. In this sense, the political system is not only the more or less passive target of social claims and protest or the neutral arbiter of conflicting social groups within society, but is also a central, powerfully organized actor in the process of production and construction of social problems.

In modern societies, state activities and interventions accompany citizens throughout life, and from birth to death their lives are regulated and controlled by the state to an extent unknown in preceding epochs of social development, which allows us to speak of modern societies as politically framed and regulated societies. Despite processes of globalization and internationalization, nation states and nationally organized political systems are still the main actors integrating societies with the claim of legitimate monopoly on the means of violence over a specified territory based on a unified system of laws and on the monopoly of taxation, which ensures the ability to make and enforce

binding decisions over citizens and social groups in the society.

This minimal definition of the state – classically developed by Max Weber (1972 [1922]) – refers to the state function of ensuring security of social and economic exchange. Ensuring social order could thus be seen as the fundamental purpose of states. If this function is not effectively fulfilled, states dissolve, as many examples of societies in civil wars show. In this context, the idea of security and of claims concerning security and safety became a central topic of claims making activities.

However, the ideas of what should be the objective of states always have been highly contested. Whereas in liberal political discourses of the nineteenth century only the task of providing public safety and security of the law to ensure economic exchange was an accepted guideline for state activities, the idea of social security was developed, especially in Western European democracies, as an institutionalized and accepted state idea in the twentieth century. Very often nowadays these fundamental state functions are supplemented by the task of preserving natural resources and international obligations.

The ideas of the state constitute a political regime, institutionalized and organized within a nation specific political system of representation, including established political parties, interest groups, and associations as well as social institutions and local organizations, with institutionalized access to centers of political decision making. These qualifications of the state and the political system provide a cultural and political frame of reference for addressing specific social problems to the political system; the national traditions of state ideas, organized in nation specific institutions, constitute a political opportunity structure for claims making activities. The analysis of these processes demands a comparative perspective on social problems (Kitschelt 1986; Kriesi et al. 1992; Jenkins & Klandermans 1995).

In a classical liberal political perspective, social problems are interpreted as "inputs" for the political system, which raises the question of influence and power of social actors to promote specific definitions of social problems and to make them political issues. The success of establishing a specific definition of social problems or

claims in this perspective depends on the capacity of mobilizing power and influence by social actors. The social issues and claims then are accepted, rejected, canalized, or redefined by specific mechanisms of selection and filters of the organizations within the political system. In this perspective, the success of claims making activities depends on the system and forms of the organizations of the political system itself (Dunleavy & O'Leary 1987; Parsons 1995). System theoretic approaches especially have radicalized this view in insisting that the political system constitutes an autonomous self referential system with one set of rules, criteria, and rationalities that directly could not be influenced from outside. The classic model of social problems as "inputs" of the political system is supplemented or substituted by the idea of "withinputs," i.e., social problems may be discussed as social issues in public, but the organizations of the political system construct and produce them according to their own political rationalities, which are not directly linked to public definitions of the social problems and most of the time are completely different from what has been claimed by collective actors in society previously.

This perspective gives way to the idea that the organizations of the political system not only are passive receivers of social inputs from the society, but also are actively engaged in producing and constructing public issues and social problems according to the criteria of the system, like election strategies, gaining public support in interorganizational or party concurrence or accumulation of resources by presenting specific problem solving capacities. In this sense, social problems are not only "inputs" or "withinputs" of the political system, but are "outputs" as well. Besides this, political interventions in social problems and their institutionalization not only produce official definitions of social problems, but also give rise to often unintended consequences for other systems and social groups as well as new social problems and opportunities for mobilization for claims in other areas. After all, it is important to notice that these consequences also appear when the politics of social problems are not directly addressed toward solving or at least treating social problems but merely follow a strategy of "symbolic politics" involving mobilizing

internal resources or political support from outside the political system.

Political theories that analyze the processes of "input" formations by social influence and power as well as the structure of the political system as "political opportunity structure" are treated at length elsewhere, so this entry will be limited to factors and explanations that are specific to the politics of social problems (see also Groenemeyer 1999; Blackman 2004).

FORMS OF CLAIMS AS POLITICAL ISSUES

The structure of the political system and its organizations influences the opportunity for collective actors in society to find support for social problems and public claims within the political system. Even if a public claim is accepted as a political issue, the political arena in which it is placed is important, as are the political actors and the strategy by which it is placed (Hilgartner & Bosk 1988). Becoming a political issue also means that the way in which the social problem has been constructed concerning its causes and effects – the "diagnostic frame" – as well as its solutions – the "prognostic frame" – are in some way compatible with the rationalities and interests of at least some organizations of the political system (Benford & Snow 2000).

There have been some attempts to develop typologies of claims and empirical hypotheses to treat these questions. One approach refers to the distributions of costs and utilities of public claims (Wilson 1973). Claims that benefit only a small group while their costs affect larger groups probably have less chance of being treated by the political system. This is one reason for the fact that collective actors are obliged to construct social problems in such a way that a significant number of people, or indeed the whole population, are affected by them.

Another classical approach developed by Lowi (1972) differentiated among "distributive policy issues," which refers to issues that demand the distribution of new resources, "redistributive policy issues" that demand a new distribution of limited resources, "regulatory policy issues" referring to claims without any distribution of resources, and "constituent

policy resources," for which new political institutions must be established or already established institutions have to be reorganized. Each policy claim that, for example, affects an established distribution of limited resources could increase the level of conflicts with other social or political actors, whereas regulatory policies or interventions without direct distribution of resources are very often open for symbolic politics.

Another set of hypotheses, first proposed by Cobb and Elder (1972), concerns the process of political agenda building and the quality of claims: the higher the degree of specificity of an issue, its scope of social significance and its temporal relevance, and the lower its degree of complexity and the less it corresponds with preceding issues (categorical precedence), the higher is its chance of being accepted as a political issue within the political system.

However, these typologies are less clear when confronted with empirical cases of political issues and social problems. The specific form of the "diagnostic frame" of a social problem, and whether this suggests a "distributive" or a "redistributive" policy, is not a quality of the issue itself but the object of conflict about its meaning. In this sense, the form or quality of a public issue or social problem is itself the consequence of conflicts in the process of social and political constructions by the institutions of the political system.

The public construction of a social problem could intersect with other public issues resulting in a kind of concurrence on the scarce goods of public and political attention. Processes and strategies of mobilization for specific issues thus can also actively be used by political organizations to reduce the potential for conflict of other issues to ensure the capacities of the political system against public claims (Hilgartner & Bosk 1988). Besides this, it is also possible that some issues are linked together under a main topic to increase the possibility of public and political mobilization. But in general, the possibility of gaining public and political attention has to be seen as a fragile public good that has to be used with caution to avoid a "problematizing overdose."

These typologies and hypotheses are just some examples of what the sociology of social problems has to address concerning the agenda

building of social problems in the political system. Currently, there seems to be no theory unifying this knowledge from different subfields of sociology, such as political sociology, the sociology of social movements, or the sociology of agenda setting by the media.

Whereas in these approaches the central questions are based on the idea of political opportunity structures provided or blocked for public issues and social problems by the structure of the political system, the organizations of the state and the political system also play an important role in actively constructing social problems, independently of claims making activities within society. It is important to separate the processes of gaining attention and support for claims being constructed outside the political system from those processes of constructing social problems by the political system.

THE POLITICAL USE OF SOCIAL PROBLEMS

Whereas in modern societies with a welfare state the political program of coping with social problems seems to be institutionalized, at the same time, the extent of social problems seems to increase. Obviously, the majority of the most pressing social problems in modern societies are not solved without bringing the social and political order into a dangerous instability. This is not only a problem of the political system's regulating capacities but is also a central characteristic of pluralized modern societies. Very often, one solution for a social problem leads to other social problems and conflicts in other areas, or the institutionalization of one solution leads to increased political opportunities for new mobilizations and discourses on new problematic issues. Obviously for the political system, social problems fulfill other purposes than being solved, and political programs and intervention could fulfill other functions than those formulated in political discourses about social problems.

Modern societies and their political systems have developed a remarkable potential for survival and stability, despite the amount of unsolved problems, conflicts, and crises. If conflicts and social problems in modern societies normally are highly interconnected and

collective actors are highly organized, then one would have to question the mechanisms of the political system to handle these claims without losing its own organizational capacities of action. As regards public claims and conflict, the political system in modern societies has normally developed a flexibility that also allows it to handle conflicts and claims strategically (Nedelmann 1986).

The acceptance of a specific definition of a social problem and its institutionalization not only means the success of public mobilization, it also constitutes resources for further conflicts about social definitions and constructions of issues. In this perspective, the success of political programs and interventions with regard to solving social problems directly very often seems to be of secondary importance. Especially in times of limited resources for social problem solving, and with regard to a constant overload of public claims, symbolic and rhetorical forms of political discourse assume central importance in the political system for ensuring its autonomy and its own capacities for action.

Starting from the assumption that the construction of social problems is always embedded in changing "cultural frames" (Tarrow 1998; Groenemeyer 2001) that give meaning to public claims, then regulating meanings and interpretive frames is one possibility for the organization of the political system to react to public claims. In this sense, the cultural base and definitions of social problems could become the object of strategic politics, and the political restructuring and manipulation of the cultural and moral milieu of social problem constructions could ensure the regulation of social conflicts. This cultural control of public claims could follow different strategies: manipulating the knowledge base of problem constructions so that alternative ideas and interpretations relating to the public claim are publicly disseminated; altering the affective loading of social problem constructions by increasing the complexity of issues and placing them within a scientific or professional agenda, which allows the reframing of morally loaded issues into technical ones; depoliticization of a social problem by denying its putative negative consequences; strategic mobilization of specific moral social contexts in order to mediate potential conflicts through reputable social institutions (e.g., religion or the courts). Support of

countermovements allows political organizations to weaken public support for a social problem and to become arbitrator in a social conflict. Publicly denying the reputation of claims makers and their putative representatives also weakens public support for social problems; this could also be achieved by reframing a public claim into a private issue affecting specific interest groups. Sometimes it is also possible to decrease the public visibility of social problems to impede public mobilization.

The rhetoric and symbolic construction of politics refers to the manipulation of symbols signaling that something is done about the social problem: "words that succeed and policies that fail" (Edelman 1977; see also Gusfield & Michalowicz 1984). This does not mean that a definition of social problems and policies is possible without reference to symbols and specific cultural constructions, but these constructions are always the object of a cultural conflict before the background of specific interests, values, and strategic considerations, and the organizations of the political system and the state are at the forefront of this struggle with their own criteria and rationalities. The aim of sociological analyses always has to be the critical disentanglement of the involvement of specific interests and values in this political process of constructing social problems.

Whereas in this perspective interactions between collective actors in society and the organizations of the political system in gaining and preventing access to political decisions are at the center of sociological analyses, it is also important to mention the role of political organizations and the state in actively constructing social problems for their own purposes. The political acceptance of and support for specific constructions of social problems is not always the result of pressure from below. Very often it is the state, and not collective actors in societies, that plays the central role in promoting mobilizations and moralizations of social problems. Even in other policy areas, the integration of political organizations with collective social actors and professional associations in society has reached an extent where it becomes difficult to disentangle who is the central actor in constructing specific social problems.

Institutionalized arrangements and law based procedures of the state not only present legal

rules and patterns of resource distribution for social claims on social problems but also participate in creating a symbolic order and a system of reference for social constructions of social problems. The central aspect in this realm is the political construction of legal and administrative categories that entitle specific social groups to claims according to administrative and official definitions of the problem, or that allow the use of state power to control them. These administrative categories, i.e., of the penal law or of social benefits, create their own social reality, whose character as a consequence of a struggle over meaning and definition has been become invisible. Nevertheless, they also constitute an important and powerful cultural and social frame of reference for standards of normality and reasonableness relating to alternative social constructions of the social problem. In this sense, the sociology of social problems always has to be a historical and sociological analysis of the politics of social problems and their social control.

social psychology

Anne F. Eisenberg

Social psychology is an approach to understanding human social relations that focuses on individuals and how their interactions impact social organizations and social institutions. Social psychological scholarship includes a wide range of theoretical perspectives, methodological tools, and substantive applications originating from diverse intellectual schools such as sociology, psychology, economics, education, and business. Contemporary social psychology is best understood by examining its range of theoretical perspectives, methodological tools, and substantive foci.

THEORETICAL PERSPECTIVES AND THEORETICAL IDEAS

The breadth and range of theoretical ideas in contemporary social psychology reflects the diverse intellectual origins of the various perspectives and approaches. Early discussions of social psychology focused on these distinctive intellectual origins by highlighting the differences between psychological and sociological social psychology. This representation of the field has been critiqued for its perpetuation of artificial boundaries that overlook significant connections between the shared subject matter of sociology and psychology. In 1980 Sheldon Stryker articulated three “faces” of social psychology: psychological social psychology, sociological social psychology, and symbolic interactionism. While each perspective represents unique theoretical ideas, they also inform one another and serve to create a comprehensive understanding of individual interactions and how they impact on the groups to which we belong as well as the environments in which group interactions occur. All three perspectives share a focus on the individual and individual interactions as the explanatory factor for all aspects of social life, such as the creation of stable group structures and the formation of successful social movements. The three theoretical perspectives in social psychology, known more generally as cognitive and intrapersonal, symbolic interactionist,

and structural, each represent different origins and intellectual affiliations and maintain a focus on different aspects of the individual and society.

Cognitive and Intrapersonal Social Psychology

Cognitive and intrapersonal social psychology originated with the work of experimental psychologists in Germany such as Wilhelm Wundt in the mid nineteenth century and focuses on understanding how internal processes affect an individual’s ability to interact with others. The internal processes most studied in this perspective are cognitive (memory, perception, and decision making) and physiological (chemical and neural activity). Each approach examines a different aspect of how interactions are affected by these internal processes. The underlying basis of the cognitive and intrapersonal approach centers on how individuals store information in the brain in the form of schemas. Schemas represent the way in which people identify objects in their environment by labeling them, which then allows the objects to be categorized. The use of schemas allows individuals to process billions of bits of information from the environment, which then enables them to easily engage in interactions. The more accurate individuals’ understanding of any given social situation, as determined by how well they label and categorize it based on information from the environment, the more successful and easy will be the interaction. The cognitive and physiological approaches in this perspective explore different aspects of the impact of schemas on interactions.

The cognitive approach examines how brain activity specifically associated with memory, perception, and decision making processes affects an individual’s ability to understand the information necessary for engaging in successful interactions. Additionally, this approach also explores how variations in cognitive processes lead to differences in individuals’ ability to interact. The study of memory examines how people categorize events, situations, and others they have encountered previously, helping researchers understand the type of schema constructed and used in particular groups, cultures, and settings. Studying memory allows

researchers to directly explore the connection between interactions and how they are labeled. Take as an example a person entering a room and observing two people interacting with each other. If she labels and categorizes the interaction as a romantic interlude between lovers, she is less likely to interrupt than if the interaction is labeled and categorized as a conversation between co workers. Further, if the person entering the room identifies and labels one of the actors as a close friend, her interactions with the two people will be different than if they were simply co workers. Theoretical ideas associated with understanding schemas and memory include stereotypes (the actual categories used in labeling people and situations) and self fulfilling prophecy (where we act in such a manner as to confirm our initial impressions of people). In studying perception, researchers are interested in exploring how people's interpretation of information from the environment affects their interactions with others. The study of perception examines the meanings individuals associate with the categories in which events, situations, and people are placed. Key theoretical ideas associated with this approach to studying interactions from a cognitive social psychological perspective include the attributions people make when judging others' actions and the outcomes of those actions, and the errors in the attributions people make. Finally, decision making research explores how schemas, memories, and perceptions contribute to the ways in which people make decisions ranging from what to wear in the morning to the level of risk they are willing to take in any situation. The decisions made directly impact whether or not an individual is willing to interact with one person as opposed to another, as well as the quality of the interactions that do occur.

While the cognitive approach examines those internal processes that impact on whether or not an interaction will occur as well as the quality of the interaction once it does occur, the physiological approach explores the ways that specific biological and chemical processes affect individuals' ability to create adequate and useful schemas, use their memory, perceive things accurately, and then make relevant decisions. The physiological approach in the cognitive and intrapersonal perspective is not normally

included in discussions about social psychology, as at first glance its theoretical focus does not directly relate to social interactions. However, recent developments in this approach link it much more closely with the cognitive approach, thereby warranting its inclusion in this discussion. Cognitive and behavioral psychologists, along with neuroscientists, have conducted what are called "animal studies" for over 100 years. The goal of such research is to more accurately explain how particular chemical and biological processes directly impact on cognitive functioning. Technology is now allowing physiologically based researchers in psychology, neuroscience, and sociology to measure and examine the relationship between these chemical and biological processes and associated actions and interactions in humans. Early research in this area focused on non human species due to the ethical issues associated with human experimentation. Newer technologies, such as the portable electroencephalogram (EEG) and the functional magnetic resonance imager (fMRI), allow researchers to study neural and chemical responses to individuals' actions and interactions. The implication is that such technologies will allow social psychologists to more accurately and directly measure social interaction.

Symbolic Interactionism

Symbolic interactionism originated from the work of George Herbert Mead and his students at the University of Chicago as well as the work of pragmatic philosophers. While Mead was formally associated with the psychology and philosophy departments at the University of Chicago, his classes on social psychology and social philosophy attracted a large number of students from the fledgling sociology department. One of the sociology students, Herbert Blumer, coined the term symbolic interactionism and other sociology students were instrumental in publishing Mead's ideas, after his death, concerning the individual. These ideas center on his discussions of the mind (what makes humans uniquely social creatures), self (how we become uniquely social creatures), and society (how our interactions are affected by social institutions). Mead wrote extensively about issues concerning more macro level social

phenomena such as the role of government in funding education and the role of education for socialization, but he is mainly recognized for his contributions to symbolic interactionism. Generally, the symbolic interactionist perspective in social psychology focuses on studying the meanings that underlie social interactions in terms of how they are created, how they are maintained, and how we learn to understand such meanings. Additionally, theorists writing within this perspective argue that individual interactions lead to the creation of formal social organizations and social institutions. Therefore, to understand society, it is necessary to understand the interactions that shape it and maintain it. There are three main theoretical approaches in the symbolic interactionist perspective, symbolic interactionism, phenomenological, and life course, each of which examines different aspects of these meanings and the self on which they are derived.

The symbolic interactionism approach is most closely related to Mead's original ideas concerning social psychology and focuses on exploring how meanings are created and maintained within social interactions with the self as the basis for such interactions. The underlying theme of this approach is that individuals create and manage meanings through the roles and identities they hold. It is important to note that each individual holds any number of roles and identities, depending on the people with whom they interact as well as the environment in which they find themselves. Classical symbolic interactionist studies include the work of Herbert Blumer, Charles Horton Cooley, and Manford Kuhn. Blumer elaborated on Mead's discussion of the social self examining itself as an object outside the individual, while Cooley focused on explaining the process in which the self recognizes itself as an object. Kuhn's discussions explored different dimensions of the self as a way of explaining individuals' ability to take on a variety of identities, depending on the situation and the other actors involved. Contemporary developments of these ideas are found in the work of Erving Goffman, Peter Burke, Sheldon Stryker, and their associates and students. Goffman's discussion of dramaturgy and the presentation of self, among other ideas, examined the ways in which individuals identified the role held in any particular

interaction and the expectations associated with that role. Stryker and others explored how roles are linked to individuals' identity and how meaningful these identities are to people. Burke and associates proposed a more formal theoretical explanation of how different parts of the self are associated with specific identities people hold.

The phenomenological approach originated from European sociology and philosophy, emphasizing the meanings themselves and how such meanings reflect unstated normative expectations for interactions. The underlying theme of this approach is that language, verbal and non verbal, represents the informal and formal rules and norms that guide social interactions and structure society. The early work in phenomenology, as represented by the ideas of Alfred Schutz and Harold Garfinkel, differentiated between different aspects of how people create social reality as well as operate within already existing social reality. Schutz examined how language and communication represented an intersubjective process of reality creation and maintenance, while Garfinkel explored how people managed reality through the development of ethnomethodology. Contemporary developments of phenomenology are found in the work of theorists such as Howard Becker, Peter Berger, and Douglas Maynard. Through a series of studies, Becker explored the way individuals' interpretations of social interactions and social experiences reflect their own experiences and unspoken norms for behavior. Berger, along with Thomas Luckmann, is considered the American introduction to Schutz's ideas and phenomenology. Equally important, Berger and Luckmann also clearly demonstrated how everyday interactions and language create seemingly formidable social institutions and organizations. Finally, Maynard further developed ethnomethodology by focusing on conversation analysis as a way of understanding how social talk creates and represents reality.

The life course approach in symbolic interactionism focuses on how humans learn the meanings associated with interactions throughout their lifetime and the stages that reflect such learning processes. The underlying theme of this approach is that the norms, rules, and values that guide interactions and shape society change throughout individuals' lives, especially

as they move into different social positions and environments. As a relatively newer approach in the symbolic interactionist perspective in terms of identifying as a unique approach, the key ideas can be traced to Mead's discussion about socialization and Georg Simmel's ideas about interactions within and between groups. Mead explained how humans become uniquely social creatures in his lectures about the self, where he describes a three stage process (preparatory, play, and game) for humans to learn the norms, rules, and values of the group into which they are born. He argued that by the end of this process, people will have a fully developed self. Simmel's discussions concerning interactions and groups examined how individuals' interactions with one another changed as group size, group composition, and social environment changed. Contemporary theorists such as Glenn Elder, Roberta Simmons, and Dale Dannefer, and their students and colleagues, build on these ideas in similar ways. First, the contemporary approaches assume that socialization is a lifelong process that changes as individuals change. Second, theorists in the approach examine both individual level factors and societal factors that contribute to the socialization process. Elder has focused on how socialization is consistent across cohorts of people, varying only in qualitative aspects related to differences in environments and resources. Simmons has examined how the socialization process itself varies depending on individuals' stage in life, and Dannefer has explored the ways in which groups with which people are associated play an important role in their continuing socialization throughout life.

Structural Social Psychology

Structural social psychology originated with the work of economists, psychologists, and sociologists interested in explaining social interactions more formally and mathematically with the goal of creating testable hypotheses. Structural social psychology assumes that social actors are driven by rational concerns centered on maximizing rewards and minimizing punishments. Another related assumption is that interactions based on rational calculations result in formally structured individual, group, and institutional

interactions. This approach is related to cognitive and intrapersonal social psychology in the focus on developing formal theories to explain interactions and creating specific hypotheses for testing in experimental situations. More contemporary work in structural social psychology uses more diverse methods such as survey research and participant observation techniques. There are three main theoretical programs that represent this approach: power, exchange, and bargaining studies; social influence and authority studies; and status characteristics, expectation states theory, and social network studies. Each set of studies focuses on different aspects of describing and explaining the underlying structure of social interactions.

Power, exchange, and bargaining studies explore how social interactions can be described as exchanges between social actors with the assumption that individuals rationally calculate the costs and benefits associated with any particular interaction. Exchange studies began with the work of George Homans, Richard Emerson, and Peter Blau. Homans argued that interactions can be better understood as exchanges whereby actors engaged in interactions that brought specific benefits. His work also explored how the need for such exchanges leads to equilibrium between actor and the idea of distributive justice. Blau further specified this work by focusing on the social aspects of such exchanges in terms of how they rely on trust between actors that each person will fulfill his or her unspecified obligations. While Homans, Blau, and others discussed that power arises out of exchanges and that power is not necessarily equally distributed among actors, Emerson and his colleagues specifically explored the development of power, how it is managed by actors, and how power differentiation affects the possibility of future exchanges. More contemporary work building on these ideas is bargaining studies, which specifies how different types of power differentiation affect the bargaining that then leads to actual exchanges. Lawler and colleagues explored the type of bargaining that occurs prior to exchanges, as well as how differing levels of power among participants affect such bargaining. Molm and her colleagues examined how exchanges varied based on inequality of participants and the availability of other sources and actors.

The second set of studies that can be categorized under the structural social psychology perspective focuses on social influence and authority. The underlying theme of these studies is that there are several factors that encourage people to be influenced by others, including the status or position others hold in comparison to themselves and group encouragement of conformity. The classic studies in social influence include Stanley Milgram's research that examined the effect an authority figure in a position of power has on individual compliance. Milgram found that individuals overwhelmingly obeyed requests to complete a task that ostensibly required hurting another person. Seymour Asch's studies of group conformity demonstrated that individuals willingly change their answer or opinion when a majority in the group indicates a different answer or opinion. Contemporary ideas build on this base by examining the varying conditions under which compliance to authority occurs, and to what degree others can influence attitude change.

Status characteristics, expectation states, and social network studies examine how social interactions are based on socially and culturally derived expectations for behavior that people have of one another. These socially and culturally derived expectations are associated with assumed predictions concerning how successfully any individual will contribute to an exchange, or interaction, process. These predictions then determine which individuals are likely to be given the most opportunities for interaction and influence in a group. Originating with the work of Berger, Zelditch, and associates, status characteristics theory explicitly identifies two main types of social characteristics that have expectations for behavior associated with them – diffuse (such as race, gender, class, and ableness) and specific status characteristics (such as job experience, education, and relevant skills) – and it is usually associated with groups working toward achieving specific goals. Expectation states theory argues that those people who hold diffuse and specific status characteristics evaluated as more likely to successfully contribute to achieving group goals will be given a greater number of opportunities for interaction as well as greater social influence among other group members. More to the point, theorists argue, and have successfully demonstrated, that

specific and stable hierarchical group structures develop based on these expectations. Contemporary work in this area includes specifying the degree to which different status characteristics affect expectations as well as how such expectations develop and whether actors perceive that such expectations are just. Social network theory and elementary theory build on the ideas of these different approaches in structural social psychology by specifically examining how an actor's position, relative to another, affects social influence processes as well as the stability of group structure. The underlying assumption of social network theory is that social influence, power, and bargaining are all affected by the way in which actors are networked to one another. Markovsky, Willer, Cook, and their students and associates examine different aspects of how actors are connected to one another and how that affects other social processes.

As the above discussion indicates, the three theoretical approaches in social psychology all examine different aspects of individuals, their interactions, and how their interactions affect groups. Cognitive and intrapersonal social psychology focuses on internal processes that impact whether, and how successfully, interactions occur among people. The insights provided by this perspective help to explain how actors create meanings concerning interactions that then lead to the creation and maintenance of specific social institutions and organizations, as discussed by symbolic interactionists. Finally, structural social psychologists examine how the fluid interactions of symbolic life create formal group structures that then impact on people's interactions.

METHODOLOGICAL TOOLS

Social psychologists use a variety of research methods with which to explore and explain specific aspects of social interactions as well as test specific hypotheses concerning these social interactions. Each of the three different theoretical perspectives in social psychology is often associated with utilizing only one type of research method – for example, symbolic interactionists are usually associated with using interpretive methods similar to those used by anthropologists, and cognitive and intrapersonal

as well as structural social psychologists are usually associated with using experimental methods. Such a simplistic view of social psychological research does not adequately reflect the breadth and diversity of research undertaken. The diversity of methods used by social psychologists and how they are used to examine specific aspects of individuals, their interactions, and the broader social environment in which they occur highlights the development of a mature scholarly area.

Interpretive Methods

Also known as “qualitative methods,” interpretive methods are used to gain an in depth understanding of social psychological phenomena, ranging from individuals to their interactions to the groups and environments in which such interactions occur. The type of interpretive research methods used by social psychologists include participant observation, unobtrusive research utilizing archival documents as representation of individuals and their interactions, and more extensive field research similar to ethnographic research commonly used by anthropologists.

Participant observation research in social psychology ranges from purely observational research to full participation while observing in selected social settings and environments. All types of participant observation research require the researcher to actually engage the setting in which the social interactions occur. Purely observational research consists of the researcher studying interactions in the environment in which they occur without the researcher becoming an active participant in the interactions themselves. An example of purely observational research in social psychology includes Kleinman’s study of a holistic health center in which she attended all meetings, parties, and retreats as an observer only. The other way of doing participant observation research is to study interactions in the environment in which they occur with the researcher becoming an active participant on some level, ranging from engaging in interactions with the actors involved while identifying as a researcher who then exits the environment to return to her own environment, to the researcher who becomes a full

participant in the interactions and the environment without identifying as a researcher. In this approach to participant observation research, the researcher conducts short term research as a fully immersed member of the interactions and environment, and then exits the environment after having conducted the research. An example of participatory participant research includes Adler and Adler’s research with a men’s college basketball team in which Peter Adler served as the coach and was an active participant of the group.

Unobtrusive research includes a variety of methods ranging from utilizing archival documents to in depth case studies as well as personal experience, such as in autoethnography. These different methods share two commonalities; first, they focus on understanding how meaning is created and interactions are structured by examining representations of human relations and social life. Second, unobtrusive research does not require interaction with the social setting and its actors in order to understand the creation and maintenance of meanings underlying social life. Unobtrusive research is particularly useful when it is difficult to gain access to the individuals, interactions, or groups being studied. An example of such research includes Gubrium’s study of the diaries of Alzheimer’s patients and their caretakers.

Ethnographic research, typically associated with anthropological research, consists of the researcher becoming a full participant with the actors being studied in their environment for a lengthy period of time. Anthropologists argue that a minimum of one year is needed before the researcher becomes fully informed and aware of all aspects of the groups and culture being studied. Sociologically based ethnographers tend to focus on the quality of immersion in the culture and group being studied, arguing that deep immersion is possible in six months. While there are disciplinary and intellectual differences in determining what constitutes ethnographic research, identifying the purpose of ethnographic research is consistent among researchers. The purpose of ethnographic research is to gain an in depth understanding of the unspoken and unwritten norms and values that guide individual interactions and group relations. Ethnographers agree that such understanding is only possible by literally living the life of the actors

being studied. An example of ethnographic research in social psychology includes Maynard's study of prosecuting and defense attorneys.

Experimental Methods

Experimental methods in social psychology serve as a way to test specific theoretical hypotheses as well as to explore particular aspects of interactions. There are a range of experimental methods, from the quasi experimental study which has fewer strict controls to the fully experimental study with formal control and experimental groups, as well as full control of all variables associated with the study. The full experimental study includes characteristics such as pre study surveys, control and experimental groups, and post study surveys. These studies are most concerned with testing specific theoretically derived hypotheses and thus seek to control all extraneous factors that may impact on the interactions. To do so, full experimental studies rely on random assignment of participants to the different conditions with the goal of increasing internal validity and reliability. Examples of such studies include the status characteristics and expectations studies conducted by Berger, Zelditch, Ridgeway, Hauser, and Lovaglia. The quasi experimental study is a variation of the full experimental study whose goal includes theory testing as well as exploratory research. There are a range of variations of the full experimental study, from the more naturalistic studies where naturally occurring experimental and control groups are treated as case studies to the experimental studies where control groups and pre study surveys are not used.

Survey and Interview Methods

Survey and interview methods used by social psychologists serve to test specific hypotheses as well as explore specific aspects of interactions, groups, and social institutions. Similarly to other areas in sociology, social psychologists use a range of survey tools and interview techniques including self completing surveys, those conducted by the researcher, and in depth interviews. It is worth noting that social psychologists often use surveys and interviews as

the second approach as a way of engaging in methodological triangulation. For example, pre and post study surveys are used in experimental studies where the participant will either complete the survey without the researcher present or be asked a series of questions by the researcher. Surveys are also used as the primary data collection tool for studies that examine self esteem and self concept definitions. Interviews are used by social psychologists to collect information to supplement field studies as well as to serve as the primary source of information. For example, in studying social networks of scientists, Eisenberg conducted in depth interviews with participants who also completed a sociometric survey on their own. Many of the early studies conducted by the Chicago School of Sociologists used interviews and surveys to gain an in depth understanding of issues such as inequality and racism.

SUBSTANTIVE FOCUS

Beginning students in social psychology are often surprised to learn the degree to which understanding the individual and her or his interactions allows them to also explain group dynamics, behavior in social organizations, whether a social movement will be successful, and the seeming durability of social institutions. Similar to the discussion of the methodological tools used by social psychologists, it is simplistic to describe the field as focused only on the individual. The substantive focus of social psychological theory and research ranges from individuals and their interactions to the groups in which they engage to the social organizations and social institutions that shape these interactions.

Individuals and Interactions

The study of individuals and their interactions seeks to explore, understand, and explain different aspects of the unique social quality of people. The range of topics includes understanding why prejudice and discrimination exist, the best way to persuade and influence people, and those topics typically found in social psychology texts – interpersonal attraction, helping and altruism, and aggression. The cognitive and intrapersonal perspective explains that the

schemas individuals use to process the billions of bits of information from the environment are socially and culturally determined. Therefore, individuals' understanding of their environment is going to reflect the biases they are taught and their experiences. In other words, prejudice and discrimination are the direct result of the schemas people use and their perception of these different categories. This information, also, provides some indication of how to decrease prejudice and discrimination by challenging people's schemas and perceptions. The symbolic interactionist perspective in social psychology provides useful knowledge with which to understand interpersonal attraction. To ensure that their interactions are easy, people normally associate with individuals for whom the meanings of their roles and identities are similar to their own. Similarly, it has been shown that helping and altruistic behavior is likely to occur in situations when doing so strongly reflects individuals' values without causing them any harm. Finally, aggression can be explained by studying the power structure that exists among groups of people.

Other substantive topics include examining self concept and self esteem, which can affect whether girls suffer from anorexia nervosa, as well as emotions and how they impact interactions. Whether discussing married partners' perceptions of one another or predicting who might become foreperson of a jury based on group members' status characteristics, social psychology allows people to understand the interactions in which they engage as well as others' actions and interactions. More to the point, understanding the social psychology underlying individuals and their interactions allows people to become far more effective in their own lives. The teacher who avoids comparing students on the basis of their status characteristics is going to be a more effective teacher. The manager who successfully works with all of his or her employees regardless of the power differential between them will be more successful. And, the people who actively engage with people unlike themselves are less likely to be prejudiced. Finally, interactions are important in all areas of social life and can determine the success of an encounter between, for example, doctor/patient, teacher/student, parent/child, and among friends.

Groups

The study of groups highlights that the group environment affects individuals and their interactions. The range of topics for studying groups includes group conformity, group performance, and intergroup relations. Group conformity is a compelling topic as it addresses issues such as why people are willing to engage in illegal activity as part of a gang initiation ritual, or why college students binge drink to the point of death. Symbolic interactionist theory explains how interactions become habitualized within groups, thus creating norms and values for other interactions. Structural theory explains how these habitualized interactions are based on fulfilling members' needs as well as the stable power structure that will develop in the group. The needs to be fulfilled can range from material needs, such as actually being rewarded something tangible by the group to which individuals are associated, to social acceptance by other group members. Structural theory also explains whether any particular group is going to successfully complete its task due to the types of people in the group and the skills they bring to the group. For example, Olson discussed how the factors that affect individual interactions also affect group cohesiveness and therefore group performance. The group that is more cohesive is more likely to succeed at specific tasks than the group that is not as cohesive.

The broad substantive topic of intergroup relations examines how groups interact with one another and the factors that predict whether such interactions will be successful. Specific examples of such relations are the relationship between rival gangs, or even rival sports teams at any level. Some of the factors that impact on intergroup relations include the cohesiveness of each group as well as the strength of the group's social identity. Some researchers have explored the ability of gangs to avoid violence in terms of the social networks that connect the two groups and the similarity of each group's social identity. Symbolic interactionist theory identifies the importance of understanding the meanings other groups share and how they reflect a particular group culture. Structural theory explains why groups would want to cooperate with one another in terms of the resources to be shared

and exchanged. The ability to understand group dynamics in terms of social networks, power distribution, and conformity allows individuals' to more successfully shape group interactions. Groups are important for the social psychologist because they represent the first place where we learn the meanings associated with social life as well as develop a fully developed self and self identity.

Social Organizations and Social Institutions

In understanding individuals and their interactions, as well as how group membership affects those interactions, social psychologists are able to discuss and study social organizations and institutions. Some of the topics examined include social movements and whether they are successful as well as the idea of deviance as a social institution. Studying collective behavior and social movements includes examining motivations for joining in collective behavior as well as the organizations that develop out of members' interactions. Symbolic interactionist theory explains how people are more likely to join in collective action or a social movement when their own ideology and values match those of the social movement. Additionally, structural theory argues that people become members of a social movement when it provides a benefit beyond any specific cost. In other words, people's participation in a social movement is determined by social psychological factors.

Social psychological theory also explores social organizations as a form of social network that represents the likelihood of success for the organization. Symbolic interactionist theory explains how institutionalization formalizes the patterns of interaction among members of the organization or social institution, and structural theory discusses how power is distributed within the organization or institution. Understanding the social psychological factors that create, shape, and maintain organizations and institutions allows individuals to more successfully work within them. For example, the person who studies both the informal and formal social networks of the organization is more likely to successfully obtain the necessary resources for his or her tasks. Researchers have used these ideas to explain why some organizations will

have a harder time surviving in a competitive market than other organizations. Finally, symbolic interactionists offer a compelling argument that since social organizations and social institutions are created out of individual interactions, it is possible to change such organizations and institutions.

CONCLUSION

Social psychology is an area of sociology that focuses on individuals and their interactions to explain a broad range of social relations and social phenomena. The area is diverse in terms of the theoretical ideas explored, the methodological tools used to test and explore these ideas, and the substantive foci that extend beyond individual interactions. In understanding the social psychology of everyday life, we can also create new realities in terms of ourselves, the groups to which we belong, and the social organizations and institutions that constrain our actions.

social psychology, applied

Elmar Schlueter and O. Christ

As it is commonly used, the term applied social psychology refers to the application of social psychological methods, theories, principles, or research findings to the understanding or solution of social problems (Oskamp & Schultz 1998). Applied social psychology encompasses a range of theories intended to address the mechanisms of various social problems. In this regard, it can be considered a theoretically based form or praxis. One of the most influential figures in this area is Kurt Lewin with his studies on intergroup relationships and the processes underlying intergroup conflict. But historically, applied social psychology has even deeper roots. Early applications of social psychological concepts can be traced to the experimental studies of Hugo Münsterberg (1914). Further senior pioneers of the field are Floyd Allport (1920) with his research on group influences, Muzafer Sherif's (1935) work on social norms, or Richard LaPierre's (1934) classic study on the relations between attitudes and behaviors.

The field of applied social psychology overlaps to a large extent with the disciplinary characteristics of social psychology, broadly defined as the scientific study of how people perceive, influence, and relate to other people. Notwithstanding this similarity, differences in the motivations underlying research in basic

social psychology on the one hand, and research in applied social psychology on the other, can be detected.

Usually, research in basic social psychology starts with the primary intention to solve problems of theoretical significance only. For fulfilling this purpose, studies in basic social psychology can, but by no means need to, refer to applied settings. In short, basic social psychology's primary interest aims at solving theoretical questions and thereby contributing to the general knowledge base of social psychology.

Contrary to this, the focus in the realm of applied social psychology is toward the solution or improvement of real life problems, as expressed above. Within this problem oriented framework, theoretical perspectives are first and foremost utilized in order to achieve applied social psychology's major goal to improve certain social conditions. Nevertheless, in several instances pragmatic applications of social psychological concepts have led to important new theoretical insights as well. For instance, classical social psychological concepts such as the definition of the situation, self fulfilling prophecy, or relative deprivation, or even influential theoretical approaches like dissonance theory originate from applied research settings. It is this reciprocal relationship between theory and problem orientation that Lewin (1951) emphasized: "Many psychologists working in an applied field are keenly aware of the needs for close cooperation between theoretical and applied psychology. This can be accomplished in psychology, as it has been in physics, if the theorist does not look towards applied problems with high brow aversion or with a fear of social problems, and if the applied psychologist realizes that there is nothing so practical as good theory." Even today, the hybrid character of applied social psychology as being theory based but oriented toward social problems can be seen as one of its most important features.

Studies applying social psychological knowledge address an increasingly broad range of substantive real life topics. To illustrate this point, social psychological concepts have frequently been used for improving social problems tied to intergroup conflict, pro environmental behavior, or health. More recent examples illustrating the ongoing expansion of the discipline focus on the consequences of part time work or

on the question of why some people adapt earlier to Internet usage than others. Frequently, such studies cross cut academic boundaries to neighboring disciplines like applied sociology, criminology, communication sciences, or social work, to name just a few.

Because of the broad and heterogeneous substantive areas of application, it comes as no surprise that researchers using social psychological concepts revert to a wide methodological spectrum. For example, experimental and survey research, observational studies, and – to a somewhat lesser extent – qualitative approaches rank among the commonly used methodologies in the realm of applied social psychology. However, a key methodological characteristic of applied social psychology today is its focus on field research. Within such field settings, the modal research designs utilize experimental, quasi experimental, or program evaluation approaches. The prominence of field research in applied social psychology can directly be attributed to the discipline's orientation toward real life problems and the requirements stemming therefrom. For instance, sufficient external validity of study findings will often be achieved more easily in close to real life situations as given in field studies than in the laboratory (for comprehensive overviews on the methods used in applied social psychology, see Edwards et al. 1990).

Three examples of applied social psychology follow. These examples refer to such substantial domains as the environment, intergroup relations at both national and international levels, and health behavior.

Typically, applications of social psychological knowledge with regard to environmental problems are concerned with the advancement of sustainable relations between human behavior and environmental contexts. This domain covers a broad range of issues such as common property resource management, effects of environmental stressors and problems, the characteristics of restorative environments, or the promotion of durable conservation behavior. Thus, in times of scarce resources and massive environmental pollution, using social psychological knowledge can provide answers on how to develop an ecologically sustainable society (Oskamp 2000). Many studies in this field explore environmental attitudes, perceptions,

and values as well as devise intervention techniques for promoting environmentally appropriate behavior. Commonly used social psychological theories in this area are dissonance theory, norm activation theory, or the theory of planned behavior. Methodologically, such studies often draw upon various research methods ranging from experimental designs to large scale survey studies.

A classic domain of applied social psychology is the field of intergroup relations and intergroup conflict. Several studies demonstrate the influence of social psychological concepts on programs for the improvement of intergroup relations, at both national and international levels (Pettigrew 2001). One famous illustration of the impact of applied social psychology on social change is racial desegregation in American schools. In the early 1950s, Kenneth Clark and other colleagues from social psychology drew up a social science appendix to the plaintiff's brief to the Supreme Court showing the detrimental effects of school segregation on colored children. This appendix was supported by the signature of 32 experts from different scientific fields. As a direct consequence, the US Supreme Court based its 1954 decision against school segregation explicitly on this report. Later evidence clearly showed the long term positive consequences of school desegregation, even with sometimes mixed short term effects. One particularly important social psychological concept in the field of school desegregation is the contact hypothesis (Allport 1954). Allport emphasized that intergroup contact per se would not necessarily improve intergroup attitudes and relations. Rather, only under certain conditions (e.g., equal status within the contact situation for members of all groups, cooperative rather than competitive activities) would contact lead to such positive effects. Although sometimes criticized, the contact hypothesis guided to a large extent research and practice of school desegregation. Further examples of applied social psychology in intergroup settings refer to third party intervention in intergroup conflict such as the Israeli–Palestinian conflict in the Middle East. A figure of central influence here is Herbert Kelman, who has applied social psychological knowledge and methods to the peace building process between Israelis and Arabs. For conflict resolution, he used small group

workshops in order to stress interactive problem solving (Kelman 1997). These workshops represent unofficial meetings between representatives with political influence (e.g., representatives of the parliament, journalists, and writers) from both conflict parties. The major intention of these workshops is, on the one hand, to cause individual change at the level of the workshop participants. Such processes can lead to attitude change, a more differentiated view of the other conflict party, a better understanding of the conflict dynamic, and new ideas for conflict resolution. On the other hand, in the long run, the workshops should cause structural changes at the macro level by influencing political debates and decision processes with new insights and ideas.

Another realm of applied social psychology is public health. Usually, such research focuses on people's beliefs, attitudes, and behavior that affect their health. Important social psychological concepts in the field of health are perceived control, stress and coping, social support, attribution, and self esteem. These concepts stem from a broad range of classical social psychological theories like dissonance theory, attribution theory, social learning theory, and attitude–behavior theories, e.g., the theory of planned behavior (Taylor 2002). Many applied studies in this field deal with coping with chronic illnesses like cancer or HIV/AIDS. For example, applied social psychological research has shown that different patterns of coping with a chronic illness have either positive or negative impacts on the course of the illness.

Beside the examples presented, applied social psychology covers areas such as media and the Internet, sport psychology, organizational and industrial psychology, communication, and mediation. Comprehensive reviews of the substantive areas of applied social psychology are given in Oskamp and Schultz (1998) and in Sadava and McCreary's edited collection, *Applied Social Psychology* (1997).

Another important aspect of the field refers to the question of which basic principles guide researchers' decisions on which social conditions are considered problematic or not. As Sadava (1997) notes, such decisions refer ultimately to the personal values of those engaged with the application of social psychology. Notably, this value dependency implies that chances

for a general consensus on which social situations need improvement are rather small. In modern societies, several different value systems usually exist, and often these value systems are diametrically opposed to one another. Therefore, different value perspectives might lead to opposing views on the need for improvement for one and the same topic. For instance, the desire to reduce environmental pollution by increasing the price of gasoline versus the freedom of consumers to choose the transport system they prefer, to name just one example. Applied social psychology is clearly not value free and classifications of which social conditions should be improved and which not are to a great extent contingent on the personal values of those applying social psychology.

However, the role of personal values in applied social psychological research requires further attention. Even if values might well influence the choice of a research problem, researchers need to be careful not to let them influence the objectivity of their research and the resulting findings. Clearly, this applies both to the methods to be used and to the interpretation of the empirical results.

Another aspect of the discipline refers to the normative question of on what grounds social psychology should be applied. One prominent perspective among scholars is to consider applied social psychology first and foremost as an empirical science. From this position, applied social psychology simply cannot respond to questions with a prescriptive character. But on a more general level, at least two alternative positions have been proposed. On the one hand, scholars advocate the well being of the individual as an ultimate aim of all efforts in applied social psychology. Others have criticized this perspective for disregarding the possibility that the maximization of well being for some individuals might well exert disadvantageous effects on the well being of other individuals. To overcome this dilemma, the suggestion has been made that the well being of humankind should be regarded as an appropriate goal of applied social psychology. A comprehensive approach to the question of which normative principles should guide the application of social psychological knowledge emphasizes that social psychology is most beneficial when it acts upon the recognition of every individual's dignity, when

respect, acceptance, and charity to one another are an integral part of it, and when applied social psychology likewise negates all forms of violence. This suggestion does not only refer to the purpose of applied social psychology. It also explicitly points to the process of how applied research in social psychology should be conducted. Perhaps this essentially humanistic suggestion fulfills its purpose best when it is considered as providing some form of general orientation rather than a definitive normative guideline.

social services

Lena Dominelli

Social services are provisions that respond to the needs of individuals, groups, or communities to improve social, emotional, and physical well being not supplied by carers who are kin. Social services are difficult to define, but constitute part of the welfare state that is the domain of social work and its practitioners – social workers and those who assist them in their tasks, social care workers, home helpers, and a range of others who work to provide services backed by society including the state, voluntary agencies, and commercial enterprises. They cover all client groups across the life course – children, families, older people, disabled people, mentally ill people, offenders of all ages, in diverse institutional settings or local communities.

Social workers as the practitioners primarily responsible for delivering personal social services to individuals and families do so in a variety of settings. They have devised forms of practice to enable them to work effectively with service users. These have focused largely on casework, including clinical social work, psychological social work, and psychiatric social work; groupwork; and community work undertaken in a range of service settings within institutions and communities. Paying professionals to minister to individual need has its origins in the Gilbert Act or Poor Law Amendment Act of 1782, which approved of salaried “guardians of the poor.”

Service delivery involves a range of providers – the state, voluntary agencies, religious authorities, and commercial enterprise, comprising the mixed economy of care. There was little coherence amongst these providers until the Seebohm Reforms of the 1970s ended this fragmentation through the creation of large bureaucratic organizations that unified provisions in social services departments under municipal control. Statutory services today come under the auspices of local authorities, but their dominance has been undermined by the marketization of service provision under the 1990 National Health Service and Community Care Act and the more recent reorganization of social services by client groups. These developments reinforce earlier competition between health and social work for authority over the provision of social services. The 1990 Act began the modern privatization of social service provision, initially for older people requiring institutional care. However, the quasi market has now expanded to include services to children and offenders. The forces of globalization and the General Agreement on Trades and Services (GATS), which requires the privatization of health, social services, and education globally, will reinforce marketization.

Meanwhile, the number of multinational companies, especially American ones entering the British scene, has risen dramatically during the early years of the twenty first century. As the private social agencies of old, these new ones are likely to cover the entire spectrum of social service provision. But there is one change that is likely to take place in the not too distant future: private social agencies are likely to assume delivery for the bulk of social service provision rather than simply supplement public ones as they did shortly after the implementation of the Beveridge Report, 1948 and the Seebohm Report, 1968. The proposed sale of 1,100 units on the Octavia Hill Housing Estate to non state buyers in 2006 is symbolic of this move and the attendant loss of social housing for low income earners is unlikely to be covered by either private or not for profit providers. Many sales of public assets have transferred funds from the public to the private sector.

That these social services are about caring for and about people raises a number of tensions that complicate their delivery. Amongst

these are the care-control dilemmas; lack of professional status of those delivering services and authority; charitable giving or societal entitlements; state or market providers; and public or personal responsibility for their provision. Service boundaries are amorphous and constantly shifting as society changes the remit of those responsible for providing services by altering legislative fiats and social policies.

Social services provision has threads of continuity and discontinuity that can be traced back through centuries of the history of social work. This history is contested as struggles to delineate its boundaries as other professions including health claim some of the territory. Differences of opinion about causation and responsibility divide understanding of need and service provision. Commitment to interagency working means that different professionals can intervene in any one particular setting or client and without necessarily agreeing about the best way forward.

HISTORICAL CONTINUITIES AND DISCONTINUITIES

The reasons that people require social services have focused on personal inadequacies or structural causes. The former blame individuals for their plight; the latter examine social causation. Social changes rooted in economic exigencies have undermined the capacity of the family and kin to provide caring services for members requiring them. Although the monied classes have been able to purchase their social services in the marketplace, those on low incomes have done without unless kin, charities, or the state have assisted them. Charitable or philanthropic benevolence that relies on individuals and religious institutions has been meeting the needs of some in poverty for a period. This help has been predicated upon notions of personal pathologies and divided claimants into deserving and undeserving ones. The former have received stigmatized and inadequate forms of support; the latter have had to fend for themselves.

These tensions go back to the Elizabethan Poor Law, 1601, when the modern nation state first began to provide meagre services through workhouses and outdoor relief. This institutionalized residential requirements and demanded

work in return for assistance. The workhouse and living in a particular parish have been consigned to the dustbin. Expressed differently, these conditions remain while being revised to accord with contemporary structures, expectations, and language. Only citizens can expect social services provisions under legally specified criteria and bureaucratically defined procedures. Additionally, services are conditional on the claimant agreeing to train to become more employable before an application for help is considered. While unemployed people have always been required to seek work, the state under New Labour has increased surveillance on compliance. It is now planning to introduce similar requirements on disabled people on Incapacity Benefit to reduce the number of claimants. These arrangements reflect a persistent strain between family and state or community support. The failure of such policies to move large numbers of people out of poverty and into gainful employment rather than the ranks of the working poor has been apparent since the New Poor Law Reform Act of 1834.

State social workers have constantly been caught in the trap of supporting individuals by stretching inadequate resources, balancing personal pathology with social causation, apportioning multiple loyalties amongst a range of stakeholders with diverse interests, trying to ensure that individuals acquire a sense of belonging and contributing to and having a place in society. Supporting individuals and groups in a holistic way is becoming increasingly difficult in a contemporary neoliberal context.

Professionals were not the only ones who challenged the assignation of claimants into deserving and undeserving categories. Claimants demanded change. Even in the days of poor relief, those receiving assistance demanded responses to need on their terms and recognition of the interplay between social causes and personal predicament when individuals could not help themselves. For example, pressures for changes that acknowledged such analyses amongst war veterans resulted in the Speenhamland Act of 1795 that enabled receipt of relief from the then local state in their own homes. Yet, Adam Smith, author of *Wealth of Nations*, like Charles Murray later, argued cogently for a laissez faire approach to welfare to ensure that the state let the economy or market provide the

mechanisms whereby individuals met their welfare needs. Smith's view was subsequently challenged by Karl Marx, who held capitalist social relations responsible for exploiting people to such an extent that they would be unable to rise out of poverty simply by selling their labor. Thus, demands for publicly provided social services were a byproduct of an economic system that constantly yielded people in need or casualties unable to care for themselves, and that remains the case today.

The Marxist tradition was taken forward by Christian socialists. Eventually, Marx's arguments underpinned the position of Fabian socialists, particularly Beatrice and Sydney Webb, who played leading roles in establishing the welfare state under the aegis of the Labour Party. This provided free school meals and medical care for school children, pensions to cover declining earnings in old age, and unemployment insurance to cover people lacking paid work. The commitment to social insurance retained the link between paid employment and entitlements and, based on men's employment careers, these promoted an institutional base that excluded those with different patterns of waged work and impacted badly on women, "black people," lone parents minding children at home, and those unable to work due to physical impairment or old age.

These debates continue to the present day and there is little agreement about whether individuals looking after their own welfare needs or state provisions produce the best outcomes. The American new right popularized arguments that the welfare state and social work "do gooders" who side with clients are responsible for inducing a "culture of welfare dependency" that saps claimants of initiative and motivation to look after themselves. The failure of this approach is evidenced by large numbers of Americans living in poverty, without health insurance and unable to meet their own care needs. Additionally, inadequate public social services ensure that claimants are ping ponged between different agencies as individuals go from one to another to secure services. Charles Murray, encouraged by the Thatcher government, attempted to make similar arguments in the UK. Yet, its welfare traditions and composition of claimant classes differ widely from those of the US.

The history of social work claimants shows an undying link between poverty, poor health, and individual hardship. The inability of individuals to pull themselves up by the bootstraps was exposed as far back as the nineteenth century by reformers like Edwin Chadwick, whose demands for public hygiene measures did more to enable working class people to enjoy healthier lives, survive longer, and earn more money than self help. However, the issue of low pay persists and is a key mechanism in excluding poor people from the marketplace where welfare resources can be purchased today.

The tension between personal pathological approaches and structural approaches to social services provision played a key role in the establishment of professional social work in the late Victorian era. The Charity Organization (COS) endorsed individual pathological explanations through its commitment to casework interventions that sought to establish a scientific basis to the social work profession. It was challenged by the Settlement Movement, which focused on structural explanations, particularly unemployment, low pay, and poor health amongst working class people. The latter was responsible for replacing the "lady bountiful" image of social work with one of social responsibility in which workers cooperated with poor people, and lived and worked amongst them. The efforts of Octavia Hill, Samuel Barnett, and Henrietta Rowlands (Barnett's wife) promoted structural understandings of poverty and worked to meet needs within this framework. Social researchers including Charles Booth after 1886 provided empirical evidence of the role of economic change in locking people into poverty, presenting a picture that remains familiar.

More evidence of the link between structural economic decline and poverty appeared at the beginning of the twentieth century in the Poor Law Commission Report of 1905 and was highlighted when British mines failed to compete with better equipped American ones that produced more tonnage per laborer. These arguments tally with findings made in the 1970s by Community Development Projects (CDPs), which were successors to the Settlement Movement's community based approaches to poverty alleviation. CDPs exposed the ties between deindustrialization and deprivation in working class communities throughout the UK, a debate

now reinforced by critics of the New Deal and demands for human rights and social justice based anti oppressive social services.

Social services have provided a fraught and contested area of service provision and delivery that is full of contradictions that exclude marginalized groups who have little purchasing power on the market. Today's shift toward private provisions enables a new breed of entrepreneurs, many from overseas, to make fortunes out of a sector that the welfare state had once sought to remove from its ambit. Whether it can provide for those on low incomes or who are outside of the waged workforce remains to be seen. It has been unable to do so in the past and its failure was responsible for the development of welfare state based social services in the first place. Meanwhile, as the rich enjoy the best social services the market can provide, poor people make do.

social structure

Stephen Hunt

The term social structure denotes a more or less enduring pattern of social arrangements within a particular society, group, or social organization. Nonetheless, despite its wide spread usage, there is no single agreed concept of social structure that exists in sociology or related disciplines. An early attempt to theorize the notion of social structure was seen in the work of Lévi Strauss, the French social anthropologist, who attempted to discover the universal rules that underpin everyday activities and custom through cultural systems (Lévi Strauss 1967). Within sociology, however, the term has been employed in various ways according to the theoretical approach within which the concept is used. For instance, in one of the earliest uses of the term, Herbert Spencer related "social structure" to increasing differentiation and specialization of the biological organism as society "evolved."

Historically speaking, sociological theories exploring the concept of social structure are generally associated with macro or structural perspectives oriented to understanding the nature of social order, and in doing so stand in stark contrast to social action (or micro) approaches which seek meaning and motivation behind human social behavior. Social structural analysis has tended to be identified with two schools of thought. First, it is associated with the theoretical speculations of structural functionalists such as Talcott Parsons, for whom the major concern of the sociological enterprise was to explain how social life was possible. For Parsons (1951), the answer lay in the establishment of a certain degree of order and stability which is essential for the survival of the social system. Parsons identified cultural values as the key to stability. Value consensus provides the foundations for

cooperation, since common values produce common goals. The value system permeated social structures which, in Parsons's schemata, constituted a fourfold system of functional prerequisites which give way to universal arrangements oriented towards adaptation, goal attainment, integration, and pattern maintenance. In Parsons's structuralist theory the notion of social structure also implied that human behavior and relationships are, to one degree or another, "structured," particularly in terms of rules, social status and roles, and normative values. Social behavior and relationships are thus patterned and recurrent. It follows that the structure of society can be seen as the sum total of normative behavior, as well as social relationships which are governed by norms.

Although remaining popular among North American academic schools of sociology for some time, social structure theory as espoused by structural functionalism was subject to scathing criticism from the late 1960s, not least of all in its apparent teleology and its normative theoretical stance, as well as strong objections related to the logic of the biological analogy. One observation was that social structures do not possess the relatively identifiable boundaries that clearly exist with biological organisms, nor do they possess the precisely identifiable homeostatic processes of organic structures. Although remaining largely within the structural functionalist school, Robert Merton also challenged what he termed the "postulate of universal functionalism," in particular, that all structures necessarily have positive social functions. Indeed some, notably religion, could have neutral or even detrimental effects on the social system (Merton 1949).

In Western Europe, in particular, functionalism has long been rivaled by Marxist schools of structuralism. Marx (1964) himself considered the importance of what he identified as the two dimensions of the social structure: the overarching economic substructure (or base) which for the most part determined the social superstructure comprised of the various institutions of society. In turn, the "hard" interpretation of Marxist thought came to identify the processes of dialectical and historical materialism as forging social structures concomitant with the economic base. In this elucidation the social superstructure was transformed into

social structures that enforced class subjugation and exploitation.

The work of Gramsci, among others, weakened the hard interpretation of Marxist analysis and took it away from the significance of the economic base to the ideological and cultural superstructure, while retaining the notion of the hegemonic structural power of the state. Also further reducing the hard interpretation of Marx's structuralism was the school of thought typified by Poulantzas. In his poststructural theorizing the state is said to be "relatively" antonymous. According to Poulantzas, ruling interest is not necessarily *directly* related to the actions of the state at any given time. Rather, the state, in capitalist democracies, retains the flexibility and autonomy to sustain the politico economic order in the long term and thus preserve the semblance of pluralism.

The emphasis on "agency," as compared to the rather deterministic framework of social structuralism, provided an alternative approach to understanding social behavior. Here the emphasis was on the motivational capacity of "actors" in dynamically structuring and restructuring the social world around them. Such an approach is usually identified with the work of Weber. However, while Weber is often interpreted as opposing structuralism in his critique of Marx, he provided the channels by which structuralist theory and social action could be reconciled without the determinism and teleology of the former (Weber 1922). This is perhaps exemplified by his work on bureaucracies and their dominant position as rationalized structures in the modern world. Such structures arose out of social (rational) action and, in turn, feed back and inform the experiences of social actors across numerous aspects of human life.

Criticisms of macro level structuralist theories were to lead to the intellectual movement of poststructuralism which developed from the 1960s. Although initially derived from structuralist schools, theorists challenged assumptions concerning society and language as signifying coherent "systems." Through major exponents such as Derrida, Foucault, and others associated with schools of postmodernism, even earlier poststructuralist theory was itself "deconstructed" in order to understand how knowledge, linguistics, and centers of power came into existence in the first place.

social structure of victims

Koichi Hasegawa

Nobuko Iijima, a pioneer of environmental sociology both in Japan and internationally, applied her notion of the social structure of victims to the multidimensional and multi layered nature of the damage caused by pollution (Iijima 1976, 1979, 1984). The physical damage done to victims is relatively easy to discern, but this is only one aspect of pollution damage. Equally costly is the mental and social damage that occurs in the wake of the physical impact. Iijima attempted to describe comprehensively the complex structure of the suffering of victims, from physical suffering to worsening relationships between family members and neighbors who may be indifferent to the pollution problem or wish to keep it hidden. This approach reveals the flow on effect of the physical damage. In fact, Iijima demonstrated how such suffering affects every aspect of a family's daily life, including loss of income and an increase in medical expenses, and often leads to family breakdown or the destruction of a family's living conditions. Through her

research on Minamata disease, mercury poisoning of Canadian Indians, and drug induced Subacute Myelo Optico Neuropathy (SMON) disease, Iijima discovered that the structure of victims was very similar whether the damage was caused by a labor accident, a drug induced disease, or an environmental hazard. The source of the pollution that caused Minamata disease was a factory already known as the site of numerous labor accidents. A systematic and institutional lack of care or consideration by industry and government for the safety of people's environment and the safety of working conditions nurtured the endemic problems that led to the Minamata outbreak.

Iijima's argument regarding the social structure of victims represented both a practical and a theoretical contribution to the field. In the case of drug induced SMON disease, Iijima testified as to her research findings in court and her argument became the basis for the plaintiffs' demands for financial compensation for their sufferings, including the mental damage inflicted on them and the destruction of their daily lives.

More broadly, Iijima discussed the way that the sufferings caused by environmental damage were not evenly distributed in society, but reflected the disparities between majority and minority groups. Hence, in Japan, where small farmers and fishermen occupy the lowest strata of society, it is they who are most likely to suffer from environmental hazards. In this way, she found a kinship with US scholars of environmental justice and racism on African Americans and Native Americans, such as Bullard (1994).

In distinguishing between environmental sociology and medical and other social scientific studies of the environment, Iijima identified the description of the social structure of victims as the primary task of environmental sociologists.

social support

Karen D. Lincoln

Social support has repeatedly been linked to a host of diverse social, economic, and health outcomes, including mortality (Berkman & Syme 1994), depression (Wethington & Kessler 1986), a variety of physical health problems, including heart disease (Kristenson et al. 1998), rheumatoid arthritis (Krol et al. 1993), and educational attainment and success (Hagan et al. 1996).

Social support, as a field of study, rose to prominence in the early 1970s and ushered in a groundswell of articles and books dealing with this topic. The burgeoning literature resulted in a plethora of definitions of the term. "Social support" usually refers to a process of interaction or exchange between individuals and significant others. Researchers have examined different *types* of support (e.g., emotional, informational, instrumental) and different *sources* of support (e.g., family, friends, neighbors, church members), as well as *functional* aspects (e.g., emotional support, sense of acceptance or belonging) and *structural* aspects (e.g., size, density, frequency of contact). House et al. (1988) recommended that studies of social support include measures representing more than one of these components in order to better understand how they relate to each other and to different outcomes. This approach has been widely adopted; however, many papers still rely on single measures of one component without a full

understanding of the definition of support underlying their selection. Most empirical studies on this topic explore the associations between social support and health. A review of this broad literature over several decades leads to the conclusion that social support is beneficial to health. People with satisfying levels of support seem to cope better with stress and have better physical and mental health, compared to those who lack support.

Despite the volumes of research on social support, many questions of conceptual, methodological, and theoretical importance remain to be answered. This entry discusses the history, evolution, and current thinking in the field of social support, as well as directions for future research.

A hundred years ago, Durkheim's (1951) study of suicide made a significant contribution to the field of social support. He found that suicides were more prevalent among those with fewer social ties, which in turn produced a loss of social resources, a reduction in social constraints (based on defined norms and social roles), and ultimately resulted in poor psychological outcomes and increased risk of suicide. Almost a century later, extant reviews of the social support literature (Cohen & Wills 1985; House et al. 1988; Thoits 1995) conclude that social support, regardless of the way in which it is measured, is beneficial and has the potential to alleviate the deleterious effects of stress and other undesirable situations on physical, mental, and social outcomes.

Caplan (1974), Cassel (1974), and Cobb (1976) laid the foundation for work on social support and established the research issue that has since dominated the field: social support as a protective factor. They provided early definitions of the construct as well as ideas about the function of social support. Caplan (1974) and Cassel (1974) suggested that social support is feedback provided by significant others that *buffers* the adverse effects of stress and thus facilitates coping with difficult situations. Cobb (1976) was more precise in his efforts to provide a conceptual definition. He defined social support as information leading a person to believe that he or she is loved and cared for (e.g., emotional support), esteemed and valued (e.g., esteemed support), and belongs to a mutually supportive network (e.g., belonging support).

A decade later, Barrera (1981) emphasized that the term "social support" lacked adequate specificity and developed a classification scheme that has proved to be quite helpful in elaborating the diversity of definitions. Barrera identified three distinct categories of social support: social *embeddedness* (e.g., assessing the frequency of contact and connection with others), *perceived* social support (e.g., subjective evaluations of support availability and satisfaction), and *received* support (e.g., assessing the amount of tangible help that individuals actually provide).

Barrera's classification scheme contributed to the next wave of research that focused on comparing different dimensions of social support and their varied effects on particular outcomes. The consequences of perceived social support, especially emotional support, have most frequently been examined in the literature. The perception or belief that emotional support is available appears to have much stronger influence on outcomes than the actual receipt of social support.

Despite these advances, the social support literature continues to receive criticism. Many of these critiques coalesce around the definitions of social support as being too vague or too broad. Little consensus exists on how social support should be defined. This lack of consensus regarding the term is a major problem because it creates difficulty in measurement, as well as in assessing the status of research findings. The use of carefully chosen and more precise measures may help curtail the creation of more conflicting research findings about social support and have important benefits for summarizing study findings regarding the costs and benefits of social support.

Most conceptual models highlight the direct and stress buffering effects of social support on outcomes. The *direct effects model* (Cohen & Wills 1985) assumes that social support has a direct effect and serves a health restorative role by meeting basic human needs for social contact regardless of the level of stress present. Thus, social support and stressors are largely independent of one another. Stressors have deleterious effects on health and other outcomes, while certain aspects of support, especially social integration and perceived support, are beneficial. Hence, these respective influences of support

and stressors are additive and, at least partly, offset one another. This generalized beneficial effect of social support occurs because social networks provide positive interactions, support, and affirmation that lead to an overall sense of self worth, self esteem, and positive affect.

Social support has also been studied widely as a psychosocial resource that potentially mitigates or buffers the deleterious psychological effects of stress on outcomes. Cohen and Wills's (1985) *stress buffering model* proposes that social support buffers or protects individuals from the deleterious effects of stress. Many prior studies suggest that the effects of perceived support, and to a lesser extent those of received support, vary according to levels of stress. That is, support may be helpful mainly for persons who face high levels of stress, but may be much less important for others. Thus, the main role of social support in the stress buffering model is to mitigate the otherwise deleterious effects of high stress. Supporting evidence for this model has been found in a variety of studies.

Discussions of social support increasingly focus on the need for theory as a guide to understanding the *mechanisms* by which social support affects health and other outcomes. This is a crucial next step to understanding how social support operates and ultimately developing a theory of social support. To accomplish this goal, researchers must (1) understand what the term social support means, (2) determine which dimensions or types of support play an especially important role in shaping the outcomes under consideration, and (3) identify the precise social mechanisms responsible for the observed effects.

There are several interesting new directions in recent research that may facilitate the goal of developing a theory of social support. First, a thorough examination of possible intervening factors can help us understand the mechanisms whereby social support operates to influence particular outcomes. Studies that examine the influence of measures of self concept, such as self esteem, personal control, or mastery, are promising. However, study findings to date have been inconsistent. Understanding the intervening mechanisms and supportive processes is a crucial next step to building theory in this area.

Another new and promising direction examines the negative side of social relationships. Negative interaction refers to unpleasant social exchanges between individuals that are perceived by the recipients as nonsupportive, critical, manipulative, demanding, or otherwise inconsequential to their needs. Research consistently shows that negative interactions exert a greater effect on health and well being than measures of supportive interactions (for a review, see Lincoln 2000). In short, studies are beginning to show that there are important limitations on the degree to which social relationships benefit health and other outcomes. Consequently, a more complete understanding of social support requires a thorough examination of the negative as well as the positive aspects of interpersonal ties, as well as the stability, change, and effects in social relations over time.

Research designs have advanced from the cross sectional correlational research that characterized early studies (Heller & Swindle 1983) to longitudinal designs that have appeared in recent studies (Barnes et al. 2004). A number of relatively underexplored questions remain, however, concerning the effects of factors such as stress and poverty, for example, on social support over time. Stressors such as financial problems and the death of a loved one are generally assumed to result in support mobilization rather than erosion or withdrawal. However, acute stressors are more likely to result in support mobilization in the short run, whereas chronic stressors may entail serious costs to the social network and thus erode support over time.

Most studies view social support primarily as an individual level or interpersonal construct. However, community psychologists have identified the need for studies that treat social support as a system level or community level phenomenon that promotes social integration and perceptions of support. A focus on community and systems level factors is consistent with a sociological approach to the study of interactions among people and how social contexts influence these relationships. One example of this approach involves studies of social support in religious settings. Although this literature is not well developed, findings to date indicate that people who are members of formal religious organizations receive a sizable amount

of emotional and tangible assistance (Taylor et al. 2004) from their fellow congregants. In addition to this line of research, more information is needed about the role of clergy in facilitating social support among parishioners. Research findings indicate that some people are more likely to consult members of the clergy than professional helpers (Taylor et al. 2004). However, more research is needed to understand what clergy actually do to assist people, whether they act as a conduit to professional helpers, and the types of problems they confront.

Questions remain about how social support operates among different populations. For example, more research is needed to understand the characteristics of social support networks among different age, gender, ethnic, racial, and SES groups. Little is known about whether extant measures of social support have the same meaning across different groups. The dramatic increase of older adults in the United States and worldwide highlights the importance of understanding social support among this population more than ever. Little is known about the effects of negative interaction across the life course or how those with limited support availability fare in terms of health and social outcomes. More discussion of policy implications of social support is needed. The widely accepted but recently challenged belief that some groups, such as African Americans, receive more social support than other groups has major implications for policies that affect long term health care, poverty, and social insurance, particularly among populations with limited resources. For example, recent findings indicate that African Americans have a higher proportion of kin in their social networks (Ajrouch et al. 2001) and have smaller social networks compared to whites (Barnes et al. 2004). Whereas negative exchanges might be relatively uncommon among more distal network members (e.g., co workers, neighbors), where few resources are transferred, they have been found to be fairly common among family members and when extensive support is provided. Consequently, African Americans may be more vulnerable to conflict within their networks compared to those with more multiplex networks (e.g., family, friends, neighbors, co workers), as well as limitations in the availability or range of supportive resources.

Another promising new direction for future research is the use of computers and the Internet to provide and receive social support. This area of study views computer mediated support groups as weak tie networks that have the potential to provide support to those individuals who have limited or restricted opportunities to engage in supportive exchanges. Persons with functional limitations or loss of mobility, illness, advanced age, time constraints due to competing demands (e.g. caring for a disabled, aging, or ill family member), or who simply prefer social contact or discussing personal problems via cyberspace rather than face to face, may benefit from this form of support. This research is in its infancy and competing claims have been presented in the literature regarding the impact of Internet use on social support, with some studies suggesting that Internet use increases social interaction and support (Shaw & Gant 2002), while others suggest that it leads to decreased interaction and support, or has no effect (Noel & Epstein 2003). There is some disagreement as to whether the Internet has a positive or negative impact on social connection and well being for older adults, in particular. Clearly, more work is needed in this area to determine who uses, who benefits, and what are the motives for using this form of exchange, as well as whether it is a replacement or supplement to face to face interactions.

The past few decades have made strides in clarifying the theoretical construct of social support and establishing how it is associated with different facets of social life. As more systematic research continues, future research will provide a more nuanced and contextualized understanding of the promise and limits of social support.

social support and crime

Ruth Triplett

In his 1994 Presidential Address to the Academy of Criminal Justice Sciences, Cullen (1994) argued that social support is an important organizing concept for criminology. Central to his argument about the importance of social support to criminological theory is Cullen's idea that social support is a concept that is actually present in many of today's criminological writings, including strain, labeling, feminist, and the works of the Chicago School. Cullen derives his definition of social support from Lin, who defines it as the perceived or actual instrumental and/or expressive provisions supplied by the community, social networks, and confiding partners.

For Cullen, there are a number of important dimensions surrounding this definition of social support. First, as one can see in the definition, two basic types of social support derive from one's relationships: expressive and instrumental. Expressive support is used to refer to the emotional support that one receives from relationships. An example of expressive support is when your spouse helps you release stress by listening to your complaints about work. Instrumental support refers to support from a relationship that leads the individual to achieve

a goal. An example of instrumental support would be when parents provide money and a place to live for their children while they attend college.

A second dimension to social support is that it involves not only what is actually given as support, but the perception of support as well. Thus there may be a difference between what someone perceives they are giving and what another perceives they are getting. Third, social support occurs at different levels. It can be discussed at the individual level, given by a friend, at the community level, with communities varying in the extent to which they offer support, or even at the societal level, with some nations offering higher levels of social support than others. Finally, social support can be given formally, by agencies or institutions, or informally, by friends and family.

Cullen next argues that social support is related to crime at a variety of levels. At the macro level, Cullen relates varying levels of social support to crime at the societal and community level. For example, Cullen argues that the lower level of social support in the US is related to its higher rates of serious crime. Cullen also sees social support as varying across families, with some offering more support to their members than others. Finally, he sees social support having a direct effect on individuals' involvement in crime through both the giving and receiving of social support, and indirectly as it conditions the effect of other factors, such as strain.

When Cullen wrote his article on social support, he argued that there was much criminological research that already lent indirect support to the importance of social support in explaining crime. Since then, Cullen and other researchers have directly tested some of his ideas. In general, the research is supportive of the idea that social support is related to crime at a variety of levels. For example, at the individual level, Wright and Cullen (2001) have examined the relationship between parental support and delinquency. They found that control and support are both important aspects of parenting that significantly affect delinquency. In addition, they found a strong joint effect of control and support on delinquency. At the societal level, Pratt and Godsey (2003) found that social support is significantly related to

national homicide rates and that the effect of inequality is stronger when social support is lacking, and diminished with its presence.

social system

Stephen Hunt

There is a sense in which a “social system” may be defined as two or more people engaged in ongoing social interaction. What might be said to be the aspect of interaction which makes it specifically a “system” is that a high degree of regularity or recurrence is conducive to more or less permanent structural arrangements. This normatively defined categorization of a social system came to be largely identified with particular schools of sociology generally located within the framework of mid twentieth century structural functionalism and the speculative theories of its leading exponents.

Making an earlier contribution was Herbert Spencer (1820–1903), who drew an analogy between the social system and biological organisms. Spencer’s speculation that all social systems “evolved” led him to develop a complex threefold scheme for categorizing social systems

based on whether they displayed complex or simple structures and whether they were essentially stable or unstable. Firstly, a “simple” system is undifferentiated by sections, groups, or tribal formations. Secondly, a “compound” system amounts to an amalgamation of communities with a rudimentary hierarchy and division of labor. Thirdly, “doubly compound” systems are more complex still and united under one organized authority (Spencer 1971).

The major contributor to structural functionalism, Talcott Parsons, drew a complex blueprint of the social system applicable at all times and all places while allowing for the dynamics of complexity as societies evolved from pre industrial to industrial forms (Parsons 1951). For Parsons, the social system was constituted by a number of interacting functional “parts” that arose to deal with universal prerequisites. The fulfillment of these prerequisites ensured the survival of the social system, as did adherence by social members to an overarching value system. Also ensuring the endurance of the system was the need of its constituent parts to evolve through the differentiation that was the hallmark of modernization.

In Parsons’s schemata, a fourfold system of functional prerequisites gave way to universal structural arrangements: adaptation, goal attainment, integration, and pattern maintenance. Put succinctly, these universal social structural formations or “subsystems” realized these prerequisites through the following: economic activity (control over the environment), political arrangements (establishing goals and priorities), integration (the adjustment of potential or actual conflict), and the maintenance of value patterns (kinship structures and socialization processes). Parsons identified cultural values as the key to stability since value consensus integrates the various institutions or subsystems. Value consensus provided the foundation for cooperation given that common values engender common goals. In Parsons’s model both value consensus and subsystem formations structured patterned and recurrent human actions and relationships, particularly in terms of rules, social status and roles, and normative values. Thus a social system constitutes the accumulative entirety of normative behavior.

According to Parsons, the very task of sociology was to analyze the institutionalization of

the social system's value orientation. When values were institutionalized and behavior structured in terms of them, the result was a stable system or state of "social equilibrium." Such equilibrium was sustained by socialization, which constituted the means by which values are transmitted, alongside forms of social control, which encouraged conformity and discouraged social deviance.

Almost paradoxically, Parsons saw changes in the value system as the mechanism behind social evolution as well as the potential for disequilibrium. In short, change in one constitutive part (adaptation, goal attainment, integration, and pattern maintenance) was likely to engender change in another. Thus no social system was ever in a total state of equilibrium as it evolved toward more complex forms. Such evolution involved a general adaptive capacity as the social system increased its control over the environment. However, while economic adaptation might provide the initial stimulus for social evolution, it was changes in the value consensus that ensured that such change was forthcoming.

In identifying the evolutionary state of any given social system, Parsons outlined five key variables, which he referred to as cultural patterns "A" and "B." The former were synonymous with more simple forms, while the display of all or a majority of the latter constituted the cultural patterns of advanced societies. These patterns, for Parsons, entailed the following: (1) the change from ascribed to "achieved" status, which allowed social mobility according to merit; (2) the move from the diffuse and organic nature of social relationships toward the more utilitarian relationships of the modern world; (3) the transformation of the particularism engrained in social action into social acts according to universal principles; (4) the change from the affectivity of immediate gratification to deferred gratification; and (5) the evolution from a collective orientation toward self orientation.

The logic implicit in the concept of a social system was criticized even from within the school of structural functionalism. In attempting to develop functionalist theory, Robert Merton (1949) focused upon the alleged efficacy of a number of underlying assumptions. In particular, Merton questioned whether any given subsystem or constituent element of the social

system may be alternatively functional, dysfunctional, or non functional. Thus, he advocated the necessity of evaluating their overall contribution to system survival. Secondly, he speculated whether the functional utility of the constituent elements of a social system is particularly integrative, especially in advanced industrial society.

There arose further critiques of Parsons's theoretical framework which were to undermine its credibility. An especially damaging criticism of the paradigm of a social system was derived from what might be interpreted as the teleology inherent in structural functionalism generally. While this school of sociology advanced the view that the constituent parts of the social system existed because they have beneficial consequences, it effectively treated an effect as a cause. Hence, the reductionist analyses of the dynamics of an abstract social system are logically unsustainable. Moreover, assessing the positive effects of these elements is often unquantifiable. Subsequently, the biological analogy on which the paradigm was initially based became perceived as flawed.

social theory and sport

Jeffrey Michael Clair and Jason Wasserman

Despite acknowledgments of sport as a legitimate focus of sociological analysis from early thinkers such as Spencer, Simmel, Weber, Scheler, and Mead (Luschen 1980), the lack

of theoretical development in sport studies has been well documented (Frey & Eitzen 1991), although there appears to be increased movement toward the generation and integration of more theoretically driven work.

Washington and Karen (2001) point out that Bourdieu's "Sports and Social Class" statement has focused much of our attention with these following key observations: (1) sports is a field relatively autonomous of society with a unique historical dynamic; (2) sport represents struggles between social classes; (3) sport shifted from an amateur elite practice to a professionally produced spectacle for mass consumption; (4) sport production and administration must be understood within the industrial political economy; (5) sports participation as exercise or leisure time depends on economic and cultural capital; and (6) sport practices vary by the conscious and unconscious meanings and functions perceived by various social classes.

Sport provides unique opportunities for understanding the complexities of everyday life. Bourdieu's (1991) original argument calls for theoretical inquiry that integrates macro and micro interests, bridging social structure and social psychological processes. Macro methodologies cover, for example: (1) concerns with developing sport as a science (Luschen 1980); (2) global politics (Strenk 1979);

(3) sociohistorical labor and leisure development (Zarnowski 2004); (4) the accessibility of sport to various classes and social mobility (Kahn 2000); and (5) the role of media in generating national identities (Lowes 1997). Micro orientations will focus inquiry on (1) sport preferences and participation (Miller et al. 2002); (2) socialization (McNulty & Eitle 2002); (3) self esteem (Adler et al. 1992); (4) immortalizing the self through sport (Schmitt & Leonard 1986); and (5) sport play to display (Stone 1955).

Coakley (2004) explicitly addresses dominant theoretical perspectives and their relation to the study of sports, which are summarized in Table 1.

Still being a young field, the areas in need of theoretical attention are vast. While race, class, gender, and media studies have moved sport away from an "orphan speciality" status (Frey & Eitzen, 1991), other intriguing substantive areas remain fertile ground for development. Three areas which are particularly fruitful are the political nature of sport, sport as art, and the moral assumptions embedded in sport.

POLITICAL NATURE OF SPORT

Viewing sports as politics is not new. This connection has been referred to as "war without

Table 1 Dominant theoretical perspectives and their relation to the study of sport.

<i>Theoretical paradigm</i>	<i>Focus in sport</i>
Functionalist	Sport as producing positive social outcomes for social networks, physical and mental health, and benefits for non-sport related activities such as school, work, and family life.
Conflict	Political-economic forces that drive sport and the class-based relations that define it, such as the commercialization of sport, the influence of sport on economic inequality, etc.
Interactionist	Relations of sport participants examining the production of athlete identity, the meaning and significance of sport for athletes and spectators, and sport involvement processes from initiation of sport participation through retirement.
Critical	Power relations involved in sporting activities, such as how sport reproduces advantage or disadvantage, the relationship of sports to images of health compared to sickness or success compared to failure, etc.
Feminist	Gender relations embedded in sport, such as the construction of gendered identities within sport activity and the exclusion of girls and women in sports.
Figurational	Attempts to bridge the macro-micro divide by focusing on sports as embedded in a variety of multi-level social networks examining the evolution of sports in a historical network context.

weapons.” Strenk (1979) points out how Nazis under Hitler and Fascists under Mussolini propagandized sport. The globalization process seems to have only increased the prominence of sport in politics. Examples of the obvious intersection of sport and politics include:

- The losers of world wars have been banned for several years from the Olympic movement (the US refused visas to East Germans for two decades).
- Egypt, Iraq, and Lebanon boycotted the 1956 Melbourne Olympics in protest of the Suez war. Spain, Switzerland, and the Netherlands withdrew over the Soviet invasion of Hungary, and China pulled out in a continuing demonstration against the International Olympic Committee recognition of Taiwan.
- South Africa was barred from the 1964 Tokyo Olympics.
- The Mexican government shot and killed students protesting the 1968 Olympics in Mexico City.
- Arab terrorists kidnapped and killed Israeli athletes in Munich in 1972.
- 32 nations boycotted the 1976 Olympics in Montreal because New Zealand maintained sports relations with South Africa.
- The US, followed by West Germany and Japan, boycotted the 1980 Moscow Olympics in protest of the Soviet invasion of Afghanistan. In return, the Soviet bloc boycotted the 1984 Los Angeles Olympics.
- North Korea, Cuba, Ethiopia, and Nicaragua boycotted the 1988 Seoul Olympics.
- Gabon, Congo, Honduras, and El Salvador have gone to war over the outcome of soccer games.
- The US and Russia attempted to proclaim superiority of their political and socioeconomic systems by winning the most Olympic gold medals.
- The US used table tennis to open relations with China.

Sports have been “justified since antiquity for providing soldiers with the physical training they would require in battle” (Semenza 2001). There is always binary opposition in battle. It is one team against another, one country against another, one individual against another, one

alliance against another. Further, encounters in both sport and war are fundamentally a physical contest. Even competitors in sports where there is no direct physical contact between opponents understand their contest as one of warlike physical opposition. Finally, there are consequences for winning or losing. These may be concrete or symbolic, but they are clearly valued by competitors, as demonstrated by fierce competition and emotional reactions to winning and losing.

Gender also links sport and war. Male gendered traits tied to physicality, power, and domination underlie both the good athlete and the good soldier. Generally, sports are not simply the random assertion of masculinity; rather, they are structured expressions of it, reflecting past, dominant, institutionalized representations of masculinity (i.e., war). Social theory can further illuminate similarities in sport and war, generating insight into current international political relations as well as reaching into the social psychological production of gendered identities.

SPORT AS ART

Athletes talk about a sense of effortless competency, a flow felt while playing where it all comes together – all the training, studying, and coaching. During this experience the mind seems to stop and there is expanded vision beyond thought. This is referred to as “being in the zone” or what we call a *creative action rhythm*. It emerges from a twofold process: (1) *learning*, by first absorbing all that one can from books, practice, and coaches/teachers, and (2) *creative acting*, where one acts *out of* what was learned instead of merely imitating. This creative action rhythm is the very essence of the true athlete as artist.

The dependence of sport on rules may suggest an opposition to creativity. But suppose the rules were restrictive and it was possible for them to remove the artistic, creative element of sport and that athletes merely applied what they had learned from their coaches. Would sport still be enjoyed by spectators? Would athletes still practice their crafts with passion and dedication? Imagine going to a basketball game where the players seldom did anything new. We would only tolerate it for young

players, and then maybe only if the players were our own children. But reflect on how excited we are when a successful, dynamic, creative play occurs. These are actually the moments which give meaning to sport. These moments, when sport transcends physical mechanics and becomes emotionally salient, are what allow individuals to experience creative participation, even as spectators.

Young (1999) shares an interesting theoretical framework in this regard. Calling on Heidegger, he reminds us, "poetically dwells man upon this earth." This means, without art, he merely exists. Sport, like art, conjures emotion in the participant as well as the viewer. This emotion pulls us away from the maze of everyday details, demands, and decisions (Goffman 1961). This emotional experience is the essence of art and it is clearly found in sport.

Attending a sporting contest is itself seeking artistic expression (Young 1999). The game setting is far from the ordinary. Our team reveals the multicultural mix of our community, but is integrated. And although we sit in hierarchical seating, we experience union with one another, a manifest integrity of our community. We share a national anthem. We see our morality in the rules (e.g., fairness, earned accomplishment, etc.). The athletic activity, although subordinated to rules, encourages equality between competitors, but yet does not get in the way of artistic expression. We can see the virtues of skills. And however well planned and rehearsed, with the final outcome, we come to grips with being mortal. Through the athletic artistic expression, we are transported from our "average everydayness" into *Augenblick*, the "moment of vision" (Young 1999). The athlete helps us see the hero that is concealed in everyday characters. Social theory, particularly in the sociology of emotions, has much to contribute and gain from studying the creative, artistic, and emotional qualities of sport, and the meanings we bring and take away from our games (Duquoin 2000).

MORAL ASSUMPTIONS EMBEDDED IN SPORT

Sport both embodies and impresses particular assumptions about human nature and a moral

order. Particularly central to youth sports, the debate about the value of competition represents broader clashes over human nature itself. In a cyclical fashion, sport both assumes competition as an innate human quality and in turn teaches that this is the case. Like much western social, political, and economic theory, implicit in sport is the ideological assumption of a human will to power. The extent to which this is innate rather than cultural, if it is at all, remains unclear. There is evidence that this sort of orientation is primarily cultural (Sahlins 1972). Many traditional societies often do not overtly reflect this will to power. Thus, one might claim that it is the institutionalization and structure of sports, which most often follow a western, capitalist model of competition, that produce these tendencies. Sahlins (1972) similarly found that small, primitive societies tended to develop westernized power orientations only after being engulfed in larger, organized states. Sport is certainly one arena in which investigation into the matter may prove fruitful.

While emphasis on competition is still the pervasive ethos of sport, some youth organizations have consciously shifted away from a competitive model. For example, there are leagues in which everyone receives a participation trophy rather than just rewarding top place teams and most valuable players. Coaches may be discouraged from emphasizing winning as a value, or even from showing too much enthusiasm for "successful" play (e.g., within the American Christian Upward Program). These organizations present an opportunity for sociology to address some competing hypotheses embedded in the ideologies of these typical and counter typical models of sport. Social theory ought to be able to contribute to and gain from the study of youth development, attitudes, and mental health by comparing these different models of sport, which seem particularly polarized concerning the value of competition.

We might compare the current diversity in the world to a prism. The nature of the prism's color spectrum is that there is no connectedness between colors, meaning there is no identifiable demarcating line that defines the end of one color and the beginning of another. It is essential to realize that one of the colors in the spectrum of global diversity is sport. Its boundaries blend and merge with the agenda and concerns of

gender, race, ethnicity, religion, family, work, leisure, economic development, politics, global relations, etc. The selected literature cited here points to the possibilities of interdisciplinary social theory development.

social work: history and institutions

Sabine Hering

From the beginning of the nineteenth century industrialization and the rise of civil society created a new framework for human welfare: the fact that poverty caused by nature was replaced by poverty caused by social deprivation brought up the need for appropriate ideas and solutions that expanded the range of regional or national welfare strategies into an international perspective. "Social welfare" is not only the old fashioned term for social work, but is also the more general term: social welfare continues to include in most parts of the world programs that promote the general welfare (e.g., social security) and involves other professions as well as social work. This entry details the main changes in the field of social welfare through the development and discussions of its international organizations.

The International Council of Social Welfare (ICSW) was founded in the context of the Conference for Social Welfare, held in Paris in July 1928. René Sand, one of the initiators of the conference and the ICSW, used to emphasize the "double origin" of the organization, pointing to the fact that it corresponds to the model of the American National Council of

Social Welfare (NCSW, founded 1874 as the Conference on Charity and Correction), as well as to organizations and networks in Europe whose activities go back to the middle of the nineteenth century – the *Congrès internationale de Bienfaisance* (1856–63) and the *Congrès d'Assistance publique et privée* (1889–1910).

Since the Enlightenment, the American Declaration of Human Rights and the French Revolution, together with the negative consequences of industrialization (e.g., poverty, slums), had given rise to public discussion about the “social question” and to new movements such as the Inner Mission of the Protestant church and the Settlements of the Social Utopians. The international peace movement, the movement for the abolishment of slavery, and the feminist movement inspired the political ideas of welfare strategies, as well as the declaration of the Geneva Convention initiated by Henri Dunant in 1864, which was the starting point for the International Red Cross. Discussions about prison reform also decisively influenced welfare discourses: the *Congrès Penitenciaire* held in Frankfurt in 1846 and in Brussels in 1847 accelerated the discourses on welfare, education, and social reform, and led to the first attempt to gather information about poverty and the needs of the working class on an international basis, in order to inform the public about the necessity of social reforms.

Although the revolutionary activities in 1848–9 made these initiatives ineffective, there was a second departure in 1851–2 when the *Congrès d'hygiène public* raised questions of welfare in the context of social hygiene in Brussels. The main topics of these conferences were the housing shortage and the state of dwellings, disease, abolition of child labor, prostitution, and venereal disease.

Probably the first international welfare conference as such took place in Paris in 1856, the *Congrès internationale de Bienfaisance*. Nearly 300 participants from 20 countries came to the conclusion that there should be regular meetings in the future to create common standards of poor relief and charity for the most serious social problems: poverty and the lack of social hygiene. Discussion was dominated by questions of social insurance and social security, as well as the principles of self help. The idea was to find a balance between the responsibilities of

the state and the resources of the clients (and the charity organizations which cared for them). Cooperation with conferences dealing with social science and statistics became closer, in order to accelerate political change in the field of social reform with “demographic evidence.”

National and international political conflicts hindered the development of international social welfare for some years. It was not until 1889 that the pioneers of social welfare met again to form a new international association: the *Congrès d'Assistance publique et privée*.

In the meantime the efforts of the first wave of international exchange in the field of social welfare began to show results. In England in the 1860s the 1834 Poor Law was reformed, while a multitude of private philanthropic activities were united under the Charity Organization Society (COS) in 1869. In the US, Buffalo was in 1877 the first city to introduce the model of the COS into its local welfare system. By the end of the nineteenth century more than 100 larger cities in the US had followed this example.

In France the *Office Central des Institutions Charitables* performed comparable work. After 1871 the Third Republic emphasized the responsibility of the state for child relief and care for the elderly and mentally ill with new legislation, together with the importance of private charity. In Germany a district oriented social system originally established in Elberfeld became influential (nationally and internationally) because it facilitated an effective relief structure based on semi professional neighborhood support. In the 1880s the Bismarck Sozial system (including social insurance against illness, invalidism, and poverty among the aged) provided protection against the most serious social risks – an important step into the future, although it was in the beginning only intended for male industrial workers.

The *Congrès d'Assistance publique et privée* turned out to be the most important precursor of the ICSW. Until 1910 it furthered progressive ideas like female participation in public welfare activities, professional training, preventive measures against tuberculosis, child protection, and eugenics.

From the beginning of the twentieth century the influence of the feminist movement all over the world had become stronger, including

within social welfare. While charity and municipal poor relief had been delivered exclusively by local authorities, priests, physicians, and other male citizens (occasionally assisted by nurses or nuns), social work was now defined as a typically female profession corresponding to "typical female attributes" like patience, compassion, and empathy. However, the "welfare takeover" by the feminist movement did not lead to more sense or sensitiveness in social work, but to more sensibility. It was obvious that the welfare system at the end of the nineteenth century urgently needed modernization, mainly in regard to the dark side of the industrial revolution and its numerous negative social consequences. Female pioneers at that time were especially interested in higher education and professional perspectives in order to take part in societal decision processes. They realized at once that social reform provided a wide area for systematic and serious activities, fitting perfectly into their ideas of public participation. Thus the feminization of welfare signaled the end of the predominance of individual charity and helped lead to the idea of social work as a profession.

The last and most important conference of the *Congrès d'Assistance publique et privée* (in Copenhagen in 1910) confirmed these ideas and focused the modern welfare system on three main principles: a balance between social insurance and social work, coordination of state and private welfare structures, and vocational training.

Although World War I furthered the processes of welfare modernization, as all countries had to cope with the welfare needs of an enormous number of widows, orphans, and disabled, international cooperation was again severely disrupted. The cancellation of a conference planned for 1915 in London was the beginning of an interruption to international welfare discourse that lasted until 1928. On the other hand, the terrible experiences of the war provided the impetus for the League of Nations (founded in 1920), the International Labor Organization (founded 1919), International Red Aid (founded 1921), the International League of the Red Cross (founded 1919) and the predecessor of the World Health Organization (the Health Committee, founded 1923), among other examples.

In this same period in the US, the NCSW became a great influence on the development of international structures in the field of social work. The main starting signal for the "great" International Conference of Social Welfare (the so called *Quinzaine Social* held in Paris in 1928) came from the US, as did financial support for the preparatory work. These incentives of the NCSW and the efforts of the International League of the Red Cross (represented by Alice Masarykova from Czechoslovakia and the Belgian physician René Sand) enabled the largest welfare conference to take place. The idea of the conference was to create a survey of the development of social work all over the world, inviting welfare experts from as many nations as possible, who were supposed to describe the social systems in their countries. Soon, however, other organizations wanted to participate and urged the planning committee to widen the range of topics. In the end, there were five conferences united in the *Quinzaine*: the International Conference of Social Welfare itself, a revived *Congrès d'Assistance publique et privée*, the International Conference of Child Protection, the International Conference of Housing and Urban Development, and an exhibition on Settlements and Social Progress. Over 5,000 participants from 40 countries attended the conferences, the reports of which (published in French, English, and German) covered nearly 2,500 pages.

The most important result of the conference in Paris was the foundation of the International Council of Social Welfare as a worldwide platform for professional development and exchange. The participants decided that all the nations present should be members of ICSW, but only Belgium, Czechoslovakia, France, Germany, the UK, and the US were also represented on the executive board. With the exception of Japan and Chile, countries from Africa, South America, and Asia, as well as Australia, were excluded.

The next ICSW conference was held in Frankfurt in 1932 and focused on just one extremely topical social problem: the consequences of unemployment for the family. The conference proceedings showed unmistakably that there were very different political and professional positions "united" in the ICSW, varying from communist ideas of partnership to the attempt of some Catholic representatives to defend

motherhood and family life against the temptations of modernization.

The third conference on "Social Work and the Community" took place in London in 1936. The most significant characteristic of these last pre war proceedings was the venture of fascist countries like Germany and Italy to functionalize the term "community" for their idea of the *Volk*, in order to create eugenic standards for its perfection. There was no agreement in respect of this question, but nevertheless there was a certain sympathy for eugenic ideas in non fascist countries.

The 1940 conference on "Youth Work and Youth Care" was prevented by World War II. In August 1946 the three former presidents of ICSW (Alice Masarykova, Mary van Kleeck, and René Sand) met to consider the future work of ICSW. Once again, they tried to reconstruct the organization so that it had close connections with the official international platform – this time, the United Nations. However, they had to take into account that other social organizations had already been established during the war to give help to refugees and other displaced persons. The United Nations Relief and Rehabilitation Administration (UNRRA) and the Intergovernmental Committee on Refugees (ICR) merged in 1948 to form the International Relief Organization (IRO). In contrast to ICSW, these organizations had adequate financial means and an enormous number of helpers. Furthermore, UNICEF and the WHO had already been instructed by the UN to develop activities in fields that had been under the direction of the ICSW before the war. Also of enormous influence was the Philadelphia Declaration of the ILO, which proclaimed that the worldwide struggle against poverty and for welfare was a human right independent of race, sex, or belief.

ICSW tried to reestablish itself within this framework of remarkable activities. Being mainly related to European traditions and networks, first attempts were hampered by the destruction of all kinds of infrastructure caused by the war and the new division between East and West. The first post war conference was held in Scheveningen in the Netherlands in 1947 to discuss "Urgent Social Problems in the War Stricken Areas of Europe" and was

attended by only 168 representatives from 18 countries. Because of this very low rate of participation, conference members discussed not only the problems of effective help for millions of people in need, but also the question of their relation to the Council of International Voluntary Agencies (IVA, including the Quakers, Oxfam, and a number of other social organizations) and the UN. They realized that they urgently needed to establish closer connections to organizations in the US. They decided to hold the next conference in Atlantic City, combining the 75th anniversary of NCSW with their proceedings.

In the short period between Scheveningen and Atlantic City (1948) many of the national committees of ICSW, as well as the board, had largely recovered from the effects of the war. Although connections with members in Eastern Europe were broken, there was general agreement to carry on because the challenges were larger than ever. After Atlantic City, two items turned out to be of great importance for the future of ICSW as an international platform of relevance. First, it became obvious that "international" meant more than Europe and the US: ICSW had to be open to members on all five continents and consider them as equal partners. The second item was related to the remarkable increase of international social organizations, which required an efficient division of labor. ICSW had to serve as a platform for international discourses about social needs and support structures all over the world – excluding the political mandate for social work (held by the UN), the representation of the profession (held by the International Association of Social Workers), and all items of education and vocational training (covered by the International Association of Schools of Social Work).

ICSW defined itself in relation to the multitude of international NGOs in the field of social welfare as a partner for theoretical and methodical discourses and as a coordinator for common incentives. Meetings of ICSW – held for example in Madras (1952), Tokyo (1958), Rio de Janeiro (1962), and Jerusalem (1978) – included representatives from all over the world and showed that this idea worked. Furthermore, ICSW was able to face the most relevant topics of social welfare in each period after World War

II, discussing "Urban and Rural Development" (1962), "Social Welfare and Human Rights" (1968), "Social Development in Times of Economic Uncertainty" (1980), "Welfare in West and East" (1992) and "Global Governance" (2004).

Nevertheless it is impossible to relate the history of social welfare exclusively to the history of ICSW after 1945. The diversification of worldwide developments in the field of social work is too large to be interpreted within the framework of just one organization, even if the reflection of that diversification is one of the main activities of ICSW. In all emergent welfare states after World War II, social work was gradually established as a key profession charged with the implementation and the fine tuning of an ever denser net of social policy measures. Its discourses reflect a polarity between universalism, which is the legacy of early international activities, and the "indigenization" of methodological orientations. Along this spectrum, international conferences and activities remain a central feature of social work's professional orientation.

Looking back on the history of social work there is one important theme that connects the past to the present: the idea of "internationality," which has always been one of the basic guidelines of social work since its modernization in the nineteenth century. Social problems cross borders. Although every country has to find national answers to these international challenges, the seeds of a global perspective were sown at the first international meetings on social welfare.

social work: theory and methods

Silvia Staub Bernasconi

Theory construction in social work which tries to bind together theory and methods and to introduce the notion of social work as discipline and profession departs from an "open triangle" consisting of theory as an interrelated conceptual system, research, and practice, or applied social science plus social work values and skills linked in a dynamic way (Lovelock et al. 2004: 3). Thus it is a basic scientific undertaking to connect the following elements: a theory of the individual as a biological, psychic, and social being and as a member of different social systems; a theory of society and culture and the interaction between the individual and

society/culture; a policy or program as a scheme for changing problematic situations; and a set of people, among them professionals, in different forms of social organization (social services, social movements, networks, etc.) committed to carrying this change through with the help of specific methods.

Looking at the history of ideas in social work (Soydan 1999), one has to start with the contributions of two classical theorists: Mary Richmond and Jane Addams, who paved the way for the two main theoretical traditions of social work focusing on individuals and/or society. Mary Richmond focused on the individual, his or her personality and unmet needs, and the social environment upon which the individual depends for need satisfaction. Seeking the main causes of social problems within the individual, her change program was therefore oriented to the individual – as in professional casework – in order to remedy social problems. Jane Addams's theoretical focus was basically on the structure and culture of society and their influence upon the individual. She developed a normative vision of integral democracy that promoted freedom and participation, but also social care and justice for all. In addition she realized that it was essential to develop social change programs on the basis of scientific knowledge and genuine research. For Addams, the causes of social problems had to be sought in societal structures and their cultural legitimization. The work of change therefore had to be directed at these conditions. Thus one had to fight – along with political parties and other organizations and professions – for the institutionalization of new laws of social security, especially for the protection of children and women in abusive work conditions, or one had to change the actual social rules or ideologies that allowed exploitation in the workplace, discrimination against women, and legitimization of wars on nationalistic grounds that made heroes out of soldiers. This approach to individual and social change was reflected in a multilevel conception of social work activities that encompassed activities on the individual, family, community, regional, state, and international levels.

The split of theory and action between Richmond and Addams into a micro and macro approach, together with the implicit or explicit

claim of exclusiveness by both parties, is not unique in the history of human and social sciences, and persists to the present day. Yet, there are mediating positions, too, the most prominent being the internationally consensual definition of social work as follows: "The social work profession promotes social change, problem solving in human relationships and the empowerment and liberation of people to enhance well being. *Utilizing theories of human behavior and social systems, social work intervenes at the points where people interact with their environments.* Principles of human rights and social justice are fundamental to social work."

THEORETICAL AND PRACTICAL APPROACHES: THE FOCUS ON INDIVIDUALS

After the pioneer contributions of Richmond and Alice Salomon in Germany, *psychodynamic concepts* became the first strong explanatory theory for many practice concepts (see Payne 1991).

Psychoanalytic social work. Florence Hollis adapted psychoanalytic theory for social work practice by developing the notions of a sustaining relationship and techniques to reduce anxiety, low self esteem, and lack of confidence. She added procedures of environmental work with people relevant to the client (family members, employers, landlords). The role of the social worker is as an interpreter of feelings, promoter of insights, provider or creator of resources, and mediator or protector (of children). Although there may be things wrong with society, the social worker's main task is to help the individual to cope with problems in developing a realistic – anxiety free – perspective of his or her situation and adapting to it. The professional seeks social reform here as a separate activity.

Behavioral theories and methods derive from the work of experimental behavioral psychologists which criticized the diffuse, untestable conceptions of psychoanalytic theory. The behavior of clients is seen as coping with frustration and aggression in different role settings. Action oriented concepts are classical conditioning by stimulus response, the techniques of operant

conditioning, and social learning. The social worker has to manage contingencies that affect the relationship between the behavior of an individual and its (un)desired social consequences. The main goal is adequate role behavior as parent, pupil, employee, and so on.

Cognitive theories work on the assumption that people construct their own versions of reality and problems through what they have learned. Stimuli are transformed by a process of awareness, description, and interpretation into overt behavior. There can be conflicts between self conceptions, perceiving self through others, and intentional self. The task of the social worker is to support strategies of learning such as discrimination, concept formation, value finding, and problem solving, sustained by a diary and tasks (homework). The social worker confronts the client with her divergent thinking, pointing out inconsistencies and faulty and alternative modes of thinking, with the aim of finding a more rational way to solve problems.

Task centered social work seeks to replace psychodynamic social work based on a "time consuming" supportive relationship with a rationally planned, "short term therapy" that has a clear time limit. It rejects any specific psychological or sociological base for its methods, because no theory can adequately explain the range of problems that social work has to deal with. Central to this approach is what the client presents or accepts as problems and what he wants to change in his life, as well as the establishing of a contract about the desired outcome, the amount of contact and time limits, and the arrangement of incentives for success.

Strength development. Strength or resilience is seen as a product of facing adverse life events and traumatic situations which can be used as a resource for actual problem solving. Strengths focused listening is the main method, i.e., observing until, through mutual discovery, events and themes can be found that mobilize the courage to try new behavior.

An integrated – systemic – view would combine these approaches in such a way that it would become clear that individuals have emotions, cognitions, values, self concepts, and so on that all influence how they cope with life tasks and social problems. The last two approaches coincide with the beginning of the

neoliberal hegemony favoring methodological "fast food versions" (James, in Lovelock et al. 2004).

THEORIES AND METHODS: INTERACTION OR NETWORKS BETWEEN INDIVIDUALS

As these theories start with a conception of the individual as a member of families, groups, communities, and organizations, it is possible to speak of the beginning of systems theory in social work. Yet, their focus is mostly on communication patterns, leaving aside an elaborated systemic theory of individual and society. Many of them focus on symbolic interaction and role expectations, especially in relation to processes of stigmatizing, scapegoating, and exclusion (Mead, Goffmann). These interaction processes describe the behavior and problems of social work clients with their social environment as a result of the possible stigmatizing effects of social workers in "people processing organizations."

A prominent approach in family treatment is *transaction analysis*, which comes from psychodynamic theory and focuses on the ego states in one person (as child, parent, adult) interacting with those in another person. When transactions involve different ego states, problems and misunderstandings arise. The role of the social worker is to analyze and change communication patterns which make the other feel bad, incompetent, powerless, and inferior. Further techniques are reframing, family sculpting, role playing, videotaping, homework assignments, and mediation (Kirst Ashman & Hull 1993).

Social work with *groups* bases its interventions on the structure, culture, and dynamics of groups. The role of the social worker can be task oriented, more supportive/therapeutic, or action oriented. The last named role can lead to economic, social, and cultural activities in the larger community.

Another set of theories conceptualizes resources of social and cultural environments in order to construct supportive social networks or organizations in a community, e.g., for the creation of new jobs suited for long term unemployed, disabled, and minority members who have no chance of getting a job in the main stream economy.

THE INTERFACE BETWEEN SOCIAL WORK AND SOCIAL POLICY

From the 1960s to the 1980s, “radical social work” – neo Marxist, structural, feminist, anti racist, anti oppressive, or anti discriminatory – emerged as a distinctive theoretical and practice approach. It criticized psychological explanations, which privatized social problems instead of transforming them into public issues, blamed the victim, and cut service users off from collective action by treating them individually. This was accompanied by a radical critique of the social welfare system for the overspecialization of its social agencies, for sharing mainstream ideologies and bureaucratic rigidity, and for selectively working with those who were easiest to help; in short, for simply being a servant of the ruling class. The general theoretical hypothesis was that service users – the poor, unemployed, women, ethnic minorities, and so on – would act rationally in their own interests once they understood that the true origins of their problems lay not in themselves but in exploitative and oppressive social structures and cultural codes (Leonard 1975; Galper 1980). Thus, social workers should not waste their energy changing clients’ behavior to make it conform to standards of so called normality. “Structural theory” extended the approach to all forms of overlapping and mutually reinforcing injustices in relation to class, gender, race, disability, sexual orientation, and religious and ethnic minority status (Mullaly 1997). Further more, the power relationships between social agency, social workers, and their clients became a target of critical reflection.

The role of social work is seen in three different ways: (1) as part of the oppressive capitalist system which has to control the working class, unwed mothers, minorities, and so on and make them fit for work; (2) as advocate of social change, promoting consciousness raising and supporting community organization and collective action; and (3) as both agent of capitalist, paternalistic, and racist society and as willing or unwilling leader of change by transmitting new perspectives, knowledge, knowhow, and power sources to the marginalized for organizing themselves to reach their goals. Following this last line of reasoning, the role of social work is to:

- organize shelter for victims of oppression and violence, help them to regain dignity in listening to their accounts, assess their power resources, and support them to carry through their claims for social justice (for black empowerment, feminist empowerment, etc.);
- transform private troubles into public issues by building cooperatives at the community level and participating in social action;
- introduce human rights, especially social justice, into the culture and practice of social agencies according to the international code of ethics for social work (Staub Bernasconi 1991, 2003; Reichert 2003).

INTERACTION BETWEEN INDIVIDUAL AND SOCIETY: FOUR WAVES OF SYSTEMS THEORY

General systems theory. The first system theorist in social work (Hearn 1958) used biological and cybernetic concepts such as homeostasis, entropy, equifinality, and feedback. Essential for growth was the maintenance of a “steady state” between the individual and social systems, avoiding states of entropy (disorder). Critics argued that the chosen concepts reflected a mechanistic, non human nature of people, especially the concept of “steady state,” which could legitimize patriarchal domination and violence in families.

Ecosystems perspective. Germain and Gitterman (1996) used the notion of ecosystems not as a theory but as a metaphor to focus on transactions within and across systems. For them, problems arise when there is a poor fit between a person’s environment and her needs, capacities, rights, and aspirations. Change endeavors focus on transactions instead of an isolated improvement of the social functioning of individuals. The life model of social work practice (Germain & Gitterman 1996) stands for the following action principles: active partnership based on mutuality and reciprocity, assessment of life stressors in passing from one system to another (family to school, school to work), and assessment of strengths and capacities, using an “ecomap” as a pictorial representation of micro, meso, and macro systems in concentric circles and their resources, in discussion with the

client. The social worker's role is to create supportive community networks. At the organizational level (school, work, social service institutions), advocacy should be aimed at changing policies if they work against client interests. This requires skills such as coalition building, positioning, lobbying, and testifying.

Complex systems theories. Complexity theorists (Warren et al. 1998) argue that it is not stability but change – as a form of “deterministic chaos” – that is the normal feature of systems, amplified by self reinforcing feedback with possible snowball effects and moments at which the system switches from one pattern of complexity to another. Thus social workers have to assess and use these moments to help the system to switch in the direction of social work goals. The criticism here is again that chaos theories emerged originally in math, physics, thermodynamics, and cybernetic engineering, and thus have limited application in human and social sciences. Proponents of the systems theory of Luhmann state that social problems are generated by the exclusion of people from social systems such as the family and educational, economic, political, and cultural systems; thus a new autonomous social welfare system became institutionalized which works with the excluded for their reinclusion or, if this is not successful or possible, for the management of the excluded.

The *systemic paradigm* of social work (Staub Bernasconi 1991, 1995; Hollstein Brinkmann & Staub Bernasconi 2005; Obrecht 2005) sees systems theory as a chance for a unifying (meta) theoretical foundation of social work under the general idea of “integrated pluralism.” It acknowledges that the reduction of systems theory to physics, biology, and cybernetics was a theoretical mistake, but that it paved the way to a more adequate, non reductionist systemic view. The main focus is on understanding the structure and dynamics/transactions of and between biological, psychic, and social/cultural systems, and on building the transdisciplinary explanatory base for social work.

Social work practitioners face individuals with needs, cognitions, wants, hopes, plans, and learning capacities who are faced with (un) responsive, discriminating, and oppressive social systems and cultural environments, from the family to world society. Transactions between

individuals as members of social systems can be cooperative, competitive, conflictive, or destructive. It is the latter that lead to social problems. Social work practitioners point to vulnerable individuals and groups deprived of resources, power, justice, and dignity under the overarching perspective of unfulfilled human needs and human rights violations (Staub Bernasconi 2003). The general goals of social work are the well being of the individual and the social reform of social systems, relying on human rights, especially social justice, as regulative ideas laid down in the UN Manual on Social Work and Human Rights and the Global Accreditation Standards for Education and Training in Social Work of 2004. Methods can comprise the theoretical base and procedures of resource identification, production, and allocation; consciousness raising; ego strengthening; changing cognitive structures, values (i.e., self conceptions, prejudices), interpretations, and plans; task focused learning and behavioral training to attain specific goals; networking and mediation in relation to an unresponsive social environment; intercultural communication; empowerment, advocacy, anti discriminatory work, and democratic participation; and finally, all the methods and techniques of influencing public and political social policy as well as legislative discourse and legislation to provide access to individuals, groups, and members of vulnerable social categories to societal resources and power.

social worlds

Adele E. Clarke

The term social worlds is used in the social sciences in two main ways. One is as a generic reference to a specific situation or social context, and the second is explicit social worlds/arenas theory within the theoretical tradition of symbolic interactionism.

In its generic form, the term social world usually refers to the relatively immediate milieu of the individuals or collectivities being studied. It is conventionally understood as pointing at the specific contexts of the situation in which those individuals and/or collectivities are to be found. For example, reference may be made to the social world of antique collectors, professional baseball, or surfing. The usage is somewhat similar to the concept of subculture. However, (sub)cultural studies generally focus on the subculture per se (who the members are, what they do, how and why they do it, etc.), such as "Deadhead" or "Trekkie" fandoms. The generic use of social world usually points outward from the individuals or collectivities being studied to their salient contexts as a means of explicitly situating them in sociocultural space and time.

In symbolic interactionist theory over the past century, a series of concepts has been built up around the core concept of social world. Here as elsewhere, interactionists have taken a general term, elaborated it conceptually, and integrated it with related sensitizing concepts to form a theoretical/analytical framework useful in empirical research.

Early Chicago School studies focused on "social wholes": communities of different types (e.g., ethnic communities, elite neighborhoods, impoverished slums), distinctive locales (e.g., taxi dancehalls, the stockyards), and signal events of varying temporal durations (e.g., a strike). The sociological task was to make the *group* the focal center and to build up a knowledge of the whole by examining it in concrete situations. Instead of emphasizing shared culture as anthropologists of the time did, these early works in the Chicago tradition focused on shared territory or geographic space and the

encounters and interactions of human groups that occurred within these environments or ecologies.

These inventories of social spaces often took the form of maps. Many traditional Chicago School studies were undergirded by an areal field model – a “map” of some kind done from “above,” such as a city map modified to show ethnic, racial, elite, and other specific neighborhoods and/or work areas, etc. Relationality was a featured concern and the communities, organizations, and kinds of sites and collectivities represented were to be viewed both in relation to one another and within their larger contexts. Blumer (1958) was a key early paper that drew upon this framing.

In the 1950s and 1960s, researchers in the interactionist tradition reframed the study of social wholes by shifting to studies of work, occupations, and professions, moving from local to national and international groups. Geographic boundaries were dropped as necessarily salient, replaced by *shared discourses* (again, not culture) as boundary making and marking. Perhaps most significantly, they increasingly attended to the relationships of those groups to other social wholes, the interactions of collective actors and their discourses.

Sociologists Tamotsu Shibutani (1955), Rue Bucher (1962), Anselm Strauss (1978), and Howard Becker (1982) then initiated explicit social worlds theory development – the high modern version of studies of social wholes. Social worlds (e.g., a recreation group, an occupation, a theoretical tradition) generate shared perspectives that then form the basis for collective action, while individual and collective identities are constituted through commitments to and participation in social worlds. Commitment was understood as both predisposition to act and as part of identity construction. Social worlds are *universes of discourse* and principal affiliative mechanisms through which people organize social life.

Strauss argued that each social world has at least one primary activity, particular sites, and a technology (inherited or innovative means of carrying out the social world's activities) and, once underway, more formal organizations typically evolve to further one aspect or another of the world's activities. People typically participate in a number of social worlds simultaneously

and such participation usually remains highly fluid. Becker asserted that *entrepreneurs*, deeply committed and active individuals, cluster around the core of the world and mobilize those around them. Shibutani viewed social worlds as identity and meaning making segments in mass society, drawing on distinctive aspects of mass culture, with individuals capable of participation in only a limited number of such worlds.

Every complex social world characteristically has *segments*, subdivisions or subworlds, shifting as patterns of commitment alter, reorganize, and realign (Bucher 1962; Baszanger 1998). Two or more worlds may intersect to form a new world, or one world may segment into two or more worlds. Larger *arenas* of concern are constituted of multiple social worlds focused on a given issue and prepared to act in some way, usually in struggles for power, authority, and legitimacy within that arena and beyond. In arenas, various issues are debated, negotiated, fought out, forced, and manipulated by representatives of the participating worlds and subworlds (Strauss 1978).

What this means methodologically is that, if one seeks to understand a particular social world, one must understand all the arenas in which that world participates and the other worlds in those arenas and the related discourses, as these are all mutually influential/constitutive of that world. The *boundaries* of social worlds may cross cut or be more or less contiguous with those of formal organizations. This fluidity and the action focus fundamentally distinguish social worlds theory from most organizations theory (Clarke 1991). Society as a whole, then, can be conceptualized as consisting of layered mosaics of social worlds, arenas, and their discourses.

As part of Chicago School interactionism, social worlds/arenas theory is a conflict theory. There typically exist intraworld differences as well as the more conventionally expected interworld differences of perspective, commitment, and inscribed attributes. For Strauss, *negotiations* of various kinds – persuasion, coercion, bartering, educating, discursively and otherwise repositioning, etc. – are strategies to deal with such conflicts and are routinely engaged. Strauss (1993) also called this *processual ordering* tive and emergent aspects of interaction.

Key sociological differences emerge when researchers focus on studying the social world's work activities, organization, and discourses rather than studying individuals or organizations. Placing work-action in the analytic foreground facilitates the analysis of social worlds qua worlds. Here social worlds and arenas become the units of analysis in studies of collective action and discourse.

There can also be *implicated actors* in a social world, actors silenced or only discursively present – constructed by others for their own purposes (Clarke 2005). This concept provides a means of analyzing the situatedness of less powerful actors and the consequences of others' actions for them, and raises issues of discursive constructions of actors. There are at least two kinds of implicated actors. First, there are those implicated actors who are physically present but are generally silenced, ignored, or made invisible by those in power in the social world or arena. Second, there are those implicated actors *not* physically present in a given social world but solely discursively constructed. They are conceived, represented, and perhaps targeted by the work of those others; hence, they are discursively present.

Star and Griesemer (1989) developed the concept of *boundary objects* for things that exist at junctures where varied social worlds meet in an arena of mutual concern. Boundary objects can be treaties among countries, software programs for users in different settings, and even concepts themselves. The object is “translated” to address the multiple specific needs or demands placed upon it by each of the different worlds involved. Boundary objects are often very important and hence can be sites of intense controversy and competition for the power to define them. The study of boundary objects can be an important pathway into often complicated situations, allowing the analyst to study the different social worlds through their distinctive relations with and discourses about the boundary object in question.

Drawing upon Bucher's (1962) insights, interactionists have examined fluidity and change within social worlds and arenas by extending social movements analysis to include studies of reform movements of various kinds undertaken by segments or subworlds within professions, disciplines, and work organizations.

Such reform movements can cut across whole arenas. Fujimura (1996), who studied the molecularization of biology, called such larger scale processes *bandwagons*. In many arenas, reform movements have centered on processes of homogenization, standardization, and formal classifications – things that would organize and articulate the work of the social worlds in that arena in parallel ways (Bowker & Star 1999). (This contrasts with theories of organizational isomorphism.)

Extending Strauss's work on articulation, Fujimura (1996) introduced the concept of *doable problems*. Doable problems require successful alignment across several scales of work organization. In her example in science, this included (1) the experiment as a set of tasks; (2) the laboratory as a bundle of experiments and other administrative and professional tasks; and (3) the wider scientific social world as the work of laboratories, colleagues, sponsors, regulators, and other players all focused on the same family of problems. Doability is achieved by articulating alignment at all three scales simultaneously to meet the demands and constraints imposed: a problem must provide doable experiments, be feasible within the parameters of immediate constraints and opportunities in a given laboratory, and be viewed as worthwhile and supportable work within the larger scientific social world.

The concept of *staged intersections* – one shot or short term events in which multiple social worlds in the arena come together – is Garrity's (1998) particular contribution to social worlds/arenas theory. The key feature of staged intersections is that despite the fact that the same representatives of those worlds probably will never come together again, the events can be highly consequential for the future of all the social worlds involved, for the arena, and beyond. They can be what Strauss termed turning points in trajectories.

The social worlds/arenas framework has recently been used as the conceptual infrastructure of a new mode of grounded theory for qualitative research called situational analysis (Clarke 2005). Here, making maps of social worlds and their arenas is part of the data analysis, providing portraits of collective action at the meso level. The key analytic power of social worlds/arenas theory, so rooted in Chicago

social ecologies, is the elasticity of the various concepts to analyze at multiple levels of complexity.

socialism

Lloyd Cox

Socialism refers to doctrines and practices sharing a pattern of family resemblances centered on collective property, social equality, cooperation, and communal forms of economic and political association. Beyond these shared attributes, socialism as doctrine and practice is characterized by immense diversity and competing claims to authenticity, which belie the frequent eliding of socialism with Marxism. This internal diversity was already present when the term was first used in English in the 1820s and in French and German in the 1830s, as well as in earlier political and religious movements that anticipated future socialist practices.

Although it is sometimes suggested that socialist forms of organization constituted the original human condition prior to the emergence of agriculture and urbanization in the Near East (8,000–10,000 BCE), the genealogy of socialism in its contemporary senses can be traced to early modern Europe. Early Christian inspired radical movements, such as the Levelers and especially the Diggers in seventeenth century England, and the Anabaptists in sixteenth and seventeenth century Central Europe, propounded ideas that had a clear socialist resonance, as did Babeuf during the French Revolution, with his “Conspiracy of the Equals.” Socialist ideas received a more systematic elaboration, however, in the works of three early nineteenth century thinkers – Claude Henri de Rouvroy, Comte de Saint Simon (1760–1825), François Charles Fourier (1772–1837), and Robert Owen (1771–1858).

While all three have routinely been grouped under the unifying label of “utopian socialist,” this tells us more about the mid nineteenth century reception of their ideas than it does about the distinctive content of their socialism. They all shared an antipathy to individualism, a desire to replace competition with cooperation, and a belief that a positive science of society and human nature was possible, which could be a guide to social organization. But they differed significantly over the concrete detail of the social forms that they advocated, how they could be realized, and the understandings of

human nature on which they were based. Saint Simon and Fourier rejected the Enlightenment view propounded by Rousseau and others that human nature, while inherently good, noble, and rational, had been corrupted by modern society in general and private property in particular. Instead, they argued that human nature was typified by fixed personality types, which could only be brought into more harmonious coexistence by cooperative social arrangements. By contrast, Owen endorsed the view that human nature was malleable and shaped by objective circumstances. The latter could and should, therefore, be arranged in ways that contribute to the perfectibility of humankind. Cooperation and solidarity should replace competition and individualism, thus ensuring human happiness and collective harmony. This vision was given practical effect in England in Owen's New Lanark textile mill and other cooperative communities that were established according to his principles.

Socialist ideas gained a more widespread currency in England, France, and the German speaking states during the 1830s and 1840s. Accelerated industrialization and urbanization, and the social problems that they brought in their wake, gave rise to various radical movements for social reform and transformation. These included early working class organizations, cooperative movements, trade unions, and Chartism, plus a range of anti modernist groupings that sought refuge in projects for the reconstruction of premodern communalism. It was in this milieu of social and political ferment that Marx and Engels began developing their distinctive brand of what Engels would later refer to as "scientific socialism."

Marx and Engels did not begin their intellectual careers as socialists, much less communists. Their early anti clerical, radical democratic politics only gave way to a more explicitly socialist position with the elaboration of a distinctive perspective on history, capitalism, and class. According to the materialist conception of history, history involves the progressive unfolding of distinct stages, each defined by a dominant set of production relations. Revolutionary transformations of society had in the past, Marx and Engels contended, always resulted in the emergence of new class divided societies, but on a more advanced material plane. It was only with

the advent of capitalism, and its relentless drive to improve labor productivity through technological innovation and intensified exploitation of the modern proletariat, that the material and political preconditions for socialism were laid.

Marx famously declined to systematically outline any blueprints for the socialist future that he envisaged. He was not, he once wrote, in the business of writing recipes for the kitchens of the future. Nevertheless, passages scattered in his political writings offer important insights into his views on socialism and the transition from capitalism to socialism. In his reflections on *The Class Struggles in France, 1848–1850*, for example, he concluded that the abolition of capitalism would necessitate a transitional political form that he labeled as the "dictatorship of the proletariat." In the immediate aftermath of capitalism's overthrow, Marx reasoned, the new proletarian ruling class would need to exercise power ruthlessly over all other classes whose actions and interests threatened a return to the old social order. But it could not do so by simply claiming the capitalist state machinery as its own. This had to be destroyed and replaced by state institutions of a new type.

The Paris Commune of 1871 – where for over two months Parisian workers seized power in the French capital – offered Marx a rare glimpse of the institutions that might constitute such a new state type. In particular, he endorsed the Commune's fledgling efforts to overcome the capitalist division between political and economic life. This was manifested in universal suffrage and the election of workers to local and national delegations of workers' deputies, which combined executive, legislative, and judicial functions. These representatives were to be accountable and recallable at short notice, and to be paid no more than the workers whom they represented. They would contribute to the administration of a society in which the means of production was taken into common ownership, where the hierarchy of bureaucratic ranks and privileges within the state was abolished, and where the standing army was to be replaced by a national workers' militia with short terms of service.

The other main source for Marx's ideas on post capitalist society is his *Critique of the Gotha Programme*, written in 1875 but not published until 1891. In it, Marx criticized the

program that came out of the conference that unified the two main wings of German socialism. Here he made a distinction between a first (lower) and second (higher) phase of communism, a distinction that later came to be recognized as one between socialism and communism. In the first phase, society would remain stamped with its capitalist origins, including the residues of class relations and attitudes. As such, this transitional stage would be one in which a state was still necessary to ensure proletarian rule, while the distribution of the social product would be in accordance with labor expended rather than differentiated individual needs – a right of inequality given the unequal endowment and needs of individual workers. With the further development of the productive forces and the transcendence of the last vestiges of capitalism, the state would wither away and social need would become the main criterion determining distribution in the higher phase of communism. All of this could only be accomplished if an initial national proletarian revolution was internationalized.

In the decades following Marx's death in 1883, his particular brand of socialism was the subject of fierce controversies both within and outside socialist circles. From the outside, Max Weber and other liberals criticized what they viewed as the illiberal implications of socialism in general and Marxism in particular. For Weber, socialism would entail an accentuation of the worst bureaucratic features of modernity. It would remove competing sources of authority within society, concentrating all power in the hands of state officials. In so doing, individual autonomy would be severely curtailed, and the key mechanisms ensuring economic dynamism under capitalism – interfirm competition and entrepreneurial initiative – would be removed. The result would be human servility combined with economic stagnation, tendencies of socialism that many liberals after Weber viewed as being confirmed by the history of the Soviet Union and all other societies created in its image. Socialism was, as the title of Hayek's book would later assert, *The Road to Serfdom* (1944).

The nature of socialism and the means by which it could be realized were also key areas of debate within socialist movements. In Germany in the 1890s, this took the form of the so called

“revisionist” controversy between defenders of Marxist orthodoxy and those who argued that the Social Democratic Party's theory had to be revised to bring it into line with its reformist practice, and with the changed conditions of contemporary capitalism. Eduard Bernstein, the key advocate of revisionism, claimed that many of the defining propositions of orthodoxy had been falsified by economic and political developments. In particular, the increased dispersal of property ownership through the growth of joint stock companies, the rise of state led social insurance that ameliorated the conditions and insecurities of workers, and the growing parliamentary influence of organized labor all contributed to social improvements that obviated the need for socialist revolution. Rather, socialism could and should be realized through the movement of incremental reforms, pursued through parliaments, which improved the lot of workers in the present rather than through a violent revolution in search of an uncertain utopian future.

This pragmatic, social reform oriented socialism was not confined to Germany. It found its corollaries in progressivism in the United States, laborism in Australasia, the establishment of reformist socialist parties in France and Italy, and Fabianism in Britain (under whose direct influence Bernstein had come while living in England). Fabianism had emerged in the 1880s, and found(ed) an institutional embodiment and medium for its ideas through the establishment of the Fabian Society and the London School of Economics. The Fabian Society was the prototypical left wing think tank, and went on to become affiliated to the British Labour Party. Its principal early figures included George Bernard Shaw and Sydney and Beatrice Webb, for whom systematic social research provided a means of illuminating and publicizing poverty and disadvantage, which could then be addressed through state sanctioned social reforms. As such, they pioneered the traditions of sociologically informed public policy, and public policy inspired sociology, which came to inseparably link sociology and socialism in the minds of many politicians, scholars, and lay people.

During their travels around the turn of the nineteenth and twentieth centuries, Sydney and Beatrice Webb had been particularly impressed

by the social reforms that they encountered in the seven British colonies that were on the verge of becoming the national states of Australia and New Zealand. They were not the only ones. The French socialist Albert Meitin had written in glowing terms of Australasia's pragmatic *Socialism Without Doctrines*, while the American socialist Henry Damerest Lloyd had espoused a "New Zealandization of the world," in reaction to industrial and social arrangements that he viewed as exemplary. Such observers were expressing an enthusiasm for institutions and reforms that in their eyes established "already existing socialism" long before that phrase had been coined. State led industrial arbitration and conciliation systems, relatively high wages for workers, early suffrage for women, and the beginnings of a social safety net in the form of invalid and old age benefits were just some of the innovations that fired the socialist imagination.

The early formation of mass workers' parties in Australasia's white settler societies contrasted with their absence in the US. It was not so much that socialism was absent in the US – Edward Bellamy, progressivism, the Industrial Workers of the World (Wobblies), and the American Socialist Party itself confirm that socialist doctrines and practice were very much present in the US in the decades before World War I – as that it failed to find expression in the formation of a mass workers' party. Consequently, Sombart's question as to why socialism fails in the US retains its relevance today. Many answers have been proffered. These include ones emphasizing the dominant individualistic ethos in the US, born of the necessity of self reliance in a frontier society; the greater opportunities for upward mobility than was the case in Europe; the damaging consequences of slavery and its political epilogue on working class solidarity; the greater religiosity of the US population, with their contempt for socialist atheism; the militancy and effectiveness of US economic and political elites in suppressing many forms of collectivism; and the association of socialism with the immigrant Central Eastern European intellectuals and workers who were early propagandists and agitators for socialism. As was often lamented, socialism failed to "Americanize." This was exacerbated by the Bolshevik Revolution and its aftermath.

The seizure and consolidation of state power in Russia by the Bolsheviks in and after 1917 was pivotal to the subsequent history of international socialism. Its consequences were several. First, the USSR came to be associated with socialism per se, by both supporters and critics of the new regime. Supporters argued that the socialization of the main means of production, the subordination of market mechanisms to central planning, and the state's monopoly over foreign trade and domestic finance were the sources of rapid industrialization from the early 1930s and a growing equality of consumption. Critics, on the other hand, suggested that this was fanciful reasoning as it ignored the basic facts of bureaucratization, continued inequality, growing political repression, and the extinction of democracy, all of which discredited the very idea of socialism. Second, the Russian Revolution was significant in that it was instrumental in establishing (in 1919) an organization ostensibly committed to world socialist revolution – the Third or Communist International. The Comintern came to dominate communist parties around the world (for which the histories of the French, Italian, Spanish, and Greek communist parties, for example, bear ample witness), with the latter being increasingly subordinated to the needs of Soviet foreign and domestic policy. This was bound up with the third critical consequence of Soviet power for socialism, namely, that the Soviet Union helped to establish a series of regimes in its own image in Eastern Europe. These came to be equated with "already existing socialism," an ideologically defined political bloc that constituted one part of the Cold War structural divide. Finally, Soviet power was significant for socialism insofar as it was the site for the elaboration and practice of "socialism in one country," which Stalin developed from the mid 1920s, and which can be viewed as a key episode in the marriage of socialism with nationalism.

During the decades of decolonization after World War II, this coupling of socialism with nationalism would become a central feature of so called third world socialism, from China and Vietnam to Nicaragua and Cuba. In Cuba, for instance, what had in the main been an anti imperialist, nationalist movement, combining sectors of the national bourgeoisie, intelligentsia, workers, and the peasantry within a popular front for national liberation (July 26

Movement), moved increasingly leftward under the pressure of internal and external circumstance. By the early 1960s, Castro had nationalized the commanding heights of the Cuban economy, implemented central planning and a radical program of land reform, and consolidated one party rule, albeit one that had greater popular support than the ruling regimes of Eastern Europe and the Soviet Union itself. This support was at least in part built on the social successes of Castro's regime. Despite a crippling US economic blockade, which has still not been lifted, Cuba established itself as a leader amongst Latin American countries in terms of health, education, and other social indicators. The 1991 collapse of the Soviet Union and hence Soviet support, however, has jeopardized these achievements.

On the other side of the Cold War divide, the Keynesian inspired welfare states of Scandinavia, Western Europe, and Australasia provided the main modernist alternatives to Soviet style socialism. Premised on Keynesian countercyclical demand management, economic nationalism, a commitment to full employment, political pluralism, and a significant degree of decommodification in the provision of social services, the welfare state blurred the boundaries between capitalism and socialism. For a time, it seemed that the five great evils of modern society that Beveridge identified in 1940s Britain – want, ignorance, squalor, disease, and idleness – could be transcended by the judicious application of social(ist) policy within what remained essentially capitalist economies. The relative economic and political success of that model, combined with its redistributive potential, was reflected in its widespread endorsement on the left and toleration on the right. Market socialism, or socialism with markets, became the dominant model advocated by a generation of democratic socialists in the three decades following World War II.

But the welfare state was not without its detractors. These became more vociferous from the early 1970s, with the emergence of stagflation and increased social and industrial unrest in the heartlands of modern welfare capitalism. Marxists argued that the welfare state contributed to the economic, political, and ideological reproduction of capitalism without significantly mitigating inequality or exploitation. At the

same time, it enhanced the state's surveillance over the working class, thus constituting a powerful instrument of social control. The "welfare" state remained essentially a capitalist state, pseudo socialism at best, despite what Marxists would acknowledge were progressive social reforms. Socialist feminists are similarly skeptical of the welfare state's socialist credentials. They point to the implicit gendered assumptions on which many welfare policies are based, not least of which are family and work policies frequently aimed at manipulating female fertility in the cause of particular demographic outcomes. Moreover, they are clear that the welfare state has had very different outcomes for middle class and working class women, typically enhancing the welfare of the former while functioning as a mechanism of social monitoring and control over the latter. For socialist feminists, socialism will only retain a progressive content and promise if it is based on an understanding of the patriarchal forms on which modern capitalism is founded.

The other main critique of the modern welfare state is as much a criticism of socialism and collectivism more generally. From the 1970s through to the new century, a resurgent economic liberalism affirmed the economic and political bankruptcy of the welfare state and socialism. Socialism in all of its variants was regarded as being inherently predisposed to economic stagnation, and restricting of human liberty. The collapse of eastern bloc state socialism in the early 1990s was presented as confirmation of this diagnosis, with an end of socialism and end of history triumphalism marking sociological and political discussion in the last decade of the twentieth century. Capitalism was now the only game in town, and debate would revolve around the forms that it should take rather than an alternative to it.

This triumphalism was the corollary of and contributor to the contemporary "crisis of socialism," which much of the left has bemoaned for the past two decades. While this crisis is real enough, being felt in the spheres of institutions, theory, and practice, there are fledgling signs of socialist renewal. Most importantly, socialist ideas and ideals have infused much of the anti globalization and environmentalist movements that have grown in recent years. Regardless, it is clear that the problems of social inequality,

injustice, and deprivation that gave rise to socialism in the first place are still with us, which makes it premature to eulogize the death of socialism.

socialist feminism

Ann Cronin

Socialist feminism, which draws on aspects of Marxist feminism and radical feminism, emerged in the 1970s as a possible solution to the limitations of existing feminist theory. While

Marxist feminism cites capitalism as the cause of women's oppression, radical feminism argues that women are oppressed through the system of patriarchy. Marxist feminism has been criticized for its inability to explain women's oppression outside of the logic of capitalism, and radical feminism for producing a universalistic, biologically based account of women's oppression, which pays insufficient attention to patterned differences between women. Socialist feminism attempts to overcome these problems through the production of historically situated accounts of women's oppression that focus on both capitalism and patriarchy.

In Mitchell's (1975) psychoanalytic model, capitalism – the economic system – is allocated to the material level; patriarchy – the rule of law – is allocated to the ideological level and assumed to operate at an unconscious level. While Eisenstein (1984) retains Mitchell's conceptualization of capitalism, she reassigns patriarchy to the conscious cultural level and dismisses any distinction between the two, leading to the term “capitalist patriarchy.” In contrast, Hartmann (1979) produces a materialist understanding of patriarchy and capitalism as two distinct but interactive systems which center on men's exploitation of women's labor. Challenging Eisenstein's single system theory, Hartmann states that patriarchy predates capitalism and exists beyond its boundaries; thus, it is inappropriate to regard them in terms of a single system.

The allocation of patriarchy to either the material, cultural, or ideological level does not permit an analysis of the pervasive nature of patriarchal structures across all three levels. Simultaneously, it assumes that all social structures can be reduced to the workings of either capitalism or patriarchy, whilst assuming there is a symbiotic relationship between the two. A focus on paid work dismisses radical feminist concerns with sexuality and violence.

Walby's (1990) dual systems approach attempts to overcome these problems through a historically and socially defined understanding of patriarchy as a system of six interrelated structures (paid work; household production; culture; sexuality; violence; the state), which in contemporary society are in articulation with capitalism and racism. This model enables Walby to chart the dynamic nature of patriarchy

over the last 150 years, including the move from a private to a public form of patriarchy.

socialist medicine

Mark G. Field

The term socialist medicine applies to a health care delivery system designed to provide preventive, diagnostic, clinical, rehabilitative, educational, and custodial services to a designated population free of charge at the time of the service. The prototype of socialist medicine is also known as Soviet socialized medicine.

At a time when health care is being recognized as a basic human right, Soviet socialist medicine has often been cited as a model for the universal provision of health care. The nature and structure of Soviet socialist medicine reflected the ideological and political orientation of the Soviet regime. There were two major ideas underlying the health care system of the former Soviet Union. One was that illness and premature mortality were primarily the product of a flawed system (capitalism) and its exploitation of the working class. This exploitation exposed workers to a series of pathogenic

elements that affected their health and well being: poor pay, child labor, long working hours, miserable housing conditions, inadequate nutrition, and a noxious social environment (Engels 1958). Thus, capitalism was indicted as the major etiological factor in illness and early death. Only socialism (and eventually communism) would eliminate the sources of most socially caused ill health.

The second idea was that the provision of health care under capitalism meant that workers were, in most instances, deprived of access to such care because they could not afford it. The removal of that payment by the patient meant the elimination of the barrier to health care. Under socialist medicine, it was society (i.e., the polity) that would henceforth shoulder the responsibility for the provision of health services to the entire population. The Soviet Union was the first country in the world to promise universal and free health services as a constitutional right (Sigerist 1937, 1947). This would also permit physicians to stop being engaged in a "commercial" transaction and enable them to treat patients without being fettered with questions of money. By the same token, hospital and other health institutions would also offer free services at the expense of the state. The promise of gratuitous and universal (though not necessarily equal) medical care to the entire nation was one of the few redeeming factors of an otherwise bleak totalitarian regime. It was often held as an example to emulate worldwide, and served as important propaganda for use at home and abroad.

The term used in the Constitution for health care is *zdravookhranenie*, a Russian language combination of two words meaning health and protection, a duality already visible in Greek mythology. Aesculapius, the God of Medicine, had two quarrelsome daughters, Hygiea and Panacea. Hygiea was the goddess of health through healthy living (thus of prevention and preservation). Panacea was the goddess of cure, but eventually the demand for Panacea's services grew so much as to exceed her capacity to help everyone and soon outstripped many people's ability to obtain needed services.

The history of Soviet socialist medicine can be divided into two phases. In the first ten years after the revolution of 1917, the ideology of Hygiea and Marxism prevailed. The basic

assumption, noted above, was that the establishment of socialism, and eventually communism, would eliminate most sources of illness and early death through an overall improvement in the living and working conditions of the workers, and eventually the entire population. The situation changed radically after Stalin assumed total power at the end of the 1920s and launched a massive program of industrialization and militarization, domestically financed primarily through enforced savings at the expense of the population (particularly the peasantry). Under these circumstances, an improvement of the standard of living of the population gave way to the transformation of the economy. Panacea took over with the responsibility of treating the population to ensure the maximum productivity and military strength. The principle of free care at the time of service, however, remained in force. It was accompanied by a rapid increase in the number of physicians (mostly women) and an expansion of medical facilities, as well as a gradual stratification in health care according to rank, residence, or occupation (Field 1957).

Health personnel at all levels became state salaried employees. It was therefore not an insurance scheme in which subscribers paid a "dedicated" premium to reimburse physicians and hospitals. It was not an indemnity scheme, a copayment or deductible arrangement, nor a private, religious, or charitable organization. It became a state public service, just like education in most countries. Furthermore, the concept of the physician as an autonomous professional practitioner was not part of socialist medicine, nor was there a corporate body of professionals able to politically influence the state or legislation (Jones 1991). The education of health personnel, at all levels, was carried out in state funded schools, the hospitals were financed by the state, and medical and related research was carried out in state supported institutes. Health and related services became a responsibility of the polity (Field 1967).

The Soviet scheme of socialist medicine was meant to serve both the state and the population; in theory the development of the health care system was integrated with the planning of the economy. What this meant was a high degree of control over the whole area of health care, implemented through a large and centralized

bureaucratic machine headed by the Ministry of Health Protection USSR, itself under the control of the Communist Party, the supreme ruling organization of the Soviet Union. Under the national ministry, counterpart ministries in the constituent republics, and health departments down to the local levels of the governmental structure were responsible for health matters in their jurisdictional areas. Each unit of the health system was under the dual authority of the ministry (vertical control) and the corresponding governmental units (horizontal control). In general, the ministry and its units provided instructions and suggestions, and the health departments determined the tasks for their area of responsibility and received financial (tax generated) support from their corresponding governmental unit.

The health care system was so organized that, in theory, every person knew where to turn for initial or primary care. There were basically two general networks of health institutions, plus a series of departmental or special establishments to serve specific segments of the population, leading in essence to a differentiated health care system reflecting the stratification of Soviet society.

Access to primary health care was provided to the general population on a *territorial* basis in outpatient polyclinics, and an *occupational* one. In the first case, it was the individual's home address that determined the outpatient polyclinic and the physician(s) to whom he or she was assigned. That polyclinic was the portal of entry into the health care system. There was thus little or no choice of physician or facility. In the second case, industrial organizations had their own physicians and facilities (the larger the unit, the more sophisticated its medical system) and workers were assigned to health care and to a physician on the basis of their department or shop. Outpatient clinics were affiliated with hospitals where individuals could be referred. In most urban areas, a system of emergency services was established with ambulances that could be summoned with a telephone call. The population in the countryside, by contrast, was in general poorly serviced; in many instances the primary caregiver was a *feldsher*, or physician assistant, not a physician.

In addition to the two above mentioned networks, there were departmental health care

systems that serviced a specific organization, for example the armed forces, railroads, research institutes, and even department stores. Finally, there was a special set of high quality special medical institutions reserved for the members of the elites and their families, the quality and the amenities of these institutions depending on the rank of the individual, and headed by the Kremlin Medical Unit. A promotion or demotion was accompanied by a change in one's medical category.

The ideological justification (or rationalization) for inequality was that in a period of scarcity determined by the "building of socialism," medical care was universal but available on a priority basis determined by the importance of the role of the individual. Only under far distant communism would all people be treated equally, medically or otherwise.

The idea that society was responsible for the health of its members was, in itself, a progressive one, and an expression of social solidarity. The Soviet Union was, as mentioned above, a pioneer in this matter. But health care was so interwoven with the fabric of Soviet society that it suffered some of the same general problems that led to the collapse of the Soviet Union.

The provision of financial support on the part of the polity to operate and manage all aspects of health care is a double edged sword: on the one hand, it can be considered as positive, since society has the power to appropriate funds for any purposes it chooses. On the other hand, what the state giveth it also taketh away. The financing of health care then becomes part of national priorities, a "line item" that must compete with many other demands, especially, in the Soviet case, national defense. In times of crisis, or change of priorities, health care is often underfunded in the light of more pressing needs, particularly since it does not produce material wealth but, on the contrary, absorbs resources. The funding of health care was often based on what the Soviets themselves called the *residual principle*; after all the line items had been taken care of, whatever was left went to health. And that was clearly insufficient. At the time the USSR broke down, it is estimated it received about 2 percent of the gross national product, down from the 6 percent it enjoyed 30 years earlier. The impact on services and health facilities and upon vital indices was catastrophic.

Health personnel in general were poorly paid, often less than regular industrial workers. Medicine was not a prestigious occupation, and its heavy feminization in a sexist society kept its status low. There was little incentive or competition among personnel, since the rewards remained the same regardless of quality, depending primarily on seniority (Knaus 1981). Because of the poor remuneration, patients often felt compelled to bribe health personnel either before the service (particularly in surgery) or after, to show gratitude and ensure future attention. Individuals, as noted, could not make a *dedicated* contribution, such as an insurance premium, that gave them a personal stake or guarantee for better care or attention. The health care system became heavily centralized, bureaucratized, subject to corruption, and rigid in responding to emergencies (as in the case of Chernobyl). In addition, the bureaucratic element often seeped into the physician-patient relationship.

The low priority given to the rural population, as a rule, meant very poor quality of health care for the peasantry. Efforts on the part of the regime to assign doctors to the countryside were often unsuccessful because the law stipulated that spouses should not be separated, and since most doctors were women, they were able to escape the assignment.

The lack of adequate funding meant that most health facilities lacked maintenance, equipment, supplies, and in the countryside, even running water. Patients often had to bring their own food, medications, sheets, blankets, and even in some instances, X ray films. Pharmaceuticals were often in short supply or not available.

The Soviet system emphasized quantitative indices at the expense of quality. For example, hospitals were financed according to the number of beds, so that "beds" were added without the necessary infrastructure, and in buildings inappropriate for medical care.

Soviet socialist medicine broke down when the Soviet Union collapsed. Cuba is the only country that has such a system at the beginning of the twenty first century. In short, the Soviet environment did not provide the necessary support for socialist medicine as originally conceived. Verdict: noble purpose, grandiose scheme, inadequate financing, flawed execution, mixed results.

socialization

Sal Zerilli

The concept of socialization figures prominently in sociology, underlying many of the discipline's major claims about the nature of society and social relations. Sociologists have

used socialization to examine the possibility of society, the nature of social order, the reproduction of social organization, the formation of personal identities, and mechanisms of social control and deviance. The concept has also played an important role in studies of families, schools, professions, organizations, peer groups, and subcultures. In general terms, socialization is a generic concept embracing the ways people acquire the general competencies required for participation in society. At the societal level, socialization helps explain how and the extent to which large numbers of individuals come successfully to cooperate and adapt to the demands of social life (Long & Hadden 1985). At the organizational level, it summarizes processes by which newcomers to social groups and organizations are transformed from outsiders to participating members. At the personal level, it refers to the social and cultural shaping and development of the mental, emotional, and behavioral abilities of individuals.

Sociology's major conceptions of socialization have shifted over time. At the turn of the twentieth century, sociologists employed the concept to address the Hobbesian question of how social order is possible given the egoistic, asocial nature of individuals (Wentworth 1980). This understanding of socialization was crystallized in prominent early conceptions of socialization as the channeling and molding of human nature into a collective unity. Socialization was seen generally at this time as the transmutation of naturally independent beings into social creatures. This way of thinking was eventually superseded by an understanding of socialization as the individual's internalization of the social and cultural constituents of the self. This dominant formula of socialization as internalization helped render questions of human nature marginal to sociological interests in the subject. Sociologists have generally come to believe that social and cultural processes permeate, even constitute, the minds and bodies of individuals. Wentworth (1980) argues that sociological thought on socialization over the last 50 years has focused almost exclusively on the social aspects of individuals, and that sociologists have tended to frame these as fully constituted by society and culture. Today, sociologists regularly argue that socialization is how the individual becomes fully human or a "person."

Sociology offers three main theoretical orientations to socialization: a functional, an interactional, and a critical perspective. Structural functionalists such as Talcott Parsons and Robert Merton view socialization as a process of role learning by which people come to adopt prescribed orientations to life which limit the ends to which they may aspire, as well as the means they can use to achieve them. Parsons claimed that role learning was society's primary mechanism for integrating individuals into the patterns of interaction that constitute the major institutions of society. From this perspective, socialization is essentially the imprinting of cultural patterns on the personalities of individuals, or how society inculcates in its members the skills and orientations required for participation in social life. As such, successfully socialized individuals learn to function in society by interacting with others in accordance with the social roles and positions they occupy. This is a deep process leading people to treat external value standards and norms as definitive and expressive of their identity. The functionalist position was heavily influenced by Durkheim's theory of society and Freud's model of internalization. This position has declined steadily in prominence since its heyday in the 1950s and 1960s. Its influence can still be detected in the tendency of sociologists to equate socialization with the internalization of elements of society and culture, and through continuing sociological interests in role learning.

Structural functionalism has been criticized for exaggerating society's control over individuals and for portraying people as utterly passive recipients of social influence. The symbolic interactionist perspective leans in the opposite direction by emphasizing the individual's active role in the socialization process. Symbolic interactionism traces its lineage to pragmatist philosophers such as George Herbert Mead and John Dewey, and sociologists of the Chicago School such as Herbert Blumer and Everett Hughes. For symbolic interactionists, the crux of socialization is the formation of self concepts in the context of social relationships mediated by shared symbols. Selves are said to emerge and develop as individuals mutually construct versions of reality through communicative processes based on shared symbols, especially language. By learning how to communicate with

shared meanings and symbols, individuals come to incorporate the responses of others into their actions and self understandings. Selves emerge and develop as individuals gain experience of (1) imagining their own demeanor from the standpoint of others, (2) interpreting and evaluating these perceptions in the light of shared attitudes, and (3) adjusting their actions accordingly. Interactionists hold that people do not automatically internalize or respond to others' perceptions, attitudes, and understandings, but rather have the ability to evaluate and select from them. There are many strands of symbolic interactionism in contemporary sociology. Taken together, they exert a significant influence on sociological understandings of socialization.

Symbolic interactionism and structural functionalism have been criticized for underplaying the role of power and inequality in social life. Though they offer different perspectives on the process, critical orientations to socialization in sociology, such as Marxism and feminist theory, are unified by deep concerns with power imbalances in society and the reproduction of structures of inequality. Proponents of these perspectives generally agree that socialization is a primary mechanism of social control. Pierre Bourdieu's critical view of socialization has gained prominence in contemporary sociology. For Bourdieu, socialization is the acquisition of "habitus," which he characterizes as individuals becoming deeply habituated to the customary ways of behaving, thinking, and feeling common to other members of their social worlds. The process is one in which members who share similar positions in society inculcate in each other deeply ingrained patterns of subjective adjustments to external social conditions. For example, Bourdieu and Passeron argue in *Reproduction in Education, Society, and Culture* (1977) that schools institutionalize, honor, and transmit the cultural values and knowledge of the dominant classes in society. As a result, the background experiences and knowledge acquired by working class students through family socialization (i.e., their habitus) do not translate easily into academic success. Many of these students adjust their aspirations and self conceptions in the light of the obstacles these dynamics present to them in school. Their resulting poor performances and withdrawal from school culture not only serve to powerfully inhibit their chances of

upward mobility, but also reinforce widespread acquiescence to economic subordination. In this way, the schools play a fundamental role in the reproduction of class inequalities. Bourdieu's ideas have found a receptive audience in contemporary sociology and exert a wide influence in many fields, most notably in studies of education in poor and working class communities.

Many disciplines share sociology's interest in socialization. Perhaps the most influential of these fields has been Freudian psychoanalysis. The classic Freudian model of socialization posits a civilizing process at odds with human nature. The process is one in which the innate sexual urges and aggressive drives of humans are tamed and channeled into socially acceptable forms of conduct and ways of thinking. For example, Freud argues in *Civilization and its Discontents* (1961) that social forces work to transform the individual's raw drive for sexual gratification into feelings of warmth and affection for others. These same forces also redirect the individual's natural aggressiveness towards others back on himself in the form of a self disciplining, guilt dispensing conscience. The individual's personality develops from the manner in which she manages the resulting internal conflict between natural drives and internalized social inhibitions. Psychological defense mechanisms (e.g., sublimation) play a critical part in socialization and personality formation insofar as they enable individuals to satisfy natural urges in socially approved ways. The classic Freudian model of socialization stresses how the locus of moral regulation of action is transferred from society to the self through the individual's internalization of external authority. Many contemporary psychoanalysts subscribe to object relations theories which shift the theoretical focus from the social channeling of natural drives to people's need for relatedness to others, as well as the manner in which people develop the internal imagery of self, other, and relationship of self to others that guide them through life.

Freudian ideas exerted a deep influence on anthropological understandings of socialization (Singer 1961). In the 1920s, anthropologists influenced by psychoanalysis began to examine the cultural antecedents of individual personalities (Clausen 1968). Prior to this period, anthropologists paid relatively little attention

to the relationship between personality and culture, favoring instead factual surveys of the characteristics of given cultures in and of themselves (Bidney 1967). The psychoanalytic impetus inspired many anthropologists to examine how culture stamps itself on individuals, how individuals internalize cultural elements, and how the personality develops from this enculturation process (Wentworth 1980). Well known examples of anthropology's culture and personality orientation include Malinowski's *Sex and Repression in Savage Society* (1927), Mead's *Coming of Age in Samoa* (1928), and Benedict's *Patterns of Culture* (1934). Many contemporary anthropologists forgo questions of personality development while maintaining the discipline's quintessential concern with how distinctive patterns of culture are preserved, understood, and transmitted across generations. Much of the work on socialization in cultural anthropology is steeped in a social constructionist paradigm that rejects psychoanalysis in favor of studying how people transmit and acquire meanings, practices, and methods of reality construction, as well as the ecological, institutional, and economic forces impinging on these processes.

Psychologists have generated an array of orientations to socialization, most of which emphasize aspects of individual development. Cognitive psychologists such as Piaget (1926) and Kohlberg (1981) envision socialization as a process of development in which new experiences spur the individual to move through qualitatively distinct stages of cognitive and moral growth. For behavioral psychologists, socialization is the learning of patterns of behavior through conditioning or through regular participation in recurring interactional activities such as observing and imitating (Bandura and Walters 1963). Blending behavioral psychology and psychoanalysis, many personality psychologists contend that the individual's personality is firmly established in early life through behavioral reinforcements and punishments (Zigler et al. 1982). Cultural psychologists such as Vygotsky (1978) and Bruner (1990) view socialization as an ongoing interplay between culture and cognition in which people internalize aspects of their sociocultural environments, giving many aspects of the mind cultural origins. Psychological thought on socialization has

generally been limited to childrearing and child development and specifically focused on direct encounters between children and major agents of socialization (Slaughter DeFoe 1994).

Sociological research on socialization is organized around substantive domains, such as families, schools, media, and work. Much of this research frames socialization as a mediating process between self, social organization, and broader social conditions.

Families, especially parents, are often framed as principal agents of socialization. Family socialization has often been conceptualized as children learning their parents' beliefs, values, worldviews, and behaviors. Some researchers argue that families serve as seedbeds of a child's basic orientations to society, and that parental social attitudes serve as powerful predictors of children's attitudes throughout life. Families are also seen as important sites for socialization into social identities. Many researchers suggest that children learn to conceptualize themselves in gendered, religious, political, racial, and class terms in and through routine interactions with parents, siblings, and members of the extended family. Feminist scholars argue persuasively that family socialization into traditional gender roles is pervasive and harmful to boys and girls, and detrimental to gender relations in democratic societies. Increasingly, sociologists are concerned with the implications of changing family forms for child development. Some researchers who compare children raised by single parents or stepfamilies to children raised by "both original parents" suggest that socialization in single parent families and stepfamilies is generally disadvantageous for children (McLanahan 1999). This is a hotly debated issue, in and out of sociology.

Studies of socialization in educational settings tend to highlight how socialization extends beyond the official academic curriculum. School settings provide many students with their earliest encounters with institutional evaluations of their competencies as people, sometimes with significant effects on their self conceptions. A prominent theme here is that teachers' expectations of students' academic growth exert a powerful influence on the intellectual gains students actually make. Schools are also known to place students into evaluative categories that affect the way teachers treat students and how

students treat each other. Such labels not only inform the self concepts of children, they also help students to draw distinctions between themselves along several lines, including racial, class, and gender lines. Scholars have shown how even routine activities in schools, such as line formations and teasing, can reinforce gender stereotypes and inequalities. A body of research influenced by Bourdieu holds that social class positions are reproduced in the way schools value or devalue the cultural and economic backgrounds of students. Some have argued that schools train poor children for low status jobs by emphasizing respect for authority, conformity, and submissiveness. The hierarchical and disciplinary nature of social relations in schools is thought to replicate the division of labor in the economy, with the effect of schools training compliant workers for job markets. Poor and working class students have also been shown to develop cultures of resistance that reflect and reinforce class inequalities. Recently, scholars have argued that race, class, gender, and culture interact in educational settings in subtle ways that lead students to reproduce in their own lives the objective conditions they face in society (MacLeod 1995).

People acquire much of their knowledge of the social world from mass media. Some theorists argue that the images and information disseminated by media overpower people's conceptions of reality to the point of obliterating distinctions between fact and fiction. People's relationship to "reality" is said to be fundamentally altered by the mediating images of television, cinema, Internet, and print media. A prominent theme suggests that consumption of television, magazines, and music reinforces unrealistic, negative, or stereotypical images of gender, sexuality, race, and ethnicity. Many scholars suggest that frequent media use leads men and women to develop distorted, often unhealthy, images of their own bodies and selves, as well as the bodies and selves of others. Research on television viewing patterns suggests that children not only learn values, attitudes, and behaviors by watching television, but that they also imitate many of these televised behaviors. Some scholars argue that images of violence lead some viewers to become aggressive and violent themselves. Alternatively, research on computer technologies suggests that they can

serve as liberating resources for self socialization, enabling children and adults to more freely experiment with alternative versions of their personal identity. Another way media affects socialization is by serving as surrogates for face to face interaction. The full implications of this apparent decentering of face to face interaction in social life remains unclear and under studied. Some scholars examining socialization and learning in complex organizations speculate that new communication technologies present "ontological barriers" to the teaching and learning of tacit and embodied knowledge.

One exception to the discipline's tendency to focus on children in socialization studies is the research on professional socialization and work setting socialization, which focuses on adults. Research on professional socialization highlights how adults learn the skills and knowledge required for both the professional roles they hope to eventually assume and the current demands of the role of apprentice. A body of research shows how, in helping one another cope with the demands of the student role, peers undergoing professional socialization collectively regulate, even block and minimize, the influence of socialization on themselves. The research on adult socialization into work roles and workplaces emphasizes how individuals change from outsiders to participating members of organizations. This transition is often portrayed as an intense process of resocialization during which individuals are pressured not only to learn the new demands of the job, but to relinquish many of the attitudes, values, and behaviors they acquired in previous settings. This research also indicates that work has pervasive effects on the adult's emotional, intellectual, and psychological functioning and identity. Longitudinal studies suggest that occupational experiences lead to broad changes in psychological functioning and personality over time. Sociologists also portray professional socialization as a long process connected to innovations in technology and market dynamics that push working adults to hold a variety of jobs during their careers.

Two public debates about the implications of societal change for socialization beg for more attention from sociologists. First, sociologists recognize how emerging technologies are reshaping many aspects of how people relate to

each other, but more research is needed on the affects of new media and computer technologies on child socialization. Second, although sociologists pay considerable attention to societal changes in family formations, they have conducted comparatively few studies of the long range implications of social changes in families for personal development. A more academic challenge for sociologists comes from the flood of empirical and theoretical developments in other social sciences, some of which challenges basic sociological assumptions about socialization. For example, Andrew Meltzoff's research indicates that newborns can intentionally imitate the basic facial gestures of adults even though they cannot have taken the position of the adult on themselves to know that they have a face with which to imitate (Katz 1999). This research calls into question sociology's longstanding cognitive bias in socialization studies, and invites phenomenological examinations of the role of the body in socialization and development. If sociologists conducting research on socialization were to engage theory and research outside of the discipline in a sustained way, they would be better able to inform public debates over the relative influence of nature versus nurture in human development.

and what it means to be an individual evolves over the life course.

Sociologists and psychologists have traditionally agreed that socialization occurs in stages. Early theories of socialization, largely reflecting cultural beliefs about development in the early twentieth century, focused on self and moral development up to what we today know as adolescence. Mead's theory of the self, for example, posited three stages: infancy, play, and game stages. The final game stage occurs during adolescence when the individual is able to learn and respond to the community's norms and standards and act accordingly in everyday life. Mead assumed that the socialized self acquired through adolescence generally remains stable throughout the remaining life span.

Symbolic interactionist thinkers following Mead have attempted to refine his theory to account for the apparent changes in the adult self concept present in modern society. Shibutani (1961) adapted Merton and Kitt's (1950) structural notion of *reference group* to interactionist thinking to illustrate how adults can be expected to be members of various groups which in turn serve as audiences to the self. In effect, the adult learns to be different selves to accommodate the multiple complex situations that mark modern life. Zurcher (1977) devised the concept of the *mutable self* to argue that contemporary adults must be able to negotiate numerous self concepts, since the requisite social skill today is being able to change who we are rapidly and gracefully.

STAGES IN ADULT SOCIALIZATION

Social psychological theories of adult socialization analytically divide adulthood itself into stages. Erikson (1982) identified three developmental stages in adult life that focus on a series of crises that must be resolved. During early adulthood (approximately age 20–40) people must manage conflicts between family life and work. They are socialized to pursue the roles of spouse and parent, yet during the same period are expected to earn a living and pursue a career. Consequently, they are faced with reconciling the conflict between spending time with spouses and children and establishing a career. In American society, traditional sex role

socialization, adult

Joseph A. Kotarba

Socialization refers to the process by which people learn and internalize the attitudes, values, beliefs, and norms of our culture and develop a sense of self. The concept of socialization is among the most important in sociology, because it attempts to illustrate and explain the tremendous impact living in society has on shaping the individual. The individual becomes a human being through socialization,

expectations have made this dilemma particularly difficult for women.

Middle adulthood (approximately age 40–60) is characterized by conflict between *generativity and stagnation*. Erikson argued that adults in this age range are aware that they are getting older and that ultimately death is in their future, yet they may want to feel a sense of rejuvenation. They may change jobs or otherwise pursue some of their youthful ambitions. If unable to do so, they run the risk of becoming depressed and stagnant and of acting much older than their chronological age. Late adulthood (from age 60 on) provides the final challenge of attempting to achieve a sense of integrity and satisfaction with one's life while not sinking into despair over impending death. Erikson contended that during this stage adults tend to wrestle with the conflict between being satisfied with their accomplishments in life and despairing over missed opportunities and could have been.

Levinson et al. (1978) identified three distinct stages in the life of an adult: early adulthood (about age 17–45), middle adulthood (approximately age 45–65) and late adulthood (age 65 on). Levinson contended that the midlife decade (age 35–45) marks one of the most crucial stages of adult development. During this period, a midlife transition occurs that involves important changes in biological and psychological functioning, as well as in social status. It marks an important turning point in which individuals reappraise their life goals, assess their accomplishments or failures, and consider the possibilities of a better or worse future. Levinson concluded that it is virtually impossible for a person to go through the midlife transition without experiencing at least a moderate crisis.

More recent thinking on adult socialization sees gender as a critical dimension to social, psychological, and moral development. Gilligan (1982) argues that men tend to rely heavily on rules and abstract ideals when determining right from wrong – what she calls a justice perspective on morality. Women develop more of a care and responsibility perspective, preferring to use personal experience and social relationships as important criteria in developing moral judgments about social situations. Gilligan argues that scholars and laypeople alike should not view women's reasoning as inferior to that of men. Sheehy (1976) proposed a set of adult

developmental stages for both men and women. Sheehy described the *trying twenties* as a time of making a break from parents, selecting mates, and starting careers: a time of high expectations, hopes, and dreams. The *catch thirties* are the years when bubbles often burst and people realize their mates and jobs are not exactly perfect. This difficult period is characterized by high divorce rates and sudden career changes. The *forlorn forties* follow, when adults enter their midlife crises. Sheehy described these as dangerous years during which the dreams of youth must be reassessed. It is common for men to become dissatisfied with their jobs and to want to stay home; it is a time when women who have not worked outside the home become dissatisfied and want to take jobs.

SOCIALIZATION EXPERIENCES

In his classic statement, Brim (1968) suggested six situations in adulthood that typically involve socialization experiences or responses. These situations do not necessarily follow a life cycle logic, although the physical and psychological effects of aging can precipitate them. First, individuals may place demands on themselves to change the people in their lives, the lifestyles they lead, and the values to which they adhere. Second, individuals may experience changes in roles or statuses, such as the movement from "church member" to "church elder." Third, individuals may experience changes in occupation, either in change or entry. Fourth, individuals may experience changes in the family, through events such as death and divorce. Fifth, individuals may experience geographic mobility, such as that related to retirement or immigration. Sixth, individuals may experience downward mobility, as a result of poor health, widowhood, and so forth.

Contemporary research has generally supported Brim's model of situations in adulthood that typically involve socialization experiences or responses. Social, cultural, economic, and political changes over time, however, have changed the content of the situational categories. As adults increasingly remain a part of mainstream society, they place increasing demands on a wide range of social institutions. For example, adult education is expanding rapidly, to the degree

education policymakers refer to *andragogy* as adult learning and *geragogy* as older adult learning (John 1988).

In summary, traditional models of adult socialization have been strongly influenced by biological models of development. Early life was posited as growth and gain, whereas adulthood and later life were posited as periods of loss and decline (Labouvie Vief & Diehl 1999). More recent thinking sees adult socialization as a very complex, non linear, and somewhat situational phenomenon involving a tradeoff between growth and decline. Neugarten's (1974) classic categories of young old and old old are less definitive today when the trend is for old old people in our society increasingly to stay at work or seek work, either to prolong a productive life or to adapt to (often negatively) changing economic conditions for the elderly.

ADULT SOCIALIZATION IN EVERYDAY LIFE

Sociologists of everyday life contend that the process of becoming an adult in our society is rich, ongoing, and worthy of detailed ethnographic analysis. Studies of adult socialization are no longer limited to traditional elderly settings. Since aging in our society no longer requires radical change in lifestyle, at least as one's health remains functional, the culture individuals acquire during a lifetime can be very functional in later adulthood. Kotarba (2006), for example, explores the many ways baby boomers continue to use rock 'n' roll music and culture as resources for refining their sense of self as they occupy the role of parents, lovers, and others. They shape and modify the musical values they acquired during adolescence to fit the needs of later adulthood, so that they may continue to attend rock 'n' roll music concerts but may prefer comfortable seating in the shade near the stage as opposed to more adventurous lawn seating. They may also convert their taste in rock 'n' roll to adult friendly styles such as country music or the blues. Fontana (1977) examines everyday life in various retirement communities in the American West to show how varied life after work can be. His basic finding is that people generally construct lifestyles in retirement that reflect their

pre retirement lifestyles. If they developed a sense of self that involved high levels of social interaction and community involvement, they will continue that way – barring inevitable health and occasionally financial problems.

Health remains a major concern for aging adults. The sources of information on what is illness, how to care for and prevent illness, and – most relevant to this entry – how to integrate issues of health and illness in one's sense of self are increasing rapidly. For example, the Internet is not only a source of information on health for those adults for whom communication at home is preferred, but also increasingly a place to locate drugs and other health materials and services (Fox & Rainie 2000).

CURRENT ISSUES

Along with scholars from other disciplines, sociological gerontologists are interested in developing new and innovative ways to conceptualize rapid changes taking place in adult socialization among the elderly. The elderly are significant because, for the first time in western history, they are the most likely of all age groups to die, as Hochschild (1978) noted when she referred to them metaphorically as society's "death lepers." The elderly are demographically elusive because they can be found in many different kinds of places – segregated retirement communities, senior centers, and nursing homes – where, incidentally, less than 5 percent reside. The elderly are socialized into being elderly from an increasing number of audiences to the self: earlier life experiences, friends and family, the mass media through portrayals of the elderly such as the immense coverage given to former president Ronald Reagan at the time of his death, and interest groups such as the AARP.

socialization, agents of

Delores F. Wunder

Socialization is the process whereby individuals learn and internalize the attitudes, values, and behaviors appropriate to people living in any

given society. Socialization ensures that an individual will develop a social identity (or self) and have the motivation and knowledge to perform the roles she may need throughout the course of her life.

It is a basic tenet in sociology that humans do not have "instincts." (In sociology and biology an instinct is a complex pattern of behavior that is genetically determined.) Humans have some basic reflexes (such as startling when frightened), but no real instincts. Because of this lack, people have to learn virtually everything to get along in life. We call this learning "socialization." Socialization is the process of social interaction through which people acquire personality and learn the ways of their society. It is an essential link between the individual and society.

Socialization is a lifelong process. It never really ends, not until death. At every stage of our lives, we confront new situations and have to learn new ways of doing things, new values, or new norms. The really crucial time of socialization is infancy and early childhood. That is when you learn the language of your group and come to understand the norms and values important to your family and society.

Agents of socialization enable us to become aware of all the various things we need to know. Agents of socialization are significant individuals, groups, or institutions that provide structured situations in which learning takes place. This continuing and lifelong socialization involves many different social forces that influence our lives and affect our self images. These agents of socialization include the following.

The family. Family is by far the most significant agent of socialization. It is within the family that the first socializing influence is encountered. Families teach the child the language of their group, acceptable gender roles, and important values. In addition, families give children their geographic location (northerners, westerners, rural or urban), and they determine their religion, race, and ethnic group. In modern societies, most early socialization takes place within the nuclear family. In more traditional families, the extended family may be equally important. But either way, children learn the behavior characteristics of their family members and community. A family's social class and parents' occupations also influence

the way children are reared and their gender and role expectations. It is important to acknowledge that children are not just passive recipients of socialization; they are active agents, influencing and altering the family, too.

School. In some societies, socialization takes place almost entirely within the family. But for children in modern industrial societies, school is an important, formal agent of socialization that influences most individuals for well over a decade. Schools teach not only selected skills and knowledge but also additional things, such as the importance of a good diet and exercise. There is often a "hidden curriculum" as well. This includes obeying authority, being punctual, not being absent unless you are ill or have a legitimate excuse, and following rules. Personality characteristics of self discipline and dependability are encouraged. (Business and industry prefer employees with those attributes and so they are taught in schools for the future workforce.) Mass education also promotes feelings of nationalism and the need to be a good citizen. American schools teach ideals of equality and equal opportunity. Some traditional societies do not include formal schools for everyone. If so, school is not an agent for those groups. For them, the family is far more important.

Peers. The peer group is a friendship group of roughly equivalent age and interests, who are social equals. They are an important agent all over the world, but particularly for teens and young adults. Peer groups can ease the transition to adulthood. In the modern world, peer relations are even more important than they may have been in earlier times. Peer groups often remain important throughout much of a person's life. They tend to be more egalitarian than some of the other agents and influence a person's attitudes and behavior. Peer groups have great influence on how children socially construct and experience gender meanings in the classroom, playground, and informal social groups.

Mass media and technology. In modern societies, these are important agents of socialization. In the United States, over 98 percent of households have at least one television set and many have several. Even in less advanced societies, the media are increasing in importance, particularly the various electronic media. Research

has investigated whether violence on television (or in movies) encourages violent behavior among viewers (particularly among children). The findings are not conclusive, but most people believe that people's attitudes and values are affected by what they see and hear in the media. A positive influence is the fact that televisions and commercials can introduce young people to unfamiliar ideas, lifestyles, and cultures.

Public opinion. In every culture, what people think about controversial issues is an important agent of socialization. But in reality, not everyone's views are equally influential. Better educated, wealthier, well connected people often carry much clout. In societies where the mass media are important, that may greatly influence public opinion, too. This agent influences appropriate gender roles, notions of right and wrong, and beliefs about controversial topics such as abortion or gay marriages.

Religion. Religion is important and relevant for some people, but in the modern world religion is losing some of its power and influence as an agent of socialization. For those that follow religious tenets, the norms influence people's values, the desired size of families, the likelihood of divorce, rates of delinquency, behaviors considered appropriate (or not), and a host of other things. Religion has a role in social integration, social support, social change, and social control.

Workplace. The workplace is also an agent of socialization. Among other things, it teaches us that the work women do is often valued less than the work men do. Until recently, women employees were concentrated into routine, poorly paid occupations. Women's opportunities were often blocked by gender stereotypes. Work also teaches us appropriate values, work ethic (or lack of it), and appropriate attire. In modern societies, full time employment confirms adult status and awards us a personal identity. In a culture that has few rites of passage, that is important. Every society has "work," but in modern societies where work and home are separate, "going to work" involves more of a transition than in traditional societies.

The state. The state has recently been added to the list of agents of socialization. We recognize the state's growing impact on the life course. Increasingly, outside agencies like nursing homes, mental health clinics, and insurance

companies have taken over functions previously filled by families. The state runs many of these institutions or licenses and regulates them. In a sense, the state has created new rites of passage, such as the age a person can legally drive, purchase and consume tobacco and alcohol, marry without parental consent, or officially retire.

Total institutions are an important agent of resocialization for some people. Total institutions are places where residents are confined for a set period of time and kept under the influence of a hierarchy of officials (e.g., the military during basic training or officer training or a prison or mental institution). Every aspect of life is controlled, from the time you get up until you go to bed. The goal of a total institution is to resocialize individuals, to totally change them and make them into something new (and presumably "better").

Socialization, and what the agents of socialization teach, differs from one society (or subculture) to another. These differences include such basics as the following.

Treatment of children. Do we allow them a great deal of freedom (both physically and psychologically) or are we more rigid in our demands? Some cultures (such as in the United States) give infants a great deal of space, with large cribs and perhaps the run of the house when they are old enough to crawl and toddle. Other societies swaddle and restrain infants for their first year of life.

What we consider fit to eat and drink. The human body can digest and get nourishment from many different substances, but what we consider "fit" or suitable to consume varies greatly by culture. Some cultures (such as some Native American tribes or some Asians) appreciate puppy meat, while others are appalled at even the thought of eating dog. Traditionally, the French have thought diluted wine suitable for children to drink with meals, but probably most Americans find the thought of serving alcohol to children inappropriate.

What we "see" or notice in our environment. In some societies in Africa, people "see" only two or three colors while Americans (thanks to Crayola boxes with 120 colors) can distinguish between a dozen shades of blue. Children who never have the opportunity to see photos, movies, or television often cannot "see" things

when given just two dimensions. We "learn" to see as young children and it may be difficult if we encounter these things later in life.

Crying and display of emotions. In American society, "big boys don't cry," but males are allowed to display anger by swearing or expressing pain with a grimace. But some Native Americans, living in what we now consider the United States, had rites of passage where both pain and anger were suppressed. We are taught by the various agents of socialization when crying, anger, or anguish is appropriate (or not).

Knowledge and what we learn. In some more primitive societies, people count only to 10 or 20 (using fingers and toes). Anything above that number is designated as "many." But in western, advanced societies many people learn advanced mathematics. In the western world we learn to read from left to right, from the top of the page going down. In other parts of the world we read from the top to bottom, or from right to left. Agents of socialization teach us these things.

socialization, anticipatory

Gordon Shepherd

Anticipatory socialization refers to preparation for status changes and role transitions and, as such, is an important aspect of most forms of human socialization over the entire life course. While socialization in general may be defined as the social process in which groups transmit their culture and individuals simultaneously acquire self concepts and personality characteristics, anticipatory socialization directs particular attention to those situations where individuals are likely either to be induced to change or prepare themselves for change in conformity or opposition to a set of normative standards.

The concept of anticipatory socialization was introduced by Robert K. Merton and Alice S. Kitt in their 1950 article "Contributions to the Theory of Reference Group Behavior," in which they amplified the theoretical implications of *The American Soldier*, a large scale empirical study of military recruiting and training published in 1949. Merton and Kitt developed the concept to explain variations in the conformity of enlisted personnel to official military values and their subsequent promotions in military rank. They then generalized the concept as a key mechanism for understanding the relationship between reference group identification and social mobility in social systems. Merton and Kitt initially defined anticipatory socialization as the process in which individuals adopt the values of a group to which they aspire but do not belong. Merton subsequently refined the definition in 1968 to include not only non membership reference group aspirations but also, more generally, social statuses to which individuals aspire and which they are likely to attain. This allowed Merton to include in his analysis the structural concepts of normatively defined status sequences and role gradations which function to facilitate anticipatory socialization, producing greater continuity over time for both groups and individuals rather than disjunctive status changes.

Anticipatory socialization may occur in both formal and informal settings. In formal settings,

organizations deliberately recruit new members and programmatically attempt to shape their attitudes and values in conformity with organizational goals. Anticipatory socialization is especially prominent in organizations that sponsor opportunities for upward mobility in a status hierarchy. In general, anticipatory socialization is characteristic of achievement oriented, open systems which function in competitive environments. Merton and others have argued, however, that the major focus of analysis should be on the informal aspects; that is, situations in which role preparation occurs but which do not require specialized training personnel or didactic learning. Even in schools or training organizations, informal anticipatory socialization takes place outside the formal agenda and curriculum. Individuals respond more or less unwittingly to cues from an assortment of role models or reference others and draw implications for future role behavior, becoming oriented toward statuses they do not yet occupy.

Anticipatory socialization in formal settings draws attention to the agents of socialization, the group interests they represent, and the methods they use to shape the attitudes and values of novices who aspire to pursue organizational careers. The agents of socialization and the normative models which they project are important to the understanding of informal anticipatory socialization as well, but attention also is drawn to the individual agency of those being socialized and the choices they make in selecting reference groups and corresponding career paths over the life course. Personal agency is particularly significant in pluralistic social systems that offer individuals a wide range of life choices, in contrast to highly traditional or closed systems in which individuals have relatively few status or role options from which to choose. Thus the nature of the larger social structure in which groups and individuals function has a major impact on both formal and informal modes of anticipatory socialization.

Informal anticipatory socialization is an implicit part of the subject matter of both developmental psychology and the sociology of the life course. In both disciplines the patterned transition between various age statuses is a central topic of analysis. In developmental psychology, maturational and cognitive changes are discussed in conjunction with the various

modes of socialization to which individuals are exposed. There is a large literature on both the intended and unintended effects of different parenting styles on personality development in childhood. Considerable attention also has been given to the sometimes mutually reinforcing, sometimes competing influence of siblings and other family members, play groups, peer cultures, and the effects of an increasing array of mass media in contemporary society in the process of anticipatory socialization for adult roles during childhood and adolescence.

In addition to the various agents and methods of anticipatory socialization, two socialization outcomes in particular have received major attention: gender role identification and occupational career orientations. The term "differential socialization" is often used when referring to these outcomes. Differential socialization in these contexts means that individuals typically are socialized differently depending on their sex and social class. Numerous studies have documented the ways in which females are systematically defined and treated differently than males by parents, siblings, peers, teachers, and various role models or reference others portrayed in books, television, movies, computer games, music videos, advertising, and other agencies of mass culture. The net effect of these influences is to reinforce identification and compliance with gender role expectations in the process of development. Similarly, research initiated by Melvin Kohn demonstrates the way in which parents' social class and own occupational experience are correlated with their approach to childrearing in anticipation of the occupations they project their children will most likely pursue in life. Working class parents typically are more successful in jobs when they observe organizational rules and consequently tend to emphasize conformity to external authority in raising their children. In contrast, middle class parents typically are more successful in jobs when they take the initiative, work effectively without close supervision, and get along well with co workers. Consequently they are more likely to reinforce self expression and self control in their children. In societies where public schools track and sort students into vocational or college bound cohorts, the link between

social class and anticipatory socialization for occupational careers is especially evident.

While many empirical studies have incorporated anticipatory socialization as an explanatory variable, little has been done to develop the concept theoretically since Merton's pioneering work. One interesting exception is Kazuo Yamaguchi's exposition of rational choice models of anticipatory socialization and, in particular, his development of a related theoretical concept which he calls anticipatory non socialization. In contrast to different types of anticipatory socialization involved in the process of role entry and status attainment, anticipatory non socialization concerns decision making processes that rational actors engage in when exiting current roles or withdrawing their investments from previous commitments and social relationships.

socialization, gender

Deana A. Rohlinger

As children grow up they develop a sense of who they are, how they should relate to others, and the role they play in a larger society. The lessons children learn and the processes through which cultural norms are passed from one generation to the next is known as socialization. The focus on gender socialization highlights that there are roles, or cultural expectations and norms, which are associated with each sex category ("male" or "female"). Sociologists make distinctions between sex and gender. While sex is based on biological categories, gender is the result of cultural processes that construct different social roles for men and women. Gender socialization, then, is the process through which boys and girls learn sex appropriate behavior, dress, personality characteristics, and demeanor.

While gender socialization is lifelong, many sociological theories focus on early childhood socialization. Four such perspectives are the psychoanalytical, cognitive development, social learning, and social interaction perspectives.

The most famous psychoanalytical explanation of gender socialization is Sigmund Freud's identification theory. Freud argued that children pass through a series of stages in their personality development. During the first two stages (the oral and anal stages), boys and girls have similar behavior and experiences. Around age four, however, boys and girls become aware of their own genitals and that members of the opposite sex have different genitalia. It is during this phallic stage that children begin to identify and model their behavior after their same sex parent, thus learning gender appropriate behavior, although this process differs for boys and girls. At an unconscious (and precognitive) level, a boy's love for his mother becomes more sexual, and he views his father as a competitor, a feeling that is frightening because of the father's imagined retribution. Fearing his own castration, the boy begins to identify with his father, who he regards as powerful since he still has a penis, and models his father's behavior. The process is different for girls. Like boys, girls initially identify with their mothers. However, upon viewing male genitalia, a girl believes that she has been

castrated and develops the desire for a penis. This desire causes the girl to shift her love to her father, but to identify with her mother in an effort to find ways to win her father's penis. Eventually, she recognizes that she can only have a penis symbolically, through intercourse and childbirth. However, her continued penis envy causes her to adopt gender appropriate behaviors and to desire men.

While Freud's theory has been largely discredited, sociologists have drawn on it to extend psychoanalytical explanations of gender socialization. Nancy Chodorow (1978) drew on Marxist theory and psychoanalytic object relations theory to argue that gender socialization processes are key for the reproduction of the capitalist economy. She argued that identification is more difficult for boys than for girls because boys need to psychologically separate themselves from their mothers and model their fathers, who are largely absent from the home as a result of the breadwinner homemaker division of labor. This results in boys being much more emotionally detached than girls, who do not experience this psychological separation. Instead, mothers and daughters maintain an intense relationship, and during their interactions the female gender role is transmitted from one generation to the next. Ultimately, gender roles are reproduced and the next generation is socialized when these children are grown and try to recreate the families in which they were raised. Men work outside the home as their fathers had done, and women desire children in order to recreate the bonds of their youth and find emotional fulfillment. Chodorow argued that the socialization of children into traditional gender roles, where women are responsible for child rearing and men for earnings, reproduces a family structure that benefits a capitalist economy because the breadwinner expectation keeps men working at unsatisfying and often exploitative jobs. Moreover, because of their powerlessness in the labor market, men exert control over their families and reinforce traditional gender roles. This, in turn, ensures that men will continue to sell their labor in the market, despite their dissatisfaction, and that women will stay at home raising the next generation of workers and mothers. Chodorow's theory of socialization has been criticized for being limited to white, middle class families in western democracies,

and thus unable to explain how children from other family structures and other cultures acquire gender roles.

The second perspective points to cognitive development as a way to explain gender socialization, arguing that socialization occurs as children try to find patterns in the social and physical world (Piaget 1954; Bem 1993). From this perspective, children's earliest developmental task is to make sense of a seemingly chaotic world. As they observe and interact with their environment, they develop schema, or organizing categories. Because children rely on simple cues to understand the world and because there are clear differences in how women and men look and act, biological sex provides a useful schema. Children first label themselves, and then apply the schema to others in an effort to organize behaviors into distinct gender categories. Schema, however, are not static. Children's understanding of gender roles changes as they grow older and reflect increased complexity in their cognitive development. Thus, very young children are more rigid and stereotypical in their understanding of gender appropriate behaviors than older children, adolescents, and adults.

Critics highlight three problems with the cognitive development perspective. First, while the perspective suggests that children develop gender identities between the ages of three and five, a body of research indicates that the development of gender identities occurs much sooner. Second, while the cognitive development perspective assumes that children's use of sex and gender schemas are undifferentiated by sex, girls generally are more knowledgeable about gender than boys and are more embracing of cross gender behavior. Third, this perspective ignores the social world in which children are embedded. Children's understanding of gender identities is not limited to mental development, but also stems from interactions with peers, parents, and teachers.

The social learning perspective (Bandura 1986) posits that gender socialization is learned. This theory draws on the psychological concept of behaviorism to argue that children learn gender by being rewarded for gender appropriate behavior and punished for gender inappropriate behavior. Rewards and punishments may be direct. For example, a parent may

directly admonish a boy for wanting to purchase a doll with his birthday money, but praise a girl for the same choice. Children also learn gender appropriate behavior through indirect rewards and punishments as when they observe peers, parents, and other adults model the behaviors that will elicit praise or opprobrium. The main problem with the social learning perspective is that it assumes children are passive recipients of gender socialization messages rather than agents who actively seek out and evaluate information.

The social interaction perspective offers a fourth approach to gender socialization. This perspective has deep sociological roots. In 1902, sociologist Charles Cooley argued that individuals develop a sense of self by imagining how they appear to others, interpreting others' reactions to their actions, and developing a self concept based on these interpretations. Thus, a person's sense of self, which he called "the looking glass self," is an ongoing process embedded in social interaction. From this perspective, interaction forms the basis of gender socialization.

One set of interactions integral to gender socialization are those between parents and children. More often than not, parents tend to interact with boys and girls in ways that reinforce traditional gender roles. For example, while on average there are no sex differences among one year olds' attempts to communicate, adults respond to boys and girls differently. Parents respond to boys when they demand attention by being aggressive, crying, whining, and screaming, and they respond to girls when they use gestures, gentle touching, or words spoken in non demanding tones. Such parent-child interactions have long term effects on girls' and boys' communication styles, leading to boys with more assertive styles and girls with more talkative and emotive styles. Parents also tend to encourage physical play and roughhousing in boys and vocal interaction games with girls. These differences affect how girls and boys handle interpersonal strife and conflict later in life, with boys more likely to resort to physical confrontations and girls attempting to "talk out" their problems. Traditional gender roles also are introduced and reinforced through the kinds of toys parents provide their children. Dolls, doll houses, and miniature home appliances

encourage girls to be nurturing and engage in domestic tasks such as cooking, cleaning, and childcare, while blocks, construction vehicles, and science kits encourage boys to engage in construction, invention, and exploration which will provide skills useful in a competitive corporate world. In short, gender socialization occurs through parent-child interactions that reinforce traditional notions of gender in which girls are emotional and nurturing and boys are physical, aggressive, and competitive.

Social institutions are crucial to gender socialization. Parent-child interactions like those described above do not occur in isolation, but are embedded in the social institution of the family. Other social institutions important to gender socialization in childhood are school, sports, and mass media. In the educational system, a "hidden curriculum" refers to the values that are not explicitly taught in the classroom but are still part of the schools' unacknowledged lessons. This curriculum reinforces traditional conceptualizations of how girls and boys look and act through the use of course material, examples used in class, and activities that separate and pit boys against girls. These messages are buttressed through interactions with teachers and peers. Teachers, for example, reinforce gender roles by encouraging girls and boys to develop different skills (encouraging boys to excel at math and science and girls to excel in humanities and social science) and by differently praising their school work (commending boys for substantive content and girls for the neatness of their work). Children also divide themselves along gender lines in the lunch room, claim different spaces of the playground, and often sanction individuals who violate gender norms (Thorne 1993).

Sports are important to socialization because they teach children about cooperation, competition, and gender. For boys, the sports arena becomes a site where masculinity is performed. A boy's success at sports is seen as more masculine by other boys, which generates prestige in his peer group, while boys who fail are ridiculed and labeled "sissies" or "girls" (Messner 1992). Rewarding boys for "acting masculine" on the sports field has lasting consequences because it teaches boys that they must publicly prove their masculinity to others. This, in turn, encourages boys to develop

instrumental relationships, or relationships in which something of value may be acquired, rather than meaningful relationships based on mutual emotional fulfillment. Most sports sociology has focused on how sports affect the gender socialization of boys. However, since the passage of Title IX in 1972 in the US, the participation of girls in sports has increased dramatically. It remains to be seen how sports will affect the gender identities and socialization of girls.

Mass media are one of the most powerful tools of gender socialization because television, magazines, radio, newspapers, video games, movies, and the Internet are ubiquitous in American culture. Like other social institutions, mass media reinforce traditional gender roles. Magazines targeted at girls and women emphasize the importance of physical appearance as well as finding, pleasing, and keeping a man. While boys' and men's magazines also focus on the importance of physical appearance, they also stress the importance of financial success, competitive hobbies, and attracting women for sexual encounters (rather than lasting relationships). These supposed "masculine" and "feminine" characteristics and behaviors are reinforced across the media system, from video games and movies that show athletic heroes rescuing thin and busty damsels in distress, to television programs that depict women as housewives, nurses, and secretaries and men as lawyers, doctors, and corporate tycoons. Print media also play an important role in socialization. In children's literature, for example, boys typically are the protagonists, who use strength and intelligence to overcome an obstacle. When girls are included in stories, they are typically passive followers of the male leader or helpers eager to support the male protagonist in his plan. This state of affairs is undergoing change, however. An increasing number of television shows (*Zena: Warrior Princess*, *Buffy the Vampire Slayer*, *Alias*, and *Veronica Mars*), movies (*Laura Croft: Tomb Raider* and *Elektra*), and books (*Harry Potter*) have crafted new visions of masculinity and femininity. It remains to be seen if these images take hold and affect gender socialization processes.

In sum, sociologists offered a variety of theories to explain gender socialization. The most fruitful to date has been the social interaction

perspective because it recognizes that gender is an ongoing process and that gender roles are produced and reproduced in social institutions. A great deal of theoretical and empirical work remains to be done, however. Much of the scholarship on gender socialization has examined middle class, white heterosexuals. Thus, sociologists need to examine how their theories and data apply across class, race, ethnic, and sexual boundaries.

socialization, primary

Leslie Wasson

Socialization is the process by which humans learn the ways of being and doing considered appropriate and expected in their social environments. We call it primary socialization when the individual is a newly born member of society and is therefore experiencing this process for the first time. Primary socialization

has the social psychological characteristic of primacy, meaning that its position as first in the acquisition of social knowledge renders it a filter and a foundation for the subsequent information internalized by the fledgling social being. Primacy also makes early socialization remarkably resilient, in that it is much more difficult to change primary habits and beliefs than those learned later in the life course.

With regard to symbolic interaction, primary socialization becomes the initial set of significant symbols by which the individual interprets the perceived social world, formulates a conception of personal identity or identities, and through which he or she communicates understanding and desire with others. Through the symbolic structure of language, coupled with non verbal communication and other cultural cues, the individual negotiates an understanding of the agreed upon realities of social settings with significant others in their environment.

An early social philosophy of childhood portrayed the newborn social participant as a tabula rasa, or a blank slate upon which society then inscribed an identity. Later theorists, however, questioned the passivity of this model of child socialization. In his discussion of the origins of the self, George Herbert Mead (1934) drew upon the "looking glass self" model formulated by Charles Horton Cooley (1902). Cooley's socialization process entailed the individual engaging in a cycle of observation of the reactions of others to a behavior and the subsequent adjustment of that behavior to match perceived expectations. Unlike Cooley, however, Mead located the self as more than a passive reflection of social observation and response. Mead's novice social being was an active participant and negotiator in the socialization process, and his conceptualization of this agency has influenced subsequent theorizing on the subject.

There may be some biological preconditions for primary socialization to be effective. The work of Piaget (1954), for example, on the development of cognitive abilities in young humans indicates that at least some of the physical elements of human life must be present in order for the social aspects to persist. Although any stage theory should be treated with caution, Piaget's schema indicates that a child may not be capable of socialization beyond a certain point if physical development is inadequate.

Ancillary implications include a consideration of the primary socialization difficulties encountered by persons born with disabilities, although their acquisition of social competency may also be influenced by social expectations of their ability.

Some recent efforts to expand primary socialization include the use of music to stimulate cognitive development even prior to birth, and the use of American Sign Language as a communication medium with babies who are not yet physically able to speak coherently. Although more data collection is under way, early results indicate that non verbal forms of socialization are effective at much earlier ages than previously believed.

Children require sociability in order to thrive. Kingsley Davis (1947) and others (Spitz 1945, 1946; Curtiss 1977) who studied children raised in isolation provide evidence of the essentiality of interaction with human others for the full development and ongoing physical well being of the child. Children who are denied interaction in the extreme fail to thrive emotionally, mentally, and physically. It appears that the causality between the physical and the social in human development is complex.

Primary socialization involves learning, and humans are capable of a complex set of learning behaviors. Learning processes that may occur during primary socialization may include operant conditioning to environmental or social contingencies, observational learning (imitation), and internalization of social and emotional norms and values. The content of primary socialization is likely to include language and other forms of communication, identities and role taking, negotiation and meaning construction, and cultural routines. Contemporary researchers such as Strand (2000) distinguish between developmental and behavioral research on the socialization of young children.

Humans emerge at birth fairly unfinished. They go through a long period of dependency and require years of training in order for socialization to be perceived as successful. Anthropological research describes a myriad of human arrangements to which children are socialized, giving credence to a view of humans as remarkably flexible in their adaptation to material conditions. For the individual, primary socialization serves the very important function of making the

world predictable and easing interaction with others.

Primary socialization performs important functions for any society. Since society exists before the individual arrives, primary socialization allows new members to be integrated into existing social arrangements. This primary socialization process also makes possible the perpetuation of culture via intergenerational transmission. In primary socialization, therefore, the earliest agents of socialization are crucial to the fundamental construction of new social beings. In most cases, the foremost agents of primary socialization are parents, especially mothers. Changes in the composition of families in contemporary society, however, such as single parent households, grandparent parenting, and day care for working families, may create a shift in the source and character of primary socialization.

socialization and sport

Jay Coakley

There is a long tradition of research on socialization and sport. The roots of this research are grounded in theories that explain the role of play in child development, in Progressive era notions that team sports constituted an environment in which valuable lessons could be learned, and in popular twentieth century assumptions that playing sports was an inherently character building experience.

Empirical studies of socialization and sport were initiated in the 1950s as the first cohort of baby boomers in North America inspired parents as well as developmental experts to seek optimal conditions for teaching children, especially boys, the skills needed to succeed as adults in rapidly expanding, competitive, national and global economies. The structured experiences embodied in competitive sports were seen by many people in Western Europe and North America – especially suburban parents in the United States – to be ideal contexts for adult controlled socialization of children. It was assumed that sports taught young people lessons about teamwork, competition, achievement, productivity, conformity to rules, and obedience to authority. Consequently, organized youth sports and interscholastic sports grew dramatically, although the pace of this growth varied by nation and regions within nations.

The growth of organized sports for young people sparked questions about the benefits of sport participation and how to attract and retain participation. Those who asked these questions were often associated with organized sport programs, and they usually had vested interests in recruiting participants and promoting their programs by linking sport participation to positive developmental outcomes. Scholars in physical education were the first to use these questions as a basis for research, and their studies were usually designed to examine sport participation as an experience that shaped social and personal development in positive ways. Most of these studies found correlations between sport participation and positive character traits, although research designs were generally flawed and

provided little information about the dynamics of specific socialization experiences in sports compared to other activities (Stevenson 1975).

Research on socialization and sport has also been done in psychology and anthropology, as well as sociology. Psychological studies have focused on the socialization effects of sport participation on personality characteristics, moral development, achievement motivation, sense of competence, self esteem, and body image. Anthropological studies have focused on the role of play, games, and sports in the formation of value orientations in particular cultural contexts, especially those in pre industrial societies. Sociological studies, published mostly by scholars in North America, have focused on three main topics: (1) socialization into sport, dealing with the initiation and continuation of sport participation; (2) socialization out of sport, dealing with termination and changes in sport participation; and (3) socialization through sport, dealing with participation and multiple facets of social development.

Through the mid 1980s most sociological research on socialization and sport was grounded in structural functionalism or forms of Marxism, neo Marxism, and conflict theory. This research was based on the assumption that socialization was a process of role learning through which people internalized values and orientations enabling them to participate in established social systems. It was also based on the assumption that sport was a social institution organized in connection with the social system of which it was a part.

Since the mid 1980s most research has been grounded in a combination of interactionist and critical theories. The approach used in these studies assumes that: (a) human beings are active, self reflective decision makers who define situations and act on the basis of those decisions; (b) socialization is a lifelong process characterized by reciprocity and the interplay of the self conceptions, goals, and resources of all those involved in social interaction; (c) identities, roles, and patterns of social organization are socially constructed through social relations that are influenced by the distribution of power and resources in particular cultural settings; and (d) sports are cultural practices with variable forms and meanings (Coakley 2004).

This shift in the theoretical approaches and the assumptions used to guide research on socialization and sport is represented in the ways that scholars have studied socialization into sports, out of sports, and through sports.

SOCIALIZATION INTO SPORTS: BECOMING INVOLVED AND STAYING INVOLVED

Research based on an internalization social systems approach clarified that socialization into sport is related to three factors: (1) a person's abilities and characteristics, (2) the influence of significant others, including parents, siblings, teachers, and peers, and (3) the availability of opportunities to play and experience success in sports. Most of this research utilized quantitative methods and presented correlational analyses, but it provided little information about the social processes and contexts in which people make participation decisions and in which participation is maintained on a day to day basis at various points in the life course.

Research based on an interactionist social process approach has focused on the processes through which people make decisions to participate in sports; the ways that gender, class, race, and ethnic relations influence those decisions; the connections between participation decisions and identity dynamics; the social meanings that are given to sport participation in particular relationships and contexts; and the dynamics of sport participation as a "career" that changes over time. This research, often utilizing qualitative methods and interpretive analyses, indicates that sport participation is grounded in decision making processes involving self reflection, social support, social acceptance, and culturally based ideas about sports. Decisions about sport participation are made continually as people assess opportunities and consider how participation fits with their sense of self, their development, and how they are connected to the world around them. These decisions are mediated by changing relationships, the material conditions of everyday life, and cultural factors, including the sport related social meanings associated with gender, class, race, age, and physical (dis)abilities.

SOCIALIZATION OUT OF SPORTS: CHANGING OR TERMINATING SPORT PARTICIPATION

Research on changing or terminating sport participation is difficult to characterize in terms of the theoretical and methodological approaches used. Even the terminology used to describe socialization out of sport has been confusing. References have been made to attrition, disengagement, desocialization, withdrawal from sport roles, dropping out, nonparticipation, burn out, transitions, alienation, "social death," exits, retirement, and involuntary retirement (i.e., being "cut" or denied access to participation opportunities). Studies have focused on many issues, including the relationship between participation turnover rates and the structures of sport programs, the attributes and experiences of those who terminate or change their sport participation, the dynamics of transitions out of sport roles, the termination of participation in highly competitive sport contexts as a form of retirement or even as a form of "social death," and the connection between declining rates of participation and the process of aging.

Prior to the mid 1970s, socialization out of sports was not a popular research topic. Changing or terminating sport participation was treated more as a fact than a problem. It became a problem when baby boom cohorts younger than 13 years old declined in size and growth trends in organized programs slowed relative to the rapid increases that characterized the 1960s. Additionally, many parents in the 1970s had come to define participation in organized sports as important for the development and social status of their children. A growing emphasis on physical fitness in post industrial nations also heightened general awareness that physical activities, especially the strenuous activities involved in sports, were important to health and well being. And finally, there was an emerging system of elite sport development that depended on an expanding pool of developing young athletes nurtured through a feeder system of youth sports and interscholastic teams. As the vested interests in participation grew, so did research on the processes related to terminating and changing participation in sports.

This research indicates that terminating or changing sport participation occurs in connection with the same interactive and decision making processes that underlie becoming and staying involved in sports. When people end their active participation in one sport context, they often initiate participation in another context – one that is more or less competitive, for example. Terminating active participation due to victimization or exploitation is rare, although burnout, injuries, and negative experiences can and do influence decisions to change or end participation. Changes in patterns of sport participation often are associated with transitions in the rest of a person's life, such as moving from one school to another, graduating, initiating a career, marriage, and becoming a parent. And for people who end long careers in sports, adjustment problems are most common among those who have weakly defined identities apart from sports and lack the social and material resources required for making transitions into other careers, relationships, and social worlds.

SOCIALIZATION THROUGH SPORTS

The belief that sport builds character has its origins in the class and gender relations of mid nineteenth century England. Although the history of beliefs about the consequences of sport participation varies by society, the notion that sport produces positive socialization effects has been widely accepted in most western industrial and post industrial societies, especially England, Canada, and the United States. For nearly a century the validity of these beliefs was taken for granted and promoted by those associated with organized competitive sports in these countries. It was not until the 1950s that people began to use research to test the validity of these beliefs.

Most research between the 1950s and the late 1980s consisted of atheoretical, correlational analyses presenting statistical comparisons of the attributes of "athletes" and "nonathletes," usually consisting of students in US high schools. The dependent variables in these studies included academic achievement, occupational mobility, prestige and status in school cultures, political orientations, rates of delinquency and deviance, and various character

traits such as moral development. Because few of the studies used longitudinal, pre test/post test designs, research findings were usually qualified in light of questions about "socialization effects" (i.e., the attributes that were actually "caused" by sport participation) versus "selection effects" (i.e., the attributes that were initially possessed by those who chose to play organized sports or were selected to play by coaches and program directors). Additionally, most of these correlational studies simply divided all respondents into so called "athletes" and "nonathletes," thereby ignoring their participation histories and the confounding effects of participation in a wide range of activities offering experiences closely resembling those offered by playing on school sponsored varsity teams.

McCormack and Chalip published a key article in 1988 in which they critiqued the methodological premises of research on socialization through sports. They noted that most researchers mistakenly assumed that (a) all sports offered participants the same unique experiences, (b) all sport experiences were strong enough to have a measurable impact on participants' characters and orientations, (c) all sport participants passively internalized the "moral lessons" inherently contained in the sport experience, and (d) that sport participation provided socialization experiences that were unavailable through other activities. These assumptions led researchers to overlook that (a) sports are social constructions and offer diverse socialization experiences, (b) participants give meanings to sport experiences and those meanings vary with the social and cultural contexts in which participation occurs, (c) the personal implications of sport participation are integrated into people's lives in connection with other experiences and relationships, and (d) sport participation involves agency in the form of making choices about and altering the conditions of participation. Focusing strictly on socialization outcomes led researchers to overlook the processes that constituted the core of socialization itself. Therefore, their studies missed the tension, negotiation, misunderstanding, and resistance that characterize lived sport experiences.

These assumptions and oversights gave rise to a body of literature containing contradictory and confusing findings often leading to the conclusion that little could be said about

socialization through sports. However, research initiated during the 1980s and 1990s, often guided by interactionist and critical theories, began to focus less on socialization outcomes and more on the social processes associated with sport participation and the social and cultural contexts in which sport experiences were given meaning and integrated into people's lives. The findings in this research indicated that:

- Sports are organized in vastly different ways across programs, teams, and situations offering many different socialization experiences, both positive and negative, to participants.
- People who choose to play sports are selected to participate by coaches, and those who remain on teams generally differ from others in terms of their characteristics and relationships.
- The meanings that people give to their sport experiences vary by context in connection with gender, race/ethnicity, social class, age, and (dis)ability, and they change through the life course as people redefine themselves and their connections with others.
- Socialization occurs through the social interaction that accompanies sport participation, and patterns of social interaction in sports are influenced by many factors, including those external to sport environments.
- Socialization through sport is tied to issues of identity and identity development.

These findings indicate that sports are most accurately viewed as sites for socialization experiences rather than causes of specific socialization outcomes. This distinction acknowledges that sports and sport participation may involve powerful and memorable experiences, but that those experiences take on meaning only through social relationships that occur in particular social and cultural contexts.

Since the late 1980s an increasing number of studies related to sports and sport culture have viewed socialization as a community and cultural process. Using various combinations of critical theories, cultural studies, and poststructuralism, researchers have undertaken textual and semiotic analyses in which they focus on sports as sites where people construct and tell stories that can be used to make sense of

their lives and the worlds in which they live. In the process, culture is produced, reproduced, reformed, or transformed. Much of this research analyzes media based discourses by deconstructing the images and narratives used in connection with sports and the personas of sport figures, especially high profile athletes.

This research acknowledges that sports and the discourses that constitute them have become one of the more influential narratives in twenty first century culture. They are implicated in struggles over meanings, processes of ideological hegemony, and the expansion of global capitalism and consumer culture. One of the goals of this research is to understand sports in ways that contribute to informed and progressive explanations of the political, economic, and social issues that influence people's lives.

socialized medicine

Sarah Nettleton

Socialized medicine is a system of health care delivery in which care is provided as a state supported service. The term was introduced in 1954 by an American academic – Almont Lindsay – on a study visit to the United Kingdom. On his return to the US, he published a book called *Socialized Medicine in England and Wales* (Lindsay 1962), describing the history, organization, and structure of the National Health Service (NHS). However, the term “socialized medicine” is one that tends to be used by “observers” (particularly North American observers) of the UK health service and it is less commonly heard within the UK itself (Webster 2002: 1). This may be because the British NHS is considered by many analysts to be a unique example of socialized medicine. Indeed, it is often described as “a socialist island in a capitalist sea.” In this respect it forms part of a welfare system which rests on collective provision, social justice, social equality, and democracy in order to mitigate the adverse effects of capitalism. The fundamental principles of the NHS are therefore: that it should be publicly funded (predominantly by taxation); health care should be universal and be provided on the basis of health “need” rather than the ability to pay; and services should be comprehensive in that they should include preventive health services as well as treatment for those who are ill.

The NHS was established by the Labour government that had won a landslide victory after World War II and came into operation on July 5, 1948 as a result of the NHS Act passed in 1946. The Minister of Health, Aneurin

Bevan – said to be the architect of the NHS – described it as “the biggest single experiment in social service that the world has ever undertaken” (quoted in Webster 2001: 171). It is unique. Other European countries and Canada developed variations on compulsory social insurance schemes. Sweden’s universal system, established in 1955, perhaps best approximates the UK system, although it required higher levels of direct payments from patients (Webster 2001).

But to what extent can the NHS be regarded as an example of “socialized medicine”? A definitive definition of the term socialized medicine that would be required in order to answer this question is not easy, in that it would invariably fail to capture the diversity of debates associated with socialism or, more accurately, socialisms (Ginsburg 1998). However, a comparison between the initial proposals for the NHS and its subsequent design may offer some clues.

Following the two world wars there was a general consensus that health care provision in the UK was partial, chaotic, ineffective, and inequitable. Experiences during World War II not only threw these facts into sharp relief but also provided civil servants, policymakers, and practitioners with opportunities for delivering more effective “emergency” services. Proposals for a new system of health care came from the influential Socialist Medical Association, the British Medical Association (BMA), and the thinktank Political and Economic Planning. The proposals were very popular with the public and the ideas formed the basis of the 1944 White Paper (that is, a government document that sets out legislative proposals) entitled *A National Health Service*. There was to be a comprehensive, universal service provided on the basis of need and divorced from the ability to pay, provided by the state which, in turn, would employ doctors on a salaried basis. The service would be run by local authorities and located in hospitals and health centers. Before the Act was passed, however, Bevan had to modify his plans as a result of the opposition and skepticism of the medical profession. The profession’s trade union – the BMA – was anxious about its clinical freedom, and negotiated a number of concessions. Bevan is regarded as a smart political operator because he managed to capitalize on a

division within the profession between those who provided specialist secondary hospital care and those who provided primary generalist care (known in the UK as general practitioners or GPs). In particular, the latter would not be employed on a salaried basis and retained their status as independent practitioners being paid on a capitation basis, whilst the former could continue with their private medical practice alongside their NHS work. Bevan gave explicit reassurance that their clinical freedom was sacrosanct, and quietly dropped the plan for health centers. In addition, instead of implementing the unified, centrally controlled, and locally run system, a tripartite structure was introduced which meant that the hospitals, local authorities, and primary care GPs, dentists, etc. were run separately. This latter concession led to insurmountable problems in terms of coordination of services. Thus the ideal of socialized medicine resulted in a compromise, not least as a result of the need to win over the powerful profession of medicine. Such compromises continued; as the health policy analyst Rudolf Klein (2002: 230–1) notes, the political history of the NHS is one of a series of conflicts between governments and the medical profession. In particular there have been conflicts over pay, private practice, and the structure of the NHS.

In recent decades this has changed. Throughout the 1980s ideologically conservative governments dominated British politics; they challenged the medical profession and altered the internal dynamics of the NHS. The NHS was established in a period of political consensus and commitment to social welfare and collectivism. Forty years later when the government led by Mrs. Thatcher was in office, the mood was for consumerism, individualism, marketization, and privatization. It is perhaps remarkable, therefore, that such a libertarian political leader proclaimed that “the NHS is safe with us” (Thatcher cited by Klein 2002: 119). The NHS remained funded predominantly out of public funds, services remain predominantly free at the point of use (although charges for drugs and services first introduced in the 1950s have increased), and health care practitioners are predominantly employed by government funded institutions. In this respect it adheres to the principles of socialized medicine. Privately financed health care and private health

care insurance remain at the margins. The margins, however, may be getting wider. Attempts to alter the internal structures of the NHS and to establish new opportunities for private finance initiatives may shift the extent to which it remains a collective and communal service. According to the official historian of the NHS Charles Webster (2002: 258), it is misguided to represent Bevan’s health service as some kind of obsolete command and control system. He suggests that politicians would do well to endorse Bevan’s conception of the NHS as a triumphant success, wherein the merits of collective provision outweigh the pernicious consequences of commercialization.

society

Larry Ray

The concept of society is both core to sociological analysis and subject to wide ranging dispute that is often informed by the theoretical disputes within the discipline. When in 1987 the British prime minister Margaret Thatcher said in an interview “There is no such thing as society. There are individual men and women and there are families,” many sociologists

offered a robust defense of the concept. But one British sociologist subsequently stated: "Thatcher might have been right [in her claim] ... or at least the riposte from the sociological community was not fully justified" (Urry 2000). This illustrates an uncertainty within the discipline as to the appropriateness of the concept, especially in a globalized age in which the idea of discrete societies bound by national borders has been widely questioned. Ironically, however, in the rest of her interview Thatcher went on to emphasize the importance of reciprocal social obligations and bonds between people – things that many sociologists would regard as central to the idea of society.

However, the idea of society as a generalized term for social relations is relatively new and appeared, like sociology, during the transition from pre industrial to industrial society. Implicit concepts of the social can be identified much earlier, for example in Platonic and Aristotelian philosophy, but premodern philosophies did not generally differentiate "society" from the political organization of the state. It is only in late seventeenth and early eighteenth century European social thought that the term society begins to be applied to the ensemble of social relations. The use of the adjective "social" to mean "pertaining to society as a natural condition of human life" derives from Locke (1695). This use of the concept of society is based in the delineation of "civil" from "political" society, which in turn reflected the increasing complexity of social life with the transition from feudal to modern society. The principle of the feudal state as the property of the sovereign slowly gave way to the principle of impersonal rule bound by juridical rules, while the state underwent a process of differentiation into administrative, judicial, and representative functions. Civil society theorists such as Adam Ferguson celebrated the new commercial social order, the rise of public opinion, representative government, civic freedoms, plurality, and "civility." Thus, society came to depict a realm of contractual and voluntary relationships independent of the state, which in turn became merely one area of social activity among others. Society was increasingly conceptualized as a realm of life no longer emanating from a political center, but rather the site of diffuse voluntary associations, in which individual self interested

actions result in an equilibrium of unintended consequences.

However, the liberal Enlightenment understanding of these processes as realms of individual liberty conflicted with Catholic conservative reactions to the 1789 French Revolution and its aftermath. For conservatives such as de Bonald and de Maistre, enlightened individualism and the revolution had destroyed the organic bases of society that lay in sacred moral authority and the institutions of church, monarchy, and patriarchal family. Although not sociologists, their ideas set the scene for the organic functionalist theories of society of Comte, Durkheim, and later Parsons and Luhmann. For Durkheim, society is an internally differentiated yet functionally integrated system whose operations could be understood only from the point of view of the whole. This complex system is an entity *sui generis*, that is, a discrete reality that cannot be reduced to or explained with reference to another ontological level such as biology or psychology. For systems theory, core problems of society are those of achieving sufficient internal integration to persist over time and boundary maintenance, that is, preserving borders between internal and external systems. This concept underpins systemic functionalist analysis, although mechanisms of integration are viewed differently in different theorists – moral integration in Durkheim; a more complex process of adaptation, goal attainment, integration, and latency in Parsons; and complexity reduction in Luhmann.

This approach has been criticized from at least two perspectives. First, Marxist and other critical theories have emphasized the centrality of power, exploitation, and conflict as central organizing principles in society such that "society" is a field of contestation around class, gendered, and racialized structures. Moreover, these structures operate to some extent "behind the backs" of acting subjects such that they are not immediately accessible to conscious reflection. From this point of view, "society" has only an illusory unity which critical analysis deconstructs to reveal patterns of hegemonic domination and resistances.

Secondly, individualistic theories drawing on liberal pragmatism appear in writers such as Simmel, Mead, Becker, and Goffman. They approach "society" as at best a metaphor for

an aggregation of human interactions rather than an entity *sui generis*. Indeed, Simmel would have had much sympathy with the view that we should not speak of “society” in abstraction from the forms of association that connect individuals in interaction.

This central issue has been core to many debates in sociological theory – that is, how to comprehend society both as social action and as a system of interrelated practices with unintended consequences. One can say that “society” refers to all forms of mutual and intersubjective communication in which the perceptions and behavior of actors are oriented to those of others. These may be specific others – such as family members, colleagues, friends, rivals, enemies, and authority figures – or they may be generalized others in the form of internalized expectations derived from cultural, moral, practical, and communicative practices. These intersubjective networks can exist on a multiplicity of levels – personal and impersonal; local and global; within regions, nations, and across borders. They exist across a continuum between informal and voluntarily entered relationships (such as friendship), through formal institutional interactions (e.g., in workplaces and with officials), to highly coercive ones such as prisons. Social relationships at each of these levels can be constituted by expressive (affective) orientations or by instrumental ones. Relationships can be highly personal and influenced by the particular characteristics of others or highly impersonal and formalized encounters, such as a money exchange or phoning a call center. “Society” thus refers to the complex patterns of social relationships that will be sustained through time and space, although encounters may be anything from fleeting to lifelong and proximate to distant. Any social interaction though will summon up or, as Giddens (1979) puts it, “instantiate” vast amounts of tacitly held, taken for granted background cultural knowledge about how to perform and attribute meaning to social interaction. This means that as well as situated interactions and communications, “society” also refers to the latent structures of linguistic, affective, cultural, and normative rules that are deployed piecemeal in any actual interaction. Systems of power and domination also inhere within these structures, although they can be accessed and subject to

critical reflection and practice through intersubjective communication.

society and biology

Adrian Franklin

Society and biology is one of the new transdisciplinary fields of sociology that emerged in the 1990s. Owing to its strong links with genetic research, medicine, health, agriculture, environment, and science and technology, it has developed a number of important research centers, such as Bios (Center for the Study of Bioscience, Biomedicine, Biotechnology, and Society) at the London School of Economics, the Center for Biology and Society at Arizona State University, the Center for Science Studies at the University of Lancaster, and the Department of Biology and Society at the University of Amsterdam.

In the 1990s it became clear, from work in the areas of the sociology of health, the sociology of the body, and science and technology studies, that it was no longer possible to conceive of a sociological domain that was separable from the biological even if biological processes and social processes could be distinguished as different (Newton 2003a, b). Critically, social phenomena operate in material and biotic contexts in which important transfers of materials, information, prehensions, and

inscriptions take place. Anthropologists, for example, are just beginning to take notice of and understand the natural construction of society as well as the social construction of nature (see Franklin 2002: ch. 4).

Foucault argued that power, surveillance, and control operate on and through the human body. However, our very conception of biology and “life itself” has enormous implications for how we think of ourselves socially. Sarah Franklin argues that we can identify three shifts in the way life itself has been considered in modern societies.

First, in the nineteenth century nature was *biologized*. According to this view, life originates in narratives of evolution and natural selection. It became possible to think of human difference in biological terms (such as race). Equally, individuals could be explained in conception stories of eggs and sperm, and of genetic blueprints. These were “the facts of life.”

Second, biology itself became geneticized in the latter half of the twentieth century, and now social issues surrounding human behavior, pathology, and risk were geneticized: social planning and management now involved *genetic* assessment. Social life oriented itself to genetic genealogy and referenced “genetic parents,” “genetic relatedness,” “genetic risk,” “genetic identity,” and “genetic variation.” Concern over genetic inheritance gave way to socially significant technologies of control such as genetic screening, the human genome project, and human gene therapy. The discourse of genetics, then, was an important language to describe not only the human condition, but also the condition of life itself, and technologies emerging in the human world were transferred to new concerns with environmental change and the future of reproduction generally. Life had been reduced to information.

Third, geneticization became inseparable from its instrumentalization or the uses that could be made of it. In addition to being able to make new life and change existing life at will (theoretically), geneticization made possible completely new forms of property and power. More can be done with genes, such as the capitalization of life itself. The commodification of genomics drove international scientific competition to claim biotechnical market share but also expertise in the management and

surveillance of genetic risk. Patents were now possible for new life. As Franklin (2000) put it, “emergent definitions of genetic risk, and their attendant techniques of detection and intervention, are indexical of changing relationships between health and pathology, disease and cure, technoscience and the body, humans and animals, and the regulation of public health. In turn, such altered understandings contextualize the ways in which life itself can be owned, capitalized and patented.”

Nature becomes biology, becomes genetics, through which life itself becomes reprogrammable information across time, space, and “species” (which become irrelevant?). Franklin asks us to think about *Jurassic Park* as an example of the emergent genetic imaginary. However, it is not just life that changes but *being*. Creatures such as Dolly the Sheep, “Onco mouse,” and Jefferson the Calf were not born but *made*; they were not beings but “done tos.” More social life will focus on accumulation strategy deals between corporate wealth generation and molecular biology. And as this happens, sociologists are beginning to ask whether society itself will become recombinant.

Tim Newton argues, however, that genetic technologies and future technologies to tackle hitherto uncontrolled natural forces such as weather and volcanic activity will dissolve finally the very distinction between biology and society: “What remains of interest is how far human techno linguistic skill will enable us to increasingly plasticize biological and physical processes and ‘short circuit’ seemingly millennial natural stabilities. Are we moving toward plastic bodies (with ‘clonable’ parts) and a pliable world where we will be able to play with *all* the times of nature? If we move toward the latter scenario, current differences between natural and social times will increasingly erode” (2003a: 27–8).

In the meantime, the sociological study of society and biology will monitor not only social change emerging from new technologies and their implications, but also its *contested* nature in the realm of biopolitics. Nikolas Rose says that “the biological existence of human beings has become political in novel ways” (2001:1). He traces the history of biopolitics, beginning with the nineteenth to mid twentieth centuries when those in power sought to discipline individuals, through health and hygiene

regimes and breeding programs, “in the name of the population.” Further into the twentieth century the massive political apparatus of health would not have been possible without the increasing health aspirations of the people themselves. This alliance between state and people shifted in the second half of the twentieth century from an emphasis on avoiding sickness to an emphasis on attaining well being (an optimization of health, but also of beauty, fitness, happiness, sexuality, and more). As Rose says: “selfhood has become intrinsically somatic – ethical practices increasingly take the body as a key site for work on the self” (2001: 18). This biopolitics merges with what he has called ethopolitics or the politics of life itself: “the ethos of human existence – the sentiments moral nature or guiding beliefs of persons, groups, or institutions – have come to provide the ‘medium’ within which the self government of the autonomous individual can be connected up with the imperatives of good government. In ethopolitics, life itself, as it is lived in its everyday manifestations, is the object of adjudication” (2001: 18). Because of this, the salience of biology and society is not just important for sociology, it is the basis on which important life choices must be made by most of the individuals it studies.

sociocultural relativism

John Curra

INTELLECTUAL AND SOCIAL CONTEXT

While the word “culture” was first used in 1877 by Edward Tylor to describe the totality of humans’ behavioral, material, intellectual, and spiritual products, it was Franz Boas who gave the term one of its most distinctive elaborations. Unlike some other anthropologists (e.g., Malinowski), Boas refused to devalue cultures regardless of how primitive they might appear to outsiders. For Boas, the principal task was to describe accurately and understand completely the cultures of the world, not to rank them from good to bad. Students of Boas, especially Benedict and Herskovits, carried on his legacy, especially his commitment to cultural relativity. They adopted cultural relativity as a principal way to generate respect and tolerance for human diversity, while defending indigenous peoples from threats to their collective and individual well being.

Sociocultural relativism is a postulate, a method, and a perspective. One implication of the postulate of relativity is that actions and attributes vary from time to time, place to place, and situation to situation. If anything “real” or “objective” exists in the social world, it is the intrinsically situational nature of both rules and reactions and the dynamic, negotiated nature of social order (Becker 1973). A second implication of the postulate of relativity is that collective *definitions* of actions and attributes are elastic and also vary from time to time, place to place, and situation to situation (Cohen 1974). Things that are mightily upsetting to one generation may be trivial to the next

(or vice versa), and a particular trait of an individual can be admired by friends but despised by enemies (Goode 2001: 37). The concept of relativism is based on the fact that at certain times and places, acts and attributes that an outsider might find distressing or wrong are not defined as such by individuals living in those times or places (Goode 2003). Sociocultural relativism is a method, too. It demands an actor relevant approach in which social scientists take the role of their subjects and understand the world through the subjects' eyes. While this does not guarantee freedom from ethnocentrism, it does make this bias less likely. In Goffman's (1961: 130) words, "the awesomeness, distastefulness, and barbarity of a foreign culture can decrease to the degree that the student becomes familiar with the point of view to life that is taken by his [her] subjects." Sociocultural relativism requires that you put yourself in the shoes of another, maybe even an adversary's, in order to understand why some one might wear those shoes at all (Fish 2001). Sociocultural relativism is also a perspective, as it is possible to find relativism or nonrelativism in human experience depending on how an observer's eye is slanted. If you are looking for vacillation, drift, and indeterminacy, they are easy to find in this constantly changing, multiplex world of ours; if, however, you are looking for stability and constancy, you can find them, too. Not all sociologists consider themselves relativists, but *all* sociologists must wrestle with the ethical, philosophical, logical, theoretical, and empirical issues that surround a discussion of sociocultural relativism.

Respect for diversity must be tempered with the knowledge that some conditions can neither be easily overlooked nor dismissed as an example of the equivalency of human cultures. We have neither a convincing moral code that can be applied to all places and times nor any theory that makes it possible to understand human experience separate from its social context (Hatch 1997). Nonetheless, situations will be found in which it is impossible to maintain an attitude of indifference. Sociocultural relativists do not have to believe in the absolute equivalency of values, norms, or customs and blindly accept whatever they find. Romanticizing diversity blunts our ability to recognize the genuine

tragedy, pathos, and harm that deviant social practices can produce.

Marx had relativistic leanings, apparent in his claim that economic forms are transitory and historical, and he was opposed to any fixed or determinate view of nature. However, the first extensive application of sociocultural relativism is found in Durkheim's *Rules of Sociological Method* when he contrasts the "normal" with the "pathological." He asks us to imagine a society of saints, a "perfect cloister of exemplary individuals" (Durkheim 1938: 68–9). Crimes like murder, rape, robbery, and drug addiction would not exist in this virtuous place, but crime would still be found even though it would seem minor to individuals from the less than saintly society. Durkheim was contending that it is the *attitude* about, and *reactions* to, some act (i.e., how it is judged and punished) by observers that is principally responsible for its categorization as criminal. Acts may be viewed as offenses even though they are not harmful in any essential or intrinsic way, as is found in proscriptions against allowing a sacred fire to die down or mispronouncing a ritual formula. Even when a crime *is* indeed harmful to a society, the intensity of the reaction may be disproportionate to the harm done (Durkheim 1933: 72). Deviance as an analytical and empirical category may be near universal, but the particular form that deviance takes most assuredly is not (Ben Yehuda 1990: 11).

A relativizing motif is a driving force of sociological consciousness, and sociologists call into question what most other people take for granted. One of sociology's strengths is that it can make sense of groups and relationships in a world in which values have been radically relativized (Berger 1963: 48). Sociologists uncover and critically evaluate the pretensions and propaganda individuals use to hide, distort, or legitimize what they are doing. They shift from one perspective to another, ranging from the impersonal and remote transformations of the wider society to the inner experiences of individuals in order to understand the interconnections between the two. Sociologists participate mentally in the experiences of individuals differently situated from themselves no matter where or when they are found. Sociocultural relativism can help us to understand the experiences of

people in groups and subcultures *within* the boundaries of any one society, as well as the experiences of people drawn from different societies and cultures.

PATHOLOGY, BASIC HUMAN RIGHTS, AND SOCIOCULTURAL RELATIVISM

To describe some culture, social arrangement, group, or human being as “sick” may be convenient, but it does little, or nothing, to further our understanding of human experience. Things do not have to be categorized as pathological for them to be recognized as harmful or to admit that humans and their societies would be better off without them. Sociologists are inclined to think that the concept of pathology fails to illuminate actual happenings and needs to be rejected. The principal defect of pathologizing diversity is that it fails to explain correctly the phenomenon under review (Matza 1969: 44). It fails to recognize the functionality and durability of deviance.

Even as the notion of pathology was being purged from sociology, it was being replaced by a notion of intrinsic harm and a normative definition of deviance. The global concern with basic human rights, principally in response to the horrors of the Holocaust and World War II, was formalized in the Universal Declaration of Human Rights (UDHR) of the United Nations (1948). Before World War II, human rights protections were viewed as a domestic, not international, project. The atrocities of the war, especially the Holocaust, changed things. It became clear that individuals were at a disadvantage when faced with governmental power, and they needed more protection against abuse than the legal system of any one nation could provide. The UDHR was sanctioned by each member country of the United Nations in 1948, and it continues to be viewed as a standard against which human decency should be measured. It forbids murder, torture, and slavery, even while it authorizes freedom of conscience, speech, and dissent. Specific sections of the document confirm the rights to employment and fair working conditions; to health, food, and security; to education; and to participation in the cultural life of the community. These

human rights claims are based on principles of fairness, rightness, justice, or equity that should in principle extend to people in all parts of the world.

A normative approach to basic human rights is not without its problems. Mills’s critique of the ideology of “social pathologists” (specialists on social problems and deviance) was thoughtful and thought provoking. His discussion offers a cautionary note to any normative approach that defines harms in terms of universal social norms. Norms, Mills (1943) instructed, reflect the interests, experiences, and resources of the people who fashion them, not a universal morality or global consensus. Norms do not simply create and channel human behavior, they also serve as the standards against which deviation is defined and measured. To the extent that norms are ideological, so are definitions of right and wrong or proper and improper. The push for universal human rights is difficult to justify in the face of substantial cultural and religious diversity, and profound doubts exist about the workability of implementing uniform moral standards cross culturally (Zechenter 1997). Rights and harms must be understood from a study of particular social historical groupings and their relationships with other social groupings, not from the application of abstract, self contained sets of rules.

We must be careful not to be duped by what may be called “expedient relativism.” This exists when elites in sovereign nations justify everything they do, no matter how harmful it is, by insisting that they should be allowed to do whatever they want. Countries that violate the human rights of their populations most often are the ones whose leaders are most likely to justify their actions by appealing to sovereignty and cultural relativity. They defend practices such as corporal or capital punishment, the abuse of women (including genital mutilation), sexism and racism, and political violence by claiming that their critics are ethnocentric or indifferent to their local customs. The concept of relativity, which was developed to encourage an awareness of, and respect for, human diversity has returned to haunt the social sciences. It is used to legitimize the subjugation of indigenous groups, women, and minorities and to excuse human rights abuses.

RELATIVITY OF DEVIANCE

Sociocultural relativism has kindred ties with Matza's (1969) idea of "natural deviation." Naturalism is an approach that views the human actor as a self-conscious, reflexive being who engages in meaningful activity. Naturalism rejects determinism, and its only obligation is to offer a correct rendition of worldly activities. It combines observation with empathy, intuition, and experience, while it views humans as individuals who intentionally create the world within which they live. "The growth of a sociological view of deviant phenomena involved . . . the replacement of a correctional stance by an *appreciation* of the deviant subject, the tacit purging of a conception of pathology by new stress on human *diversity*, and the erosion of a simple distinction between deviant and conventional phenomena, resulting from more intimate familiarity with the world as it is" (Matza 1969: 10). The difficulty in defining deviance is due neither to flaws in the concept of deviance nor in sociocultural relativism. The difficulty lies in the unruly nature of society and the indeterminacy of interpersonal relationships. Definitions of deviance are naturally ambiguous because deviance lacks inherent or essential characteristics, and human relationships are characterized by both drift and defiance. We have a right to our views of proper and improper but, if we are studying deviance, we have to pay attention to how such judgments are constructed and vary through time and space. How visitors to some culture or group react to some act, attribute, or condition is a completely separate issue from how its members do (Goode 2003).

Sociocultural relativists are inclined to view deviance as a relationship instead of a condition that some people have that others lack (Curra 2000). Social control can actually cause deviance by categorizing acts, attributes, and actors as deviant and helping to mold deviance into a pattern or career (Becker 1963: 25–39). Goffman (1961) showed that rules and reactions regularly produce counter rules and resistance, which inevitably produce new categories of "deviance" and "deviant" because resistance to authority is usually defined as a serious matter by those who do not want their authority challenged. Cohen (1974) noted that social definitions continually work to ensure that all positions on a continuum

from good to bad are always filled, so some individuals will always be classified as worse than other individuals. The wickedness of the villain, like the virtue of the saint, may have to be invented. Parsons (1951) made it clear, at least as clear as he could, that social control agents assigned the status of "deviant" to individuals and "deviance" to acts because it helped to support and sustain the normative order, as well as masking or disguising legitimate social conflicts over proper and improper motivational orientations and behaviors. In creating an "other," groups may manufacture a scapegoat that can be used to explain away continuing or worsening social problems.

Becker's writings synthesize the sociological concept of deviance with sociocultural relativism. In fact, relativism is at the core of the interactionist or labeling approach to deviance. With his ideas of "sides" (Becker 1967), "sentimentality" (Becker 1964, 1967), "hierarchies of credibility" (Becker 1967), and "moral entrepreneurs" (Becker 1963), Becker was able to draw attention to the role played by labeling, power, and audience reactions in producing careers of deviance. By moving away from the inclination of many other theorists to define deviance in terms of intrinsic qualities of actions and attributes, Becker gave a new spin to the sociology of deviance. Groups of people create deviance as they act together; no individual can create deviance alone. Social control agents, as Goffman (1961) showed with both precision and elegance, have both personal and bureaucratic reasons to create labels and apply them to individuals. If individuals refuse to follow rules or resist the labels being applied to them, control agents will view the resistance itself as a problem and in need of correction. In this way, deviance grows exponentially to the number of institutions established to deal with it (Sumner 1994).

Lemert's idea of "putative" deviance allowed sociologists of deviance to clarify the parameters of sociocultural relativism in regard to *warranted* or *unwarranted* definitions and reactions. "The putative deviation is that portion of the societal definition of the deviant which has no foundation in his [her] objective behavior. Frequently these fallacious imputations are incorporated into myth and stereotype and mediate much of the formal treatment of the deviant" (Lemert 1951: 56). Reactions to deviance can be

disproportional, and individuals can be falsely accused (Becker 1963). Members of a society may come to believe that the threats from deviance are greater than they actually are (Goode & Ben Yehuda 1994). Objective mole hills can be transformed into subjective mountains (Jones et al. 1989), and moral enterprises can evolve into moral panics (Goode & Ben Yehuda 1994).

Becker's concept of sentimentality shows that what is deviant depends on whose view is being taken. He borrowed the term from Freidson's (1961) study of physicians and their patients. Freidson was willing to give credibility and authority to patients' views of their physicians, even when these views were at odds with what physicians thought of themselves. Becker defined sentimentality as a disposition on the part of a researcher to leave certain variables in a problem unexamined or to refuse to consider alternate views or distasteful possibilities (Becker 1964). We are sentimental particularly when we refuse to consider the merits (or lack thereof) of *both* conventional and unconventional social actors only because we do not want to face the possibility that some cherished sympathy of ours might be shown to be untrue (Becker 1967). Putative deviance, coupled with "unsentimentality," can serve as an excellent foundation upon which to identify and, if necessary, condemn inhumane practices and, more important, the sociocultural features that produce them in the first place. If sociocultural relativists believe in anything universal, it is their belief in human potentialities and their confidence that individuals can be better than they are.

socioeconomic status, health, and mortality

Richard G. Rogers and Jarron M. Saint Onge

The World Health Organization broadly defines health as “a state of complete physical, mental, and social well being and not merely the absence of disease or infirmity” (WHO 1948). Health can be assessed in a number of ways, but generally includes subjective health, physical impairment, vitality and well being, and chronic disease. Health is a measure of the quality of life, whereas mortality defines the risk of death and can be used to measure length of life. Socioeconomic status (SES) exerts a profound influence on all dimensions of health and mortality. Individuals who are situated in elevated positions in the social hierarchy tend to experience superior levels of health and survival.

Mortality captures the extreme consequences of socioeconomic disadvantage and in some cases reflects the ultimate state of poor health (Rogers et al. 2000). Mortality outcomes are a useful way of understanding the negative effects of socioeconomic disadvantage. For example, while death rates in the general population have fallen overall, more advantaged groups have experienced greater declines in mortality, which has resulted in increased mortality disparities between socioeconomically advantaged and disadvantaged groups (Pappas et al. 1993).

SES MEASURES AND RELATIONSHIPS

SES is usually conceptualized to include multiple dimensions (knowledge, employment, and economic status) and is often indexed by educational and occupational attainment and income. Individuals who are employed, with higher levels of education, and with greater incomes

tend to enjoy better health and lower mortality than socioeconomically disadvantaged individuals. SES is measured in a variety of ways, depending on data availability and the specific research questions posed.

Education is regarded as the most important dimension of SES. It is typically measured categorically by highest degree attained, with the assumption that qualitative differences exist between those with less than a high school degree, a completed high school degree, and advanced degrees. Educational attainment usually occurs prior to employment, may be a prerequisite for occupational advancement, engenders a broader world perspective, contributes to a sense of personal control, is related to healthy behaviors, and provides the requisite knowledge and skills to obtain health information (Mirowsky & Ross 2003).

Education has a graded effect on health and mortality, with higher educational levels contributing to better health and survival prospects. Figure 1 shows this education gradient for both sexes. The gap in life expectancy between high and low levels of education is larger for males than females. And the returns to education are substantial: a 25 year old male with less than a high school degree can expect eight fewer years of life than a comparably aged male with an advanced degree. Increased education adds years to life.

Income can be measured for the individual or family. Family incomes are noteworthy because families can pool resources to provide for all members and they benefit from economies of scale. Methods of measuring income include per capita income, poverty rates, income to needs ratios, and various consumption thresholds. Income can also be measured through relative comparisons. Whereas incomes can directly affect health through access to health care and opportunities for healthy lifestyles, income inequality can indirectly affect health outcomes and mortality through underinvestment in social spending, erosion of social cohesion, and stress. For example, reduced social spending can limit life opportunities for less privileged groups by means of public goods such as education. The disintegration of social cohesion may increase levels of mistrust and reduce civic attachments, thereby limiting important social buffers to mortality. Finally, income inequality can

Figure 1 Education-specific life expectancies at age 25 by sex, USA.
Source: Derived from Richards & Barry (1998) and based on 1990 data.

increase stress and frustration levels by means of relative deprivation in which perceived disparities contribute to potential health problems.

Recent research has expanded measures of economic status. Diversified income portfolios, higher levels of wealth, home ownership, and a lack of credit card debt predict better health and lower mortality. Income portfolios demonstrate that individuals derive income from multiple sources, such as job income, self employment income, interest income, dividend income, pensions, and Social Security. Additional income streams help individuals buffer against the loss of any single income source, and higher levels of wealth can translate into better health at older ages.

Researchers have begun to examine the associations between SES and health and mortality among individuals with limited socioeconomic resources. In an innovative analysis, Krueger and colleagues (2004) examined the effects of Food Stamp receipt on mortality. Food Stamp aid can improve health and reduce mortality by directly providing access to adequate nutrition, while also indirectly allowing households to allocate other earnings to such factors as health

care, education, job training, or simply paying bills, which could reduce stress, and thereby improve health and survival. Not all eligible individuals participate in the Food Stamp program, but those who participate experience reduced risks of death.

Assessing the causal direction between income and health is complicated: does low income produce poor health or vice versa? In some instances, sick, ill, and frail individuals may suffer job demotions and pay reductions. But the overwhelming evidence supports the strong and persistent effects of income on health. Low income increases the likelihood of poor health and contributes to higher risks of death.

Compared to individuals who are not in the labor force, employed individuals are generally healthier, in part, because they have access to income, workplace camaraderie, workplace health factors such as gyms and exercise programs, and health insurance. This employment benefit is termed the healthy worker effect. Again, causality is difficult to assess: poor health also impedes the likelihood of employment.

Specific occupations affect health behaviors, health risks, and mortality. For instance,

Academy Award winners can expect to live 3.9 years longer than less recognized actors and actresses (Redeimeier & Singh 2001). Others, using measures of occupational status, such as the Nam Powers Occupational SES Scores (OSS), or indicators of occupational prestige, such as Duncan's Socioeconomic Index (SEI), show that mortality and morbidity decrease with increased status and prestige.

FUNDAMENTAL CAUSES AND PATHWAYS

There are many explanations for the existence of health disparities by SES. Explanations can be examined through both resource and non resource dependent characteristics. According to Jonathan Feinstein (1993), resource dependent characteristics include, for example, income and wealth, whereas non resource characteristics are composed of psychological, genetic, and cultural factors. Additionally, the non resource dependent characteristics depend on life span experiences and differential access to health care services.

Bruce Link and Jo Phelan (1995) make a persuasive case that higher levels of SES translate into behaviors that minimize the risks associated with morbidity and mortality. Compared to individuals with lower SES, individuals with higher SES are more likely to engage in healthy behaviors – exercise, abstention from smoking, more nutritious diets, use of seatbelts, avoidance of drug use or excessive alcohol consumption – which translate into lower risks of death from such causes as cardiovascular disease, many forms of cancer, diabetes, accidents, and homicide.

Researchers have demonstrated that poor SES conditions in infancy and childhood may predispose individuals to later health problems. Poor SES conditions early in life may expose individuals to additional infectious diseases, environmental hazards, or stress that may contribute to health problems in middle and older ages.

A stress paradigm may also explain deleterious health effects. Individuals with lower SES are more likely to suffer greater environmental and social insults, such as discrimination and social subjugation, which contributes to higher

psychological and physiological stress. Higher stress can translate into detrimental health behaviors, including drug and alcohol dependence, which result in increased risks of chronic conditions, functional limitations, and mortality. Lower SES individuals also have fewer resources to deal with these stressors, which further exacerbates their poor health and survival prospects.

Contextual or structural components may lead to deleterious negative health outcomes. Lower SES individuals have less access to health information and healthy foods, and are less able to implement health recommendations. Additionally, the marketing and location of fast food restaurants target lower SES groups and lead to poorer diets. Lower SES groups are more likely to be exposed to violence, crime, disorder, and fear that adversely affect health and mortality.

FUTURE DIRECTIONS IN RESEARCH, THEORY, AND METHODOLOGY

Although a vast literature on SES and health and mortality exists, a number of questions warrant further investigation. Researchers have shown strong associations between education, measured as formal years of schooling completed, and health outcomes. The use of more refined measures of education might provide additional insight into what it is about education that is health enhancing. Is education merely a proxy for ability or IQ or is it the knowledge, skills, training, and certification that education confers that leads to better health outcomes? There may be measurable differences between individuals who obtain a high school diploma, a GED, or who do not graduate but all of whom obtain 12 years of formal schooling. In addition, many individuals acquire extensive on the job training. Others may not accrue additional years of formal education but instead dedicate substantial time and effort to, and gain important insight through, workshops and seminars. Further, some individuals, especially in professional positions, are required to maintain levels of certification. Formal years of education is a crude measure of the multiple aspects of knowledge attainment that may influence behaviors that either enhance or impede good health.

Some researchers are investigating an expanded array of occupational characteristics that may also be related to health and mortality. Jencks et al. (1988) have proposed new measures of job desirability. They have asked individuals to rate their job relative to others based on such characteristics as educational requirements, hours worked, on the job training, level of supervision, repetitiveness, and job dirtiness. Some jobs are more physically demanding, requiring twisting, turning, vibrating, and bending. Other jobs may expose workers to hazards such as chemical exposure to insecticides, pesticides, solvents, and acids, or to radioactive material, risk of fire, or risk of accidents.

Longitudinal panel data, life course conceptual frameworks, and related analytic techniques allow the assessment of time varying covariates, or changes in statuses over time, and the effects on later health outcomes. For example, we need to know more about how job loss, income shocks, job transitions, or temporary layoffs affect health and mortality. Also, individuals do not live in social isolation; they are nested within families, households, neighborhoods, and communities. Future analyses must examine these multilevel dynamics. For instance, families often make employment decisions for family members. Thus, families may endeavor to optimize the health of all family members rather than focus on selected family members. Finally, new research on social capital and social networks may also provide valuable insight into health and mortality.

sociolinguistics

J. K. Chambers

Sociolinguistics is the systematic study of the social uses of language. It proceeds by observing the way people use language in different social settings. People adjust their vocabulary, sounds, and syntax depending upon who they are speaking to and the circumstances of the conversation. Such adjustments are often linguistically subtle and socially meticulous and largely subconscious. They are not taught or consciously learned, but are part of the innate linguistic competence of all normal people.

Philosophers have always recognized that socialization is the primary function of language. In 1690, Locke wrote: "God, having designed man for a sociable creature, made him not only with an inclination, and under a necessity to have fellowship with those of his kind, but

furnished him also with language, which was to be the great instrument and common tie of society.” Yet linguistic research into its social significance is relatively recent, having emerged as an international movement only in the second half of the twentieth century. Sociolinguistics extends social science methods to the venerable study of language, which since Plato has been conceived as the abstract study of the combinatorial possibilities of parts of speech (syntax) and speech sounds (phonology). Around 1960, linguists began tracking social variables in speech acts, such as the age, sex, and social class of the participants, and correlating them with dependent linguistic variables.

Variation in language is socially motivated and linguistically insignificant. To take a simple example, it is possible in English to say either *John doesn't need any help* or *John doesn't need no help*. Those two sentences convey the same linguistic meaning and both are readily understood by anyone who speaks the language. Linguistically, they are perfect paraphrases. Socially, however, they are not equivalent at all, with the former deemed to be correct, educated, standard usage, and the latter, though it differs by only one small word, deemed to be incorrect, uneducated, or rustic.

Variables with widely held social evaluations, like double negatives (and *ain't* for *isn't*, *hissself* for *himself*, and *me wasn't* for *me weren't*), are said to stigmatize. Most variables carry more subtle social evaluations. William Labov (1966), in the seminal sociolinguistic masterwork, showed that New Yorkers, who variably pronounce /r/ in certain contexts, so that *cart*, *pork*, and *bird* are sometimes pronounced “r less,” like *caht*, *pohk*, and *boid*, carry complex biases. Labov's subjects, when asked to guess the occupations of speakers based on tape recorded samples of their speech, guessed “TV personality” for one woman, but on hearing another sample, unwittingly spoken by the same woman, they downgraded her to “receptionist”; the second speech sample was identical to the first except that it contained one r less pronunciation. Moreover, the New Yorkers made that judgment regardless of whether they themselves usually used r less pronunciations.

Hallmarks of the sociolinguistic enterprise are (1) the identification of linguistic variants correlated with social factors, (2) the incorporation

of style as an independent variable, and (3) the apparent time apprehension of linguistic changes in progress. All represent innovations in language studies due to sociolinguistics (Chambers 2002).

Social factors largely determine the linguistic realization of speech acts. Janitors speak differently to lawyers in the office block than they do among themselves, and vice versa. Young mothers meeting by chance at the local doctor's office chat to one another more familiarly than they do to elderly neighbors in the same situation. Men and women in sex exclusive domains such as locker rooms tend to slant both the topics of their conversation and their speech styles in different ways. These responses are partly predictable in terms of the social attributes of the participants.

Social class, age, and sex are overriding determinants of linguistic variation, but others also play roles. Ethnicity figured crucially in the development of sociolinguistic concepts because close study of African American varieties became a testing ground and sounding board at the inception of the new discipline (as summarized in Rickford 1999). American sociolinguists like Labov, Walt Wolfram, and John Baugh demonstrated beyond any doubt that African American varieties, notwithstanding more than a century of disparagement by cultural arbiters, were as systematic, rule governed, and complex as main line Philadelphia speech or any other English dialect, or for that matter any human language from Latin to Laotian.

In modern industrial societies the speech of the educated middle class in capital cities tends to gain acceptance as the national norm and get codified (in somewhat idealized form) in dictionaries, grammar books, and usage guides. Working class varieties typically differ from the standard dialect both grammatically and phonologically, and the differences are socially stratified, so that they become greater down the social hierarchy, with lower working class more different from the standard than middle working class, and so on. Within social classes, women tend to use fewer stigmatized and nonstandard features than men, a robust difference that apparently holds in all complex societies. The age groups at the social extremes also tend to differ most from the standard, with the oldest groups preserving some features that have

become archaic or old fashioned in the dialect, and adolescents accelerating changes and adopting innovations at a greater rate than their elders.

Most variation is a matter of degree rather than kind. Only stigmatized variants like multiple negatives occur as absolute differences, in that they almost never occur in middle class speech but do occur in working class speech. Most variants typically occur with graded frequencies in all the social classes. For instance, the common English variable known as (ng), which indicates variant pronunciations of present participle endings as *walking* vs. *walkin'*, *running* vs. *runnin'*, and *telling* vs. *tellin'* (phonetically, a final velar nasal vs. alveolar nasal), is graded throughout the social hierarchy (as summarized in Chambers 2003: 121–6). A study in Norwich, England, showed lower middle class people used the *walkin'* variant 18 percent of the time in casual conversation, while upper working class used it 72 percent and lower working class 91 percent in the same circumstances. Consistent with sex patterns, women always use it less than men of the same social class: for instance, upper working class Norwich women use it 66 percent of the time, but the men who are their brothers, husbands, and neighbors use it 79 percent of the time. Consistent with the acceleration of variation by adolescents, a study in Sydney, Australia, showed that working class teenagers used the *walkin'* variant 26 percent of the time, but their parents and grandparents only 4 percent of the time.

Style cuts across the social variables and adds a second dimension to linguistic variation (Schilling Estes 2002). Stylistic adjustments in more casual contexts usually result in an increase in the frequency of vernacular variants, and vernacular variants are generally the ones that characterize working class speech. So, in terms of the *walkin'* variant, middle class speakers use it more frequently among friends in recreational situations than among colleagues at business meetings. Casual styles thus bear some of the characteristics of social class speech lower on the social hierarchy, but since the adjustments take the same direction for all social classes the styles remain stratified, with little or no overlap between the classes. This recurring pattern shows that a speech community is defined not because its members speak the same

as one another, but because they share the communal norms.

Adjustments in style are usually explicable in terms of self monitoring. As social settings become more casual, participants become less self conscious about their behavior. Linguistically, they use more vernacular variants. This explanation presupposes that the vernacular is more natural than standard speech, more relaxed, and presumably more deeply embedded in the language faculty. Under special circumstances, stylistic adjustments are highly self conscious, as when a white adolescent adopts African American features with his peers (called “crossing,” Rampton 1995), or an adult with social airs adopts features of the higher social class (called “aspirers,” Chambers 2003: 101–5). Self conscious adjustments like these attract attention and are sometimes subject to criticism, whereas style shifting toward the vernacular in casual settings generally goes unnoticed.

Understanding language change constitutes perhaps the greatest advance in language study that is a direct consequence of sociolinguistic methods. Labov noticed consistent differences in the speech of people in different age groups, and postulated that the differences represented changes in progress, such that the younger people were using features that were supplanting the ones used by older generations. Prior to sociolinguistics, historical linguists had studied change in what is called “real time,” by comparing two (or more) states of a language at different periods. Studying change in “apparent time,” by comparing two (or more) age groups in the same period, reveals its dynamics and introduces the possibility of determining how the change is progressing, which groups are leading it, and how it is spreading socially (summarized in Bailey 2002).

The apparent time hypothesis assumes that people acquire their accents and dialects in their formative years, say, by age 20, and retain them throughout their lifetimes. The speech of 80 year olds thus reflects the language norms of the community some 60 years earlier. Generally, the hypothesis holds, as shown in tests whereby apparent time results have been subjected to real time comparisons, by linguists revisiting a community 20 or more years later. The apparent time hypothesis provides a framework that yields, as Weinreich et al. (1968) put it

in a seminal article, “a theory of language change that bypasses the fruitless paradoxes with which historical linguistics has been struggling.”

Nevertheless, as a hypothesis, it must be applied prudently and tested rigorously. It can be disrupted, for instance, by individuals going against the grain of their social cohort, like the aspirers mentioned above, and one subcategory of individuals can defy communal norms in predictable ways (discussed as “oddballs and insiders,” in Chambers 2003: 93–115). A type of linguistic change that disrupts the apparent time hypothesis is “age grading,” the regular adjustment of linguistic features as maturity emblems (Bailey 2002: 324; Chambers 2003: 206–11). For instance, Japanese boys use honorific markers characteristic of women and only gradually adopt the adult male system as adolescents; an apparent time study would thus show differences between boys and men, indicative under ordinary circumstances of change in progress, but a real time study of those boys 10 years later would reveal them perfectly aligned with the adult males, evidence that no change had taken place in communal norms.

Sociolinguistics has discovered nuances such as social subcategories and age graded changes in coming to grips with the manifold ways in which interacting variables of class, sex, age, ethnicity, and style affect the way people speak. For the first time, a branch of linguistics studies grammar and phonology as they are enacted in the service of communication. Sociolinguistics is necessarily variant, continuous, and quantitative, and in all those respects it differs from older branches of linguistics. For centuries, thinking people have recognized, at least tacitly, that our speech expresses who we are and how we relate to the social setting, as well as what is on our minds. The social uses of language are so deeply engrained in our human nature that they were thought to be beyond human comprehension, as were consciousness and genetic coding. Like them, when sociolinguistics came into being in the second half of the twentieth century, its very existence represented an assault on the presumed limits of knowledge. Also like them it made rapid progress, a consequence undoubtedly of the fact that there was every thing to learn. It is now firmly established as a core area in the study of language.

sociological imagination

Christopher Andrews

The term “sociological imagination” comes from a book with that title by American sociologist C. Wright Mills (2000 [1959]) and describes an understanding of one’s own position and experiences as reflective of broader social and historical forces. According to Mills, the sociological imagination is more than just a

theoretical concept or heuristic device: it is a “promise.” The promise of the sociological imagination is to allow individuals to understand their place in the broader social and historical context. As Mills says in the first sentence of *The Sociological Imagination*, people today increasingly feel that their private lives are a series of “traps” (p. 3). The promise of the sociological imagination is to understand the nature of these traps and to determine if they are in fact private in nature, or if, as Mills suggests, their actual origin lies with broader social and historical forces.

In this regard, the sociological imagination provides a “fruitful distinction” between individual and social problems. Some problems faced by individuals simply reflect those which threaten individually held values or lifestyles, and are problems whose origin and resolution, according to Mills, lie in the personal sphere (p. 8). Other problems, however, reflect broader social or public issues. While the individual may experience these problems subjectively or first hand, the sociological imagination prompts one to imagine or speculate as to how such problems may be tied to broader structural or historical trends.

The “promise” of the sociological imagination involves the linking of “personal troubles” to “public issues” (p. 8). Described by Mills as a form of “self consciousness,” the sociological imagination directs attention to the linkages between “the personal troubles of milieu” and “the public issues of social structure” (pp. 7–8). “Troubles” reflect one’s personal problems and are “private matter[s]” undeserving of sociological attention, whereas “issues” reflect problems that transcend the private sphere of the individual, and are therefore “public matter[s]” (p. 8).

One example offered by Mills concerns unemployment. When one person is unemployed, he notes, it is a personal matter. However, when a significant number of people are unemployed, it becomes a public issue concerning a lack of economic opportunity. Thus, broad social and historical trends, such as deindustrialization, produce outcomes felt and experienced by individuals as private or “personal troubles,” masking their structural origins. The key, therefore, is in linking experiences such as unemployment to broader social and historical

trends (e.g., deindustrialization). When many people experience similar personal troubles or find themselves in a similar set of “traps,” it suggests structural rather than personal origins.

In this respect, the sociological imagination is reflective of a broader sociological preoccupation with the micro–macro linkages of society. For Mills, many of the individual, or micro level, problems that people face in fact reflect broader structural, or macro level, phenomena. Thus, by focusing on these macro level or structural arrangements, one can grasp a better sense of one’s own life experiences or “biography.” Rather than individuals blaming themselves for their own problems, Mills offers the sociological imagination to the American public as a way of linking personal troubles and the “traps” of daily life to larger social and historical trends. As Mills suggests, many of the pressing problems in our daily lives are problems of social structure; the key is in linking individual outcomes or “biographies” to broader social structures and structural trends.

In viewing one’s own life or “biography” as reflective of larger social and historical forces, Mills saw those focused on the intersection of history and biography as being directed toward three key questions concerning (1) the structure of society, (2) its relation to other past or contemporary societies, and (3) the types of people such a society produces. Accordingly, the sociological imagination in practice denotes a focus on the nature of social institutions, the way in which they interact and change over time, and the effect they have on the outlook, attitudes, and orientations of individuals.

Mills himself arguably utilized the sociological imagination in much of his own work. With Hans Gerth (1953), Mills explored how certain types of institutions create or select for certain traits and personalities, such as authoritarianism. In *White Collar* (2000 [1951]), Mills documented how the shift from entrepreneurship and small businesses toward corporations and bureaucracy brought about changes in how individuals defined “success” and experienced work, while *The Power Elite* (2000 [1956]) linked the increasing concentration of power or “ascendancy” of the executive branch to growing political disillusionment and the emergence of a “mass society.”

sociology

Gerard Delanty

Sociology is a form of social inquiry that takes wide ranging forms. As is the case with many disciplines, it is contested and there is no generally accepted definition of what constitutes sociology. But we should not draw the conclusion that the contested and diverse nature of sociology amounts to the absence of any sense of self understanding and that the discipline has lapsed into irreversible fragmentation. Sociology can be partly defined by citing examples of what sociologists actually do, but it can also be defined by referring to some of the major intellectual statements of the discipline, such as classic works or theoretical and methodological approaches that are characteristically sociological. To begin, it is helpful to look at sociology in terms of its subject matter, its approach, and some of the classical works that have shaped the discipline.

Many disciplines have a clearly defined subject matter, although very often this is due to

the absence of methodological scrutiny and uncritical consensus, as in the general view that “the past” is the subject domain of historians while political scientists study “politics.” Sociologists generally have a tougher time in defending their territory than other disciplines, even though they unhesitatingly take over on the territory of others. Sociology’s subject domain can arguably be said to be the totality of social relations or simply “society,” which Durkheim said was a reality *sui generis*. As a reality in itself the social world is more than the sum of its parts. There has been little agreement on exactly what these parts are, with some positions arguing that the parts are social structures and others claiming that society is simply made up of social actors and thus the subject matter of sociology is social action. The emphasis on the whole being greater than the sum of the parts has led some sociologists to the view that sociology is defined by the study of the relations between the different parts of society. This insight has tended to be reflected in a view of society as a movement or process. It would not be inaccurate to say that sociology is the social science devoted to the study of modern society.

In terms of theory and methodology, sociology is highly diverse. The paradigms that Thomas Kuhn believed to be characteristic of the history of science are more absent from sociology than from other social sciences. Arguably, anthropology and economics have more tightly defined methodological approaches than sociology. As a social science, sociology can be described as evidence based social inquiry into the social world and informed by conceptual frameworks and established methodological approaches. But what constitutes evidence varies depending on whether quantitative or qualitative approaches are adopted, although such approaches are not distinctively sociological. There is also considerable debate as to the scientific status of sociology, which was founded to be a social science distinct from the natural sciences and distinct from the human sciences. The diversity of positions on sociology today is undoubtedly a matter of where sociology is deemed to stand in relation to the experimental and human sciences. While it is generally accepted that sociology is a third science, there is less consensus on exactly where the limits of

this space should be drawn. This is also a question of the relation of sociology to its subject matter: is it part of its object, as in the hermeneutical tradition; is it separate from its object, as in the positivist tradition; or is it a mode of knowledge connected to its object by political practice, as in the radical tradition?

A discipline is often shaped by its founding figures and a canon of classical works. It is generally accepted today that the work of Marx, Weber, and Durkheim has given to sociology a classical framework. However, whether this canon can direct sociological research today is highly questionable and mostly it has been relegated to the history of sociology, although there are attempts to make classics relevant to current social research (Shilling & Mellor 2001). Such attempts, however, misunderstand the relation between the history of a discipline and the actual practice of it. Classic works are not of timeless relevance, but offer points of reference for the interpretation of the present and milestones in the history of a discipline. For this reason the canon is not stable and should also not be confused with social theory: it was Parsons in the 1930s who canonized Weber and Durkheim as founding fathers; in the 1970s Marx was added to the list – due not least to the efforts of Giddens – and Spencer has more or less disappeared; in the 1980s Simmel was added and in the present day there is the rise of contemporary classics, such as Bourdieu, Bauman, Luhmann, Habermas, and Foucault, and there are recovered classics, such as Elias. It is apparent from a cursory look at the classics that many figures were only later invented as classical sociologists to suit whatever project was being announced. The word “invented” is not too strong here: Marx did not see himself as a sociologist, Weber was an economic historian and rarely referred to sociology as such, and Foucault was a lapsed psychiatrist; all of them operated outside disciplinary boundaries.

The impact of Foucault on sociology today is a reminder that sociology continues to change, absorbing influences from outside the traditional discipline. The range of methodological and theoretical approaches has not led to a great deal of synthesis or consensus on what actually defines sociology. Since the so called cultural turn in the social sciences, much of sociology takes place outside the discipline itself, in

cultural studies, criminology, women’s studies, development studies, demography, human geography, and planning, as well as in the other social and human sciences. This is increasingly the case with the rise of interdisciplinarity and more so with post disciplinarity, wherein disciplines do not merely relate to each other but disappear altogether. Few social science disciplines have made such an impact on the wider social and human science as sociology, a situation that has led to widespread concern that sociology may be disappearing into those disciplines that it had in part helped to create (Scott 2005).

ORIGINS, TRAJECTORIES, AND NATIONAL TRADITIONS

Sociology today still remains in the shadow of its origin. As Levine (1995) has pointed out, sociology has always continued to return to its history and all the major schools have elaborated trajectories of their own history. So the story of the emergence of sociology is often inseparable from the attempt to define sociology.

In the most general sense sociology arose as a mode of knowledge concerned with the moral problems of modernity. The origins of sociology go back to the discovery of the existence of the social as a specific reality independent of the state and the private domain of the household. The eighteenth century marks the emergence of social theory as a distinctive form of intellectual inquiry and which gradually becomes distinguished from political theory. The decline of the court society and the rise of civil society suggested the existence of the social as a distinctive object of consciousness and reflection. Until then it was not clear of what “society” consisted other than the official culture of the court society. By the eighteenth century it was evident that there was indeed an objective social domain that could be called “society” with which was associated the public. This coincided with the rise of sociology.

One of the first major works in the emergence of sociology was Montesquieu’s *The Spirit of the Laws*, which brought about the transformation of political theory into sociology. The central theme in this work, which was published in 1748, was that society is the source of all laws.

Society was expressed in the form of conditioning influences on people, shaping different forms of life. Durkheim claimed that the notion of an underlying spirit or ethos that pervades social institutions was a resonating theme in modern sociological thought from Montesquieu – a thread that is also present in Weber's *The Protestant Ethic and the Spirit of Capitalism*. *The Spirit of the Laws* demonstrated the sociological notion that social laws are socially and historically variable, but not to a point that human societies have nothing in common. According to Montesquieu, who was acutely aware of the diversity of societies, they differ most notably according to geographical factors, which have a conditioning influence in norms, morals, and character. His empirical method demonstrated a connection between climate and social customs and gave great attention to the material condition of life. It was this use of the empirical method to make testable hypotheses that Durkheim admired and which had a lasting influence on French sociology to Bourdieu and beyond.

Although generally regarded as one of the founders of modern political philosophy, Rousseau anticipated many sociological theories. He was one of the first to identify society as the source of social problems. In the *Discourse on the Origin of Inequality*, published in 1755, he argued that inequality is not a natural characteristic, but a socially created one for which individuals themselves are not responsible. The notion of the “general will” – itself based on Montesquieu's “spirit of the laws” – influenced Durkheim's concept of collective representations. The general will signified the external normative and symbolic power of collective beliefs. But Rousseau's enduring legacy is the theory of the social contract, which can be seen as an early notion of community as the basis of society and the state as a political community. In his most famous work, *The Social Contract*, published in 1762, he postulated the existence of the social contract to describe the social bond that makes society possible.

The discipline of sociology has been strongly influenced by the French sociological tradition, for in France social science – where the term first arose – was more advanced as an officially recognized activity. Auguste Comte coined the term sociology to refer to the science of social

order and which he believed to be the “queen of the sciences.” Comte's plea for a positivistic sociology must be seen in the context of the age, where social inquiry was largely associated with the speculative approaches of Enlightenment intellectuals and the officers of the restored *ancien régime*. Against the negative critiques of the intellectuals, Comte wished sociology to be a positive science based on evidence rather than speculation. But his legacy was his notion of sociology as the queen of the sciences. In this grandiose vision of sociology, the new science of modernity not only encapsulated positivism, but it also stood at the apex of a hierarchy of sciences, providing them with an integrative framework. While few adhered to this vision, the idea that sociology was integrative rather than a specialized science remained influential and has been the basis of the idea of sociology as a science that does not have its own subject matter but interprets the results of other sciences from the perspective of a general science of society. From the nineteenth century this general conception of sociology became linked with the problem of the moral order of society in the era of social and political unrest that followed the French Revolution. This is particularly evident in the sociology of Durkheim, whose major works were responses to the crisis of the moral order. This was most acutely the case with *Suicide*, which was one of the first works in professional sociology, but was also the central question in the *Division of Labour in Society*. Thus it could be said that the French tradition reflected a general conception of sociology as the science of the social problems of modern society.

Attention must also be paid to the Scottish origins of sociology, which go back to the moral philosophers of the Scottish Enlightenment, who can be regarded as early sociologists in that they recognized the objectivity of society (Strydom 2000). This tradition, too, provided a basis for a tradition of sociology as a general social science of modernity. Adam Ferguson's *Essay on the Origin of Civil Society*, published in 1767, emphasized the role of social conflict and in terms very different from John Hobbes's account of conflict and individual egoism. For Ferguson, conflict between nations produces solidarity and makes civil society as a universal norm possible. He recognized that society is

always more than the sum of its parts and can never be reduced to its components. In marked contrast to the prevailing ideas of the age, Ferguson argued that the state of nature is itself a social condition and that sociality is natural. John Millar's *Origin of the Distinction of Ranks*, published in 1770, contained one of the first discussions of social class and can be seen as a pioneering work in historical sociology. Millar and Ferguson were particularly interested in the historical evolution of society, which they viewed in terms of a model of progress. But it was in the writings of Adam Smith that the notion of progress was most pronounced. Smith developed moral philosophy into a theory of political economy coupled with a theory of progress that was influential for over a century later. Society progresses in four historical stages, he argued, which can be related to stages – hunting, pastoral, agricultural, and commercial – in the development of the means of subsistence. Commercial society is based on private property and the economic pursuit of individual interest. Smith argued, however, that the well being of commercial society and indeed the very fact of society is due to a collective logic – which he called an “invisible hand” – at work, which ensures that individual actions function to serve collective goals. Although Smith came to personify laissez faire capitalism, his concerns were largely philosophical and must be understood in the intellectual and political context of the age. Like the other moral philosophers in Scotland, Smith was acutely aware of the contingent nature of the human condition, which could never be explained by natural law. Moral norms and the rules of justice must be devised in ways that function best for the needs of society and in ways that will reduce evil and suffering. In this respect Smith, Ferguson, and Millar established a vision of sociology as a moral science of the social world, the outcome of which was that the social and the natural were separated from each other and sociology became the science of the social.

From its early origins in Enlightenment thought, sociology emerged along with the wider institutionalization of the social sciences from the end of the nineteenth century. In France, as already noted, it was most advanced and the Durkheimian tradition established a firm foundation for modern French sociology,

which was based on a strong tradition of empirical inquiry. In Germany, where sociology emerged later, it was more closely tied to the humanities. While in France sociology had become relatively independent of philosophy, in Germany a tradition of humanistic sociology developed on the one side from the neo Kantian philosophy and on the other from Hegelian Marxism. While Weber broke the connection with psychology that was so much a feature of the neo Kantian tradition, German sociology remained strongly interpretive and preoccupied with issues of culture and history. Weber himself was an economic historian primarily concerned with the problem of bureaucracy, but increasingly came to be interested in comparative analysis of the world religions and the relation between cultural and moral meaning with economic activity. His work was testimony to the belief that social inquiry can shed light on moral values that are constitutive of the social condition. Where German sociology as represented by Weber was concerned with the problem of subjective meaning, French sociology was animated by the concern with social morality. For this reason it is plausible to argue, as Fuller (1998) claims, that sociology has been a kind of secular theology. Underlying both the German and French traditions has been a vision of sociology – distilled of Comtean positivism – as a general social science of modern society.

According to Talcott Parsons in one of the classic works of modern sociology, *The Structure of Social Action* (1949), Hobbes and Locke articulated the basic themes of sociology, namely the problem of social order. But we cannot speak of a British sociological tradition before the Scottish Enlightenment thinkers mentioned above. Hobbes and Locke have been claimed by political theory and were not influential in sociological thought. Modern British sociology initially emerged from the work of such Victorian liberal reformers as J. S. Mill and Herbert Spencer. Although Spencer broke from Mill's utilitarianism, his biological evolutionism led to a restrictive approach that has now been largely discredited. British sociology has on the whole been shaped by a vision of sociology as a social science concerned with specific issues. By far the dominant trend has been a view of sociology concerned with class and social structure. The social relations and

associated social institutions – class mobility, work and industry, education, poverty, and social problems – that defined sociology for several decades were of course closely linked to industrial society and the kind of political values it cultivated. Modern British sociology was strongly influenced by Marxism. Another significant British tradition in sociology was one allied to social policy, as reflected in the tradition associated with Hobhouse and the London School of Economics, where sociology and social policy were closely related. To this tradition belongs T. H. Marshall and what broadly can be called policy relevant social science. In the British tradition the continental European vision of sociology as a general social science has mostly been absent. However, it must be noted that much of modern British sociology was the product of continental European traditions that had come to Britain since the 1930s. Sociologists such as Norbert Elias and Karl Mannheim who came from Germany and John Rex from South Africa gave to British sociology a varied character that was not encapsulated in a specific tradition. In addition, of course, there was the Marxist tradition, beginning with Marx himself in exile in London. Nevertheless, British sociology tended to reflect a view of sociology as in part having a special subject matter: class and social structure.

There is little doubt that the international prestige of sociology in the twentieth century would not have been possible were it not for the tremendous expansion and institutionalization of the discipline in the US. American sociology arose out of economics and was professionalized relatively early, with the foundation of the American Sociological Society by Albion Small and others in 1905. The Society, renamed American Sociological Association in 1959, in fact was a break away movement from the American Economic Association. Small, Charles Horton Cooley, and William Thomas were the most influential figures in shaping American sociology, which was closely related to the American philosophical tradition of pragmatism at least until the 1940s. Comparable to the British reformist concern with social policy, pragmatism reflected a belief in the public role of social science. Early American sociology was thus shaped in the spirit of scientific knowledge assisting in solving social problems (Lynd 1939).

The twentieth century, however, saw a growing professionalization of American sociology, which shed its reformist origins. On the one side, a strong tradition of empirical sociology developed which was largely quantitative and often value free to a point that it ceased to be anything more than hypothesis testing. On the other side, a tradition of grand theory associated with Parsons developed, but it rarely intersected with the empirical tradition. Existing outside these traditions was the remnant of the early pragmatist tradition in the sociology of symbolic interactionism, stemming from George Herbert Mead.

This short survey of some of the major national histories of sociology tells us that no one national tradition has prevailed and within all these national traditions are rival traditions. This has led some critics to complain that sociology has somehow failed. Horowitz (1993) complains that sociology is in crisis due to its specialization and also due to its over politicization. Sociology is decomposing because it has lost its way. The great classical visions of sociology no longer prevail and the discipline has lost its integrity. Much of what is called sociology is merely untheoretical empirical case studies, he argues. Such pessimistic views often depend on whether one believes that sociology is based on a single method or vision that can provide a foundation for the discipline. But this may be too much to demand. It is certainly the case that a single school or method has not emerged to define the discipline, but this could also be said to be the case for much of the social and human sciences. It would be an oversimplification to characterize the history of sociology as a process of decomposition or fragmentation of an inner unity guaranteed by a discipline. The classical tradition was not a unified one and much of this has been reflexively constituted by a discipline that changes in response to changes in the nature of society.

INSTITUTIONALIZATION OF SOCIOLOGY

Sociology has been shaped in three major phases: the pre institutional period prior to the early twentieth century, the era of institutionalization and disciplinary specialization, and the

current period of post disciplinarity. As discussed, sociology arose out of different national traditions of social science. In the nineteenth century only Comte, Spencer, and later Durkheim used the term sociology to describe their particular mode of social inquiry. Even with Durkheim this was a pre institutional period. Durkheim's chair was in educational thought and much of early sociology was a development out of economics, psychology, philosophy, law, or history. In this early phase the disciplinary identity of sociology was formed to a large extent by the question of its scientific status. Durkheim's *Rules of the Sociological Method*, published in 1895, provided the first systematic outline of sociology as a scientific inquiry. Weber's essay "Objectivity in Social Science and Social Policy," published in 1904–5, provided an additional statement of what social scientific objectivity consists (Weber 1949). In these accounts, despite their different perspectives and backgrounds, sociology was established as an empirical science based on objective factual knowledge. Both accounts (perhaps Weber more so) were aware that the scientific status of sociology was a limited one, as is apparent from Weber's neo Kantian styled attempt to qualify the limits of objectivity. But social science could nonetheless attain objective knowledge. This was a debate that continued up to the 1960s, when the neo positivist philosophies of science espoused by Carl Hempel and Ernst Nagel provided new justifications for sociology to claim scientific status. The result of some of these efforts was to reduce the scope of sociology to testable hypotheses in order to uncover the laws of society (Adorno et al. 1976). While sociology was pulled in the direction of the natural or experimental sciences on the one side, on the other it remained allied with the human sciences. This bifurcation of sociology led to an uncertain relation to social and public policy, with the result that sociology tended to enter the period of institutionalization relatively depoliticized.

The institutionalization of sociology coincided with the formation of disciplines in the twentieth century. As a profession, one of the early statements was Weber's address "Science as a Vocation" in 1918, which although addressed to the wider question of a commitment to science as a different order of

commitment than to politics, has been recognized as one of the major expressions of the professionalization of sociology (Weber 1970). The notion of *beruf* invoked referred to both the idea of sociology as a profession and as a vocation whose calling required certain sacrifices, one of which was not to seek in science answers to fundamental moral questions. As a science, sociology is concerned with providing explanations about social phenomena and in Weber's view it also has a role to play in guiding social policy.

In its formative period sociology had to compete with the natural sciences. As social science gained general acceptability as an area distinct from both the human sciences and the natural sciences, sociology found that its greatest challenges came in fact from the more established of the social sciences (Lepenies 1988). In Britain the prestige of anthropology overshadowed sociology. The older disciplines, geography and economics, as well as political science tended to command greater prestige than sociology, which never held the same degree of reliance to the mission of the national state. It must be borne in mind that much of social science owed its existence to its relation to the state: it was the science of the social institutions of the modern state.

The institutionalization of sociology did not fully commence until the period following World War II, when the discipline expanded along with the rise of mass higher education. The professionalization and institutionalization of sociology was marked by the foundation of academic journals such as the *American Journal of Sociology*, founded in 1895, and the later *American Sociological Review*. Professional associations such as the American Sociological Association and the British Sociological Association, founded in 1951, greatly enhanced the professionalization of sociology as a discipline, which subsequently underwent a process of internal differentiation with new subfields emerging, ranging from urban sociology and industrial sociology to political sociology, historical sociology, and cultural sociology. By the 1960s sociology became increasingly taught in secondary schools and in the 1970s it became an A level subject in British schools. The 1960s and 1970s saw a tremendous expansion in the discipline in terms of student enrollments and teaching and

research careers. In this period sociology became recognized by governments as a major social science and many chairs were created. Sociological research became recognized by the principal national research foundations and acquired prestige within the university system. In the US there are over 200 sociology journals, a professional associational membership of some 14,000, and more students major in sociology (25,000) annually than in history and economics (Burawoy 2005a). As sociology became one of the major social sciences in universities throughout the world, it became increasingly seen as the most comprehensive science of society. This was viewed by some as a source of the strength and relevance of sociology, but in the view of others it was in danger of becoming a pseudo science, lacking subject specialization, since when sociologists specialize they cease to be sociologists. Neo positivist philosophies attempted to check the dangers of over generalization, while the growing politicization of the discipline that came with its widening social base led to fears that sociology was too closely linked to radical causes, such as Marxism.

Many influential sociologists openly questioned the institutionalization of sociology. If the first era was one of the struggle for the institutionalization of the discipline, the phase that drew to a close in the 1970s was one that was marked by calls for the political engagement of sociology with everyday life. Gouldner (1970) argued that sociology needs to be reoriented to be of relevance to society. In his view, sociology went through four main phases: sociological positivism in nineteenth century France, Marxism, classical European sociology, and finally American structural functionalism as represented by Parsons. Contemporary sociology must articulate a new vision based on a completely different sense of its moral purpose. For Gouldner, this had to be a reflexive sociology and one that was radical in its project to connect sociology to people's lives. The purpose of sociology is to enable people to make sense of society and to connect their own lives with the wider context of society.

This turn to a reflexive understanding of sociology had been implicit in C. Wright Mills's *Sociological Imagination*, which was published in 1959 and was widely read in the 1960s and 1970s. Sociologists such as Mills and Gouldner were opposed to the depoliticized kind of

sociology that was emerging in the US. They wanted to recover the moral purpose of sociology that had become lost with its institutionalization in specialist subfields. Mills provided a definition of sociology that continues to be relevant: "The sociological imagination enables us to grasp history and biography and the relations between the two within society. That is its task and promise" (Mills 1970: 12). This conception of sociology was as much opposed to general theory as it was to administrative social research. Mills was primarily inspired by the American pragmatic tradition, which predisposed him to be critical of social science that was cut off from the practical purposes of improving social well being.

The vision of sociology articulated by Mills was not too far removed from the continental European conception of sociology as a diagnosis of the age. In this tradition, which was represented by a broad range of sociologists, such as the Frankfurt School and the humanistic tradition of western Marxism, sociology was connected to social renewal and was primarily a critical endeavor. As represented in the programmatic thought of Theodor Adorno, sociology must recover its mission in philosophical thought as a mode of critical thinking. For Adorno, the rise of neo positivism had a detrimental effect on sociology, which had the promise to become the leading critical science of what Daniel Bell and Alain Touraine in their respective works called the "post industrial society." Habermas (1978) outlined the basis of a view of sociology as concerned with critical knowledge tied to an interest in human emancipation.

Since the 1970s, which saw the expansion and institutionalization of sociology as a discipline, the question of the scientific status of sociology became less important. Although major methodological differences continued to divide quantitatively oriented sociologists from those in the humanistic tradition, sociology had become too broad to unite under a common method. With the consolidation of the discipline, sociology developed in many directions. The large scale entry of women into sociology in the 1980s inevitably led to different concerns and feminist approaches emerged around new research fields, which on the whole tended to orient sociology in the direction of cultural issues concerning identity, gender, and biographies. The shift from

industrial to post industrial societies and the growing impact of globalization have led to a series of shifts in the subject matter of sociology. Without a common method, a cumulative theoretical tradition, the result has been that sociology has been drawn in different directions. While this has led to some weaknesses, it is also a source of strength. Today, sociology has many different approaches which together constitute an influential body of methodologies and theories that have made considerable impact on the wider social and human sciences.

As a discipline acutely aware of the overall reality of society and the historical context, sociology has been more versatile than many sciences. This has been especially the case with regard to the “cultural turn” of which postmodernism has been one expression. Sociologists have been very prominent in developing new frameworks that have greatly advanced the scientific understanding of the social world. One only has to consider the influence of sociologists such as Ulrich Beck on the idea of the risk society, Pierre Bourdieu on the habitus and the forms of capital, Anthony Giddens on structure and agency, Jürgen Habermas on modernity and the theory of communicative action, Edward Soja on space, Bruno Latour on science and technology, Niklas Luhmann on systems theory, Manuel Castells on the information society, Roland Robertson on globalization, and Bryan Turner on citizenship. Sociology, in particular social theory, played a leading role in the reorientation of human geography around space. Much of urban geography today is simply the rediscovery of sociological approaches to the city. The shift in anthropology from the study of primitive societies to modern western societies has made it more or less indistinguishable from sociology. Anthropology, which enjoyed greater prestige in the past, has suffered a far greater crisis in its self understanding than sociology. In this context the rise of cultural and contemporary history as well as cultural studies can be mentioned as relatively new interdisciplinary subject areas that have been closely linked to sociology.

This, however, comes at a price. Much of sociology today is outside of sociology. As sociology becomes more specialized on the one side, and on the other more influential, the result is that it easily loses a specific identity. Thus, the sociology of crime has influenced criminology

where most specialized research on crime now occurs and which is not essentially sociological but interdisciplinary. Norbert Elias in 1970 complained of “pseudo specialization” and the retreat of sociologists into sub areas; but he noted what was occurring in sociology was something that had already happened in other disciplines. It would only be a matter of time, he wrote, before the “fortress will be complete, the drawbridges raised.” Like many continental European sociologists, Elias held to the Comtean vision of sociology having the distinctive feature of a general science. Despite Elias’s resistance to specialization, sociology did undergo specialization and it may be suggested that social theory took over the general conception of sociology (Delanty 2005b). But the resulting kind of specialization that sociology underwent led to fears that sociology cannot in fact be a specialized science, since what it does is merely to open up the ground for specialized interdisciplinary areas elsewhere. Thus, specialized sociological research occurs only outside the actual discipline – it is a question of sociologists without sociology. While some see this as the end of sociology, others see it as a new opportunity for a post disciplinary sociology, which should not retreat into the false security of a discipline. John Urry (1981), for instance, argues that sociology does not have a specific disciplinary area in terms of a method or subject matter and it has often been (and necessarily so) “parasitic” on other sciences. Consequently, it should cease to think of itself as a science of society and enter the diffuse territory of post disciplinarity (Urry 2000). This is a contentious position and there have been several recent defenses of sociology, such as the notion of a public sociology advocated by Ben Agger (2000) and Michael Burawoy (2005a, 2005b) and the various attempts of John Scott (2005) and Steve Fuller (2006) to revive the sociological imagination. On the other side, there is a position advocated by John Goldthorpe (2002) that confines sociology to a narrow methodologically grounded science. Is it a choice of “disciplinary parochialism” or “imperialism,” as Andrew Sayer (2000) asks?

CURRENT CHALLENGES

It is evident that the challenges facing sociology are no longer those that it faced a century ago; it

is no longer a question of the scientific status of the discipline and the need to demarcate a space between the natural sciences on one side, and on the other the human sciences. Some of the major debates of the second half of the twentieth century will continue to be important, but will not define the field of sociology, such as the micro macro link, agency and structure, quantitative versus qualitative methods, the nature of theory and its relation to empirical research, the question of normative critique, the status of evidence and the limits of explanation, etc. Three major debates have emerged in recent times which capture the current situation of sociology more fully than these methodological and theoretical issues: the question of the subject matter of sociology in light of globalization; the question of disciplinarity; and the debate about the public function of sociology.

As the science of society, sociology has always been a contested inquiry. Many of the major disputes have been about the nature of method and the scope of social science more generally. The debate about the subject matter of sociology has mostly resolved around issues of the knowability of the social world. In recent years an additional challenge has emerged around the very conception of the social (Gane 2004). To a large degree this has been due to major changes in the very definition of society. While much of classical sociology on the whole took society to be the society of the nation state, this is less the case today. It should be pointed out that while the equation of classical sociology with national societies has been exaggerated, there is little doubt that sociology arose as the science of the modern industrial nation state. The comparative tradition in sociological analysis, Weber's historical sociology, and much of Marxist sociology is a reminder of the global concerns of sociology. However, as an institutionalized social science, sociology has mostly been conducted within national parameters. By far the greatest concentration of sociological research in the second half of the twentieth century has been in the US, where sociology has been the science of social order and national consensus. While the national institutional frameworks continue to be primary in terms of professional accreditation, teaching, funding, and research, the global dimension is coming more to the fore. International sociological associations such as the International Sociological Association and the

European Sociological Association now offer rival contexts for sociological research.

It is true too that much of what might be called global sociology is merely the continuation of the comparative tradition, which can be located within an "international" view of sociology. But this would be to neglect a deeper transformation which is also a reflection of the transformation of the social itself. While many social theorists (e.g., Urry 2000) have argued that the social is in decline and others that the social does not coincide with the notion of society, conceived of a spatially bounded entity, it is evident that notwithstanding some of these far reaching claims the social world is undergoing major transformation and the notion of society is in need of considerable reevaluation (Smelser 1997). Exactly how new such developments are will continue to be debated. A strong case can be made for seeing current developments as part of a long term process of civilizational shifts and transformation in the nature of modernity. It is no longer possible to see the social world merely in terms of national structures impacting on the lives of individuals. Such forces are global and they interact with the local in complex ways. The turn to globality in contemporary sociology is not in any way an invalidation of sociology, even if some of the classical approaches are inadequate for the demands of the present day. Indeed, of all the social and human sciences, sociology – with its rich tradition of theory and methodology – is particularly suited to the current global context. Just one point can be made to highlight the relevance of sociology. If globalization entails the intensification of social relations across the globe, the core concern of sociology with the construction and contestability of the social world has a considerable application and relevance.

This leads directly to the second challenge, the question of disciplinarity. According to the Gulbenkian Commission for the Restructuring of the Social Sciences: "To be sociological is not the exclusive purview of persons called sociologists. It is an obligation of all social scientists" (Mudimbe 1996: 98). Does this mean the end of sociology? Clearly, many have taken this view and see sociology disappearing into new interdisciplinary areas and that it can no longer command disciplinary specialization due to its highly general nature. This is too pessimistic, since the Gulbenkian Commission report also

points out that the same situation applies to other sciences: history is not the exclusive domain of historians and economic issues are not the exclusive purview of economists. In the era of growing interdisciplinarity, sociology is not alone in having to reorient itself beyond the narrow confines of disciplinarity. Political scientists hardly have a monopoly over politics. Sociology now exists in part within other disciplines, in particular in new post disciplinary areas which it helped to create, but it also exists in its own terms as a post disciplinary social science. In the present day it is evident that sociology takes disciplinary, interdisciplinary, and post disciplinary forms.

While much of sociology has migrated from sociology to the other sciences, sociology today is also increasingly absorbing influences from other sciences. A survey of the discipline's most influential works noted that a large number have been written by non sociologists (Clawson 1998). This is nothing new: from the very beginning sociology incorporated other disciplines into itself. Of course, this is not without contestation, as in the debate about the influence of cultural studies – itself partly a creation of sociology – on sociology (Rojek & Turner 2001). Sociology is well positioned to engage with other sciences and much of modern sociology has been based on a view of sociology as a science that incorporates the specialized results of other sciences into its framework. As Fuller (2006) argues, today this engagement with other sciences must include biology, which can now explain much of social life. Sociology must engage with some of the claims of biology to explain the social world and offer different accounts. In this respect, then, interdisciplinarity and post disciplinarity need not be seen as the end of a sociology, but a window of opportunity for sociology to address new issues.

One such issue is the public function of sociology. The specialization of sociological research by professional sociology has led to a marginalization of its public role. Michael Burawoy argued this in his presidential address to the ASA in 2004 and opened up a major debate on the future of sociology (Burawoy 2005a, 2005b; Calhoun 2005). Public sociology and professional sociology have become divorced and need to be reconnected, he argues. Public sociology concerns in part bringing professional society to wider publics and in shaping public

debates and it may lead to a reorientation in professional sociology as new issues arise. However, as Burawoy argues, there is no public sociology without a professional sociology that supplies it with tested methods and theoretical approaches, conceptual frameworks, and accumulated bodies of knowledge. Public sociology is close to policy relevant sociology, which is a more specific application of sociology to problems set by the state and other public bodies. Public sociology is wider and more discursive and takes place in the public sphere. Burawoy also clarifies the distinction between public and critical sociology. The latter concerns a mode of self reflection on professional sociology and is largely conducted for the benefit of sociology, in contrast to public sociology. Critical sociology has a normative role to play for the discipline. While critical and professional sociology exist for peers, public and policy sociology exist for wider audiences. Of course, many of these roles overlap, as is apparent in the connection between critical and public sociology.

According to many views, one of the functions of sociology is to raise social self understanding. Adorno (2000), for instance, held that while sociology may be the study of society in some general sense, society as such is not a given or a clearly defined domain that can be reduced to a set of “social facts” in Durkheim's sense. Rather, society consists of different processes and conflicting interpretations. Sociology might be defined in terms of the critical analysis of these discourses in a way that facilitates wider public self reflection. This is a view of sociology reiterated by Mills (1970) and Habermas (1978). In different ways it is present in Scott's (2005) and Fuller's (2006) cautious defense of a disciplinary sociology. This means that sociology must be relevant; it must be able to address major public issues (Agger 2000). Inescapably, this means sociology must be able to ask big questions. The success of sociology until now has been in no small part due to its undoubted capacity to address major questions, in particular those that pertain to everyday life.

CONCLUSION

Sociology is the only science specifically devoted to the study of society in the broad sense of the term, meaning the social world and the open

field of the social. Like many of the social and human sciences it does not have a clearly defined subject matter. This situation often leads to the assumption of a crisis. Sociology today is often faced with three broad choices. One is the classical vision of a field that is based on the interpretation of the results of other sciences from the perspective of a general science of society guaranteed by a canonized sociological heritage. Second, those who reject the first as too generalist, parasitic, and lacking a clearly marked out specialized field argue that sociology must confine itself to a narrow territory based on a tightly defined conception of sociological research and disciplinary specialization. Third, those who reject the highly specialized understanding of sociology and resist the generalist understanding of sociology tend to look to post disciplinarity, whereby sociology is not confined to the traditional discipline and occurs largely outside sociology.

These are false dilemmas, despite the fact that there are major challenges to be faced. Interdisciplinarity is unavoidable today for all the sciences, but it does not have to mean the disappearance of sociology any more than any other discipline. It is also difficult to draw the conclusion that sociology exists only in a post disciplinary context. However, it is evident that sociology cannot retreat into the classical mold of a general science. Sociology is a versatile and resilient discipline that takes many forms. One of its enduring characteristics is that it brings to bear on the study of the social world a general perspective born of the recognition that the sum is greater than the parts.

sociology in medicine

Carey L. Usher

Sociology in medicine is the label given to the collaborative work between sociologists and medical or health personnel within medical institutions or health care organizations. This distinction represents the applied work of medical sociologists in the pure versus applied dichotomy of the social sciences. In its most extreme form, sociology in medicine encompasses sociological work aimed at the provision of technical skills and problem solving for the medical community while neglecting contributions to the parent discipline.

Medical sociology, like its parent discipline, experienced dual roles early in its institutionalization. The distinction between applied and pure work in medical sociology arose in conjunction with the desire for a communication network that would identify the activities and affiliations of medical sociologists in the United States. Sociology in medicine and sociology of medicine were the names designated for applied and pure work, respectively, by Robert Straus in 1957. Sociology in medicine represents the thrust toward reform, advocacy, and application, with which medical sociologists responded to the call for inclusion of clinical research in the social components of health and illness. During the 1950s and 1960s, the roles of the social sciences in health care organizations experienced significant increases due to expansion of medical schools, increased private and public supports for medical research and training programs, and significant proportions of funds granted for establishment of social science units within schools of medicine, public health, and nursing. The primary aim of medical sociology during this time was to serve medicine, with a large majority of medical sociologists employed by health science schools, and only 30 percent holding appointments in traditional sociology departments. The ascendancy of sociology in medicine was short lived, however, as the effects of the Cold War, which equated sociology with socialism, decreased the influence of sociology on public health issues and policy. The role of the medical sociologist in medicine decreased, while academic work in medical sociology, or sociology

of medicine, began to increase. During the 1980s, increasing opportunities for nonacademic sociology applications were recognized by the American Sociological Association. Sociology in medicine again became an exciting career choice for medical sociologists, although they were now competing with other health related researchers for funding in medical institutions.

The work of the sociologist in medicine is intended to be directly applicable to health issues, and consists of teaching and research activities focusing on disease processes or factors influencing patients' responses to illness, with the goal of improving diagnosis and treatment. Sociology in medicine may examine doctor-patient relationships, various therapeutic situations, or social factors that affect and are affected by specific health disorders. The sociologist in medicine may also have responsibilities of educating health science students in the sociology of health and illness. The major contributions of sociology in medicine have been to medical education, social epidemiology, and knowledge of utilization and compliance. Sociologists in medicine seek to answer questions of interest to their sponsors and institutions rather than to the discipline of sociology.

Sociology in medicine, then, treats sociology as a supporting discipline to medicine, which involves achieving the goals of medicine while neglecting those of sociology. For this reason, sociology in medicine has been severely criticized since its inception. Sociologists in medicine are less compelled to defend the significance of their work, theoretical or otherwise, to the academic community than are conventional sociologists. The demands placed upon the sociologist in medicine are for practical applications rather than sociological significance. Therefore, sociology in medicine has consistently battled with the question of whether or not it is real sociology. Aside from the criticisms of its parent discipline, sociology in medicine has historically faced problems within its working environment as well. Communication, status, and relationship issues have surrounded sociology in medicine since the first tenure track position was created for a sociologist in a medical school in 1953. Howard Freeman and Leo Reeder, as early as 1957, point out the difficulty the sociologist in medicine has in attaining co worker status with the physician, stating that

all PhDs working with MDs face a continual threat of relegation to subordinate status. Communication and understanding have been problematic as well, as neither the sociologist nor the physician would freely discard discipline specific, esoteric rhetoric to adopt that of the other.

When the distinction was made between pure and applied work of medical sociologists, the predominant opinion of sociologists was that the two were incompatible. Academic sociologists believed sociologists in medicine showed more loyalty to the medical institution than to their parent discipline, and did not contribute to the discipline. Those working in medicine, however, considered themselves to be quite practical sociologists, as their work was directly applicable to human health, and they had less restricted access to research funds than did conventional sociologists. The opinion of incompatibility has changed dramatically and will continue to change in the future. Robert Straus, who as we saw named the distinction in 1957, wrote in 1999 that it is possible for the medical sociologist to do both pure and applied work at the same time. Many medical sociologists consider the structural position of the scholar to be irrelevant today, and have called for a renaming of the work of medical sociologists. Rather than distinguishing between sociology *in* medicine and sociology *of* medicine, the work of medical sociologists may be aptly called sociology *with* medicine.

sociometry

Barbara F. Meeker

The word "sociometry" was coined by Jacob Levi Moreno (1889–1974). Moreno, one of the pioneers of psychotherapy, is also credited with developing psychotherapeutic techniques such as psychodrama and role playing. As he used it, sociometry was a way of uncovering the underlying emotional structure of a small group by asking group members which other members they would choose or reject as partners in specific roles such as roommate or fellow team member for a work project. Moreno believed that if group activities were set up according to these preferences, the task performance and morale of the group would be maximized and individual group members would experience satisfaction, empowerment, and personal growth. Jointly with Helen Hall Jennings (Moreno 1934), he applied his methods to the assignment of girls to residential cottages in the New York Training School for Girls, concluding that the predicted positive results did occur. Moreno also founded a journal named *Sociometry* to promote his research. This journal eventually became one of the official journals of the American Sociological Association where it has been for many years the primary outlet within sociology for social psychological research in general. Reflecting this more general interest, it changed its name and is now the *Social Psychology Quarterly*.

Within research sociology, "sociometry" refers to the measurement aspect of Moreno's concept, not to its use as a principle for organizing groups. It also refers to results about interpersonal attraction and group structure and cohesion that have been found using sociometric techniques, and to statistical and mathematical techniques for analyzing sociometric

data. Typically, in a sociometric study respondents are asked in a paper and pencil survey to name their best friends, or the three or five others they like best, or to rate the name of each other group member on how much the other is liked, admired, respected, or other evaluation; these ratings may extend into negative sentiments such as dislike. Some may include behavioral ratings (such as how often the respondent talks to or works with the other). In a historical reflection of Moreno's intentions, these ratings are referred to as "choices." Analyzing choices identifies social isolates (individuals neither giving nor receiving choices); mutual pairs (two individuals each choosing the other); pairs with unreciprocated choices; transitive triads (three individuals all choosing each other); sociometric stars (an individual receiving more choices than others); and cliques (a set of individuals making positive choices within the set but no choices or negative choices outside). These patterns can be displayed as a diagram called a sociogram, in which points represent individuals and arrows represent their choices. Influential early use of sociometry includes Theodore Newcomb's study of the development of friendships in two college dormitories and George Homans's emphasis on interpersonal sentiments as basic building blocks in a theory of individual and small group behavior.

A large body of research in natural settings as well as in laboratories shows that the principles that affect the formation and maintenance of sociometric choice are: (1) propinquity (or proximity) – bonds of attraction form between individuals who encounter each other in daily life; thus, sociograms show choices between people who live in adjoining rooms in dormitories, have offices next to each other, sit in adjacent seats in a classroom, etc., or marriages that occur between persons from the same neighborhood; (2) reciprocity – attraction tends to be mutual, people choose others who they think choose them; (3) perceived similarity – individuals choose others they think share socially important characteristics, attitudes, or values; and (4) status – individuals choose others who have high prestige within the group. The principles of reciprocity and perceived similarity produce mutual attraction and increase the number of reciprocal pairs, while the principle of status produces one way or unreciprocated

choices as persons with higher status are more often chosen.

Cognitive balance theory, especially as formulated by Fritz Heider (1958), has been used by many students of sociometry. Heider proposed that a basic principle of individual cognitive organization is that people seek to agree with others whom they view positively and to disagree with others whom they view negatively; these are *balanced states* and are assumed to be stable and to provide personal satisfaction. On the other hand, when an individual finds that she or he disagrees with a positively valued other, or agrees with a negatively valued other, this is an *imbalanced state* which produces dissatisfaction and a motivation to change at least one bond, that is, imbalanced states are unstable. This explains both reciprocity and similarity as types of cognitive balance and also predicts that relationships among three or more persons will become transitive and positive bonds will form in larger structures transitively.

Sociometric structure also concerns the relationship among behavior, attitudes, and interaction. Informal interaction tends to occur between persons who have positive bonds and such persons tend to influence each other and hence to become similar. Thus, a sociogram can give predictions about the flow of gossip, attitude change, formation of group or organizational culture, and boundaries of cliques or conflict groups within organizations. An example of an application is work examining effects of school integration on the interracial friendships of students (Hallinan & Smith 1982).

The formal properties of consistency and transitivity appeal to mathematically inclined sociologists, overlapping with rapidly developing work in social networks and using the mathematics of graph theory.

solidarity

Rodney Coates

Solidarity, defined as the perceived or realized organization of individuals for group survival, interests, or purposes, may result from either external threats or internal needs. Solidarity, reflecting various dimensions and forms of organizing, may best be described in Durkheimian terms as ranging from organic to the inorganic. That is to say, we may describe solidarity that derives from some intrinsic characteristic of the participants or from extrinsic characteristics. When we speak of intrinsic characteristics, related to organic solidarity, we typically include such types as family, racial/ethnic groups, national and to some extent religious affiliation. Alternatively, inorganic solidarity, related to the more voluntary, associational characteristics of such organization, suggests greater volition on the part of its members. When we speak of inorganic solidarity we typically make reference to neighborhood associations, clubs, political organizations, and the like. Given the more transient nature of today's populations, religion and national identity may also fall into this latter category for obvious reasons associated with mobility and personal choice. Depending upon type, solidarity comes into being for multiple reasons. Social and political movements, community organizing, and social activism rely upon the ability of respective leaders to organize and solidify significant groups for the purposes of social action. The capacity of groups to solidify is directly associated with their capacity to

organize about significant issues, events, visions, and/or threats. Thus the capacity to solidify is evidence of the capacity to survive, thrive, persist, and promote group interests, viability, and/or vitality.

While it is possible, for heuristic purposes, to distinguish between organic and inorganic solidarity, in reality such distinctions are blurred. Hence successful social movements, political or social activism, and collective actions often depend upon multiple types and methods for generating solidarity. Hence, if we were to discuss the successful Civil Rights movements in the United States of the 1960s, or that led by Mahatma Gandhi in India – we clearly see the overlapping of family, religion, political, civil, ethnic/racial, and social groups. More simply, we would see the cultural, social, and political elements within specific societal contexts solidifying about specific issues, visions, and interests. These complex moments of heightened solidarity, so critical for social, political, and cultural activism, are rare examples of multiple forms, dimensions, and levels of solidarity coalescing at the national and often international levels.

Differing forms of solidarity (to include dimensions, levels, and types of solidarity) may be associated with different types of groups, institutions, or organizational components. Hence, along the organic continuum and within the family, issues of kinship and major life events such as marriage, births, deaths, reunions, holidays, celebrations, and so on form the basis of specific events that may evoke episodes of solidarity. These events, repeated over time, and depending upon frequency, intensity, and level of interaction, produce a sense of family solidarity. Thus we can talk about solidarity in the family as being a process experienced over these various and collective life events.

Alternatively, within religious or other cultural institutions, we can likewise talk about events which serve to enhance, inspire, or evoke episodes of solidarity. Such events typically revolve around the ceremonial, but may also include the commemorative, induction of new members, proselytizational, and other significant life events of members which have been serialized within the cultural institution (e.g., typically marriage, birth, coming of age, and so on find expression within religious and other

cultural institutions and also serve as solidifying events). Religious and other cultural institutions also provide, encourage, and to a great extent require vision and visionary leaders that serve to express institutional wide ideas, values, and purpose which not only transcend the every day events and issues of its members, but also give members a sense of collective identity, thus encouraging solidarity. These visions and visionaries, occurring periodically through the institutional memories of members, serve to produce and sustain group cohesion. Collectively, then, within religious and cultural institutions, the ceremonial, those life events that are commemorated, and visions and visionary leaders provide the organizational glue that accounts for solidifying events. These events over time are what we refer to when we speak of solidarity within religious and cultural institutions.

Often solidarity is held out to various groups (e.g., racialized, gendered, political) as if it were some actuality that can be achieved. As such, and given the reality that it is often presumed to be associated with specified dominant groups, it only manifests itself oppositionally. Solidarity, for heterogeneously large groups, presumes a level, form, and/or quality of unity which is prevented by the very nature of heterogeneously large groups. What solidarity that does come into being tends to be experienced not universally but partially by specific sections of groups whose interests, goals, and/or opportunities are perceived to be challenged, effected, or affected. More generally and typically, members of groups seek to organize or mobilize as a consequence of perceived organization or mobilization by external groups, forces, and/or threats. Consequently, solidarity is not an event but a process that is never quite complete and is dependent upon such things as perceived threat, advantage, and disadvantage to which and by which organizational resources are expended. The nature of these organizational resources is defined by the resource base(s) of the group, the historical progression or context to which the group owes its existence, and the ability of group members to effectively acquire, access, and mobilize resources and members for the purposes of obtaining levels of solidarity.

The problem inherent in a constant insistence upon solidarity is that such calls may be at the expense of legitimate, necessary, and

important conflict. Conflict, differences of opinion, and critical discussions require opposing perspectives, the ability to be heard, addressed, and exist. The notion that solidarity somehow eliminates or minimizes such critical dialogues fails to understand the nature of group dynamics. Solidarity, as a relative construct, therefore exists to the extent that group members feel free to express critical differences, identify alternative strategies, and explore multiple frames of references. The extent to which relative solidarity becomes a reality is determined to the extent that agendas, priorities, and goals can be identified which garner significant group support, to which members are willing to devote their individual resources. Further, to the extent that the understanding of solidarity advanced here does not preclude multiple agendas, goals, and interests within and overlapping various groups, we may speak of a more elaborate conceptualization (i.e., one which is not monolithic but pluralistic) that is being envisioned.

Ideally, solidarity is achievable across the full spectrum of group members. In reality, solidarity tends to be tenuously associated with specific threat levels, opportunities, and member interests. Specific external inducements, threats, and/or events can serve as catalysts to solidarity initiatives, but these initiatives tend to be uniquely experienced and structured by the internal dynamics of the specific groups. Hence, solidarity episodes may be identified, catalogued, and understood within specific historical contexts for specific groups.

When we observe these solidarity episodes across time, i.e., within specific historical contexts, we may note increasing or decreasing levels of solidarity associated with what we may call social movements. Social movements, here being defined as increased group cohesion aimed at effecting system changes within societal or community contexts, are successful to the extent that solidarity events are sustainable over multiple events and/or episodes. The effectiveness of these social movements is directly associated with the appearance of solidarity, but in actuality may be associated with the ability of group leaders to control external impressions. The implication of this is that solidarity is more about impression management than actual (perceived or otherwise) levels of solidarity.

It is in the interests of group leaders to present the impression of high levels of solidarity as this gives credence to their legitimacy and credibility. This is especially true for social movement leaders, whose political currency is tied to these impressions and who are keenly aware how notions of solidarity impact upon their effectiveness as leaders, both within and external to the group. Hence, such things as marches, meetings, and various types of protests are selectively used to demonstrate the level of solidarity, leaders' ability to encourage solidarity, and their ability to promote specific issues and/or advance specific agendas as a result. What this also suggests is that numbers, counts, and levels of involvement become highly subjective and contested pieces of information as they are related to perceptions of levels of solidarity, leadership capacity, and group viability.

solidarity, mechanical and organic

Anne M. Hornsby

French sociologist Émile Durkheim (1858–1917) coined the terms mechanical and organic solidarity to describe two types of social organization, that is, ways in which individuals are connected to each other and how they identify with the groups and societies in which they live. Social solidarity is a state of unity or cohesion that exists when people are integrated by strong social bonds and shared beliefs and also are regulated by well developed guidelines for action (values and norms that suggest worthy goals and how people should attain them). In his first book, *The Division of Labor in Society* (1893), Durkheim argued that social solidarity takes different forms in different historical periods and varies in strength among groups in the same society. However, reflecting the popularity of social evolutionary thought in the late nineteenth century, Durkheim summarized all his torical forms of solidarity into a traditional–modern dichotomy. Mechanical solidarity is a simple, pre industrial form of social cohesion and organic solidarity is a more complex form that evolves in modern societies.

In developing his mechanical–organic distinction, Durkheim drew on the organicist thinking that influenced many intellectuals of his generation, where human societies are analyzed with analogies to biological organisms. A single cluster of embryonic cells, where each cell is initially identical in structure and function,

develops by dividing into separate clusters with cells changing form and specializing into kidney cells, skin cells, etc. Over time they form organs that have distinct boundaries but must be inter dependent for the functioning of the whole organism. By analogy, settlements of small kin ship groups are scattered across territories and organized similarly. Over time these simple societies disappear as rural and urban areas emerge, cities grow, and a complex division of functions appears within cities.

Specifically, mechanical solidarity occurs in small, simple organisms, where people live in small groups and each group is likely to perform all the functions needed to survive (familial, economic, political, religious, etc.). There is no specialization or differentiation of function. Each person feels and lives a similar connection to group life because everyone's experience of the world comes from a religiously based common culture that reproduces in each person the same ways of thinking, feeling, and acting. By mechanical, Durkheim does not mean machine like or artificial. He means that the conditions of life are the same for everyone so there is little diversity in people's experiences and ideas. Individuals do not have a sense of identity separate from being a member of a family, clan, or a warrior caste. Consequently, "the ideas and tendencies common to all the members of the society are greater in number and intensity than those which pertain personally to each member" (Durkheim 1964: 129).

Organic solidarity occurs in complex organisms composed of specialized parts, each of which performs distinct functions to support the whole. No one household, neighborhood, town, or economy can produce everything its members need to survive. Economies begin to depend not only on the family but also on educational institutions to produce dependable workers with a range of needed skills. A complex division of labor has developed, where there are many different occupations, a great diversity of racial and ethnic backgrounds, and a wide range of religious beliefs and political views. Such diversity of people, groups, and institutions is organized into distinct yet interdependent roles and functions. Moreover, a cultural concept of the individual and individualism emerges, and people are integrated by social exchange among free individuals in market economies.

Durkheim grew up as the son of a rabbi in the long established and tightly knit Jewish community of Alsace Lorraine. He left his traditional world to pursue his studies in the cosmopolitan world of Paris. Many scholars have observed that Durkheim's personal experiences of tradition and modernity inspired his lifelong interest in the nature and condition of solidarity in contemporary democratic society. The central question Durkheim posed in *The Division of Labor* is what is the basis of social solidarity in modern societies where there is a great diversity of people living in vastly different settings? How do the parts of a modern society (individuals, groups, institutions) become more interdependent while at the same time becoming more distinct from each other?

His argument is summarized in a well known statement: "Social life comes from a double source, the likeness of consciences and the division of labor" (Durkheim 1964: 226). Here, Durkheim identifies the two key variables that distinguish mechanical and organic solidarity, which continue to be important variables in sociology today: (1) the extent (degree of complexity) of the division of labor, by which he means differentiation of distinct functions or roles, such as the historical separation of economic production from family and kinship systems, and the organization of economic production into differentiated occupational groupings and industries; (2) the extent to which members of a society share a collective consciousness (i.e., all the ways of thinking, feeling, and acting that are common to a group or society). (The extent of collective consciousness means the number and intensity of the values, beliefs, norms, emotions, and activities that are shared.)

In mechanically organized societies the division of labor is absent or weak, and the collective consciousness contains a large number of clear, powerful beliefs, values, and traditional practices shared intensely by all members. In contrast, organic societies have a complex division of labor and a smaller number of more ambiguous and thus less constraining ideas and practices that everyone shares. A complex division of labor and great diversity of people creates the condition where the collective consciousness becomes more abstract by virtue of including only values and norms that are meaningful to

everyone. Durkheim notes that perhaps the only value widely shared and strongly held in modern western societies is individualism – the inherent dignity, worth, and freedom of the individual. As the collective consciousness becomes more abstract because shared ways of thinking, feeling, and acting are far fewer in number and are more ambiguous, society is less able to regulate all behavior.

Exactly how does the evolution from mechanical to organic solidarity occur? Durkheim argues that physical and social density increase, which generates competition among people, resulting in differentiation of roles and institutional functions. Population size increases and is distributed across a territory differently due to improvements in transportation and communication that link people and villages more easily. Villages and towns grow, cities emerge, and as urbanization increases, each person has more contact with a great many more people. This increase in social density – the actual pattern of who interacts with whom, how, and with what frequency – stimulates competition for jobs and other resources. From competition emerges a more complex division of labor, where people find occupational niches, firms find market niches, and different zones of a city specialize in different functions.

In short, social ties are based on difference instead of likeness. Everyone is more interdependent, in worlds separated yet linked by specialization. Durkheim concludes that "even where society relies most completely upon the division of labor . . . the members are united by ties which extend deeper and far beyond the short moments during which the exchange is made. Each of the functions that they exercise is, in a fixed way, dependent upon others, and with them forms a solidary system" (Durkheim 1964: 227).

In *The Division of Labor* Durkheim argued that as specialization and interdependence of function increase, the extent and intensity of collective consciousness recede in importance as a source of social solidarity. Together, both changes produce a different type of society. In subsequent work, however, Durkheim became less convinced that the collective consciousness recedes in importance in modern societies. Over time his work focused more on the pre rational basis of solidarity (i.e., the moral and emotional

effect of social ties), especially how groups produce ideologies through mechanisms such as ritual practices (Collins 1994: 190, 204). Durkheim did not discuss mechanical and organic solidarity per se after *The Division of Labor*. Yet over his lifetime he continued his interest in both manifestations of the structural relations among people: the evolution of institutions and the symbolic and emotional components of social life that unify groups and societies.

Sombart, Werner (1863–1941)

Alan Sica

Werner Sombart was born in the small Protestant town of Ermsleben (Harz region) and died in Berlin, an event fully recorded in the *New York Times* with obituary and editorial (May 20 and 22, 1941). His father, Anton Ludwig Sombart, was from seventeenth century Huguenot stock and personified what Sombart's friend Max Weber would call in 1905 the Protestant ethic, and what Sombart himself named the bourgeois

spirit. The elder Sombart was elected *Bürgermeister* of Ermsleben in 1848, and became rich as an industrialist and estate owner through the sugar trade. Not satisfied simply to enjoy his wealth, he co founded the famous *Verein für Sozialpolitik*, an influential organization of concerned citizens that sponsored social research prescribing government policy, particularly pertaining to the liberation of agricultural workers from virtual serfdom on large estates. Bismarck invited him to become minister of agriculture, but he declined owing to poor eyesight.

Despite his own eye disease and nascent tuberculosis in youth, Werner Sombart was able to use his family's great wealth to study economics and humanities at Pisa (1882), Berlin (1893), and Rome. His Berlin dissertation on the ancient Roman *Campagna* (1888) (substantively similar to Weber's) was directed by Gustav Schmoller, the leading exponent of sociohistorical economics. It remains an impressive scholarly achievement by virtue of the way primary documents from the Roman state archives were examined. Sombart's first professional position was as a city lawyer for Bremen, which he was loath to leave after 2 years when offered a professorship (partly through the machinations of his father) at remote Breslau in 1890. (Max Weber unsuccessfully applied for the very position in Bremen which Sombart had vacated.)

Sombart's first classes treated the Communist Manifesto and *Capital* (Vol. 1), to which he had been drawn after becoming radicalized, not by reading social science, but instead the fiction of Emile Zola. He decided at this early date to commit his prodigious scholarly energy to the study of the proletariat and the nature of capitalism as they evolved in unison throughout history. Like today's sociologists, he toured worksites in order to understand the proletarian's plight, a practice which did not sit well with his hidebound academic colleagues, who already regarded him as "a young and conceited person." Thus, from this unusual background of familial wealth and connections, childhood disease and poor early school performance, wide travel, and passionate interests in literature, economics, and history, plus the usual linguistic capacity of mandarins of his period, Sombart perfected a style of living and writing which throughout his life shocked his staid peers while thrilling readers and auditors. He was known as

a dandy among the more straitlaced, yet was able through sheer force of style to write books that sold 30,000 copies, some in cheap editions to the working class. C. Wright Mills, writing about Veblen, quoted from Bernard Shaw's *Man and Superman* – “he who has something to assert will go as far in power of style as its momentousness and his conviction will carry him” – which could as well be applied to Sombart (quoted in Grundmann & Stehr 2001). Once again in the history of social thought, a son of privilege dedicated himself utterly to the interpretation of life among the lower orders (as with Weber, Simmel, and Lukacs), and for reasons not entirely clear, perhaps even to himself.

Beginning with the belief that Marx was “the greatest social philosopher of the nineteenth century,” Sombart elaborated his predecessor's arguments. For some years his fellow leftist intellectuals fully expected him to succeed Marx as the foremost analyst of capitalism. The wide spread belief that he was heir apparent to the leftist tradition began early, after he published a brilliant analysis of Marx's *Capital* (Vol. 3) at the age of 31. This 40 page work (Sombart 1894) has won steady encomia ever since it appeared, beginning with Engels's celebrated remark in a letter from 1895: “It is the first time that a German professor has made the effort to try to understand from his writings what Marx really has been saying” (published in an appendix to *Capital*, Vol. 3). Yet eventually he became impatient with the proletariat – which he knew first hand – for its inability to transcend its quotidian self definition by becoming an effective agent of social change, and found others to admire, principally among the leaders of National Socialism. Nor could he accept Marx's utopian tendency, substituting for it the hardnosed English and German view of economic life – perhaps due to a sobering realism that sprang from witnessing his father's efficacious business activities. (He also rejected full scale political work and “self sacrifice” when invited by his friend Ferdinand Tönnies to join the Social Democratic Party in 1893, partly at least for fear of losing his job and jeopardizing his young family's welfare.) In brief, he wanted to substitute an evolutionary for a revolutionary brand of Marxist theory and practice, and he enunciated this viewpoint

before other leftist thinkers, like Eduard Bernstein, had done so. By 1900 he was speaking regularly to large trade union audiences and had been publicly branded as a Marxist, despite the fact that by 1908 he announced in print that most of Marx's ideas about capitalism's dynamics he found unsupportable when measured against the evidence of economic history. Some critics argue that Sombart peaked as a scholar and thinker when quite young, and the older he became and the larger his audiences, the poorer his analysis and the less credible and admirable his political allegiances became.

Sombart's lingering fame in the anglophone sphere is mostly due to a short book, *Why is There No Socialism in the United States?* (1976), which he would have regarded as ancillary to his major project. It is ritually cited by authors discussing “American exceptionalism,” but there is little evidence that it is any longer read with the sort of care lavished, say, on Weber's *The Protestant Ethic and the Spirit of Capitalism* (1930). And ever since Sombart's death, his magnum opus *Der moderne Kapitalismus* (1902 and thereafter) – never fully translated into English (Sombart 1967b) – has been eclipsed in importance by two briefer works, *The Jews and Modern Capitalism* (1913) and *Luxury and Capitalism* (1967a). In the former work he imaginatively argues that the Jews, due to their money lending and trading skills, were pivotal in the formation of capitalism, a point which caused some proud, early Jewish reviewers to embrace the book. But others, due perhaps to Sombart's thoroughgoing support of the Nazis in later years, find his argument anti Semitic because he juxtaposes rationalist Jewish economic practices against Germanophilic industrial behavior, all to the detriment of the former. In taking this position he was quite self consciously extending Tönnies's 1887 argument about the forgiving warmth of *Gemeinschaft* versus the urban chill common to life within *Gesellschaft*. And Sombart (unlike Weber or Tönnies) explicitly attributed the former to “real” Germans and reserved the latter, unhappy condition to the influence of Jewish commercial practices and the worldview that went along with it. Later critics insist that Sombart's notion of Judaism is fantasy, a result of his lack of Hebrew and consequent misunderstanding of the religion's social and sacred practices. The canonical comparison is with Weber's

Ancient Judaism (1952), which had held up well even after decades of study.

More useful today, however, is Sombart's book on luxury, which some scholars believe is more suited for the explanation of contemporary consumerist culture than is Veblen's more famous sister tome, *The Theory of the Leisure Class* (1899). Sombart held that the desire for what Veblen wonderfully called "conspicuous consumption" played a vital role in the birth of capitalism, beginning with courtiers wishing to outdo each other in the presence of their sovereigns. Veblen regarded this as a pathological condition, but Sombart, anticipating the late twentieth century, saw in it the roots of capitalist behavior, and as such not in itself ethically or morally questionable.

Werner Sombart's legacy is a troubled one, to be sure. On one hand, he wrote a multi volume study of capitalism which for sheer detail and historical sweep has no rivals, after Marx's own works. Yet it has often been noted that his use of data lacked precision and his powerful prose style swept him, and his unsuspecting readers, into unsupportable claims. His occasional anti Semitic remarks coupled with a longstanding support for *Deutschum* (chauvinist German ness) via the Nazi party have naturally made him permanently anathema to many readers. Yet some scholars argue (e.g., Stehr and Grundmann in Sombart 2001) that he deserves continued study. They see him as a potent counterbalance to the ideas of Weber, Simmel, and others in that luminous circle, whose principal scholarly preoccupation was the explanation for capitalism's wild success in Europe and America, and also for its corrosive nature and high social costs across the globe.

Sorokin, Pitirim A. (1889–1968)

Edward Tiryakian

By any objective criteria of contributions to macrosociology, Pitirim Aleksandrovich Sorokin ranks alongside such twentieth century figures as Max Weber, Émile Durkheim, and Talcott Parsons. His pioneering contributions in the comparative historical study of revolutions, social mobility, cultural sociology (considerably in advance of the "cultural turn" of sociology), rural urban sociology, and the sociology of altruism are lasting landmarks with a prime focus on the hows and whys of what he designated as sociocultural change.

As Coser (1977: 489) has noted, there is considerable overlap in the general structural functional perspective of Sorokin and Parsons regarding the significance of culture, values, and meaningful symbols in social organization (both consequently highly critical of economic reductionism, as in later rational choice theory). Yet these departmental colleagues differed as to

the course of social change in the period of late modernity. Sorokin came to reject a linear view of social change, opting for a more cyclical and critical perspective; Parsons in later writings on social change and the value system of modernity took a more optimistic perspective of current western cultural orientations becoming globally accepted.

During the length of a long, productive career, Sorokin filled many roles as a sociologist: he was an entrepreneur in founding departments of sociology at Petrograd University on the eve of World War I and at Harvard in 1931 (where Robert K. Merton was the first graduate student to enrol and became his early collaborator); he engaged in “public sociology” as a student activist in prerevolutionary and revolutionary Russia, and again in the last decade of his life in his opposition to the Vietnam War; like C. Wright Mills at Columbia, he was highly critical of the “establishment,” including the “power structure” of the United States and of the dominant, reductionist methodology of the profession. Sorokin readily took on the role of prophet in various writings on the cultural crisis of modernity, and experienced a double exile – an exile from his native Russia after being banished by Lenin for obstructing the Bolshevik Revolution (a fate he shared with his contemporary Georges Gurvitch, who became a leading figure in French sociology after World War II), and a second symbolic exile from American mainstream sociology after World War II. His “banishment” came to an end with his election after a write in campaign to the presidency of the American Sociological Association in 1964, and perhaps as important, symbolically in 1969 when the radical students protesting the Vietnam War adopted the recently departed Sorokin as their icon at the ASA meetings in San Francisco by having a special session on “Sorokin Lives!”

EARLY RUSSIAN PERIOD

Born in a remote rural ethnic enclave of Russia, Sorokin came of age in a period marked by modernization as well as by agrarian and urban unrest, culminating in the failed revolution of 1905 and the successful revolution of 1917.

Noted as a brilliant student, Sorokin developed his interests in law and criminology (his doctoral dissertation was *Crime and Punishment*) and broadened them to sociology. He was a participant observer of the revolutionary setting, later making use of his observations at close hand of how people behave towards one another in extreme situations, including the condition of mass food deprivation (*Hunger as a Factor in Human Affairs*, eventually translated into English). His political involvement led to various arrests subject to capital punishment, but his academic reputation and scholarly publications provided the grounds for clemency from Lenin, subject to Sorokin’s permanent exile.

Not all or even the majority of his writings of this period have been translated (see the selections in Sorokin 1998). Beside providing him with a treasure house of observations on collective behavior and social movements, the ruptures of World War I and Revolutionary Russia provided Sorokin with materials to reject the naïve positivism associated with an evolutionary and linear view of change.

EARLY AMERICAN PERIOD: 1920s

Coming to the University of Minnesota and a more tranquil academic life, Sorokin brought to American sociology an important comparative historical perspective in major volumes dealing with rural urban differences and convergences (Sorokin & Zimmerman 1929), stratification and mobility (Sorokin 1927), and schools of sociological theory in terms of their major premises and orientations.

In *Principles of Rural Urban Sociology* Sorokin noted that the city plays predominantly the role of innovator, the countryside that of the preserver of existing national culture. The heterogeneity of the population and a greater percentage of foreign born inhabitants generates a more “international” character to city culture, while rural classes have a greater development of patriotism, which as a particular attachment to one’s region and place of birth becomes a part of personality. Urban dwellers, with greater mobility and heterogeneity, are more prone to atheism and secularism; rural societies have a better chance of preserving the integrity of their

national culture in times of foreign political subjugation and to regain their political independence than highly urbanized societies. These observations of Sorokin and Zimmerman were borne out in African colonial rule and Eastern Europe under communist rule.

Although much more is to be found in this massive comparative study, for the purpose at hand it may be noted that (in contrast to other perspectives prevalent at the time, which looked at rural society with nostalgia as a setting of virtue and *Gemeinschaft* only) the perspective deployed is one of even handedness concerning rural–urban differences. There is not, in other words, an idealization of rural life and “small town” community. The volume also looked at dynamic aspects of the modern rural urban setting rather than as set in fixed poles. As important sociologically as the differences of rural and urban are their interchanges, with increasing urbanization of the rural world and also with the “ruralization” of the city world (a dialectical process which a later generation recognized as gentrification and suburbanization, and yet later as the global–local interplay).

MIDDLE AMERICAN PERIOD: 1930s AND 1940s

In addition to launching and chairing the Harvard department of sociology, Sorokin produced a four volume magnum opus, *Social and Cultural Dynamics* (1991), the most comprehensive sociological analysis of the institutional components of civilizations understood as dynamic cultural systems. Other publications in this period apply the theoretical perspective of a decaying “sensate” phase of civilization to diagnoses of the global crisis of the later 1930s, culminating in World War II (*Crisis of our Age*, 1941; *Man and Society in Calamity*, 1942). In a different vein, Sorokin published a methodological treatise having affinity with phenomenology (*Sociocultural Causality, Space, Time*, 1942) and a comparative study of the two countries that became the superpowers of the postwar era (*Russia and the United States*, 1944). While aware of some obvious differences, Sorokin in the latter study also pointed out important similarities and structural bases of compatibility.

LATE AMERICAN PERIOD: 1950s AND 1960s

This bitter sweet period of Sorokin’s career was marked initially by an increased estrangement from the profession (*Fads and Foibles in Sociology and Related Sciences*, 1956) and a very critical orientation to cultural and political aspects of American society (*The American Sex Revolution, Power and Morality: Who Shall Guard the Guardians?* 1959). His “critical” writings, published well in advance of critical sociology, tended to be dismissed by the profession, with grudging accolades given to more “mainstream” works (*Sociological Theories of Today*, 1966). However, the accolades became more pronounced in his last decade, and a certain reconciliation of Sorokin with the profession is best manifest in his ASA presidential address “Sociology of Yesterday, Today and Tomorrow” (published in the *American Sociological Review*, December 1965).

His most creative activities in this last period were devoted to setting up the Harvard Research Center in Creative Altruism, which generated several important volumes (see the discussion in Johnston 1995). These relate to Sorokin’s view that sociology needs to provide from empirical data possibilities of social reconstruction emphasizing creativity, love, and normative ideals as alternative to prevalent emphases in popular culture and in research on what in a comparative historical perspective are malevolent features of the human condition.

MAJOR THEMES OF SOCIAL CHANGE

For Sorokin, echoing the insight of Heraklitus, the social order is characteristically in flux. The social order is given its orderliness by the cultural integration of its component parts, which are themselves institutions and systems of ideas (political, economic, philosophical, cultural). These parts of a complex whole sociocultural system (a civilization) are grounded in a basic worldview of ultimate reality, with three primary modes of apprehending reality as truth. First, reality may be taken to be given by the senses and the objects of the senses: this Sorokin termed *sensate* reality. Second, in contrast, ultimate reality may be seen as lying beyond the

senses and their time space coordinates; it is apprehended by intuition, intuitive experience, a moment of “enlightenment” and the like, recognized in various cultural and religious traditions, from Plato to Zen Buddhism. This Sorokin termed *ideational*. Third is a combination or synthesis of the first two by means of the faculty of reason and rational thought – what Sorokin called *idealistic*.

All three cognitive modes are present in any complex social order, though in any period of the existence of a social system one mode may have salience over the other two. But because all three are features of social organization, in order to have a comprehensive understanding of the structure and dynamics of social reality – of the comportment of social actors and of inevitable changes in social organization – sociology must be an “integralist sociology,” that is, it must have a multidimensional methodology that can treat social reality in all three modes. Stated in different terms, an adequate methodology for sociology is one that is empirical (Sorokin utilized quantitative data in various studies), rational, and interpretive.

However integrated sociocultural systems and their component parts may be, there is no perfect, permanent integration – humans can imagine a perfectly integrated society (as in socialist and other totalitarian systems), but history shows that change is prevalent and that the major factors producing change are internal factors (Sorokin’s *principle of immanent change*). Over time, the cultural premises exhaust their creative capacity of integration, and in periods of decay (or decadence), normative disarray is reflected in social pathological behavior, from anarchy and civil wars to world wars and genocides.

Drawing from his early observations on the Russian scene, but also from secondary sources of other settings, Sorokin proposed that in periods of crisis and at the end phase of a given system of cultural integration, particularly the modern one of a late sensate period, there is the phenomenon of *polarization*. Instead of the modal “average” conduct of morality, the majority may be drawn to acts of violence and brutality against others, but a creative minority will engage in acts of abnegation, sacrifice, and altruism.

Lastly, Sorokin’s perspective on change is a rejection of a linear view of change in favor of a *principle of limit*. There is a limit to how far in extent a given cultural mentality can go, and there is only a finite number of immanent possibilities available to a given sociocultural system. Hence, the historical process can be observed through various indices to have recurrent rhythms and patterns, rather than being unidirectional.

In brief, long term change is cyclical with a *longue durée* of the dominant mentality, whose exhaustion results in crises of malintegration manifest in social disorders and wars. In essential respects, Sorokin’s analysis of change in late modernity converges with and amplifies Durkheim’s theory of anomie.

CONCLUSION

Sociology has at various times “discovered” major figures of the past, as their overlooked or forgotten writings take on new relevance with changing societal conditions: Karl Marx, Georg Simmel, and Norbert Elias come to mind as receiving new “upgrades” in the decades after World War II. Sorokin is a prime candidate for “upgrade status,” with his focus on civilizational change as a unit of macrosociology (a theme accentuated by the “clash of civilizations” replacing the clash of superpowers), with his studies of by products of social deterioration in an era of the accelerating decline of sensate culture (witness Internet pornography, “reality” TV shows, and other anomic manifestations of popular culture), and with his comparative historical research on the creative and beneficial aspects of altruistic behavior. The “postmodern condition,” however elusive this may be, is one of flux and ambiguity. The rosy optimism of a “new international order” at the end of the Cold War has given way to a more sober realism of late modernity in the face of new cycles of genocide and warfare. In this period of transition, Sorokin’s integralist sociology offers methodological guidance for dealing and researching with emerging sociocultural phenomena, and his studies of altruistic behavior (which he designated as the study of “amity”), well in advance of current emerging research on

philanthropy, point to a possible new paradigm of modernity, a new “idealistic” period, though not a new utopia.

sovereignty

Stephen D. Krasner

The term sovereignty has been used in many different ways. The most important and widely understood distinction is between internal (domestic) and external (international) sovereignty. Internal sovereignty refers to the existence of an authoritative decision making structure within a political entity, a structure that is both legitimated and effective. External sovereignty refers to the autonomy or independence of a political entity and its associated authority structure from external control or interference.

INTERNAL OR DOMESTIC SOVEREIGNTY

Internal sovereignty is associated with the principle that within each political entity there is a structure capable of making authoritative determinations. In its modern formulations this idea is rooted in the work of Bodin and Hobbes, both of whom wanted, above all, to create a basis for domestic political order in the face of religious conflicts that were undermining the major states of Europe. Bodin's *Six Books of the Commonwealth* was motivated by the religious wars in France and was a rebuttal of the claim made by some Huguenot theorists for the right to rebel. Bodin himself was almost killed in the St. Bartholomew's Day massacre of 1572. For Bodin, the basic goal of government was to ensure order, and order could not be preserved if there was a right of rebellion against the sovereign. Bodin recognized that the sovereign could be a tyrant and he accepted the possibility that such a tyrant could be killed by outsiders, but he rejected in principle the right of domestic resistance.

Hobbes published the *Leviathan* at the end of the English Civil War, the bloodiest conflict in per capita terms for Britain until World War I and one of whose victims was the British king. Hobbes's basic contention was that once individuals had entered into the social contract, they had given up any right of rebellion. The alternative to the Leviathan, the sovereign, was the state of nature in which life was “nasty, brutish, and short.” Both Bodin and Hobbes believed that there must be some one final point of authority within the state, an idea never realized in practice and perhaps even inimical to domestic order because of the dangers presented by the arbitrary exercise of power. Locke's idea of the state as a fiduciary trust for the citizens who did have the right of rebellion if that trust was violated has proven a more durable formula for establishing stability. Regardless, however, of whether domestic sovereignty is organized in some single hierarchy or based on a separation of powers, the basic claim of internal or domestic sovereignty is that decent human existence requires an independent authority structure capable of providing order and, ideally, justice and prosperity as well.

Domestic or internal sovereignty has never been taken for granted. Issues of order and justice, which informed the work of the great political thinkers of the past, continue to be the concern of modern scholars. In the contemporary environment there are huge variations in the quality of domestic sovereignty or governance. In the modern industrialized countries of North America, Western Europe, and East Asia economic prosperity has grown, life expectancy has increased, and the lives of most individuals are secure. Domestic sovereignty works. In other parts of the world, however, there are populations in many countries that suffer under failed, weak, incompetent, or abusive national authority structures. Life expectancy is declining. Public services are not delivered. Per capita income is falling. Civil war is endemic. In the most extreme cases, any semblance of an effective national or even regional authority structure may have collapsed. Internal or domestic sovereignty has failed.

EXTERNAL OR INTERNATIONAL SOVEREIGNTY

External or international sovereignty refers to a way of organizing political life among political entities. In its ideal typical form external sovereignty is defined by three characteristics: territory, autonomy, equality. A sovereign state has a defined territory. A sovereign state is autonomous or independent; no external actor has authority within the state's territorial boundaries and each sovereign state accepts the autonomy of other sovereigns. Finally, sovereign states are formally equal. Although they obviously vary with regard to size, population, resources, and wealth, every sovereign state has the right to sign treaties with others and to be free from interference by external actors. With regard to equality, sovereign states are analogous to individuals in a liberal society; each state is regarded as having a basic set of rights regardless of other attributes.

Conventional analyses by international lawyers and by international relations scholars as well have treated international or external sovereignty as fundamental for any adequate understanding of the modern international system. The sovereign state system has been seen as

emerging from the Peace of Westphalia of 1648, which ended the Thirty Years' War. In his classic "The Peace of Westphalia, 1648–1948," Leo Gross wrote that the "Peace of Westphalia, for better or worse, marks the end of an epoch and the opening of another. It represents the majestic portal which leads from the old world into the new." For Gross, the Peace marked the end of the hierarchical medieval system within which the emperor and the pope stood at the pinnacle of religious and secular authority.

For the conventional perspective, once sovereignty was accepted at Westphalia it became increasingly embedded over time. Conventional sovereignty became the foundation upon which international law was based. Law was the result of treaties or customary behavior undertaken by sovereign states, each of which was free to choose its own course of action. For international relations scholars, especially those associated with realism, the dominant perspective for American political scientists from the 1950s through the 1990s, sovereignty was the fundamental assumption upon which their analyses were based: outcomes in the international system were the result of the distribution of power among states, each of which was assumed to be independent from all others. For many scholars, as well as policymakers, international or external sovereignty came to have a taken for granted quality.

Conventional understanding of international and domestic, of external and internal, sovereignty is complementary. An autonomous territorially based political unit capable of entering into agreements with other such units on an equal basis, the key to international sovereignty, must also be a unit in which there is a domestic authority structure capable of guaranteeing that international commitments can be honored.

ALTERNATIVES TO SOVEREIGNTY

Sovereignty can be contrasted with other ways of organizing political life. Traditional tribal groups claimed authority over their members but did not have a defined territory. Authority relations were defined in terms of individuals rather than territory. Colonies had specific territory but they did not have autonomy; final authority rested with the colonizing state. In

the traditional sinocentric world, imperial China was regarded as superior to other political entities; these other entities, tributary states, sent periodic tribute missions to China (missions that were often as much concerned with trade as with deference), and China sent investiture missions to tributary states when new rulers were chosen; but in most other ways tributary states were effectively independent.

SOVEREIGNTY IN PRACTICE

Observers have always recognized that in practice domestic or internal sovereignty can be problematic because domestic authority structures can break down. There is also now increasing recognition of the fact that external sovereignty as well can not be taken for granted. External or international sovereignty can work in practice only if two fundamental rules are observed by states. The first rule, a corollary of the idea that each state is supposed to be independent or autonomous, is that no state should intervene in the internal affairs of another. The inhabitants or rulers of each state can create whatever domestic authority structures they want free from outside interference. The second rule is that there should be mutual recognition among juridically independent territorial entities. Mutual recognition allows states to enter into international agreements on the basis of formal equality. In the contemporary world, it also provides membership in international organizations and, for poorer states, access to the resources of international financial institutions. The official representatives of recognized states are accorded special privileges such as diplomatic immunity.

Both of these rules, the rule of non intervention and the rule of mutual recognition, assume the absence of any final authority structure in the international system. Indeed, it is the absence of such a final authority that distinguishes a world of sovereign states from an imperial system in which there is a final arbiter for all political entities. If, however, there is no final authority in the international system, why would we expect that the rules of non intervention and mutual recognition would be honored? One possibility is that these rules, which define a logic of appropriateness for the

international system, are so taken for granted that political leaders cannot conceive of violating them. This possibility, however, is not consistent with the empirical evidence.

The rule of non intervention has frequently been violated. For example, during the Cold War, the Soviet Union and the United States both sought to promote their own model of domestic authority in other states. In Western Europe after the war, the United States used both financial resources and military threats to weaken the position of the Communist Party in Italy. In what became West Germany and in Japan, the occupying powers led by the United States pressed for the creation of authority structures based on democracy and capitalism. The Soviet Union, for its part, supported or imposed communist regimes in the countries of Eastern Europe that its army occupied at the end of World War II. In the developing world, both the Americans and the Soviets supported political leaders who, at a minimum, would shun the other side. In Korea and Vietnam the United States intervened to prevent a communist regime from assuming control of the entire country, an enterprise that was successful in Korea but not in Vietnam. The United States sent troops into the Dominican Republic and Grenada to prevent what American political leaders perceived to be the dangers of a communist takeover. In Afghanistan the Soviets intervened, ultimately unsuccessfully, to prevent the overthrow of a communist regime.

The inescapable tension at the core of international or external sovereignty is that a logic of consequences may dictate a different behavior than a logic of appropriateness. The international system is characterized by power asymmetries, differing interests, and the absence of any final authority. The core interests of powerful states have repeatedly been threatened by the nature of domestic political regimes in weaker states. To lessen this threat, political leaders in powerful states have moved to change the domestic authority structure in weaker ones. If the interests of powerful states are furthered by intervening in the internal affairs of weaker ones, there is no authority that can prevent such policies from being implemented. Violations of the rule of non intervention are not an aberration but rather an enduring characteristic of the sovereign state system.

In the post Cold War environment failures of internal or domestic sovereignty, violations of basic human rights, and the threat of transnational terrorism have created new tensions between a logic of appropriateness and a logic of consequences. Genocidal developments have led major countries to condemn developments in some countries, for instance Rwanda, and to intervene in others, for instance Kosovo. Concerns about terrorism motivated wars against Afghanistan and Iraq. Transitional administrations with executive authority, usually authorized by the United Nations Security Council, have been created in a number of countries since the end of the Cold War, sometimes for short periods, such as in East Timor, and sometimes for much longer periods, as in Bosnia, where the high representative, a Western European essentially appointed by the major European powers, continued to make key political decisions for many years after the signing of the Dayton accords in 1995. Thus, while ideological differences between the Soviet Union and the United States during the Cold War created tensions between the logic of appropriateness associated with external sovereignty and the logic of consequences driven by the desire of the superpowers to support regimes that mimicked their own domestic authority structures, in the post Cold War period failures of domestic authority and the dangers of terrorism have led to similar tensions.

In an environment as complex as the international system, strains between logics of appropriateness and consequences are inevitable. In their relations with each other powerful states with effective domestic sovereignty may honor the rules of international sovereignty because such behavior is consistent with a logic of consequences. But in relations between powerful states and weak states with either poor or abusive domestic governance, logics of consequences driven by material interests will trump logics of appropriateness. Both internal and external sovereignty have not been, and cannot be, taken for granted.

space

Leslie Wasson

Space has many faces: the bubble of individual space, the private spaces we maintain for our personal lives, the situated space defined for social interactions, the public spaces of wider social activity, and space as a scarce distributed resource in the organization of human social life. A sociological examination of space might look at one or more of these aspects. Although some theorists use the terms space and place interchangeably, they are not the same concept. A place is a social organization of space to which we have attached a particular meaning, and in which certain activities are more likely to occur. Space is the physical distance among the elements of which that place is constituted.

Hall's groundbreaking text *The Hidden Dimension* (1966) treats space as a sociological category of experience. For Hall, as for other well-known theorists of space such as LeFebvre (1991), space is ordered by human custom and definition. The reverse is also observed: the design or definition of a space can affect the sort of activities and meanings that occur within it. Hall cites the transitory character of late industrial society, and ties it to conflict among the unspoken cultural assumptions about space,

time, and other abstract concepts. His exploratory study raises many subtopics, such as proxemics, which is the individual's need for space between people in order to interact, and which varies by culture. He also suggests an examination of the city, wherein he delineates three kinds of spaces: fixed feature, semifixed feature, and informal spaces.

INDIVIDUAL SPACE OR PROXEMICS

Individuals carry an invisible bubble of space around them in order to feel comfortable interacting with others. The size of this cushion of space varies from one individual to another, and also varies across cultures. For example, a person in one of the Arabic cultures needs to get very close, about 1 foot away, in order to communicate effectively. In other cultures, about 4 feet is the acceptable communication distance. Most Americans need about 30 inches (Sommer 1969). The implication for diplomatic missions and everyday conversation is that others may be perceived as either too pushy or too cold and distant for reasons that have nothing to do with the content of their communications, and much to do with the amount of intervening space.

PRIVATE SPACE: HOMES

There is, according to conventional wisdom, no place like home. Home is the essential private space. Douglas (1991) suggests that homes need not be large, but that a home begins by bringing some space under control. She characterizes the private space of the home as being regarded with a mixture of resistance and nostalgia. The sociological interest in this construction of meaning, however, is that home as a private space may or may not be "fixed" in its location or attributes. As Levinson and Sparkes (2004) find in their study of Gypsy culture and space, when previously nomadic people leave their home on the road and start living in houses they may experience a loss of cultural identity.

Homes are domestic spaces. They reflect the interests, roles, and statuses of the men, women, children, and pets who are their inhabitants (Walker 2002). Walker provides the

example of the space allocation and semiotic relations of the rooms in a Victorian house, and ties that architecture to the prevailing assumptions about age, gender, and social roles of the time.

SITUATED SPACE

Spaces of any kind are subject to a variety of social definitions. This variety is not infinite, but spaces can be flexible to different definitions of the situation and accompanying interactions. A small space beneath a kitchen table may be room for feet and legs, a cave or a castle to a young person, or the land of bountiful opportunity to the family dog. For the situational attributes of space, an excellent starting source would be Goffman (1959), who describes the settings and spaces of everyday life as stages for scripted social interactions. Lessons from the world of architecture and design indicate that more flexible spatial frames can lead to greater participation in sociability, as participants engage in the process of fine tuning a space to a more transient situated meaning that suits their needs of the moment.

PUBLIC SPACES

Oldenburg (1999) demonstrates the importance of everyday community spaces to the construction of social relationships and meanings. His examination of the "third spaces" that people spend time in after home and work highlights the importance of semi private and public spaces in providing meaning and continuity to human life. Historians and political scientists have examined the roles of taverns and coffee houses as community facilitators and sites for political discourse and organization. Milligan (1998) looks at what happens to the definition of a community place when it is moved into a new space. Community bonds forged in the crucible of one intense social space lose their integrity when those facilities and their limitations are no longer extant. Du Bois (2001) provides examples from his consulting work as an applied sociologist of space sensitive designs that encourage social interaction in nursing homes, bars, and other public spaces.

HUMAN SPACES AND URBAN GEOGRAPHY

Although space as a form of social organization has been studied most thoroughly by human geographers (Tuan & Hoelscher 2001), their studies have had a significant influence on sociological research. Jones (2001) proposes that sociology could and should be done in concert with the design professions who create human habitations. He provides a rationale based on many classic sociological studies of cities, beginning with the Chicago School. Subsequent researchers and theorists have examined the relationship between behavior and environment in both directions, from the perspective that all social interactions are guided or constrained by their physical contexts, to the proposition that all physical designs occur partly as a result of social processes.

Many studies of the use of space in human communities focus on urban settings. Some research examines the contestation of the finite commodity of public space in crowded urban conditions, and the marginalization of some public spaces over others (Madanipour 2004). Also, some research indicates that the homogenization of public urban spaces discourages intercultural communication (Rahder 2004). This can be an unproductive use of scarce space in crowded and diverse city settings, as it silences the participation of some groups. Kitchin (1998) explores social responses to disability as a spatialized political economy combined with social constructivism in which spaces are defined to exclude certain kinds of people and limit their visibility.

Space in suburban communities can influence interaction patterns as well. Gans (1967) described the layout of space in the early Levittown communities and suggested how this kind of organization affected the interactions of the residents. Rural sociologists might include space, in the form of isolation and transportation issues, in research on dispersed households or agricultural communities. They might also examine the transformation of food producing agricultural space into housing developments.

There may be a growing view of residential sprawl as a loss of open space and therefore a decline in the quality of life of a community. Such a perception can result in

social movements and legislation attempting to limit uncontrolled or unplanned development (Romero & Liserio 2002). Communities with abundant space may negotiate a balance between the individual tendency to spread out more or less evenly over available space versus distinctions in the allocation of location, acreage, and square footage by social status. Communities with more limited space may experience competition and rising prices that place ownership or even tenancy beyond the means of a significant percentage of their population.

Related to the idea of urban or suburban space is the political theory concept of "civic spaces," which contribute to the exercise of shared governance in a democratic society. An example of this might be Speaker's Corner in Hyde Park in London. To complicate matters, occasionally a convergence will occur between civic or political spaces and sacred religious spaces, as in Jerusalem. Such a contest of meanings may result in conflict over the space and its use.

CONFLICT AND CONTROVERSY OVER SPACE

Competition over desirable space has a long history. Many wars have been fought over territory. Much of American history is a tale of expansion into larger spaces perceived as uncultivated or marginally tenanted by their native caretakers.

There is some ethnocentric bias in defining anything as "open" space. Spaces that are not already saturated with urban or suburban forms of development are assumed to be empty and therefore available. Some ecological writers in the popular press, for example, suggest that conserving land by evicting its indigenous residents is illogical and unethical, and also potentially disruptive of an existing ecological balance. With an ever expanding global population and dwindling non renewable resources, this competition over space, and the emergence of social movements aimed at preserving it, may increase.

Cyberspace may be viewed as a nearly infinite virtual commodity in the age of computers, but not all human interaction has the benefit of Internet access. Space may indeed be the final

frontier, but perhaps not the space above us. In a rapidly globalizing world, we may find it more pressing to address the space around us and between us.

spatial mismatch hypothesis

Ted Mouw

The spatial mismatch hypothesis argues that the movement of jobs away from central city areas, combined with constraints on geographic mobility imposed by continued residential segregation, limits the employment prospects of inner city minorities. The basic story is straightforward: as jobs decentralize to the suburbs or beyond, black workers find it difficult to move to where the jobs are because of racial residential segregation, resulting in a “mismatch” between the jobs and black workers that raises unemployment and/or lowers wages. The spatial mismatch hypothesis has been widely discussed since it was first proposed in the late 1960s as an explanation for black–white differences in unemployment rates. At the same time, there are longstanding and unresolved debates in the literature regarding the magnitude of the effect that it has on racial differences in unemployment and wages.

John Kain (1968) was the first to attempt to empirically test the spatial mismatch hypothesis. He used data on employment location from the 1950s to divide Detroit and Chicago into 98 workplace areas. He then regressed the share of black employment in the workplace area on the share of the population and the spatial distance from the black ghetto area and found a strong relationship between black employment share and distance from the ghetto. He estimated that the geographic mismatch between workers and jobs resulted in a loss of about 22,000 jobs for Chicago and 9,000 for Detroit.

Despite changes in residential segregation and job decentralization since Kain's initial formulation, the basic story behind the spatial mismatch hypothesis is still relevant today. Residential segregation between blacks and whites has declined slowly over the past two decades, but is still high, suggesting that in many metropolitan areas the geographic mobility of black workers is constrained. The evidence on employment decentralization suggests that the general trend over the past several decades has been one of job loss and decentralization in large urban areas as jobs moved toward the suburbs or left the metropolitan area entirely. John Kasarda (1995) shows that between 1980 and 1990, employment growth was much higher in suburban counties of metropolitan areas than in their central cities. Recent data indicate that this pattern held during the economic boom of the 1990s; between 1992 and 1997, for example, central cities experienced an increase in employment of 8.5 percent, compared to 17.8 percent in their suburbs. Steven Raphael and Michael Stoll (2002) calculate segregation indices between workers and jobs using data on population and employment by zip codes and argue that the mismatch between black workers and jobs declined slightly during the 1990s, but that blacks are still significantly more isolated from employment than whites.

CRITIQUE

In a prominent critique of the spatial mismatch hypothesis, David Ellwood (1986) tests the effect of average commuting time on youth (ages 16–21) unemployment in Chicago. He finds little effect of commuting time on neighborhood unemployment rates, and concludes that it is “race not space” that is of central importance in understanding the high unemployment rate of black workers.

Keith Ihlanfeldt and David Sjoquist (1990) argue that Ellwood's results are misleading because of the small sample sizes that he used to calculate neighborhood commuting times and because he did not estimate separate equations for black and white workers. They estimate the effect of average travel time on youth unemployment using micro level census data for Philadelphia, Chicago, and Los Angeles, and find results consistent with the spatial mismatch hypothesis.

A one standard deviation increase in average commuting time for black youth in Philadelphia (3.7 minutes) is associated with a predicted reduction of employment rates of 4 to 6.3 percentage points. Overall, Ihlanfeldt and Sjoquist estimate that spatial job accessibility explains about 33–39 percent of the racial difference in unemployment among 16 to 19 year olds who are not enrolled in school.

In general, most tests of the spatial mismatch hypothesis use neighborhood black unemployment rates as the dependent variable and some measure of distance to jobs as the central independent variable. The empirical question is whether neighborhoods with better spatial access to employment have lower unemployment rates for black workers. Two important difficulties in assessing the magnitude of the spatial mismatch effect, however, are the measurement of the spatial proximity of employment and the problem of endogeneity posed by selective migration.

THE MEASUREMENT OF EMPLOYMENT PROXIMITY

In order to calculate spatial job proximity, one needs to measure how far the average job seeker in each neighborhood has to travel to find employment opportunities. Recent research has done this in two ways. A number of studies use the average travel time for employed black workers in each neighborhood as a measure of spatial accessibility. A problem with this is that an unemployed person's travel time may be longer because nearby jobs may already be filled with local workers. An alternative is to use data on the spatial location of jobs and calculate the number of “nearby” jobs for each neighborhood. There are two measurement difficulties with this approach. First, one must take the number of competing workers into account. Hence, the jobs to workers ratio is a better measure of job availability. Second, one has to take the two dimensional spatial data on the location of jobs and workers and transform it into a measure of job accessibility. Raphael (1998) and Ted Mouw (2000) both borrow the “gravity model” of commuting behavior from the transportation literature to calculate spatially weighted indices of job accessibility (as well as

the size of the competing labor force), where “near” jobs are given more weight than “far” jobs based on the analysis of actual commuting behavior. Using data from the San Francisco metropolitan area, Raphael (1998) calculates changes in the proximity to jobs between 1980 and 1990 and controls for the size of the competing labor supply. In regressions of youth unemployment rates that combine both black and white workers, Raphael estimates that changes in job proximity explain about 29 per cent of the racial gap in unemployment. Nonetheless, when he estimates these models separately by race, job proximity is statistically insignificant for black workers, reflecting a small sample size ($N = 367$).

Mouw (2000) estimates a “fixed effects” model of the spatial mismatch hypothesis by calculating changes in job proximity and adult unemployment rates between 1980 and 1990 in Detroit and Chicago. Data on job location from the 1980 and 1990 Census Transportation Planning Packages (CTPP) are used to calculate spatial measures of job proximity. The data document the substantial decentralization of employment that occurred during the 1980s in Detroit; within a 10 mile radius around the average black worker’s home there was a net loss of about 100,000 jobs between 1980 and 1990.

ENDOGENEITY

In addition to the problem of calculating job access, estimates of the spatial mismatch hypothesis may be biased if workers sort themselves into different neighborhoods based on unobserved characteristics that affect labor market outcomes. If housing prices and neighborhood quality tend to increase with distance from the city center, then more “successful” workers may end up living closer to suburban areas of employment growth. To the degree that this is true, proximity to regions of suburban job growth may be the result of labor market outcomes rather than the cause. Recent research on the spatial mismatch hypothesis has studied unemployment of teenagers rather than adults as a way to get around this problem of endogeneity. If teenagers live at home, then their residential location might be considered an exogenous factor uncorrelated with unobserved

labor market factors that would affect their ability to get a job. Even in this case, however, the decision of a teenager to work full time instead of being in school is probably correlated with his or her parents’ socioeconomic status, and hence this research is not immune to questions about endogeneity. Examples of this approach are Ihlanfeldt and Sjoquist (1990) and Raphael (1998).

An alternative approach is to study changes over time. As mentioned above, Mouw (2000) used “fixed effects” models of changes in neighborhood unemployment and job proximity between 1980 and 1990. Provided neighborhood selectivity – i.e., the tendency for workers to sort themselves into neighborhoods on the basis of their labor force characteristics – has remained constant over the time period, fixed effects models represent an alternative way to get around the problem of endogeneity in residential location. Based on his results, Mouw concluded that a 10 percent drop in job proximity would result in an increase in the black unemployment rate of 5.6 percentage points in Detroit and 2.9 percentage points in Chicago.

In another approach to the problem of endogeneity, Jefferey Zax (1991) and Zax and Kain (1996) studied the effect of a single firm’s decision to move from downtown Detroit to the suburbs, about 8 miles away. The advantage of studying a single firm is that it represents a “natural experiment” to observe the effect of distance on employment. By studying employment records for racial differences in quit rates, Zax and Kain (1996) concluded that the resulting spatial mismatch between the location of the firm and the residences of their black workers forced about 11 percent of the black workers to quit after the relocation. While this research is persuasive, studies of a single firm cannot assess the magnitude of job decentralization as a whole or follow the employment outcomes of those workers who quit the firm.

Recent quasi experimental evidence from government funded housing programs, the Gautreaux program and Moving to Opportunity (MTO), has been used to assess the spatial mismatch hypothesis. In both of these programs, inner city black residents were given housing vouchers to allow them to move to different neighborhoods in their metropolitan area. In the Gautreaux program, voucher recipients

were randomly assigned to either suburban or urban neighborhoods in Chicago. James Rosenbaum (1995) showed that, in the Gautreaux program, respondents who moved to suburban neighborhoods had higher post move employment rates than urban movers. Nonetheless, the suburban movers did not have significantly higher employment rates than before they moved (64.3 percent employed pre move and 63.8 percent employed post move; see Rosenbaum 1995: 237). The MTO program is a large scale housing mobility experiment conducted in five cities. Families were randomly assigned to an "experimental" group and offered vouchers to live in a low poverty neighborhood, a "Section 8" group that was given vouchers with no geographic restrictions, and a control group that did not receive vouchers. Five years after random assignment, there is no statistically significant difference in employment rates or earnings between the experimental and control groups. Nonetheless, Jeffery Kling et al. note that these MTO results do not directly contradict the spatial mismatch hypothesis, as an analysis of employment growth by zip code suggests that the experimental group was not living in regions of higher job growth than the control group (employment in the control group zip codes increased by 5 percent compared to 4.9 percent in experimental group zip codes).

Overall, research during the past decade, with better measurement and methodological approaches than earlier research, has found substantial evidence to support the spatial mismatch hypothesis. Ihlanfeldt and Sjoquist (1998), for example, found that 21 of the 28 studies they reviewed that were published between 1992 and 1997 reported findings consistent with the spatial mismatch hypothesis. Nonetheless, the modest size of the effects in most studies indicates that the spatial mismatch hypothesis cannot be the only explanation of the black-white employment gap. Individual cities may differ greatly in their degree of "spatial mismatch" between workers and jobs, and even in Detroit, which because of high levels of racial residential segregation and job loss would seem to be the poster child for the mismatch hypothesis, a recent empirical estimate (Mouw 2000) suggests that the large scale decentralization of employment during the 1980s explained no

more than 30 percent of the 1990 racial gap in unemployment rates.

spatial relationships

Martin Hess

Traditionally, the analysis of spatial relationships has been considered to be the domain of geography, whereas the academic discipline of sociology was concerned about the relationships between societies and social actors. Following a period of regional geography approaches in the first half of the twentieth century that had emphasized territorial differentiation as being at the core of human geography, this view has been subsequently contested. Rather than space being conceived of as a Kantian *a priori* for human existence and action (absolute space), the focus of many human geographers began to shift towards the analysis of spatial relationships between objects and events, thus introducing the concept of relative space.

During the 1960s and 1970s this concept underpinned an emerging strand of spatial science studies, with mathematical space superseding physical space to the extent that more and more human geographers became concerned about the “spatial fetishism” of the discipline (Gregory 2000). This is not to say that social interaction never has been a subject of geographical enquiry. But the prevalent tendency of treating social relationships as purely spatial relationships at the time was increasingly criticized, calling for a different ontology of space as being socially constructed and shaped by human practices (relational space).

As an increasing number of human geographers have adopted such a social science perspective, at the same time there has been an increasing awareness among sociologists of the spatiality of social structures and social action, to the extent that it sometimes has been called the spatial turn in social sciences. This alleged spatial turn and the related dialogue between sociology and geography recently have become most pronounced in the subdisciplines of economic sociology and economic geography (Grabher 2006); however, according to commentators from both sides there still is too little serious engagement in sociology with issues of space and place and how they shape and are shaped by social interaction (Tickamyer 2000; Peck 2005).

When analyzing spatial relationships, we need to make a distinction between different aspects of the notion of space as discussed above. On the one hand, space is seen as an arena in which social interaction takes place. On the other hand, space has to be conceived of as being relational, and therefore is much more than a mere “container” for human activities (Pries 2005). The analogy of a football match may serve as a good illustration of these two conceptualizations: while a football match is played out on a pitch within a confined, Euclidean space (the spatial “container”), it ultimately is the spatial relations of players on both sides and their interactions that define the match and its outcome.

Among social theorists, Anthony Giddens is one of the relatively few academics in sociology to have theorized space (see Giddens 1984). For example, Giddens (1990) argued that in premodern times the spatiality of social relations was very much place bound, as well as time and space being linked together in particular places. With the decoupling of time and space in the modern age, Giddens argues, space and place have become separated as social interaction is now possible through spatial relations beyond the place or locality. One of the consequences of modernity – highlighted by what has become the catchword of globalization – is thus the dislocation or disembedding of spatial relationships.

The notion of embeddedness is very often at the center of debates about the relationships between sociology and geography, between social and economic relations and spatial relations

(Peck 2005; Grabher 2006). Based on Karl Polanyi's seminal work about the relationships between markets and societies, embeddedness has become a key concept in some social sciences, particularly through the work of American economic sociologist Mark Granovetter. Unlike the schools of thought that apply a methodological individualism approach, Granovetter (1985) conceptualizes economic action as being embedded in a set of ongoing social relations. This relational view of human action – albeit silent on the spatial nature of these social relationships – has been adopted by geographers who have used it in particular at the local and regional scale of analysis.

This emphasis of localized social interaction and embeddedness is mirrored in other branches of social science (e.g., the sociologies of everyday life), where social relations are assumed to be based on face to face contact and thus spatial proximity is paramount. However, such a reading of locally embedded social relationships runs the risk of becoming an over territorialized concept by privileging one geographical scale over others (Hess 2004). This is problematic for a number of reasons. First, it tends to create a false dichotomy of place and space, where social interaction is either “in here” (the place) or out there (the space). Second, it does not fully recognize the multi scalarity of sociospatial relations. Third, it often fails to acknowledge the importance of embedded ties beyond the locale.

As Massey (2004) rightly observes, in academic as well as in policy discourses place is considered to be more “real,” more “grounded,” and thus often seen as much more meaningful than space, which denotes the outside: an abstract spatiality outside place. Such a perceived antagonism of place vs. space often comes hand in hand with questions of power and identity, whereby the latter is often seen as being created through spatial relations on the local level, and, according to Massey, through a process of “othering” – negatively defining local identity by regarding others (non locals) as outsiders. Likewise, place is often regarded as powerless in a globalized world, where power is overwhelmingly exercised outside the place, in a global arena.

A relational view of sociospatial interaction, however, will take seriously the multiple forms of identity that characterize individuals and

communities, as becomes clear by – for instance – having a look at global cities like London. There, as elsewhere, most identities are shaped simultaneously by local–non local social relations, creating relational spaces of belonging as in the case of transnational communities. Likewise, places are by no means powerless vis à vis global actors out there, but part of much wider networks of power within which a locale is not automatically condemned to passivity. Spatial relations across the scalar spectrum thus require an understanding of spatial scale not as something mutually exclusive or separable like the different shells of a Russian doll, but as intrinsically interwoven.

As we have seen, space is an integral conceptual part in the analysis of social relations. And over the last few years there was certainly progress in the development of more elaborate multi scale or multi level concepts, the lack of which has recently been criticized by Tickamyer (2000). A case in point is the emergence of work in social sciences that is informed by actor network theory (ANT). Although ANT is too critical of concepts that are concerned with social relations in space and time at the expense of non human agents, it has nevertheless contributed to a less deterministic analysis of spatial relationships, applying an understanding of space as topological stratifications and linking time and space in dynamic, heterogeneous relations (Hess 2004). In their theorization of space, Mol and Law (1994) develop a threefold typology of space and spatial relations, echoing previous discussions of multi scalarity and multiplicity: regions, networks, and fluid spaces. In their work there is still the acknowledgment of territories as regions in which objects are clustered together and social relations may be concentrated. These regions, however, are criss crossed by networks as topological spaces, where distance is a function of social and cultural relationships rather than designating physical proximity. Finally, there are fluid spaces, characterized by “liquid continuity” and constituted by mobile agents (Hess 2004).

The nature of spatial relationships and how to conceptualize them are still subject to ongoing debates in human geography. But it seems that their analysis is no longer considered to be the sole domain of this academic discipline, with sociology and economics, among others,

sharing for instance an interest in questions about spatial inequality that has long been at the core of much research, yet with an often unsatisfying or insufficient reflection on the spatiality of social interaction and the social construction of spatial relations (Gregory & Urry 1985). As it is, there is still much work left to do within and beyond academic disciplines if we want to improve our understanding of how space is folded into social relations through human practices and interactions (Harvey 1996).

speaking truth to power: science and policy

Javier Lezaun

“Speaking truth to power” refers to the belief that scientists, unimpeded by economic self interest or partisan bias, will deliver honest and often uncomfortable truths to those in positions of power.

It is the foundational claim of the sociology of science that only certain types of social structure enable scientists – or, rather, science as a social institution – to reach the truth and present it with due authority. In a series of pioneering articles, written at a time when science was actively enlisted in the service of the state and made subservient to totalitarian projects, Robert K. Merton (1938, 1942) argued that a self governed science was most congenial to the aims and principles of a free society, and that this autonomy was best guaranteed by the distinctive “ethos” of its practitioners, which he characterized by the norms of universalism, communitarism, disinterestedness, and organized skepticism. Capable of regulating itself through these normative principles, science was entitled to demand freedom from external influences and pursue unhampered the acquisition of fundamental knowledge.

Merton’s depiction of a self regulating science as the pillar of a democratic society and the best guarantee of uninterrupted scientific and technological progress reinforced the case of those scientists and politicians who, in the aftermath of World War II, believed that the state should continue its active support of science but ought to leave the management of resources and the setting of research agendas to the scientific community. A peculiar “social contract” between

science and the state was established following the demobilization of science. This consensus was embedded in new institutions, like the National Science Foundation, through which government continued to provide enormous amounts of funding for basic scientific research, conducted mostly in academic institutions, but abstained from intervening directly in the setting of research priorities or the evaluation of the knowledge being created.

Thus, the model of science as a community driven by an ethos of disinterestedness, organized skepticism, and universalism allowed the drawing of a sharp boundary between science and the state. It is this balance of separation and mutual dependency between science and politics that has become the central object of investigation of the sociology of science ever since.

Starting in the 1970s, sociologists and historians began to explore more closely the historical origins of the "ethos of science" and to question the degree to which it informed the actual practice of science. Studies of both the paradigmatic American case (Price 1965) and the contrasting experience of totalitarian regimes shed light on the historical imbrications of science and political power. These works were either skeptical of the idea of an autonomous science, driven solely by the curiosity of its practitioners, or at least put this image in a historical and comparative context. They expressed an uneasiness over the subjugation of science to the objectives of its patrons and the emergence of the infamous "military industrial scientific complex." The image of a "basic," or "pure," science, innocent and deaf to the interests of power and in a position to provide useful advice to policy makers, appeared increasingly untenable, and sociologists began to question the demarcations of the scientific and political realms.

In other words, what *kind* of truth does science speak to power, and how does its close engagement with state and market affect the scientific community? Detailed analyses of the role of scientific and technical expertise in policy debates highlighted the inability of science to bring technical closure to policy discussions, and showed how the truths that science speaks to power are often shaped and informed by the powers it hopes to speak to. The work of Dorothy Nelkin (1979) and others

showed that groups of scientists, committed from the start to different policy options rather than disinterestedly searching for the independent truth, used their expertise to shore up their positions and to challenge alternative views that were themselves supported by equally confrontational scientific advocates. The scientification of policy leads to an intensification of differences rather than to their smooth resolution.

Similarly, Collingridge and Reeve (1986) showed how the desire to influence policy, and the consequent obligation to address the concerns and interests of policymakers, brings science to violate the very conditions – autonomy, clear disciplinary boundaries, and a low level of criticism of scientific claims – on which its ability to produce clear answers and unquestioned consensus is predicated. The result is almost paradoxical: to speak truth to power, science must abandon many of the normative and institutional conditions that protect its autonomy and efficiency. Science cannot deliver consensus when it is oriented toward questions posed by external actors, and on terms defined by those actors, and its legitimacy suffers as a consequence.

The intimacy of science and politics gives rise to forms of knowledge production and validation that differ significantly from the model offered by Mertonian sociology. Terms such as "regulatory science," "trans science," or "mandated science" convey the sense in which science is increasingly a hybrid product, constituted by the constraints of political and economic agendas; they also express a desire to distinguish these hybrids from the paradigmatic "pure" or "basic" science, the kind of unencumbered truth finding enterprise from which the social authority of science still derives. This "boundary work," through which science shores up its autonomy and authority, has been a constant theme in the sociology of science (Jasanoff 1987; Guston 1999). In a similar vein, science's ability to provide public truths to powerful institutions becomes more a matter of rhetoric and "staging" (Hilgartner 2000) than of revealing self-evident truths.

When science speaks truth to power, then, it often has to answer the questions that power poses to it, and the truths it can speak are of a particular kind – they are a form of knowledge deeply attuned to the logic and demands of the

policymaking process. The complexity of political issues, most conspicuously in the regulatory arena, where matters of fact and technical assessment are inextricably linked to political and societal choices, turns science into a more complex, less pure, and less autonomous social institution. Some may think this threatens its integrity; others believe that it enriches it, and reintegrates science into the fabric of politics.

Species-Being

Rob Beamish

Species Being (*Gattungswesen*), a controversial Feuerbachian inspired term refashioned in Marx's critique of Hegel's idealist philosophy, is central to Marx's conception of alienation.

Hegel had argued the form and substance of knowledge developed historically. The conscious mind (*Geist*) initially experiences reality as external and separate; true knowledge seems to reside in that alien reality. Exploring that world, consciousness becomes self-consciousness as mind progressively grasps the complex, dialectical subject/object basis of knowledge. An increasingly comprehensive intellectual Spirit (*Geist*) emerges, culminating in an Absolute form. Overcoming the original perception of separation – alienation – Mind's full potential is actualized in grasping the totality of Absolute Being.

Hegel's philosophy buttressed nineteenth century Prussia's narrow, intolerant state. Ludwig Feuerbach's *Essence of Christianity* – a democratically inspired critique of the supreme religious Absolute – challenged the state's Hegelian foundation. In religion, the powers of humankind are alienated from it, extrapolated, made infinite, and then impose themselves as an Absolute Being. Feuerbach's anthropologically based critique of theology undermined idealism by emphasizing humankind's material Being as a species (*Gattungswesen*) – the real, existent, identifiable, characteristics of humankind that religion hypostatized.

Species Being in Marx emanates from his critiques of Hegel and Feuerbach. Following Feuerbach, Marx began with real, active humans, but "inverting" Hegel's idealism produced a dramatically different conception of Species Being. Hegel, Marx (1975) argued, "grasped the self-creation of humankind as a process, objectification as loss of object [*Vergegenständlichung als Entgegenständlichung*], as alienation [*Entäußerung*] alienation." Hegel "grasped the essence of labor and objective [*gegenständlichen*] humankind," but only as mental (*geistige*) labor.

For Marx, humankind was a materially active, social being, compelled to produce (labor) in order to exist. Production (labor) – the ontological basis to praxis – changes and develops humankind's knowledge, conditions of being, and social arrangements. Labor, the material mediation of subject and object, is the ontological basis for humankind's mental, creative, social, and material development. This is humankind's Species Essence. Species Being is not a set of fixed natural characteristics – our species' Being is materially active, interactive,

and creative, producing our material life, thereby changing our circumstances.

Mind developed through intellectual subject/object mediation with Hegel; with Marx, human life develops in the material practice of subject/object mediation – labor. Humankind's Species Essence or Being is the praxis of such development.

Under conditions of private property, humankind's fundamental Species Being – its creative laboring activity – is dominated by an external reality. Rather than developing workers, the externalization process creates products, a process, and a system that confronts and stultifies their physical, emotional, social, and political development. Labor's alienated products confront the producers and oppose them. Only by overturning private property can humankind's Species Being fully flourish in freedom.

Spencer, Herbert (1820–1903)

Jonathan H. Turner

Herbert Spencer was the most widely read sociologist of the nineteenth century, but by the second decade of the twentieth century his

influence had declined dramatically, prompting Talcott Parsons in 1937 to ask “who now reads Spencer?” Today, very few sociologists read Spencer, who, through sociology's biased eye glasses, is seen as a political conservative and as a crude functionalist. This contemporary conception of Spencer is not only incorrect but, more fundamentally, it also keeps present day sociologists from realizing the power of Spencer's ideas. The other classical figures in sociology have been canonized, with each generation of sociologists continuing to read the canon with the same dedication as biblical scholars. In contrast, Spencer is ignored, to the detriment of the cumulative sociological theory (Turner 1985). Nowhere is Spencer's genius more evident than in the topic of social change. Spencer developed several models of social change. One is a stage model of societal evolution from simple to complex forms; another is a dialectical model emphasizing the transformative effects inherent in the centralization and decentralization of political power; still another explores “selection” as a force behind social change; and a final model deals with the rise and fall of empires and interstate systems.

Before reviewing these models, it is wise to deal with the functionalism that runs through Spencer's sociology. Spencer argued that all superorganic systems composed of relations among organisms must address three fundamental problems: *operation* or the need to secure resources (production) and to generate new members (reproduction); *regulation* or the coordination and control of system units through power and cultural symbols; and *distribution* or the movement of resources, commodities, people, and information. These three “functional requisites” are critical to understanding all of Spencer's sociology, as we will come to appreciate.

THE STAGE MODEL OF SOCIETAL EVOLUTION

Like all functional theorists, Spencer saw differentiation as a master social process as societies move from simple to complex forms. As populations grow, structural differentiation ensues in order to support the larger “social

mass” (an ideal that Spencer first developed in *The Principles of Biology*, 1864–7). Structural differentiation occurs along three axes corresponding to the functional requisites: operation (production and reproduction), regulation, and distribution. The first node of differentiation is between new kinds of productive and reproductive structures, on the one side, and regulative structures revolving around the consolidation and centralization of power. Later, as differentiation continues, new kinds of distributive structures (markets and infrastructures for transportation and communication) emerge. For Spencer, then, long term evolution revolves around continued differentiation of structures within each of the axes and between these three axes. In the 2,000 plus pages of *The Principles of Sociology* (1874–96), Spencer provides a wealth of empirical detail (taken from his monumental 16 volume *Descriptive Sociology*) in describing each stage of evolution. He denotes each stage in terms of the degree of “compounding” from simple to more complex societal formations: simple without political leaders (e.g., hunting and gathering); simple with political leaders (Big Man hunting and gathering as well as horticultural systems); double compound (agrarian societies); and treble compound (industrial societies). If he had lived through the twentieth century, he would have no doubt described post industrial societies as the new level of compounding. Spencer’s description of these stages of evolution is by far the most sophisticated of the nineteenth century, and it certainly rivals any description on the stages of societal evolution in the twentieth and twenty first centuries. This stage model is largely descriptive, but evolutionary stages are all driven by dynamics outlined in Spencer’s other models of social change.

THE DIALECTICAL MODEL OF SOCIAL CHANGE

Probably the most important pages in *The Principles of Sociology* are those devoted to the analysis of “militant” and “industrial” societies. Spencer made this distinction in order to examine the dynamics of power (as it is consolidated and centralized along the regulative axis of differentiation); and this analysis of power is woven

throughout the pages of *The Principles of Sociology*. In fact, Spencer is a theorist of power more than any other topic – an emphasis that goes against the perception of Spencer as a stage model functionalist. For Spencer, once power emerges in human societies at *any* stage of evolution, it reveals an inherent dialectic between highly centralized (militant) and more decentralized (industrial) forms. There is, Spencer argued, a tendency for systems with highly centralized power to sow the seeds for their transformation to a more decentralized profile, and conversely, decentralized political systems establish the conditions for the centralization of power. Societies thus cycle between centralized and decentralized patterns of political power. Let us start with a society revealing centralized power (militant). Power in such systems is used to regulate operative (production and reproduction processes) and distributive structures to a very high degree, while at the same time increasing the level of inequality as elites with power usurp resources for their own privilege and for sustaining the administrative and coercive structures necessary for tight control of a population. Such regulation generates problems of productive stagnation and market contraction, as well as resentments over growing inequality. The result is for liberal ideologies stressing freedom from such control to emerge, leading actors involved in production, reproduction, and distribution as well as those in lower social classes to exert political pressure for less regulation and redistribution of elite privilege. The end result is a more decentralized political system that, in turn, sets into motion its own set of dialectical forces. Decentralized power allows for increased differentiation within and between the operative and distributive axes, but as this differentiation occurs, problems of coordination, control, and conflict escalate, leading to the formation of conservative ideologies emphasizing the need to control the emerging chaos; and eventually these ideological pressures and the social movements that they inspire cause the consolidation and centralization of power which, over time, will set into motion pressures for decentralization of power. Thus, long before Vilfredo Pareto’s analysis of the circulation of elites, Spencer had developed a far more sophisticated model of dialectical change.

SELECTION AS A TRANSFORMATIVE DYNAMIC

Nine years before Darwin published *On The Origin of Species*, Spencer (1851) coined the famous phrase “survival of the fittest,” and unfortunately his sociology has been tainted by this view of human social organization. But a sympathetic reading of Spencer leads to a more favorable view of what this phrase means in his sociological reasoning. For Spencer, the social world is driven by social selection within and between societies. When populations grow, competition for resources increases, with the more fit securing resources and the less fit dying out or finding new resource niches. This is the argument that Durkheim would adopt 20 years later in *The Division of Labor in Society* (1893); and of course, it is the basic point of emphasis in all contemporary theories of human ecology. Spencer also used this phrase to describe war between societies. Indeed, Spencer viewed war as a powerful force in the evolution of societies from simple to complex forms. He argued that the more complex and differentiated society typically wins a war, absorbing the conquered society (often repressively). Yet, with each round of conquest of the simpler society by the more complex, all human societies become more differentiated. Thus, an important force behind the long term trend toward differentiation of societies has been war and conquest of the simple by the more complex.

Spencer also developed another view of selection as a transformative force. For Spencer, populations often encounter problems of adaptation that require the invention of new structures. For example, if a population grows, it requires new kinds of productive and regulative structures to feed and control the larger population, but if such structures cannot be developed, a society “dissolves” or “de evolves.” Here, then, is another kind of selection in which new organizational problems and logistical loads facing a population generate selection pressures for new structures if the population is to survive in its environment. If individual and collective actors find a way to respond to these selection pressures, the development of these new structures increases the level of differentiation in society and makes it more adaptive to its environment (an idea that Talcott Parsons was later

to develop into the notion of “adaptive upgrading,” apparently unaware of Spencer’s reasoning 100 years earlier). The most important selection pressures arise from the functional needs for operation, regulation, and distribution. That is, as populations grow or confront problems internally or in their environment, the selection pressures almost always revolve around developing new structures for resolving problems of production, reproduction, regulation, or distribution.

THE MODEL OF EMPIRE FORMATION AND DISINTEGRATION

Spencer was one of the most important early geopolitical theorists, although most sociologists remain unaware of his analysis of intersocietal dynamics. When populations grow, Spencer argued, they mobilize power; and often this power is used to conquer neighboring populations (frequently under selection pressures to secure more resources to support the growing population). As neighboring societies are conquered, the logistical loads for regulation and control increase. The result is for governments to impose ever more taxes in order to support the administrative and coercive bases of power that are needed to maintain control. As government imposes additional taxes, it increases the level of inequality in the expanding empire, thereby generating another kind of logistical load for control. Conquest thus generates enormous pressure on polity to control the larger population, conquered territories, and problems inherent in inequality. As a polity copes with these selection pressures, it often conquers more territory to secure needed resources, but in doing so, it only increases the logistical loads: more people must be controlled; larger territories must be governed; ethnic diversity and diverse cultures of the conquered must be managed; and the threats arising from growing inequality must be repressed. Eventually, these logistical loads and the selection pressures that they generate cannot be managed, leading to the collapse of the empire and the devolution of societies back to simpler forms. The history of the world, Spencer felt, was very much a history of these dynamics, as empire formation increased societal complexity, only to be undone

by the logistical loads inherent in all empires and the need to concentrate power. These inevitable dynamics led Spencer to oppose British colonialism. For, at the height of the British Empire, Spencer argued that colonialism concentrated too much power in the hands of elites, increased tension generating inequalities, diverted capital (in the long run) from production, and eventually imposed logistical loads that would lead to the collapse of the empire.

It is impossible to communicate the sophistication of Spencer's analysis. Moreover, Spencer had professional historians and ethnographers develop the large database in *Descriptive Sociology* to illustrate his theoretical models (the largest database ever created in the nineteenth century, and one that served as the model for George P. Murdock's Human Relations Area Files). Indeed, when *The Principles of Sociology* was first published, readers complained about what they saw as too much descriptive data, but Spencer wanted the reader to be sure that each analytical point in his theoretical models could be assessed with data from a wide variety of societies – from the simplest hunter gatherer society to the England of his time. The great tragedy is that Spencer is often viewed as an “armchair theorist” who had no contact with data but, in fact, Spencer paid professionals to collect the largest database ever assembled by a sociologist. And, while he was an armchair theorist in that he did not collect the data himself, his sociology avoided speculative ideas that could not be assessed with data. The models of social change summarized above represent only one theme in Spencer's sociology, but their sophistication should encourage other sociologists to mine this classic work.

spirituality, religion, and aging

Robert C. Atchley

Religion and spirituality are enduring aspects of the human condition. Some of the earliest human records were accounts of the spirituality and religious culture of the day. Religion and spirituality have also fueled human conflict for thousands of years. Our concern here is how religion and spirituality interact with aging: how aging affects religion and spirituality, and how religion and spirituality affect aging.

Religion is a social institution concerned with ultimate questions such as the meaning and purpose of life, the existence of a higher power, coping with the reality of suffering and death, the existence and nature of an afterlife, and what it means to lead a moral life. Religions are also social organizations that meet not only the need to join with other believers, but also various social needs such as comfort, aid, and social support. Most American adults are associated with a local congregation of a major faith. There are hundreds of religions with widely varying answers to life's ultimate questions. Religious beliefs are among the most deeply held, and religion can be a source of both comfort and conflict. There are also people who attach no significance to religion. Religiousness is an individual attribute – the extent to which a person

has internalized a religious culture and uses it to make decisions in their life.

Spirituality is an experiential, inner aspect of consciousness. It is the capacity to experience the sacred directly. Such experience can be cognitive, emotional, and/or motivational. For many people, the sacred can be experienced in an enormous variety of situations: nature, in relationships, in music, dance, and art, in religious devotions, in inspirational texts and orations.

The inner experience of spirituality and socially constructed religion are related for most people, and for some people are inseparable. But there are also people who consider themselves spiritual who disavow religion and still others who find neither term applies to them.

In the US, a large majority of elders have had a lifelong identification with their religion and are long time members of their local religious group. Local religious groups are the most common type of community organization membership for middle aged and older people. About half of the general population attends religious services at least twice a month. Frequency of attendance increases with age up to age 60 and then declines gradually thereafter. Informal religious behavior such as reading scripture, personal prayer or meditation, or participation in religious study groups also increases with age and is especially important for disabled elders. Religious involvement is particularly important for African Americans and women.

Local religious groups and regional and national denominations vary considerably in how they approach the needs of aging and older members. Some consciously work to maintain integration of older members in the life of the religious community by taking steps such as recruiting elders for leadership positions, making special efforts to provide transportation to elders, and mobilizing the religious group to attend to the special needs of frail elders. Other local religious groups may do very little to encourage continued participation or attend to the needs of their older members, even in situations where the proportion of older religious group members is rapidly increasing. Religious groups are not immune to the agism that permeates their culture.

More than 90 percent of adults express a religious preference, and a large proportion of older adults believe that their faith has grown

stronger over time. Life stage appears to be related to spiritual development. In middle age, many adults begin to address seriously the issue of life's meaning. They may find that conventional superficial answers to this question are increasingly unsatisfying. During this stage, many adults embark on a quest that may involve systematic study and reflection, which in turn often gives a sense of deepening understanding. Tornstam's (1994) theory of gerotranscendence holds that as people move into later adulthood, they begin to develop a more universal and less personal stance toward the meaning of life. By old age, many people take more enjoyment from their inner life, feel greater connection to the entire universe, and are less afraid of death.

Experiences of spirituality begin in childhood for many people and contain an element of transcendence in the sense that the experience transports the individual from his or her conventional perceptual field to being able to see things in a wider context. It could be said that spirituality is a direct experience of the source of spirit, the life force that animates all being. Spiritual practices such as prayer, meditation, or making sacred music and art aim to cultivate a deeper awareness of spirit within the individual. For most people, spirituality is integrated with religious values, beliefs, and attitudes, but some see themselves as spiritual but not religious. A lifetime of spiritual practice makes a difference. From middle age onward, people may find that many years of spiritual practice and life experience combine to soften the edges of their religious ideas and create a more inquiring, spacious, and tolerant attitude toward other faiths. Spiritual development seems to lead toward more interest in common ground among religions and peaceful coexistence. One of the unfortunate results of age segregation in large urban communities is the loss of everyday interaction with spiritual elders, people whose high degree of spiritual development can be an important source of wisdom within the community.

Involvement in organized religion, subjective religiousness, and spiritual experience are associated with greater physical and mental well being and longevity. People affiliated with religions that prohibit tobacco, alcohol, and drug consumption tend to be healthier and live

longer than others. As people age, the degree of participation in both formal and informal religious activities has been associated with better health and greater life satisfaction.

In general, the greater the degree of religiousness, the better people's health and subjective well being. The greater the religiousness, the lower the prevalence of anxiety, fear of death, and loneliness. Highly religious people also cope better with grief. Religious beliefs and spiritual orientations are the very prevalent resources for coping with negative aspects of life, especially in old age. The more serious the problem, the more likely that people will use religious coping. However, religiousness can also be maladaptive if it isolates elders from others, if it defines negative aspects of aging as resulting from sin, or if elders seek support from their congregations and do not get it.

Sociologically, the subject of aging, religion, and spirituality represents a relatively new field of inquiry, filled with important questions begging for better answers. There can be no doubt that those who see themselves as religious and/or spiritual have a different, often better, experience of aging compared with those who do not. But better analytical description is needed of what happens, how, and why. In addition, we need better maps of how aging people relate to various types of religious organizations and better understanding of the effects of specific religious and spiritual beliefs and practices over time. Major challenges facing research in this area include incomplete theory development, difficulty in constructing measures that are valid across faith groups, and coping with the enormous diversity of religious beliefs and practices and their potential interactions with aging.

sport

John W. Loy and Jay Coakley

Sport is an embodied, structured, goal oriented, competitive, contest based, ludic, physical activity. Given the multitude of sport forms and the vast variety of specific sports, ranging from rural, primitive athletic folk games of old, to new urban, hi tech, extreme sports, this definition is unlikely to satisfy one and all. It does, however, (1) highlight the major social characteristics of modern sport; (2) suggest the specification of the embodied structural properties and social processes underlying the social development of modern sport; and (3) provide a set of common features for examining the magnitude and complexity of sport as a social phenomenon at different levels of analysis, including sport as a unique game occurrence, sport as a particular type of ludic activity, sport as an institutionalized game, sport as a social institution, and sport as a form of social involvement (Loy 1968).

SPECIFIC CHARACTERISTICS OF MODERN SPORTS

Sport is Embodied

The degree of physicality varies by sport, but the body constitutes both the symbol and the core of all sport participation (Hargreaves 1986). The essence of embodiment in sport is

that sporting activities involve many kinds and degrees of physicality, including physical activity, physical aggression, physical combat, physical exercise, physical presence, physical prowess, physical recreation, physical sexuality, physical training, and physical work. In short, sporting bodies represent a range of desiring bodies, disciplined bodies, displaying bodies, and dominating bodies.

Sport is Structured

There are at least four ways in which sport is highly structured. First, all sports (whether informal or formal) are *rule governed* by either written or unwritten rules. Second, most sports are *spatially circumscribed* by the sites of their venues, whether they be arenas, courts, fields, pools, rings, rinks, stadiums, or tracks. Third, most sports are *temporally circumscribed* as illustrated by designated time periods such as innings, halves and quarters; or number and time of bouts and rounds; or allocated attempts within a specific time period. Indeed, to prevent indefinitely long sporting encounters sports have instituted tie breakers, “sudden death” playoffs, and “shorter versions” of selected sports (e.g., one day cricket matches). Fourth, modern sports tend to be *formally administered*, whether by local clubs, universities, professional teams, or sport federations.

Sport is Goal Oriented

Individuals, teams, and organizations are typically goal directed in sport situations, especially in terms of the perennial overriding goal of winning. Athletes and coaches alike continually attempt to achieve various standards of excellence. And numerous forms of self testing and contesting take place in all sporting encounters. The sporting media constantly stresses the theme of being Number 1 in terms of games won, points earned, medals obtained, rank on the money list, most career victories, or number of Grand Slam titles.

Sport is Competitive

A key feature of all forms of sport is physically playful competition. Such competition may be

between individuals or teams, and may involve either an animate object of nature (e.g., a bull in a bullfight), or an inanimate object of nature (e.g., climbing the highest mountain in the world), or it may be focused on competition against an “ideal standard” (Loy 1968). A spectator typically perceives three basic forms of competition (McPherson et al. 1989: 16): First, *direct competition* where two opponents, either individuals or teams, directly confront one another, as for example, in boxing or football. Second, *parallel competition* wherein participants compete against one another indirectly by taking turns as in bowling or golf; or contesting in separate spaces, as for example, separate lanes in swimming events or track sprints and hurdle races. Third, there are forms of competition which are largely *competition against a standard* such as trying to make a qualifying time for an Olympic running event, or attempting to set a world automobile speed record on the Bonneville Salt Flats in Utah.

Sport is Contest Based

Many, if not most, sporting encounters are contests, that is, competitive activities characterized by two or more sides (individuals, teams, or larger organizations), agreed upon rules, and criteria for determining the winner, with a non reciprocal outcome. As defined below, most sport contests are either agonal games or sporting matches.

Sport is Ludic

Even the most highly professionalized forms of sport possess some play like elements. Two ludic or play elements inherent in all sports are *artificial obstacles* and *realized resources*. Individuals and groups are confronted in daily life by obstacles they must attempt to overcome. Unfortunately, individuals and groups often do not have the required resources to cope adequately with the specific obstacles that they confront. Contrarily, in the context of sports, individuals and groups artificially create obstacles to overcome, be it a hurdle in a steeplechase or the height of a pole vault. And unlike real life situations, individuals and teams

in sport situations are typically provided with the needed resources (e.g., coaching, equipment, training, etc.) to cope with their artificially created obstacles.

Sport, as defined and described above, represents a particular type of ludic activity and thus is closely related to the social phenomena of play and games.

COMMON CHARACTERISTICS OF LUDIC ACTIVITIES

Like play and games, sport is ancient, ubiquitous, and diverse.

Antiquity and Ubiquity

Play precedes culture and humankind: some mammals exhibited play activity about 65 million years ago. Human play is a universal activity found in all institutional sectors of society. Similarly, games, at least games of physical skill, have been found in all societies, past and present (Chick 2004). Although games are not as old as play, archeologists have discovered gaming artifacts that are several centuries old. Today, board games like chess and new electronic video games are pervasive throughout the world.

In turn, sports are at least as old as the first recorded Olympic victor in Greece in 776 BCE. Although sports are particularly characteristic of modern societies, and while the phenomenon of sport is not found in all past societies, many contemporary sport forms have long cultural traditions and historical legacies.

During the past century sport has become a social phenomenon of great magnitude and complexity, having both positive and negative consequences for individuals and groups throughout the world. The ubiquity of sport is illustrated by Boyle's (1963: 3–4) observations about American sport in the early 1960s. He explains that sport pervades all spheres of social life and influences everything from values, status, and race relations to business, fashions, and ideas about heroes. The pervasiveness of sport in society today is best indicated by the mass media that covers sundry forms of sport throughout the world on a daily basis.

Diversity

There seems to be an infinite number of play forms worldwide. And there are hundreds, if not thousands, of different game forms throughout the world. In turn, the great variety of sports throughout history and in very different cultures and diverse geographical regions of the world amply attests to the diversity of sport. Moreover, it is evident that modern sports have diverse historical roots and social derivations.

First, some of our contemporary sports are derived largely from relatively primitive, fundamental movement activities such as climbing, diving, kicking, jumping, running, swimming, throwing, vaulting, and weightlifting. Many events of our modern Olympic Games are based on such basic fundamental movement activities.

Second, several forms of modern sport have their roots in early survival activities and often represent transformations of work practices to play practices. Noted examples of such sport forms are fishing, hunting, skating, sledding, and skiing. Sporting activities such as dog racing, horse racing, pigeon racing, and rodeo events may also be assigned to this category, as they represent the transformation of human use of domestic animals for work to purposes of play.

Third, still other forms of sport today represent modifications of ancient martial arts and military exercises. Readily recognizable examples include archery, boxing, fencing, javelin throwing, and wrestling.

Fourth, less directly, but no less importantly, a number of modern sports have distant roots in ball games, dances, and ceremonies associated with the religious practices of traditional, preliterate societies. Lacrosse is perhaps the most prominent example of a modern sport having its origins in religious ritual.

Fifth, some contemporary sports are the patent result of individual invention. Classic examples are basketball (invented by Canadian James Naismith in December 1891 while a student at the YMCA Training College in Springfield, Massachusetts) and volleyball (invented by William G. Morgan in 1895 while serving as physical education director at the YMCA in Holyoke, Massachusetts).

Sixth, other modern sports represent a continuum of development from informal (if often brutal) play, to formal competitive play, to

athletic folk games, to recreational and representational sports. For example, it may be reasonably argued that selected forms of folk football (Elias & Dunning 1986) led to the development of soccer (Chick 2004), which led in turn to the development of rugby (Dunning & Sheard 1979), and in turn to the development of intercollegiate gridiron football (Riesman & Denny 1951), and finally the emergence of both American and Canadian versions of professional gridiron football.

Although modern sports may differ markedly from their original folk forms they nevertheless possess significant residual sporting traditions, styles, and practices (Ingham & Loy 1993).

BASIC DIFFERENCES OF LUDIC ACTIVITIES

On the one hand, physically competitive play, agonal games, and elite sports are similar in that they typically involve competition between two or more sides, with agreed upon rules, criteria for determining the winner, and the outcome largely based on the display of superior physical skill. Because they share the same basic features, play, games, and sport are often treated as one and the same. For example, tennis is considered a sport, but we play a game of tennis, and the person who wins the most games and takes the most sets wins the match. A tennis match is, of course, a contest, like a boxing match or a wrestling match. And tennis matches are an official sport of the modern Olympic Games.

On the other hand, play, games, and sport differ in degree, if not in kind, in terms of formalization, reciprocal activity, and non reciprocal outcome. *Formalization* refers to the formal structure of ludic activities in terms of social, spatial, and temporal organization as well as the rules that govern them. Play is generally informal in terms of both structure and rules, whereas most games are more highly structured and have more formal rules. In turn, sports are extremely structured, with some having large volumes of published official rules.

Reciprocal activity denotes the degree of interaction among rival participants and the degree of sociability among both playful friends

and foes. Informal competitive play ranks high in terms of reciprocal activity; face to face games involve at least moderate degrees of interaction; while sports tend to show the lowest degrees of sociability, especially among opponents at the elite and professional level.

Non reciprocal outcome refers to the degree to which the end result of a ludic encounter is zero sum, with only one winner or side taking all. Among play, games, and sport there is an inverse relationship between reciprocal activity and non reciprocal outcome. Traditional play places little emphasis on non reciprocal outcomes, most games give moderate emphasis to such outcomes, while nearly all sports clearly stress the importance of non reciprocal outcomes. The most extreme examples of non reciprocal outcomes are found in terminal contests such as bullfights, cockfights, dogfights, and, most critically, war.

Specific similarities and differences among play, games, and sport are denoted by the following definitions of ludic action and typology of ludic activities.

DEFINITIONS OF LUDIC ACTION

Ludic, from the Latin term *ludus*, refers to any play like and/or game like expressive activity. *Agonal*, from the Greek term *agon*, refers to any contest involving struggles of physical prowess. *Physical prowess* denotes the display of athletic ability in terms of varying degrees of skill (accuracy and coordination), strength, speed, and stamina (endurance). *Play* is a voluntary, expressive activity, which is both uncertain and unproductive, characterized by spontaneity, pretense, and non linearity, which focuses on process rather than product, and which can be initiated and terminated at will. *Competition* denotes active efforts by individuals or groups to reach a goal, to achieve a superior position, or to win a prize or title. *Physically playful competition* represents earnest struggles for supremacy in agonal games or sporting matches. *Contests* are competitive activities characterized by two or more sides (individuals, teams, or larger organizations), agreed upon rules, and criteria for determining the winner, with a non reciprocal outcome. *Matches* are contests between opposing

individuals. *Sporting matches* typically involve individual demonstrations of physical superiority in terms of speed, strength, stamina, accuracy, and coordination (Weiss 1969). Although some team sports may be called matches (e.g., cricket matches and soccer matches) they are classified here as agonal games. *Games* are playful contests whose outcome is determined by physical skill, strategy or chance, employed singly or in combination. *Agonal games* are games whose outcome is largely determined by the demonstration of superior physical prowess in combination with superior tactics and strategy. *Sports* represent institutionalized agonal games or sporting matches.

These definitions are summarized in the following typology of ludic activities:

- 1 *Non play contests* (e.g., deadly fights, duels, wars)
- 2 *Non contest play* (e.g., drama, humor, music)
- 3 *Playful contests* (e.g., puzzles, riddles, spelling bees)
- 4 *Non sport games* (e.g., bridge, checkers, chess)
- 5 *Sporting matches* (e.g., boxing, tennis, wrestling)
- 6 *Agonal games* (e.g., basketball, ice hockey, soccer)

THE FUN FACTOR IN LUDIC ACTIVITIES

Given the plethora of play forms in culture and the pervasiveness of games and sports throughout the world, one must ask why these ludic activities are so attractive and appealing for participants and spectators alike. Perhaps the primary answer is given in Huizinga's (1955) assertion that *fun* is "the essence of play." He contends, however, that "the *fun* of playing, resists all analysis, all logical interpretation." Huizinga may be correct, but some sociological reasons can be given as partial explanations for why play, games, and sport are fun. For example, sociability, euphoric interaction, quest for excitement, and emotional dialectics may in large measure account for the fun factor in ludic activities.

SOCIABILITY

Simmel (1950) views sociability as the play form of human association and proposes that the principle of sociability rests on maintaining reciprocity in the values offered and received in interaction. Henricks (2003) observes that, for Simmel, the distinctive characteristics of sociability are fourfold. First, sociability is simultaneously connected to and disconnected from everyday life. For example, in "real life" situations, individuals must confront serious obstacles without the resources needed to overcome them, whereas, in ludic activities, individuals create artificial obstacles to overcome and all participants are provided the resources to meet the challenge of the obstacles adequately.

Second, the dynamics of sociability involve depersonalizing participants. The masks worn by gridiron football players, the costumes worn by participants at fancy balls or children on Halloween, and the personas assumed by professional wrestlers ensure the playing of distinctive roles while keeping personal matters to a minimum.

Third, sociability calls for cooperation and tactfulness. For an expressive configuration of positive affect to hold, the instrumental concerns and ego demands of the participants must be minimized, equalized, or ruled as irrelevant (Ingham & Loy 1973). As Goffman (1967) notes, in order to maintain the expressive frame of sociability, it is expected that participants will make efforts to support the feelings and face of interaction partners, and that these efforts will be made spontaneously and without second thought because participants mutually identify with each other's emotions and feelings.

Fourth, sociability is fostered by the social equality of participants. For example, Loy (1968) notes that the contestants in a game act as if they were equals, and status distinctions related to income, occupation, education, and race are not considered relevant through the contest. Ingham (2004) observes that games are democratic, and sociability is sustained only when intrinsic outcomes are available to all participants and when extrinsic gains are perceived as shared.

EUPHORIC INTERACTION

Goffman (1961) refers to the pleasurable sociability provided by gaming encounters as "euphoric interaction." He argues that the bases of fun in games are twofold: an uncertain outcome and sanctioned display. "A successful game would then be one which, first had a problematic outcome and then, within these limits, allowed for a maximum possible display of externally relevant attributes" (p. 68). Goffman's two primary bases of fun in games are an inherent part of the structural dynamics of modern sport. In order to ensure an *uncertain outcome* in sporting contests, a variety of efforts are made to establish equality between opposing sides. Efforts to establish equality of competition typically focus on the factors of age, gender, size, and skill. For example, youth sport teams typically represent age groups, and at the level of elite sport, men and women seldom compete against one another. Examples of controlling for size are restricting competition according to weight class for boxers and wrestlers, while examples of control for skill level are the handicap systems developed in golf and bowling to help equate the contestants. Chance also plays a role in efforts to ensure equality for purposes of ensuring an uncertain outcome, as for example, flipping a coin to determine which team begins play, or randomly drawing a number for a lane in a running or a swimming event.

Sanctioned display is another important structural feature of sports for generating excitement. The display of bodily excellence in terms of various forms of athletic ability and physical prowess provides pleasurable excitement to participants and spectators alike. However, too much extraneous display, in the form of taunting and other player antics, can greatly detract from the pleasurable excitement of a ludic activity. As Stone (1955) pointed out, play and display are precariously balanced in sport, and once that balance is upset, the whole character of sport in society may be affected. Furthermore, the spectacular element of sport, may, as in the case of professional wrestling, destroy the game.

It is evident that Goffman believes that sanctioned display and a problematic outcome lend

excitement to game encounters by creating tensions. Elsewhere he implies that a third element also generates tension in a game encounter, namely, "what is at stake." The value of the stakes that players compete for, in combination with the value of the stakes that players risk, adds excitement to any ludic activity. Gaming encounters with *high stakes* involve what Goffman calls "action," referring to engagement in activities that are consequential, eventful, and problematic, which are undertaken for what is felt to be their own sake, and wherein participants may put their very lives "at risk" (Goffman 1967: 185). A world championship poker game or a bullfight are ready examples of ludic activities providing exciting tension because the stakes are high.

QUEST FOR EXCITEMENT

While Simmel speaks of pleasurable sociability, and Goffman talks about euphoric interaction, Elias and Dunning (1986) analyze sport and leisure in terms of what they call "quest for excitement." They distinguish between "real excitement," such as that associated with seriously critical situations in everyday life, and "mimetic excitement," characteristic of sporting encounters. They propose that sport situations are structured in such a way as "to stir the emotions, to evoke tensions in the form of a controlled, a well tempered excitement without the risks and tensions usually connected with excitement in other life situations" (pp. 48–9). Elias and Dunning discuss a number of tension balances built into sport situations, which are designed to evoke tensions related to mimetic excitement. They place particular emphasis on the controlled expression of emotions related to aggression, conflict, danger, risk, and violence.

With reference to the structural dynamics of team sports they stress the importance of "interdependent polarities" for generating tension balances in sporting encounters. For example, they cite the overall polarity between competing teams; and the tension balances between offense and defense, cooperation and competition within teams, and the external control by sport authorities versus the internal control of players (pp. 202–3).

EMOTIONAL DIALECTICS

The theorizing of Elias and Dunning about “quests for excitement” can be considered an important example of what Sutton Smith has termed “emotional dialectics.” As Goodger and Goodger (1989) have summarized the work of Elias and Dunning: “It is not a case of there being a special type of relationship between the content of mimetic events and that of critical situations that they appear to resemble (for example, a sporting contest and a ‘real life’ struggle), but rather there is a relationship between affects simulated by mimetic events and those simulated by real life events, the affects in the former resembling those in the latter in a ‘playful and pleasurable fashion.’” In a somewhat similar vein, Goffman (1961) discusses “subversive ironies” and the “function of disguise” in his interactional analysis of “fun in games.” Fun, he explains, occurs when participants abide by rules of irrelevance and are careful to conceal reality to the point that it does not disrupt encounters.

Like Huzinga, Sutton Smith (2003) thinks the primary purpose of play is having fun. Further, like Elias and Dunning, he believes fun in play provides mimetic excitement. In turn, like Goffman, he believes play offers contexts for subversive irony and treats play as a parody of emotional vulnerability. In reference to what have variously been called involuntary emotions, reflexive emotions, or survival emotions, Sutton Smith focuses on what he calls the six primary emotions of anger, fear, shock, disgust, sadness, and joy. In proposing a dialectical hypothesis, he suggests that these emotions must be exercised (as in play) because they are fundamentally required for survival in the face of emergencies, but must also be constrained in the familial emotional contexts of contemporary social life. However, Sutton Smith also recognizes that there are times when the expression of these emotions surpasses normative limits and results in “excessive noise, riots and hooliganism.”

The preceding account supports the Goodgers’s (1989) supposition that people have a basic, socially induced desire to experience “enjoyable excitement.” But Ennis (1967) observes that societies face a sociological

challenge when determining how such a motivational state can be institutionalized when it is grounded in the sense that all institutional enclosures are being broken or transcended. Some insight into how society institutionalizes this motivational state is given in accounts of both ludic institutionalization and sportification.

LUDIC INSTITUTIONALIZATION

Ingham (1978) aptly calls the transformation of play and games to modern sport the process of ludic institutionalization. He suggests the process can be understood most clearly if it is viewed in terms of multidimensional continua in which play and sport constitute the polar extremes. This enables one to see that sport involves ludic activity that is, to relatively extreme degrees, regulated, formalized, instrumentalized, regimented, and estranged. In general, what have been variously called traditional games, folk sports, or folk athletics fall at the expressive end of the continuum; whereas, what has been variously called elite sport, top level sport, or professional sport falls at the most instrumental end of the continuum. However, even the most instrumental forms of ludic action possess some play like elements; thus, modern sports can be placed on a truncated expressive instrumental continuum. For example, “recreational sports” (e.g., street or playground pickup games), largely based on the principles of play, pleasure, and participation, represent expressive sporting activities; whereas “representational sports” (e.g., intercollegiate and professional sport), largely based on the principles of performance, profit, and prestige, represent instrumental sporting activities.

In sum, the ludic institutionalization of sport is best understood in terms of the tension balances associated with the expressive and instrumental dimensions of sport. Current analyses of the sportification process reflect thoughtful examinations of the expressive and instrumental dimensions of modern sport.

SPORTIFICATION

The transformation of modern sports from primarily expressive activities to largely instrumental

activities reflects the process of sportification. More specifically, as Renson (1998) notes: "Sportification is depicted as a universal hegemonic trend of standardization and globalization of sport practices." The global sport monoculture of representational sport denoted by the concept of sportification is also reflected in Heinila's (1998) concept of the "totalization of sport" and Donnelly's (1996) concept of "prolympism." Heinila (1998) argues that due to the totalization process, international sport has been transformed from contests between individuals and/or teams to contests between nation states that have unequal resources to produce elite athletes and teams. In a similar manner, Donnelly (1996) documents the articulation of professionalism and Olympism as the two dominant sport ideologies of the twentieth century. He demonstrates how these formerly very different alternative codes of sport merged into a single organic hegemony. Donnelly argues that prolympism is self reinforcing, in that it marginalizes alternatives and becomes a standard against which other forms of physical culture are assessed.

BASIC QUESTIONS AND SOCIAL PROCESSES

The degree of sportification of any particular sport can be usefully examined by answering four questions in terms of four related social processes: (1) What is the *social structure* of the sport? What are the kinds and degrees of *rationalization* characteristic of the sport? (2) What is the *social thought* about the sport? What are the ideologies and rationales put forth to *legitimize* the sport? (3) What are the kinds and degrees of *social participation* in the sport? What are the kinds and degrees of *democratization* characteristic of the sport? (4) What is the *social diffusion* of the sport? What are the kinds and degrees of *globalization* of the sport?

These questions direct attention to specific social parameters, polarities, foci, and social processes that aid the assessment of the degree and kind of sportification for a particular sporting activity or sport form, as shown in Table 1.

RATIONALIZATION OF SPORT

The most fundamental characteristic of the monolithic social structure of elite international or representational sport is its instrumental rationalization. The totalization of international sport and the prolympism of representational sport indicate that for the principles of performance, profit, and prestige, virtually every basic component or element of sport has been rationalized to the ultimate degree for reasons of efficiency and effectiveness. Examples of the key elements of representational sport and the specific processes underlying their rationalization are shown in Table 2.

LEGITIMIZATION OF SPORT

Both recreational and representational sport have been legitimized in a variety of ways at various historical periods of different societies. Table 3 lists some of the selected rationales that have been used to justify the social significance of modern sports. As is also indicated in the table, modern sports must continually confront problems of delegitimatization, such as the use of illegal performance enhancing drugs.

DEMOCRATIZATION OF SPORT

A notable historical trend of the sportification process has been the increasing democratization of modern sports. For example, the early modern Olympic Games were noted for their elitism, sexism, and racism. Today, few Olympic events are closely linked to social class per se,

Table 1 The sportification process

<i>Social parameters</i>	<i>Social focus</i>	<i>Social binary</i>	<i>Social process</i>
Social structure	Efficiency	Expressive/Instrumental	Rationalization
Social thought	Efficacy	Legitimate/Illegitimate	Legitimization
Social participation	Equality	Inclusion/Exclusion	Democratization
Social diffusion	Equatorial	Export/Import	Globalization

Table 2 The rationalization of sport

<i>Element</i>	<i>Focus</i>	<i>Process</i>
Players	Personnel	Resource allocation
Rules	Regulation	Formalization

Health and wellness	Cheating
Military preparedness	Doping
Community spirit	Drug abuse
National prestige	Gambling
Patriotism	Game fixing
Escapism	Hazing
Entertainment	Sexual harassment
Corporate profits	Violence

there is a marked increase of women participants and events in which they can compete, and many Olympic athletes, both male and female, are persons of color. Further, games and sports have been developed for special populations (e.g., the Special Olympics, the Paralympics, the Gay Games, and various "Senior" Games). Table 4 highlights the major forms of social discrimination that scholars, journalists, and cultural critics have addressed in the sportification process over time.

GLOBALIZATION OF SPORT

It is difficult to determine precisely the general emergence of the globalization of sport, but as evidenced by the diffusion of British sports

Table 4 Democratization of sport

<i>Opposing social categories</i>	<i>Discriminatory process</i>
Able vs. Disabled	Ableism
Young vs. Old	Agism
Class vs. Mass	Elitism
White vs. Black	Racism
Men vs. Women	Sexism

Cultural globalization	Media empires and satellite telecasts of events
Global migration	International professional athletes
Global tourism	Sport ecotourism
Global slavery	Third world labor for sporting goods
Global terrorism	1972 Munich Olympic massacre; Athens spends est. \$1.5 billion on security for 2004 Olympic Games

throughout the world, the development of international sport federations, and the establishment of the modern Olympic Games, by the beginning of the twentieth century sport was already a worldwide phenomenon (McIntosh 1971: 95). Today, we can find examples of nearly every different form of globalization within the world of sport, as shown in Table 5.

COUNTER REACTIONS TO THE SPORTIFICATION PROCESS

Broadly viewed, a strong case can be made that the sportification process has or will result in a monolithic global sport culture. On the other hand, folk sports and forms of recreational sport survive in the face of powerful global economic

and cultural processes. This illustrates that sporting practices are dynamic ongoing activities always subject to change and transformation in connection with local and global actions. For example, traditional sporting activities are constantly being modified as the conditions of play are negotiated through relationships and processes that involve a combination of players, managers, administrators, owners, media personnel, and spectators. All sports are historically produced and socially constructed. And while the most prominent cultural forms of sport embody systems of dominant meanings and practices, new sports and sporting practices are continually being invented which may generate forms of resistance and/or offer alternative structures and subcultures. In this sense, sports constitute contested cultural and social terrains.

A case in point is what are currently called extreme sports or variously known as adventure sports, alternative sports, action sports, panic sports, X sports, or whiz sports. These sports are typically characterized by risk, speed and vertigo, and a desire by participants to maintain control of their bodies and physical activities without the intrusion of formalized administrative structures and hierarchical supervision. Many participants in such sports express a rhetoric and follow norms that are anti establishment and often transgressional in their nature (Rinehart 2004). These sports might be considered as modern folk sports, given their grassroots origins and local variations. At the same time, some of these new and alternative sport forms have been captured in the "iron cage of play" of the monolithic global sport culture. Their technology and popular appeal among young men and women with money to spend has attracted the attention of mainstream sporting bodies and commercial enterprises, including media organizations and sponsors. As some participants resist commercial cooptation and others maintain parallel forms of non commercial, participant controlled activities, there are questions to be asked about the dynamics of cultural production and transformation (Honea 2004) and about sport as a game occurrence, a ludic activity, an institutionalized game, a social institution, and a form of social involvement. In this sense, sport constitutes a pervasive social phenomenon of great magnitude and complexity that continues to

attract the attention of sociologists and other scholars.

sport, alternative

Joy Crissey Honea

Many sports can be considered alternatives to dominant sport forms, but the term alternative sport has generally been used in sociology to refer to a group of activities that meet a particular set of organizational criteria. Alternative

sports initially existed outside of formal sports organizations and participants were primarily young people who, for one reason or another, did not fit into the world of traditional youth sports such as baseball and football. Though they differ greatly from one another, Robert Rinehart (2000) suggests that alternative sports can be loosely defined as: (1) participant controlled and directed, rather than organized through a governing body or other official organization; (2) individually focused, emphasizing personal achievements; (3) focused less on competition than traditional sports; and (4) generally possessing an insider requirement. That is, they are more likely than traditional sports to encompass their own subculture – one that stands in opposition to the dominant culture. In other words, skateboarders, for example, are not just people who happen to ride skateboards, but are “skaters,” expected to participate in a lifestyle associated with involvement in the sport.

Some alternative sports were originally titled “extreme.” This appears to have meant that they involved risk taking that more mainstream sports did not (like BASE jumping or cliff diving). The term was appropriated by the media and applied to any sport that was not generally considered a sports staple on television in the 1990s, and the label has by and large been abandoned by participants and, to some degree, by the media. Increasingly, mass media narratives refer to alternative sports as “action sports.”

Throughout the 1990s, alternative sports became increasingly popular. All sports cable television networks like ESPN and Fox Sports have been instrumental in exposing the sports to the public, particularly targeting the attention of young males (aged 12–34) in their coverage. These sports are now featured on ESPN, ESPN2, ESPNNews, ESPN Classic, and ABC. The best known alternative sporting events are ESPN’s annual X Games and Winter X Games, which feature a varying array of sports including skateboarding, snowboarding, inline skating, motocross, bicycle motocross (BMX), ski boarding and snow mountain biking. The X Games premiered in 1995 (originally titled the eXtreme Games). ESPN reported that between 1994 and 1998 its audience for alternative sports increased 119 percent and that the 2003

X Games were expected to reach more than 110 million homes in 145 countries and territories worldwide. Corporate sponsors have also gotten into the action and previous X Games sponsors include AT&T, Coors, Nike, Taco Bell, Mountain Dew, Chevrolet, VISA, and Snickers. According to a recent newspaper article, sales of skateboard shoes exceed \$1.4 billion annually, more than the total regular season game receipts of major league baseball, and skateboarder Tony Hawk's series of video games earned him a \$20 million advance from Activision while his clothing line brings in \$50 million annually.

Participation rates also reflect the increasing popularity of alternative sports. According to a survey conducted by the National Sporting Goods Association (NSGA), between 1996 and 2001 participation rates for snowboarding increased 72 percent and skateboarding participation rates increased 106 percent. These two historically alternative sports had the highest growth rates of all sports surveyed. For example, baseball, a more traditional sport, had a growth rate of only 8 percent and two other traditional sporting activities had declining participation rates – football was down 4 percent and basketball was down 12 percent.

The rapid increase in popularity of these sports has led researchers to examine why they are attracting so many (especially young) people and what they offer that perhaps mainstream sports do not. NSGA Vice President of Information and Research Thomas B. Doyle points out that snowboarding participation rates have tripled since 1990, while alpine skiing rates dropped more than 30 percent, and adds that skateboarding has experienced phenomenal growth since 1995, when it hit a low of only 4.5 million participants. Doyle contends that the growth of these two sports may reflect the fact that young people often choose activities that set them apart from adults. He suggests that traditional sports like skiing may have become too mainstream to be of great interest to adolescents and young adults.

Sociologists have addressed the claim that traditional sports are too mainstream for young people today and have examined what has historically attracted individuals to alternative sports. Beal (1995) analyzed the subculture status of alternative sport in her study of skateboarding in the early 1990s. Using Gramsci's theory of hegemony, she examined

the competing potentials of sport as an enforcer of dominant ideology and as a site of social resistance. Her findings indicated that members of the skateboarding culture she studied held beliefs about their sport that stood in contrast to the ideals of commercial sport. They were generally non competitive, process rather than goal oriented, and emphasized participant control of sporting events. She determined that, to some degree, the skaters were successful in resisting outsider control of their sport. Rinehart and Grenfell (2002) studied a group of BMX riders and examined the differences between the participants' experiences of riding at a self made bicycle track and at a corporate sponsored "park." They found that the riders often preferred the home made course, as it was truer to the original values of the sport, including participant control and informal organization.

Rinehart (2000) has studied a variety of alternative sports and their associated subcultures and has addressed the conflicts that arise as the sports become increasingly commercialized. He argues that participants' desire to have their sports legitimated and to prosper individually from their participation leads them to take part in commercial events like the X Games, but there they encounter conflicts with corporate and media sponsors who have different ideas about how to organize and present the sports. Rinehart contends that, while athletes participate in commercial events like the X Games, they simultaneously resist outsider definitions of what and who they are. He concludes that control over the presentation of alternative sports is significant because those who own and control the presentation of these events control not only the economics, but also the very core or "soul" of these sports.

What is emerging within alternative sport subcultures are struggles between corporate culture producers who are attempting to organize and present these sports like mainstream sport forms and the participants themselves, who seek to maintain some control of their sports and of the "authentic" roots of their cultures as they become commercialized. Beal and Weidman (1998), for example, found that skateboarders were indeed resisting outsider definitions of their culture and were participating in the production of their culture by influencing the advertising industry in its marketing

strategies toward skaters. Within snowboarding, Crissey (1999) found that Winter X Games participants were dissatisfied with ESPN's organization and presentation of their sport and engaged in symbolic forms of resistance to the commercialized nature of the event. Snowboarders refused to be interviewed, criticized the judging format, and called the competition "a joke." However, this resistance did not appear to be having much success, as the opposition was largely in the form of verbal complaining rather than organized action directed at change. In addition, their complaints were certainly not broadcast by ESPN or affiliates and the participants were essentially supporting the commercialized version of their sports by participating in the X Games events. The snowboarders appeared to be ambivalent about the role of commercial interests. Kleinman (2003) comes to a similar conclusion in his analysis of professional skateboarders, who expressed both positive and negative sentiments toward the commercialization, or "mainstreaming," of their sport.

Commercialization can be both beneficial and detrimental for alternative sports and their adherents. While commercialization results in organizational changes such as outsider control, increased competition, and extrinsic rewards for performances, it also provides new opportunities for participants including monetary rewards, product endorsements, new facilities, and video and television appearances. The most current data indicate that while athletes dislike the organizational changes and the commercial versions of their sports, they recognize that the newfound popularity and media coverage of their activities have opened new avenues for involvement in alternative sports, in terms of both sport participation and business ventures. For example, public and privately funded skateboard parks can now be found in many cities and towns, ski resorts now cater to snowboarders by building terrain parks, and the most talented athletes can earn income through contests, corporate sponsorships, and media performances. Though many alternative sport participants continue to view participation in the commercial version of their activities as "selling out," there is evidence of an increasing acceptance of the mainstream status of alternative sports and attempts to capitalize on their current popularity through participant owned

businesses that market equipment and apparel, host demonstrations and contests, and produce videos of sport performances.

While commercialization and social resistance are the most common targets for analysis, researchers have also examined other aspects of alternative sports and their subcultures. For example, sociologists have studied gender relations within alternative sports to determine how alternative sports either reinforce or challenge dominant gender roles. Alternative sports are overwhelmingly a male activity. Approximately 17 percent of skateboarders, 20 percent of surfers, and 30 percent of snowboarders are female. At ESPN's X Games, arguably the most publicized current alternative sporting event, only 15 percent of the competitors in 2000 were female. Of the three most popular events, skateboarding, BMX, and inline skating, only inline skating featured a women's division, and there were six female competitors as compared to 20 in the men's division. While some competitors and ESPN organizers attribute the disparity to a genuine lack of interest on the part of women, many female participants call it sexism.

Male participants in alternative sports often attribute the lack of female involvement in their sports to the difficulty of the activities – claiming, for example, that BMX requires exceptional upper body strength. Advocates of women's participation in these sports contend that it has little to do with physical ability or lack of interest and much more to do with discouragement from male participants. Beal (1995) found that, in her study of skateboarding, girls and women were marginalized as a result of discouragement by male skateboarders and trivializing terminology such as referring to female skaters as "Skate Betties." Although four of her 41 participants were female, Beal found that, within skateboarding, girls and women were most frequently relegated to the role of girlfriend or supporter of male skaters.

Although the marginalization of female athletes occurs in both traditional and alternative sport, gender relations are not identical across the two sport forms. Beal (1996) points out that male skateboarders construct an alternative masculinity that, while continuing to privilege males, rejects the "jock mentality" of traditional sports. Within snowboarding Kristen Anderson (1999) argues that the alternative nature of

snowboarding means that the construction of gender in the sport is different than it is in mainstream, organized sports. She asserts that male snowboarders construct the sport as a masculine practice through a variety of social practices including sporting a "street punk" style of dress, adopting an aggressive and superior attitude, emphasizing the danger of their sport, and stressing their heterosexuality. Because alternative sports like snowboarding are individualistic, loosely organized, and controlled by the participants, standard methods of constructing and enforcing gender are less readily available to male participants than they are in the organized world of mainstream sports, especially team sports, where gender borders can easily be patrolled through the sex segregation of teams.

Other areas of inquiry within alternative sport include issues of identity, subcultural membership and cultural production, and, particularly within skateboarding, the use of urban space. Sociologists interested in the use of public space have studied how skateboarders utilize urban locations for purposes other than what was intended, and, in this way, "disrupt" city space. Methodological approaches in the study of alternative sport have been largely qualitative, employing methods such as participant observation, interviewing, and content analysis of sport media. Future analyses of alternative sports are likely to continue to explore the strategies commercial interests use to "mainstream" these sports, the changes that occur as they become mainstream (as is currently the case within snowboarding), and forms of social resistance employed by participants as they seek to retain some control over the future of their sports. Quantitative data are also needed to assess the reasons for the popularity of alternative sports among participants and to investigate possible future directions for these sport forms.

sport, amateur

Bruce Kidd

Amateurism in sport is at once ideology, a network of sports organizations, and a system of athletic eligibility. First articulated in Victorian England – there is absolutely no substance to the

International Olympic Committee's oft made claim that amateurism governed the athletics of ancient Greece – amateurism melded the upper class desire for social hierarchy with the middle class belief in education, self discipline, and social responsibility. The amateur ideal has always been to improve individuals and society by instilling the values of hard work, team sacrifice, and fair play, and inspiring community pride through inspirational performances. Amateurism resonated with the aspiration to “rational” or “improving” recreation that led urban reformers and the respectable working class to start public libraries, adult education classes, community orchestras and theater companies, public playgrounds, and children's summer camps.

In sport, amateurs sought to enforce adherence to their beliefs through a system of eligibility known as the amateur code. The first codes required competitors to be gentlemen, excluding women, workers, and, in some countries, aboriginals and persons of color simply on the basis of their status. As sports organizations became more meritocratic, in the face of growing working class political power, the spread of democratic ideas, and the outstanding performances of black and aboriginal “professional” athletes, amateur governing bodies replaced the ascriptive code with rules that required participants to adhere to the value of disinterested play. The adoption of amateurism in 1894 by the newly formed International Olympic Committee (IOC) for its quadrennial Olympic Games gave enormous affirmation and clout to this system of regulation and, in many countries, linked it strongly to nationalism. By World War I (1914–18), the principal test of eligibility in most international, national, and local governing bodies, including educational and faith based leagues, was whether an athlete had accepted monetary benefit from his participation or had ever played with or against a professional (i.e., someone who had accepted pay for play).

Although the prohibition against remuneration discouraged working class participation, especially during periods of high unemployment, it encouraged those who could afford to participate to combine athleticism with education and careers and realize the ideals. Not surprisingly, amateurism drew its greatest strength from the male urban middle class. It resonated

with their belief in education, self discipline, and social order, and enabled them to win most of the prizes. In many countries, the advocacy of amateur sport also contributed to the development of more universal programs of sport development in state schools and municipal recreation departments. But when strictly enforced, the amateur rules had telling consequences. Those deemed to have violated them were usually banished from amateur competition, without any of the basic rights of “natural justice” or due process. When the aboriginal American Jim Thorpe, who won the pentathlon and decathlon at the 1912 Olympics in Stockholm by overwhelming margins, was reported to have received \$25 a month for playing baseball, he was stripped of his medals and records. Numerous other athletes met the same fate at the hands of international, national, and local amateur officials. In many countries, the definition of an amateur, and its interpretation and enforcement, often divided clubs, coaches, athletes, and entire sports into warring factions. Not surprisingly, during the heyday of amateurism, the public and scholarly discourse was almost entirely preoccupied by these debates.

By the 1960s, the pressures against a strict financial definition of amateurism had grown to the point where they threatened to split the entire network of Olympic and amateur sports organizations worldwide. The rapid post war growth of spectator sports in the capitalist world gave athletes the incentive to train and compete on a full time basis and sporting goods manufacturers and event impresarios the revenue with which to pay them, while the state financed victories of Soviet bloc athletes in international competitions gave western sports leaders the rationale for liberalization. In 1974, the IOC dropped the term “amateur” from its eligibility code and gave member International Federations the right to set the terms of participation. By 1983, virtually all prohibitions against athletes receiving remuneration were dropped in Olympic sports. These changes were accompanied by new scholarship, which focused on the “social control” represented by amateurism and “rational recreation” and the socioeconomic status of those who benefited.

While amateurism has disappeared as a code of eligibility, the ideas it represents remain as

strong as ever. The amateur ideal continues to provide motivation and legitimation for the vast network of public and voluntary sports organizations in the developed world, as any award banquet speech or appeal to private or government sponsors will attest. Beginning in the early 1990s, the amateurs' claim that sport can serve as a vehicle for education, health, and citizenship has also begun to inform a new wave of "rational recreation" for children and youth "at risk" in the ravaged areas of the developing world, and in international development assistance, particularly at the United Nations. In 2003, the General Assembly endorsed the idea of sport as a major tool of development and peace, and declared 2005 the International Year of Physical Education and Sport. Even the Olympic Movement has retained the structure of amateur regulation in the strict prohibitions against performance enhancing drugs it now enforces through the World Anti Doping Organization. Not all of these interventions are progressive, as concerns about the "assimilative reform" implicit in such well publicized programs as "Midnight basketball" in US inner cities make clear. There is much social scientists can contribute to our understanding of these changes and continuities through an analysis of the auspices of contemporary forms of amateurism and the impacts upon/resistance by the peoples involved.

sport and the body

Pirkko Markula

Given the centrality of the body in sport performance, it might be assumed that the corporeality of athletes has been an essential facet of sport sociological analysis. Despite its vital role, however, the body has occupied "an absent presence" in this research and only since the late 1980s have sport sociologists expressed a growing interest in this topic.

This rather late awakening to the social construction of the body can be attributed to the persistent mind/body dualism that has had a deep impact on how the sociology of sport and sport studies view themselves as academic disciplines. The break of sport sciences from physical education reflected the move away from the bodily experience into an intellectual understanding of sport and a validation of sport as a scientific discipline. Opting for the science route, in its early phase from the mid 1960s to the early 1980s, sport sociology was dominated by structural functionalist theorizing that focused on examining human beings as role actors within social structures ignoring the embodied actor. However, in the late 1980s and during the 1990s, along with other social sciences, the "non body bias" started to lift and there was an increased awareness of the importance of studying how the sporting body has been constructed within power relations.

Examinations of the sporting body have evolved through several theoretical traditions. Inspired by the work of Norbert Elias, several sport sociologists have looked at how the (male) sporting body has become more civilized when molded through different figurations of power over time. This has evolved into further process sociological examinations of interrelationships between the body, power, and identity construction.

Interpretive sociology, particularly the dramaturgical work of Erving Goffman, has inspired sport scholars to examine the presentation of the body in its everyday context. In addition, phenomenological approaches have been used to examine how the lived body is experienced within the sporting context.

Critical cultural studies examine how the body has been shaped by the ideological construction of sport and by the dominant groups that maintain the current structure of sport. In addition, researchers using this approach have drawn attention to how different bodily identities – such as gendered bodies, lesbian/gay bodies, disabled bodies, ethnic bodies, and aging bodies – have been constructed within commercialized, globalized sport. They have also examined how a body can act as site of agency to resist the dominance of the powerful groups in sport.

More recently, the work of French poststructuralists such as Pierre Bourdieu and particularly Michel Foucault have become increasingly visible tools to examine the social construction of the sporting body. Bourdieu's work has enabled sport scholars to locate the body within the context of social fields where different sport practices construct distinctive habitus for its participants. Foucault's understanding of the body as a material site of disciplinary, discursive practices has been used to examine sport as a technology of domination. However, there is also an expanding literature on how the body might act as practice of freedom from the truth games that dominate sport and subvert the ethics of self care. Feminist sport research, particularly, has contributed to growing Foucauldian interpretations of sporting bodies (Markula 2004).

Against this theoretical backdrop, several major topics emerge. One of the major premises for the current investigation of the sporting body as socially constructed is not just about how it is shaped but also about how individual bodies are shaping the power relations in sport. From the modernist perspective, the sporting body is seen as a contradiction: simultaneously being constructed by and constructing the dominant ideologies of sport. Sport, therefore, has been identified to act as a social field that has potential to liberate such oppressed identities as women, lesbian/gay people, disabled, aged, minority ethnicities, or economically underprivileged groups, but who simultaneously conform to the current dominant ideologies of sport. Similarly, different sports, such as male contact sports, have been identified as particular sites for oppressive bodily practices, whereas other sports, such as women's team/contact

sports or women's bodybuilding, have been analyzed as sites for liberation from the structures of power.

Poststructuralist/postmodern theorists aim to expand the possibilities for the body's ability to change the existing power relations by assuming the embodied human being as an anti-essentialist self who, instead of struggling to resist against power that someone else exclusively holds, assumes a certain amount of power themselves. In this scenario, power relations turn from something to be resisted and eventually overturned into a potential source of creative and positive change through bodily practices. These examinations have also transgressed the boundaries of "traditional" definitions of sport to examine bodily dimensions of such popular phenomena as extreme and adventure sports, "trash sport" events such as the performances by World Wrestling Enterprise (WWE), and the fitness industry within the increasingly global economy of leisure.

While sport scholars have used a variety of methods, their examination of the sporting bodies can be located within two broad categories: textual readings of the sporting body and the sporting body as experienced by the athletes. The textual readings range from the representation of women athletes' bodies in the media, to the signification of celebrity athletes in the current socioeconomic climate. Individual bodily experiences have been mapped primarily by interviewing athletes within a diverse range of sports and at diverse levels of sport. These studies have focused on such bodily issues as violence, physicality, the impact of injury in a sporting career, body image, disordered eating, sexuality, sexual harassment, sport for disabled, and becoming disabled through sport. Several researchers have also embarked on interview studies to determine whether a particular sporting body can be interpreted as a transgressive body. In addition to interviewing, ethnographic studies have been conducted to trace the social construction of sporting bodies within such contexts as bodybuilding, boxing, the fitness industry, sport spectatorship, football hooliganism, football industry, adventure sports, WWE, women's ice hockey, and rugby union. There is also a growing literature of autoethnographically based examinations of

bodily experiences. These studies trace, through the authors' personal experiences, how the physically active body has been lived into existence within the structures of power.

The sporting body has been examined from diverse theoretical perspectives using multiple methods to create a rich and varied body of literature. This multiplicity is likely to characterize future research on the social analyses of sporting bodies. However, there appears to be a theoretical trend toward the postmodern/poststructuralist analysis of the body. Therefore, while the modernist body as ideologically constructed into such categorical identities as gender, class, race, or sexuality will persist as part of sociological examination of the sporting body, the performative, postcolonial, queer, cyborg, and embodied postmodern body that is fragmented and in constant flux in the hyperreal, global economy of the sign will feature strongly in future research, as scholars expand their research horizons to further transgress the definitional boundaries of sport. In addition, the storied bodily writing continues to challenge social science research texts through their engagement in performance and performative writing.

sport and capitalism

Rob Beamish

As an analytic term, capitalism refers to the economic system that began to emerge in thirteenth century Europe and extends into the present. Sport is an abstraction that denotes a variety of cultural practices that occur and develop within the context of specific socioeconomic formations. "Sport" and various sports exhibit several particular tendencies and characteristics when they occur within capitalist socioeconomic formations.

As an economic system, capitalism is a mode of "providing for material wants, animated by a definite spirit, regulated and organized according to a definite plan and applying a definite technical knowledge" (Sombart 1930: 196). The spirit of capitalism is based upon a historically unique approach to acquisition, specific attitudes about unfettered competition, and the use of instrumental reason (Weber 1927: 352–68). Acquisition under capitalism is not directly or centrally related to human need; it is focused on money (capital) and its potentially unlimited accumulation. As a result, each economic unit competes to extend its sphere of acquisition as far and as advantageously as possible, using all available means (within the existing penal code).

Instrumental reason pervades the capitalist system, as all economic units plan (usually long term), calculate the best means for acquisition, carefully manage all resources, and develop and

employ technology to enhance profitability and competitiveness (Borkenau 1934). Most important, the "strict adaptation of means to ends, one of the essential ideological props of capitalism, permeates the totality of culture and leads in the course of time to a purely utilitarian valuation of human beings, objects, and events" (Sombart 1930: 198). Within the spirit of capitalism, everything is viewed as a means for accumulation. People are labor power or consumers; nature is a repository of resources; perfecting the business enterprise dominates the working day; progress is the creation of new wants, advances in technology, reductions in costs, and increases in the speed of capital circulation.

Within this socioeconomic context, all of the key issues related to sport and capitalism arise. Sport becomes a market opportunity for owners or promoters to purchase the skills of individual athletes to produce an athletic spectacle that can be sold to live spectators, sponsors, and various media. Athletes are workers engaged in labor processes that are tightly controlled by their employers and the corporations employing them accumulate the profits. In addition, just as the education system develops future workers, youth sports and schools provide opportunities for young athletes to feed into professional sport. To mitigate the excesses of the drive for acquisition and the unbridled application of instrumental reason in industries centered upon maximizing human physical performance in a competitive, zero sum, environment, local, regional, and national governments have more or less successfully regulated different aspects of sport (Houlihan 1991).

The ascendance of town over country as the center of economic activity characterized the early emergence of capitalism. The associated shift in population facilitated the transformation of rural folk and traditional pastimes and games into urbanized, rule bound games and sport forms that could be carried out in defined and confined spaces, creating the conditions for commercialized sport (Ingham & Beamish 1993; Kidd 1996). While amateur sport and tradition tempered the ascendance of capitalized sport forms, the exclusion of workers, the existence of paying spectators, traditions of gambling and gaming, interest among various media, and the spirit of entrepreneurialism

created opportunities for open competitions and professional sport.

The early pursuit of sport entertainment revenues pitted promoters and owners against each other, as they bid for the best athletes to produce the most commercially appealing spectacles. To prevent their own self destruction, owners in many sports formed leagues which acted as cartels to control costs, prevent economic competition internally, and to set prices in the marketplace (Beamish 1988). Though illegal in other forms of commerce, a 1922 Supreme Court decision granted baseball immunity from American anti trust laws – a decision that had tremendous repercussions for all professional sports. The 1922 *Federal Baseball Club of Baltimore, Inc. v. National Baseball Clubs* decision centered on the control of players through the "reserve system." In their efforts to gain the freedom of movement all other employees enjoy, the players in North America used labor laws, the courts, and engaged in open conflict with league owners. After a number of court challenges, it became apparent that athletes' interests could be best defended through unionization and collective bargaining. The leagues in which the players had the most leverage unionized first – basketball in 1954 and hockey in 1967. Organized in 1956 and recognized in 1968, the owners used replacement players in 1987 to break the National Football League Players Association (NFLPA). The NFLPA was recertified 6 years later. From the Brotherhood of Professional Base Ball Players (1885) through to the American Baseball Guild (1946), the attempts to organize baseball players did not succeed until 1965 (signing its first collective agreement in 1968).

Once drastically underpaid and toiling under conditions set completely by owners, collective bargaining has balanced owner–player power relationships so that today's professional athletes in most North American sports receive an increasingly fair share of the tremendous revenues they generate for their teams and leagues. While players' salaries dwarf those of regular working people, their remuneration is consistent with the television celebrities they have become and the revenues accruing to the near monopoly conditions established by team owners.

Pierre de Coubertin launched the modern Olympic Games as a sport spectacle that would

inspire and reestablish traditional values in opposition to the crass materialism and decadence of nineteenth century capitalism. From their inauguration in 1896 through to the present, commercial interests and nationalist political objectives – seen especially in the Nazi Games of 1936 and the Cold War confrontations between 1952 and 1989 – the Games have become as commercialized and profit driven as any other professional sport in the modern era. The International Olympic Committee's 1974 decision to revise the "Eligibility Code" in the Olympic Charter removed the last vestiges of amateurism and any barriers that genuinely separated the Games from other professionalized sport forms (Beamish & Ritchie 2004). The dominant instrumental rationality of the contemporary Games has led to significant questions about child labor, the neglect of athletes' rights, performance enhancing substance use, and financial and ethical corruption (Hoberman 1992; Voy & Deeter 1991). As a movement that began as the antithesis of the capitalist spirit, the Olympic sports now rank among those that are the most deeply entrenched in the drive for acquisition, accumulation, the use of instrumental reason, and a purely utilitarian approach to human athletic performance.

Oppositional forms like "extreme sports" and other alternative sport forms have sprung up to resist the logic of capital, but they are quickly incorporated into the marketplace and begin to display the same ethos as mainstream, commercial, and high performance sport.

sport as catharsis

Michael L. Sachs

The word catharsis comes from the Greek *katharsis* or *katairein*, which means a cleansing or a purging. *Webster's Dictionary* definition reads: "A discharge of pent up emotions so as to result in the alleviation of symptoms or the permanent relief of the condition." Catharsis essentially refers to a release or discharge or cleansing of emotions, generally with the purpose of relieving the stress that develops from holding these emotions within the individual. English and English (1958) talk about "the relaxation of emotional tension or anxiety by any kind of expressive reaction." We often refer to the cathartic nature of sport (and exercise), relieving stress or tension that might build up, or serving as a release for anger and hostility (that may be seen as acceptable on the playing field or in the arena).

In exercise and sport settings the concept of catharsis may actually be seen as encompassing

two possible areas. The most "popular" is the use of sport as a means to express one's anger or hostility in a setting where such behavior is sanctioned. The less commonly thought of application of catharsis is the use of exercise and sport as a stress reducer, a reliever of the stresses and tensions that may build up in an individual.

In considering the most popular use of the term, the thinking is that some individuals have elevated levels of anger or hostility (we all have differing levels of many different personality traits, some more socially acceptable than others). While expressing these emotions overtly is generally considered anti social or even illegal, depending on how and where the expression occurs, the playing field or arena often offers a site where expressing certain emotions is permissible, and even desirable. This is likely to be the case when emotional expression facilitates competitive success. Given the importance in our society of success in the form of winning, coaches in some sports, such as those involving heavy contact, prefer players who express emotions related to aggression and motivation.

Many theories are related to this notion that catharsis is especially valuable for releasing aggression through sport. Instinct theories often assume that we have innate instincts to be aggressive, and catharsis allows us to release them in socially acceptable ways. Little empirical evidence supports this theory, despite its intuitive appeal to many people. The frustration aggression theory suggests that, as the name implies, aggression is manifested when frustration is caused by failure to achieve a goal. But again, little research supports a sport/aggression link because frustration does not always result in aggression, and aggression may be manifest even when frustration does not appear to be present. Indeed, aggressive acts may increase during the course of a sport event rather than decrease in the later stages of the event due to catharsis.

Other theories that apply to aggression (social learning and a revised frustration aggression theory which incorporates elements of the original frustration aggression hypothesis as well as social learning theory) are available, but they have similar weaknesses: some individuals may find exercise and sport settings cathartic in relieving anger/aggression, while others do not

(or even find themselves learning to increase aggressive acts). The general public tends to support the notion that aggressive actions, by athletes and/or spectators, have a cathartic effect. However, research supports the exact opposite: engaging in or viewing aggressive actions often leads to increased levels of aggressive feelings and actions. Additionally, learning theory suggests that for those whose aggression facilitates success (winning), emotions related to aggression are reaffirmed and legitimized rather than being purged or cleansed as catharsis theory would predict.

In psychoanalysis, therapeutic approaches (following the lines of Freud) dealt with recalling traumatic events in one's past and venting these experiences, reaching a point of understanding these emotions, and then cleansing/draining these pent up feelings to achieve symptom relief. Some schools of therapy incorporate the potential healing power of cathartic experiences. This potential may be seen in considering the second use of the term, as a stress reliever. Herein we find a more frequent application of the concept of catharsis, although most exercise and sport participants would not use the term in this way. Many sport participants see physical exercise and sport as stress relievers (although in some competitive situations stress/pressure may be perceived to increase). This is an appropriate hypothesis, and when considering catharsis more metaphorically (or more broadly) it is easy to see that exercise and sport participation could reduce the physical and even cognitive manifestations of tension and stress. Exercise and sport are ideal for this function, especially when stripped of their competitive elements, allowing one to focus on the process of physical activity and the potential joy that comes with human movement. Other activities such as yoga and meditation may be helpful as well. There are, of course, undesirable stress reducing activities, such as drinking alcoholic beverages and using recreational drugs. Exercise and sport, however, are preferred, because they produce physical and psychological benefits in addition to the stress release/catharsis role they may serve.

sport and the city

Kimberly S. Schimmel

As even a casual observer may recognize, the phenomenon of contemporary sports bears little resemblance to that of the fairly recent past. At the turn of the twentieth century, sports were occasional and unregulated events played by members of local sports clubs. In the late 1950s and early 1960s, an individual's association with sport might have been limited to participant, spectator, or consumer of sport news mainly through radio or newspaper. However, as sports became meaningful to more than just the people who played them, the emergence of crowds at local sport club contests provided the opportunity for risk taking entrepreneurs to turn games into profit making ventures. In a relatively short time, traditional agrarian pastimes became today's urban commercial spectacles. Voluntary participation was replaced by binding contractual arrangements, and small hometown rivalries gave way to regional and international urban mega events produced for global television audiences.

Historians agree that the urbanizing landscapes and expanding capitalist economic system that transformed the societies of Europe and

North America fueled the evolution of contemporary sport. The mass production of agricultural and material goods necessary to sustain and stimulate urban growth disrupted traditional patterns of work, leisure, and land use. In large cities such as London and New York, immigrants with widely diverse sporting backgrounds adjusted to the routine of congested urban industrial culture, which created both the demand and the means for the development and growth of sports. Cities were the sites of the dense populations, transportation networks, technological innovations, discretionary incomes, and entrepreneurial spirit necessary for the success of commercial sports. Additionally, cities were the focus of concerns for health, morality, and community, which continually served as rationales for promoting sports to urbanites. Through numerous case studies, sport historians have documented how the development of sport and the development of cities was intertwined. David Nasaw (1993), for example, shows how cities were not just the problems for which sports were an answer; only cities had the necessary conditions and elements to sustain the rapid growth of sports. Other scholars, including Melvin Adelman and Steven Hardy, considered sports as both cause and effect in the development of physical structures, social organizations, and ideologies in Boston and New York between 1820 and 1915.

A dominant theme in the social science literature on sports and the contemporary city is an examination of the ways sports have come to be valued not for their own sake, but as a means to some other desirable end. City governments, for example, support inner city "midnight basketball" leagues in an effort to reduce crime rates. In many cities, sport is advertised as a way to generate a sense of civic pride or to create a civic identity. In cities around the globe, sport stadium and infrastructure construction is promoted to have both tangible and intangible benefits for city residents. The tangible benefits are connected to urban regeneration through the belief that sport facilities will attract elite sport teams and events that stimulate the local economy and create jobs. In turn, this investment in sport related construction is thought to enhance the quality of life for urban community residents. However, many social scientists view with deep caution any notion that sports can act as a

solution to general urban problems. While sports may create a sense of attachment that is important at an interpersonal level, these scholars point out that sports does not significantly change the economic, social, and political realities of every day urban life. Many scholars who study sport related urban development, for example, refute the claim that this type of civic investment provides real benefits for the city as a whole. Empirical evidence shows that while some groups in a city may profit, others are actually burdened. As has been the case since the rise of sport in an urban industrial context, ethnic assimilation, class conflict, control of urban space, and race and gender relations are inseparable from the promotion of contemporary sports.

sport, college

D. Stanley Eitzen

Organized sport competition and institutions of higher education are inseparable in the United States. But the intertwining of the two as found

in the US is not present in other countries. In European and Scandinavian countries, for example, intercollegiate sports competition is virtually nonexistent. Rather, there are club sports outside of the school system where young people in teams compete against other clubs. Canada fits somewhere between the European way and the American system. Jay Coakley and Peter Donnelly describe the Canadian system as one where interuniversity sports are a normal, but not highly significant, part of student life. There just are no parallels with the highly publicized "big time" sports programs in US universities. However, sport in the Canadian schools is akin to other levels of university sport in the US, such as the NAIA level of competition (2004: 453). In short, sports are social constructions. In this sense, sport and education can be organized and played in many ways.

College/university sport in the US is organized into six divisions, five administered by the National Collegiate Athletic Association (NCAA) and one by the National Association of Intercollegiate Athletics (NAIA) (Coakley 2004: 494-6). These divisions reflect athletic budget size, level of competition, rules, and the availability of athletic scholarships. The NCAA Division I is subdivided into three categories: 117 schools with big time football programs (I A), 123 schools with smaller football programs (I AA), and 85 schools without football teams but with big time basketball programs (I AAA). Division II and Division III with 270 and 410 schools, respectively, have smaller programs with smaller budgets and few, if any, full time athletic scholarships. The NAIA has about 300 relatively small schools with meager athletic budgets.

To illustrate the differences, the range in athletic budgets is from \$70 million at Ohio State University to less than \$400,000 at small liberal arts colleges. Large universities may field as many as 18 varsity sports for men and women, while small colleges may have only a few varsity sports, supplemented by a number of club sports. In Division I schools, sports have multiple coaches who are separate from the educational part of their schools, while coaches in Division III and NAIA schools often teach academic classes and may coach two or more teams. The Division I schools are popular on a regional and sometimes a national basis because of

television and other media coverage, while schools in other Divisions play in relative obscurity. And, most significant, at the big time level, student athletes, with few exceptions, are athletes first and students second. At the lower levels, they are students first with the athlete role second. Throughout the world there is no equivalent to the highly commercialized system where athletics supersedes education, as found in the US version of big time college football and basketball.

Big time college sport involves many contradictions. The overarching contradiction is that sport is organized as a commercial entertainment activity where educational goals have been compromised. At the heart of this contradiction is that institutions of higher learning allow the enrollment and subsidization of ill prepared and uninterested students, solely for the purpose of winning games, enhancing the visibility of the university, and producing revenue. This occurs even at the most prestigious institutions where athletes are admitted below the standards applied to others (Shulman & Boyer 2001). Add to this mix demanding coaches who require so much for practice, watching film, travel, weightlifting, and meetings. The athletic sub culture also discourages athletes from identifying primarily with the student role (Adler & Adler 1991; Curry 1991).

Positively, college football and basketball offer entertainment, spectacle, excitement, festival, and excellence. Negatively, educational goals have been superseded by the quest for revenue. Because winning programs receive huge revenues from television, gate receipts, fees for seating, bowl and tournament appearances, boosters, and even legislatures, many sports programs are guided by a win at any cost philosophy, which leads to a second contradiction.

This contradiction is that while higher education should be a model of ethical behaviors, the enormous pressures to win result on occasion in scandalous behaviors. Sometimes there are illegal payments to athletes. Education is mocked by recruiting athletes unprepared for college studies, altering transcripts, having surrogate test takers, providing phantom courses, and by not moving the athletes toward graduation. As a result, the graduation rates of male athletes in the revenue producing sports of

football and basketball are relatively low compared to other athletes and to the general student population.

To this contradiction related to ethics add problems associated with the exploitation of athletes. This abuse of athletes takes several forms (Eitzen 2003). One form of abuse is that athletes' freedoms are restricted. Once athletes sign a contract to play for a school, they are bound to that institution. They make a four year commitment to that university, yet the school makes only a one year commitment to them. If an athlete wishes to play for another big time school, he is ineligible for one year. Yet, if a coach wants to cut an athlete from a team, the school is merely bound to provide the scholarship for the remainder of that school year. Furthermore, the right to privacy of athletes is invaded routinely, for example, with mandatory drug testing and bed checks, social controls not applied to other students. Some coaches insist that their athletes not engage in political protest. Some prohibit athletes from associating with individuals or groups that they deem undesirable, and some demand dress codes, organize mandatory leisure time activities, and even inflict their religious beliefs on their athletes. Another form of abuse, although by no means a universal trait of coaches, involves instances of physical and mental cruelty toward athletes. This may take the form of intimidation, humiliation, and even physical aggression.

A third contradiction found in big time athletic programs is that while universities promote diversity and equity, they have historically denied women and minorities equity in athletics. Using African Americans as an example, they were denied athletic participation in most colleges and universities until the 1950s. Now they are the majority of players in the revenue producing sports of football and basketball, but are underrepresented as head coaches (in 2004, only five of the 117 Division I A head football coaches were African American), athletic directors, athletic trainers, and directors of sports information.

Another area of concern in big time college sports is the dominance of male elite sport. Title IX, which Congress passed in 1972, mandated gender equity in school sports programs. While women's intercollegiate sports programs have

made tremendous strides toward that goal, they lag behind men's programs in participation, athletic budgets, athletic scholarships, and coaches' salaries. Moreover, a majority of women's teams are coached by men and the top administrators of athletic departments are overwhelmingly men. If participation in sport is educational in and of itself, a common rationale that university administrators advance in support of college sport, then these educators are caught in a contradiction because many of them willingly accept, and sometimes actively resist, changes to correct the present maldistribution of resources, scholarships, and opportunities for women's sport.

A fourth contradiction is that although big time sports are revenue producing, for most schools they actually drain money away from academics. This occurs when more scholarship moneys are given to students with athletic abilities than to students with cognitive abilities, and when athletic budgets are supplemented with generous sums from student fees and subsidies from the academic budgets.

Another contradiction involves the influence of money on decision making as the power to decide tends to leave the university and flow toward the sources of revenue. Television money dictates schedules. Prominent donors may influence the hiring and firing of coaches. When a football coach makes over eight times more money than the university president and when the coach has a powerful constituency outside the university, the athletic "tail" often wags the university "dog," thus subverting the independence of colleges and universities (Sperber 1990: 35).

A final contradiction is that although the marketing/sales side of big time sport is big business, the production side is an amateur extracurricular activity in which athletes are "paid" only with an "education" (e.g., room, board, tuition, fees, and books). This limitation is to keep the activity "amateur." Economist Andrew Zimbalist (1999: 6) describes this unequal system as like no other industry in the United States, since it manages not to pay its principal producers a wage or a salary. Meanwhile, individuals, schools, and corporations make huge amounts of money off of these "amateurs" (Sack & Staurowsky 1998).

Dealing with these contradictions presents challenges to university administrators. The most commonly suggested reforms are based on a goal of achieving educational objectives and include the following:

- Athletic departments must not be self contained corporate entities that are separate from the university; rather, they should be placed under the control of university presidents.
- Presidents must monitor athletic programs for illegalities such as recruiting violations, dehumanizing behaviors by coaches, and other unethical acts.
- Athletic departments must also be monitored by an external body other than the NCAA, which has a fundamental conflict of interest.
- Limits should be placed on coaches' income (e.g., no more than the college president).
- Athletes should be paid a living wage.
- Only those athletes who have the potential to compete as students should be admitted – no special admissions and no special curricula for athletes.
- Student athletes must make satisfactory progress toward a degree.
- Time demands on athletes should be kept within reasonable bounds and strictly enforced.
- A comprehensive athletes' bill of rights should be established to ensure a non exploitive context (Eitzen 2003: 131).
- Moneys from student fees and discretionary funds from the administration, as well as from legislatures, should be funneled exclusively to women's sports and to minor men's sports to achieve greater equity.
- The expenditures for football should be reduced by limiting scholarships and the size of teams, reducing the number of coaches, and eliminating costs unrelated to the health and education of athletes.
- The financial spending race should be stopped by placing limits on the amount that can be spent on capital expenditures for athletics.

In light of these suggestions for reform, administrators have three choices. First, they

can retain the current system with all of its contradictions. Second, they can remove the hypocrisy by accepting a semi professional team that is separate from the educational mandate, but this choice assumes that universities should sponsor commercial entertainment activities outside the sphere of education. A third possibility is to shift to a sports system such as that found at the NCAA Division III level or among the NAIA schools where athletic programs are more likely in harmony with educational goals.

What will happen? If history is a guide, university presidents involved in big time programs will push the NCAA for cosmetic changes, but they will balk at meaningful structural changes and passively allow athletic programs to do what they have to do to win.

sport and culture

David Rome

For sociologists subscribing to a hierarchical model of culture, sports may be regarded as its antithesis: a bodily practice, of little cultural consequence, gazed on by passive spectators for the enrichment of the leisure and media industries. The neglect of sports as a sociological subject until relatively recently may be attributed to a common resistance within intellectual culture to engagement with the corporeal realm of popular pleasure. However, the increasing prominence of (especially electronically mediated) sports, a more open minded attitude within sociology to what has often been dismissed as "mass" or "low" culture, and the influence of interdisciplinary approaches (especially cultural studies) has created space for a developed cultural sociology of sport. This shift by no means signals a theoretical, conceptual, and methodological consensus concerning sports and culture in the discipline, but, rather, a new willingness to explore their relationship within a sociological framework.

One obstacle to a sociological engagement with sports and culture is establishing an agreement on the defining characteristics of the objects of analysis, a particular problem given their diversity and dynamism. Precisely what constitutes sports and culture presents, in itself, grounds for dispute, alongside contending evaluations of their relationship. In broad sociological terms, sports can be conceived as the social institution developed out of the rationalization and commercialization of physical game contests that has occurred since the mid nineteenth century (notably, first, in Britain), and culture as the shifting ensemble of symbols, signifying practices, and texts that give expression and

meaning to the social world of which sports is an increasingly significant part. The twin focus of this entry, then, is on the place and influence of sports within the wider sociocultural sphere, and on the specific, rapidly developing characteristics of sports as a “subset” of society and culture as a whole.

SPORTS AND THE “CULTURAL TURN” IN SOCIOLOGY

Many sociologists have noted – and often regretted – the “cultural turn” in sociology that has produced, among other subdisciplinary shifts, an increasing interest in sports. Prior to the 1960s there was a tendency for sociologists to be suspicious of the everyday subjects that appeared epiphenomenal to the main sociological determinants – class structures, state relations, and so on. However, analyzing culture, especially in its popular form, became a more compelling activity in the light of what can be called “culturalization” and “mediatization” – the heightened social, economic, and political importance of the making of meaning and the circulation of symbols, especially through popular media such as television, radio, magazines, newspapers, and recorded music. Stuart Hall (1989: 128) makes this point eloquently in proposing that, in the late twentieth century, a “New Times” had emerged that demanded new perspectives. For Hall, culture is no longer, and probably never has been, the epiphenomenal symbolic superstructure determined by the material socioeconomic base. Culture is now deeply material in its productive processes, and the material world is permeated by cultural practices and meanings.

Sociologists in the post World War II era began to find the objectivist tradition of mainstream sociology (and the streak of puritanic rationalism that it often displayed) overly austere and lacking in contemporary relevancy. The influence of youth culture, for example, now registered in subcultural and deviancy theory, and the popularization and personalization of politics (encapsulated in the catchcry “the personal is the political”) taken up by feminist and postcolonial scholars also resonated within sociology. More sociologists felt licensed to

embrace everyday life as a legitimate starting and reference point for their investigations of the social. Addressing popular cultural subjects like rock music, television consumption, and sports enabled a more reflexive mode of analysis that conceived culture as dialectically constitutive of structural relations, not as the predetermined outcome of them. New strands of social theory, such as postmodernism, and interdisciplinary perspectives like cultural and media studies, challenged the grand narratives of sociological theory and the integrity of its disciplinary boundaries. The distanced, all seeing eye of macrosociology was criticized for producing a universalist regime of knowledge that obscured its own historically conditioned, subjectivist limitations. The cultural turn enabled (mainly male) sociologists who were “closet” sports aficionados (fans), as well as those who had felt victimized by sports (through compulsory physical education at school or by the ideologies embedded in the sports media), to interrogate, critically and self reflexively, their own and others’ cultural tastes and consumption. Adopted excessively, such an approach can be condemned as unscientific, impressionistic, narcissistic, and self indulgent. But with appropriate attention to the enduring questions and techniques of sociology, it is able to illuminate the ways in which contemporary culture (aided and abetted by capital and state formations) is both shaped by and profoundly influences the social.

Taking sports seriously as culture, therefore, was a crucial step in a more general reinvigoration of sociological inquiry. Instead of seeing sports and other forms of popular culture simply from, say, a functionalist perspective – and thereby necessarily emphasizing its adaptive and integrative ramifications for the social whole – it became possible to explore sports as a social domain of contending ideologies and values with a disparate range of relations to social reproduction and change. Similarly, from an orthodox conflict (including Marxist) sociological perspective, sports tended to be seen as a straightforward product of social class relations, especially those involving commodification and “false consciousness,” but a less mechanical engagement with sports as culture offers a more dialectical, complex understanding that is less

reliant on a single, central axis of domination and subordination.

The analysis of sports in traditional macro sociological terms can still be productive, but a culturalist approach, appropriately informed by social theory, is able to draw on a richer, more contingent theoretical repertoire as well as a more intimate, ethnographic insight into how sports culture is “lived” as everyday practice. This intellectual project does not necessitate the abandonment of formative sociological questions of structure, agency, and power, but helps to “rehabilitate” and extend them into hitherto neglected areas of growing prominence. In this regard, sports, by a series of measures, can be seen to be a pivotal element of contemporary society and culture. Its raw popularity as spectacle alone makes it so – for example, it has been estimated that the cumulative audience for the 2002 Korea/Japan World Cup of association football was 28.8 billion viewers; that 9 out of 10 people in the world with access to television watched some part of the Sydney 2000 Olympic Games; and that there was 35,000 hours of dedicated broadcast coverage of the 2004 Athens Olympic Games among 220 countries. Such “mega media” sports events are profoundly instructive about cultural change in (post)modernity.

THE RISE OF SPORTS CULTURE AND THE CULTURAL SOCIOLOGY OF SPORTS

Over the last three centuries, occasional physical folk play and game contests have become codified, scheduled practices, and the love of the game (the “amour” at the root of “amateurism”) has progressively given way to professional spectator sports. The relatively modest remuneration of sportspeople (mostly male) that followed the decline of the class based, aristocratic ideal of the “sporting gentleman” involved first the payment of expenses and lost wages by those who had to exchange their labor power to live; then payment for play that was usually insufficient to provide a living wage; and, later, reasonable returns for “sportswork” for the duration of the usually short and uncertain career of the professional athlete. But, just as in other areas of the labor market where income inequality grew

between fellow workers in the same industry and between industries, so the emerging cultural “sale ability” of sports has produced “superstars” compensated at extraordinary levels. Conspicuous examples of celebrity athletes include the African American basketballer Michael Jordan, surveyed in the 1990s as the world’s most recognizable individual, and English footballer David Beckham, whose high profile, like Jordan’s, derives from “leveraging” his sports standing for a diverse range of pecuniary purposes. The restructuring of the athletic labor market into a tiny minority of the “super rich,” a larger but still small group of modestly rewarded professionals, and a vast number of aspiring professional athletes with little prospect of success, reflects a “structure of culture” in sports that now aligns it closely to the broader entertainment industries.

Even those (the majority of active sportspeople, although not of the whole population) who play sports but earn little or no income from it are part of a large sports industry supplying facilities, clothing, training, and equipment. Thus, professional athletes represent the alluring face of contemporary sports, behind which lies the “industrial” engine that produces it – including sponsors, advertisers, media companies, sports agencies, peak sports organizations, management, equipment and clothing manufacturers, privately and publicly funded sports educators, administrative and training bodies, and research scientists. Systematic planning, design, and operation are central to contemporary sports, while retaining a crucial symbolic element of a spontaneous culture of play.

Sports is, then, both symptom and cause of a much larger sociocultural shift, as the highly localized cultural practices of spatially fixed settlements such as villages and small towns have become concentrated in large urban centers, only for sports to be redispersed in mediated form through their dissemination as images and sounds. This symbolic sports communication, in turn, has become a pivotal means by which national cultural identity can be constructed through the sports press, and public service and commercial broadcasting. Mediated international sports events are extraordinary opportunities for internal and external representations of nation, an inherently ideological practice demanding close sociological interrogation,

not least because of its apparent innocence. This brief sketch reveals how mediated sports culture can attract the interest of sports sociologists, who have found its terrain richly productive, pursuing questions surrounding social relations, economics, politics, ideology, and culture within and beyond the sports world.

Dimensions of Sports and Culture

The major dimensions of the sports–culture relationship concern the impacts of the industrial development of sport, the social ideologies that circulate within the “media sports cultural complex” (Rowe 2004: 4), and the positioning and influence of sports within the wider socio-cultural sphere. In relation to sports and industry, the developments outlined above can be regarded as important elements of the penetration of the logic of capital into everyday culture. Inducing, from the mid nineteenth century onwards, spectators to pay to enter the controlled space of the sports stadium in order to watch paid athletes perform, is a significant instance of the industrialization of leisure time and practice. The combination of the incipient sports industry and the betting and hospitality industries proved an effective way of facilitating the congregation of large crowds and the expenditure of the discretionary income that organized labor secured from the owners of capital. A class cultural dimension to the sports industry reproducing wider social structural relations is an important feature of its historical formation. For example, cricketers were divided by class into (amateur) gentlemen and (professional) players well into the twentieth century, and horse racing – the “sport of kings” – displayed a hierarchy extending from the member’s enclosure down to the “punters” restricted to the open areas of racecourses. As the sports industry has grown and “massified,” these overt class cultural distinctions have been less sharply drawn, but they have not been eradicated. For example, the “bourgeoisification” of contemporary sports stadia, including expensive seating, corporate boxes, and high class catering, has ensured that quality of access and service provision are governed by socioeconomic circumstances. Similarly, the sports labor market

is stratified and segmented, with privileged access to individual expensive sports (such as golf and tennis) more readily available to the already privileged, while in team sports there are patterned divisions of labor that commonly restrict leadership positions to the socially advantaged (the practice of “stacking”).

Although these spatialized aspects of sports culture remain important – major stadia, for example, are invested with the kind of quasi-spiritual qualities that lend support to the proposition that sports is a secular religion – the most important force in the development of sports over the last century has been its increasingly intense relationship with the media. Without the media, sports would be hampered by the restrictions of time and space, with itinerant caravans of sports people displaying their wares in different towns, cities, and countries. This practice is, of course, still evident, but in economic terms it is much less significant than another, more flexible process: the symbolic transportation of the unique sports event to the domestic hearth. The simultaneous development of the sports and media industries has been, although not without some tensions, synergistic. The development of sports was limited while it relied on the staging of events for the exclusive pleasure of those present. Correspondingly, the commercial media could not flourish without regular, popular uses for their communicative infrastructure enabling exposure of large audiences to the advertisers who underwrote their print and electronic texts. In sports, with its large, passionate audiences, regular, relatively inexpensive and “long form” programming, and capacity to function in both news and entertainment genres, the media found an ideal industry partner. As a result, sports became an integral component of contemporary culture, inescapable for all citizens regardless of their cultural tastes because of the efficiency and reach of the sports media.

Because of its intimate involvement with the media, sports is a highly effective bearer of social ideologies disguised as natural, self-evident truths. The sports industry is imbued with a highly performative ethos, with its outcomes organized around measurable qualities and outcomes – winning and losing, faster and slower, stronger and weaker, and so on. When coupled with an ideology of transparent

meritocracy (those who succeed deserve and can be seen to do so) and a mythology of a sports world that stands aloof from the “ordinary” world, sports culture can be seen to offer a microcosm of a simpler, fairer universe. In this sense, there is a close articulation between sporting values and neoliberal ideology. But sports culture also contains within it anti modernizing values reliant on tribalism and collective identity. Sports as cultural practice is arbitrary and trivial in that it consists of rule governed physical game contests onto which meaningful significance is projected by participants and spectators. The often nostalgic (and, indeed, sometimes atavistic) forms of identification on which sports draws its cultural power may, then, release reactionary impulses that are inimical to the “disembedding” that is constantly attempted by modernism and neoclassical economics. For example, as discussed below, the spatial relocation of a sports team (economically classified as a franchise), as has occurred with many grid iron and ice hockey teams in the USA, or the attempted takeover of a sports club, can stimulate anti market, anti capitalist sentiments among sports fans. Such ideological tensions within sports mean that its institutional analysis cannot be reduced to an assumed capture by a commercial ethos. Instead, sports can be seen as a social site – albeit one that is heavily scored with ideologies of dominance – in which the cultural interplay involves social ideologies that are both reinforced and contested.

These ideologies in and of sports do not only involve, directly, matters of capital and labor. The (re)construction of the nation through international sports competition can reinforce, in some instances, racism and xenophobia, but also challenge the power of globalizing processes to erase the specific qualities of the local. Sports culture displays a discourse that is split between universalism (humanity united by the love of and respect for the game) and particularism (humanity fractured into competing, partisan clusters that support one team – sometimes violently – against national, racial, and ethnic others). The critical task of sports sociology is to analyze, “without prejudice,” these fissures and tensions within sports culture.

The linkage between nationalism and gender – the “masculinization” of citizenship criticized by feminists – suggests the potential role of

sports in the cultural “enforcement” of the societal gender order. Sports, like many other cultural forms, is marked at many levels by sex and gender, although there are few forms of culture that have been so clearly and consistently divided by sex (reflected most obviously by sexually segregated competitions). The social construction of sexual difference in sports – its gendered complexion – is an important subject when analyzing the ideological reinforcement of notions of masculine superiority and exclusion.

Sports, both with regard to participation and spectatorship, is historically a key aspect of masculine culture. According to the “objective” performative measures of sports, men dominate in terms of athletic records, athlete remuneration, and spectator interest. Over the last century, in which women have challenged men in many domains – such as the workplace, representative government, and the home – sports has tended ideologically to reproduce male (pre) dominance. Those sports prizing the qualities in which men have an advantage (biologically inherited and socially learned) with regard to strength, speed, and aggression (as opposed to, say, style, subtlety, and cooperation), have consistently been the most valorized in sports culture.

However, the logic of capital accumulation has simultaneously eroded this gender segregation, as the saturation of the male and the neglect of the female spectator markets have been recognized. The commercial importance of television sports spectating, in particular, has prompted systematic strategies to attract the female viewers who also make many of the purchasing decisions on household products. Sports broadcasts are now increasingly tailored to mixed sex audiences, but greater recognition of women as viewers has not been matched by higher status in sports. Thus, apart from a small number of elite sports, such as tennis and golf, and relatively infrequent multi sports events, like the Olympic and Commonwealth Games, the gendered culture of sports is largely one of males and females watching predominantly male sports (such as the football codes of soccer, rugby, gridiron and league, and other major team sports such as basketball, ice hockey, and baseball). Male viewing of female sports is routinely accompanied in sports journalism and

commentary by their sexual objectification, and an emphasis on their performative inferiority (in relation to men), maternal and marital status, and dependency on males. This assertion of “hegemonic masculinity” is also applied to other men, especially those who are homosexual, and is expressed in sexist and homophobic insults in sports (such as “playing like a girl/queer”). Again, however, the gendered repositioning of sports marketing has fostered the sexualization and reconstruction of sporting masculinity, leading sportsmen (such as David Beckham) who adopt a more flexible, (post)modern masculine style, to become subjects of popular debate concerning new forms of manliness.

By such means, the space of sports culture can operate as a forum for wider social debate about change and continuity. Recurrent sports scandals, intensively covered by the media, are especially prominent vehicles for collective reassessments both of the institution of sports and the societies of which it is a part. For example, financial impropriety (such as betting related match fixing in association football and cricket, or secret inducements to the International Olympic Committee members who decide on which city is to host the Summer and Winter Olympic Games) and the use of performance enhancing drugs in sports (for example, in Olympic athletics and weightlifting, and Tour de France cycling), provoke intense debates about the corruption of sports by commerce and the associated privileging of ends over means. Personal indiscretions by sports stars, ranging from the criminal (such as rape) to the individual ethical (like infidelity), also discursively bridge the sports and wider social worlds, enabling the airing of issues that concern both the corrosive effects of celebrity culture and the everyday dilemmas confronting “ordinary” people that are held in common with sports stars. Sports culture, from this perspective, can be regarded as a vivid symbolic canvas onto which grand pictures of contemporary society are drawn, often with reference to idealized representations of the past.

Sports discourse and language is also highly influential in framing the wider society in its own image – the “sportification” of society. As noted above, there is an apparently simple competitive logic within sports that conjures up a world of clearly defined competitors, rules, and

outcomes. As a result, sports metaphors, such as those involving “level playing fields,” regulatory “hurdles,” and “races” for company acquisitions and profit goals, have insinuated themselves into business discourse, not least in news bulletins. Similarly, political discourse in representative liberal democracies is suffused with the language of sports, with electoral contests, parliamentary debates and policy disagreements routinely framed in the language of sports encounters. Advertisers also often “pitch” products and services in sporting terms, with companies and consumers represented as “teams” and “oppositions,” and the visual imagery of sports used to depict producers and consumers. The ideological implications of representing diverse organizations, relations, and practices as analogous to sports phenomena require skeptical sociological examination given their symbolic reduction of complex social, economic, and political processes to simple, imagined sports contests and outcomes.

Such ideological deployments of the culture of sports also impute to it a “purity” of contest (based on talent, tactical acumen, and diligence) that is highly contestable. For example, success in international sports, while often represented as reflecting national character and physique, is also deeply influenced by the resources provided by capital and the state to support the sporting effort. Success in sports, as in commerce and politics, is the product of the mobilization of existing (often inherited) social advantage; “behind the scenes” maneuvering, not all of which is legal or ethical; and contingencies (favorable or unfavorable conditions). The idealization of sports draws misleading, ideologically loaded contrasts between it and other domains of social practice. For this reason, sports sociologists and their counterparts in cultural studies, gender studies, postcolonial studies, and so on, have counseled skepticism when the “lessons” of sports have been extended to other social spheres.

Nonetheless, the resilience and influence of sports culture cannot be underestimated. Elements of sports culture constantly threaten to spill out into the wider sociocultural spaces. For example, viewers of television – the medium that, despite “post broadcasting” challenges by new media technologies such as the Internet, remains the most popularly significant form of

contemporary culture – have increasingly been presented within the high profile television genre of “reality TV.” Formats such as *Survivor*, (*American*) *Idol*, and *Big Brother* are profoundly influenced by sports and sports television. They all involve, like sports, “actuality” coverage of contestants in competition with each other for a prize, shot from multiple angles, points of view, and speeds. The contests require strategic and tactical maneuvers akin to sports contests, with competing teams and individuals, and performative tasks and goals. There is also, like sports, fan participation, including expressions of approval or disapproval of contestants, and large, staged real time events with boisterous audiences. In other words, it can be argued that sports has not only, as is often claimed, taken on the values and practices of entertainment but, by means of a cultural feed back loop, it now influences other major forms of popular culture. Indeed, sports has challenged the prime place of rock music as the principal source of popular cultural “cool” style in the last two decades.

Central to popular culture is the figure of the fan, and sports is a key arena in which a dynamic interplay between culture and commerce in fandom can be discerned. The sports fan is often represented in sports sociology as something of a victim of powerful commercial forces, stripped of agency by the capture of their pastime by capital and the state. The media, in particular, are often accused of taking over sports, with television reducing its physical practice to sedentary spectacle, and shaping sports contests to fit the demands of audience maximization and broadcast schedules. Sociologists have also been critical of the media’s imputed seizure and deformation of sports discourse. Because sports is a cultural form that can be readily adapted to fill cultural space throughout the media – including live, replayed, and edited broadcasts, quiz shows, news bulletins, feature films, documentaries, newspaper sections, photo essays, magazines, novels, and biographies – sports culture can appear reducible to a simple, unidirectional relationship between a range of media producers and passive cohorts of media sports consumers. However, this is a misleading account of how popular culture is made, remade, and used that relies on totalizing and static analyses of cultural relations.

While there is a corresponding danger of romanticizing the resistive agency of the fan, sports culture displays many examples of fandom in action that do not correspond to orderly and guided consumption. Fans are by no means inherently progressive – indeed, as was noted earlier, sports culture is often deeply nostalgic and characterized by xenophobia, leading on occasions to racially motivated abuse and violence. The inequitable gender order described above that is structured into the formal institutions of sports can also be viewed as a common feature of “informal” sports fandom – for example, in the many exclusive, homosocial fan groupings in association football, or in some crowd chants and behavior towards women in sport stadia. In this regard, though, sports culture can be seen to be connected to wider social structures, practices, and values – it would be profoundly unsociological to imagine otherwise. Reactionary behavior and values are not the preserve of sports, but it provides a vivid popular theater in which all forms of signifying practice – whether socially progressive or regressive – can be accentuated and “writ large.” Indeed, the pivotal presence of the media creates circumstances in which sports spectators are not just watchers, but also the self consciously watched, and so can be performing, like the professional athlete, for each other, for others present, and for the vast, unseen television audience. The mediated spectacles that are so central to sports culture are, then, opportunities for spectators to be key participants as essential producers of the atmosphere (“ambience”) of the sports event.

Sports fandom, then, exhibits a number of responses to the transformation of sports and the society of which it is a part. For example, the aforementioned “bourgeoisification” of sports, through which spectatorship is systematically subjected to a commodifying, “civilizing” leisure consumer influence intended to replace earlier unruly, proletarian, and aggressively masculine forms of sports fandom, has provoked some (mostly male) sports fans to protest against its sanitization. The unhappiness of some fans with what they see as clichéd and compromised professional sports journalism has also encouraged the emergence of “fanzines,” which range from technically rudimentary publications with small circulations to more sophisticated, widely read, idiosyncratic magazines

that take both sports journalism and the sports industry to task for their lack of consideration for grassroots fans.

Fan activism can also take on more formal political dimensions, as in the case of lobbying by the Independent Manchester United Supporters Association against the attempted takeover in 1999 of Manchester United Football Club by the dominant force in English football television, the Rupert Murdoch controlled BSkyB. The British government accepted the view, put by these football supporters, the fans of other clubs, and the non Murdoch media, that such a move would overly concentrate power in football, reduce economic competition in the football industry, and have deleterious social effects by disadvantaging smaller football clubs and so their local communities. Here it can be seen that sports culture is a test bed for both economic and social debates, with the proponents of the takeover arguing that the primary locus of the association football industry was no longer national but international (in this case European), and that city based fans look beyond the nation to new, transnational communities (in this case involving supporters of equivalently elite clubs from Italy, Spain, Holland, and other countries). The deregulation of the football labor market through the so called 1995 "Bosman ruling," and its associated freedom of labor migration within the European Union, challenged received ideas of local and national sports, just as the extension of the functions of the European Union, the operation of the World Trade Organization, and other transnational arrangements and agreements have caused wider anxieties. The highly charged area of sports, therefore, can symbolize and articulate in a concrete, dramatic fashion often abstract notions of transnational regulation and national identity.

In the same year that many Manchester United fans agitated against a takeover of the club, in the United States fans of the Cleveland Browns gridiron team (supported by its local elite), following the owner's relocation of the franchise to Baltimore, successfully lobbied the National Football League to award it an expansion team, allow it to retain its key signifiers (name and colors), and even to provide a loan to renovate its stadium. Not all such activist campaigns are successful and, indeed, most of

them are defensive rather than proactive in nature, but they reveal that sports culture is in part created by affective, identity based communities and coalitions that are sometimes able to influence developments in sports, rather than the product of a monolithic "sportsbiz" with an unstoppable commodifying momentum.

Thus, sports fans sometimes identify themselves as citizens who demand respect for the rights of "cultural citizenship" associated with sports. This extension of the concept of citizenship to the cultural domain reflects the strengthening of the broad processes of "culturalization" and "mediatization" discussed above. It registers in the successful petitioning of many governments to enshrine access to prime free to air television sports (as opposed to its delivery only through paid subscription) as part of a citizen's cultural entitlement and heritage, and in the reluctance of peak sports bodies like the IOC to allow sports broadcasting exclusivity to "pay" television operators. It is also evident in agitation to provide citizens' access to sports infrastructure – including community sports facilities, elite institutes of sport, and high quality sports stadia – to be guaranteed by state subvention. Furthermore, opposition to sports sponsorship promoting and advertising unhealthy products (such as tobacco) and support for the use of sports in health promotion campaigns (such as the landmark "Sport for All" and "Life. Be In It" campaigns) have prompted positive and negative intervention in sports by the state. Thus, as sports culture has become increasingly pervasive in social life, it has taken on a range of features, including athletic display, carnivalesque fandom, commercial deployment, and state regulation.

The participants in this culture are, in some form, almost of necessity the entire population, which is confronted daily by sports, willingly or not. The omnipresent signs of sports in public and media space ensure that, to a degree, contemporary culture has been "sportified." These circumstances have stimulated more discerning, interactive forms of sports fandom and consumption. For example, new media technologies have reduced the power of a small number of television companies and their producers to determine when and how a televised sports event can be seen. Digital broadcasting has made it possible for viewers to make many of their

own spectatorial decisions, such as which match to watch in a tennis tournament, which camera angles to use, and what statistical data to summon. The advent of the Internet, furthermore, has created multifarious opportunities for fans to access written sports texts and still and moving images, thereby eroding the centralized power of large media corporations. However, such choices can only be made by those affluent enough to invest in the requisite equipment and services (apart from those provided freely or cheaply by public service broadcasters), thereby indicating that debates about empowering sports fans cannot be isolated from broader questions of social equity and access.

SPORTS AND CULTURE: INTO THE FUTURE

The sociological analysis of sports and culture has to deal adequately with the size, complexity, scope, and volatility of its immediate subject, and then to seek to encompass its deep intrication with the sociocultural world as a whole. This is no mean task, and, as Crawford (2004: 111) has noted in relation to sports fandom and consumption, there has been a strong temptation to concentrate on out of the ordinary phenomena and to advance already constructed theories founded on binary notions of hegemony and resistiveness. Crawford complains that little serious attention has been given to the mundane, everyday experience and consumption of sport, with researchers drawn to unrepresentative groups of especially ardent fans, whose very conspicuousness makes them relatively easy to research. Thus, he argues, sports researchers have tended to conceive sports fandom as an artifact of a theoretical predisposition that neatly divides it into dichotomous clusters of passive sports consumers and actively resistant sports fans. This observation is a reminder of Raymond Williams's famous dictum that "culture is ordinary." Sports culture, it might be observed, is now an ordinary element of social life, punctuated by extraordinary moments, both of which offer multiple opportunities to research the dynamics of increasingly heterogeneous, evanescent social formations.

Sociological inquiry into sports and culture is, then, an exacting exercise. It has been

limited, once belatedly commenced, by inherited dualistic theoretical frameworks, with a functionalist assessment of social adaptation and integration posited against a conflict theory based (often Marxist inflected) critique of sports culture. Each tradition has produced its own variants and developments, with those emphasizing the more benign ritual dimensions of sports culture challenged by assertions of its repressiveness, although sometimes conceding that sport can be a site of popular cultural "productivity" where structures and ideologies of dominance are countered by (self reflexive or unconscious) communities of resistance. The theories and methods adopted in this field of research and scholarship have tended to reflect these divergent positions. Disciplinary debate is crucial to the health of sociology, but the divergent approaches of political economy, ethnography, discourse analysis, textual interpretation, and so on evident in analyses of sports culture have often resulted in an unproductive series of parallel, disconnected conversations.

In current and anticipated trends, though, there are some signs of more auto critical and less predictable approaches to sports and culture. These are less likely to imply that sports culture can be hermetically sealed from its global, national, and local social context, and are more attuned to the specific, contingent ways in which sports culture can exert its influence on wider society. This research and scholarship demands a closer attention to what constitutes sports, how it is mediated, and the diverse, structurally influenced ways in which it is encountered and used by human subjects in their various social locations and relational networks. The overwhelming available evidence is that sports is an increasingly important component of culture and society in nations with conspicuously different histories. The global "club" of sports is no longer exclusive (there are, for example, currently 202 National Olympic Committees across five continents), but the power that can be wielded within sports culture is highly variable and clearly related to other resources of power (including economic, military, and geopolitical). The form that sports culture takes in different national and transnational contexts is both highly diverse and globally connected, and demands a rejuvenated, theoretically rigorous, historically informed,

and culturally attuned sociology of sports and culture.

sport culture and subcultures

Peter Donnelly

Research and theoretical approaches to sport culture and subcultures in the sociology of sport fall into three overlapping periods: (1) early interest in sport subcultures from an interactionist perspective; (2) a transition period during which more critical theoretical approaches to culture and subcultures and more rigorous methodological approaches emerged; and (3) a wholehearted embrace of “cultural studies” and the consequent fragmentation of approaches to sport culture and subcultures. These changes were accompanied by parallel theoretical and definitional concerns about the meaning of culture and subculture.

Following the example of sociologists such as Howard Becker and Everett Hughes, some of the earliest work in the emerging subdiscipline of sociology of sport concerned sport subcultures. Weinberg and Arond's (1952) study of boxers preceded studies of professional baseball players, professional wrestling, pool hustlers, ice hockey players, and the various jobs involved in horse racing. These were followed by a series of striking comparative studies of, for example, hockey players and Hollywood musicians, professional wrestlers and physicians, and female gymnasts and professional wrestlers.

These studies of occupational subcultures were grounded in the US tradition of subcultural research. Definitions of culture had not really developed beyond Tylor's (1871) “complex whole which includes knowledge, belief, art, morals, law, custom, and any other capabilities acquired by man as a member of society.” Culture was that which humans passed along socially, rather than biologically; subcultures

were sub units of the larger culture; and even Fine and Kleinman's (1979) attempt to "rethink" subculture maintained a basic interactionist definition in which "the referent group" encourages potential members to take on the cultural characteristics of a particular subculture. The original subcultural research in sociology, focusing on youth and deviance, had spread from "deviant careers" to other occupations and avocations, and Arnold (1972) provided justification for the study of sport subcultures by arguing that they "have a sociological importance in and of themselves." Arnold proposed that membership in such "achieved" (as opposed to ascribed) subcultures provided an alternative identity status as the institutional significance of work decreased.

Ingham (1975) signaled the critical shift in the sociology of sport subcultures by combining Marx, Weber, and Goffman in his analysis of "occupational subcultures in the work world of sport." His work was contemporary with a "cultural turn" in both sociology and the sociology of sport. Culture was no longer something relatively inert, "meanings and ways" that were passed from generation to generation; rather, it was a social construction, a site of struggles, something that was produced, reproduced, and resisted – and subcultures could now be seen as both the engines of cultural production and the battlegrounds for contesting culture. As Bourdieu (1993) pointed out: "The field of sporting practice is the site of struggles in which what is at stake, *inter alia*, is the monopolistic capacity to impose the legitimate definition of sporting practice and the legitimate function of sporting activity."

Thus, in sport, these struggles were fought over the "meanings and ways" of what was now being recognized as a dominant sport culture – a culture that was outcome, achievement, and record oriented; a culture that was characterized by homogenizing principles of governance and commercial interest. In the dominant sport culture, sport was rationalized and utilitarian – it was for the purposes of entertainment and/or to encourage civic/national pride; it was to demonstrate the effectiveness of a political ideology (e.g., Olympics during the Cold War); it was for the purposes of health (in the new era of privatized/personal conceptions of health); and it was primarily for socialization – character,

work habits and discipline, individual achievement and teamwork, etc.; or even just to occupy the time of those considered to be "dangerous" or "youth at risk" (e.g., "midnight basketball" for the social control of urban youth).

Studies of sport subcultures slowly began to incorporate these changes, influenced both by Geertz's (1973) "thick description," which produced richer and more nuanced ethnographies, and by the more politicized ethnography and subculture theory that was developing at the Centre for Contemporary Cultural Studies in England. Although the broader notion of "career" was still at the root of most research, there was also the beginning of a change toward socialization and identity factors in sport subcultures, an interest in class cultures and sport, and the beginning of a focus on sport subcultures as sites of cultural production. Gruneau (1981) pointed out that the study of sport subcultures now concerned how "subcultures, with their various 'establishment' and 'countercultural' emphases, have been constitutively inserted into the struggles, the forms of compliance and opposition, social reproduction and transformation, associated with changing patterns of social development." Bishop and Hoggett (1987) similarly argued that sport and leisure subcultures are crucial sites for the transmission, resistance, and negotiation of the dominant values of the larger society.

Research during this second period maintained an interest in careers – extending that interest to the life cycle of a career in sports, and to processes of socialization and desocialization or retirement from participation (for a collection of studies representing this type of research, see Coakley & Donnelly 1999). Identity issues also began to emerge in terms of how individuals developed appropriate subcultural identities and how those identities are negotiated and accepted (or not) by other members.

Further evidence of transition during this period concerns what are now referred to as alternative or extreme sport subcultures – they were "alternative" to the dominant sport culture, openly rejecting many of the "meanings and ways" noted above. Earlier research on sports such as surfing and rock climbing had focused on the activities as deviant subcultures; research emerging at this time began to reinterpret the alternative nature of such subcultures as

"resistance" rather than "deviance." This work also led to recognition of the ephemeral nature of resistance to the dominant sport culture, and the ways in which activities such as freestyle skiing, skateboarding, and snowboarding were subject to commercial and media pressures, and to incorporation by the dominant sport culture. The life cycle of freestyle skiing, from its "hot dog" origins, resisting all of the trappings of mainstream sport, to almost complete incorporation into the international skiing federation (FIS) and recognition as an Olympic sport, represents a classic example of such resistance and incorporation (Donnelly 1988). Using Raymond Williams's approach to hegemony and resistance, Donnelly (1993) also showed how alternative cultural formations were evident in both residual and emergent contexts.

Recent research on sport culture and subcultures represents a completion of the shift toward cultural studies evident in the transition period, and an increasing fragmentation of approaches to subcultures parallel to the broader fragmentation of approaches to sociology following the postmodern turn. In addition to an increasing interest in identity work in sport subcultures, there has been increased interest in (and opposition to) the idea of a global sport culture, increasing amounts of research on fan culture and celebrity culture in sports, and a substantial focus (given the embodied nature of sports) on body culture. Research in the sociology of the body now covers a wide range of bodily practices, including sports. As Bourdieu (1993) pointed out, the definitional struggles associated with sport also extend to defining the "legitimate body" and "legitimate uses of the body." Definitional concerns have also reappeared with regard to the concept of subculture itself, with some contending that "subworld" represents a better descriptor than "subculture" of the cultures that emerge around sports; they argue that "subculture" implies a condition of domination and subordination that does not exist in some sport "subworlds." And theoretical issues range from concerns that some researchers have overused the concept of resistance to the point that it no longer has a political impact, to concerns that studies of subcultures imply a homogeneity of culture where heterogeneity is widespread.

Recent research suggests that sport sociologists will continue to be interested in fan

culture, celebrity culture, and body culture in sports, and interest in alternative sport subcultures is increasingly popular. To the extent that sport subcultural research continues to shed light on the historical processes by which a way of playing a sport becomes *the* way of playing the sport; on the ways that cultural meanings and ways are produced in sport subcultures; and on the ways in which sport subcultures are involved in larger processes of resistance, social reproduction, and social transformation, such research will continue to be of interest to sociologists. The recent reemergence of interest in class cultures in sport suggests that this is still the case.

sport and the environment

Otmar Weiss

Everything outside the boundaries of the sub system *sport* is considered to be its environment, and this can be influenced and altered by sport or, conversely, can itself influence sport. Examples of the latter are to be observed, for instance, in the effects on athletic performance of certain climatic qualities of the environment of Mexico City (tropical uplands) during the Olympic Summer Games 1968, or of Lagos (humid tropical lowlands) during the Pan African Games in 1973. In the sociology of sport it is principally the first mentioned influence – sport on the environment – that is the subject of discussion and study, and in particular the integration of sport in ecosystem structures is at the centre of consideration.

Since the United Nations Conference on Environment and Development (UNCED) in 1992, the guiding principle of sustainability has been internationally recognized. This principle says that nature must be protected from over exploitation so that it will be available to future generations in sufficient quality and quantity. And it is also a guideline for sport (e.g., when choosing the location for sports grounds). Here it is important to exploit areas which can stand ecological strain, and to spare sensitive areas (Schemel & Erbguth 2000: 13–22). This principle not only applies to the construction of buildings and development of sports grounds, but also to the practice of outdoor sports. Originally looked upon as harmless leisure activities, they are now being subjected to harsh criticism. For

even though sport is a secondary problem compared with the main causes of environmental destruction (agriculture, industry, settlements, and traffic), it is nevertheless imperative to reconsider various aspects of the subject “sport versus environment.”

Noxious emissions and pollution caused by sports tourism and by athletes and spectators traveling to and from events must be mentioned in this context. There is also the construction of stadia, hotels, roads, etc., all too often in other wise unspoiled countryside, and sometimes exclusively for one single big event, such as the Olympic Games. A further matter for discussion is the huge consumption of energy at big athletic events, and all the effects of various individual sports, such as alpine skiing, on the environment. Every year 120 million tourists and athletes go to the European Alps. This figure makes it clear that the compatibility of sports and leisure activities in the Alps with nature and the environment must be subjected to scrutiny in the light of the principle of sustainability. Building ski lifts not only means the loss of trees and the natural appearance of the local landscape, but, above all, also results in damage to vegetation cover due to the use of crawler type vehicles, which also brings up the question of erosion. Then there is the damage caused by each individual: the noxious emissions produced during travel to and from the mountains, garbage, ski wax and waste water left on site, vegetation damaged by skiing off piste or when there is too little snow to protect it (Weiss et al. 1998). This is discussed more often since 1990 due to recent climatic changes. On the other hand, all the alpine ski pistes and slopes together only represent a total of 0.9 percent of the entire area of the Alps (Baetzing 1997: 215), so that damage to mountain regions is in effect very slight.

The effects of sport on the environment need not necessarily be negative. Opinions can be subjective and often differ greatly. Laying out a golf course, for instance, will probably be regarded by conservationists as a negative alteration to the natural environment. Golfers, on the other hand, will look upon it as conservation of the countryside. This is mainly due to differences in the appreciation of nature. For those who understand “natural” to mean “unspoiled” or “untouched,” sport appears to be a threat to the environment, for it brings mountain bikers,

joggers, hikers, riders, skiers, and other sports people into regions hitherto unused by human beings. However, if humans are seen as a legitimate part of a common habitat together with flora and fauna, then specially bred plants, flowerbeds, paths, or skiing pistes are all part of nature. From this point of view, sport has a positive effect on the environment, in that it gets human beings out of their over heated living rooms and air conditioned cars and (following Rousseau) back to Nature.

sport and ethnicity

C. Richard King

Ethnicity has proven fundamental to sport. It has long determined who has played, what participation and performance has meant, treatment by fans, media representations, and presentation of self.

Ethnicity is closely related to race. In fact, the two concepts are often confused with one another and used interchangeably, because both provide means to classify and organize observable differences among people. It is important, however, to distinguish between them, particularly in the context of sport. Whereas race describes the use of biological features, especially skin color, to understand people and define social groups, ethnicity refers to the use of cultural characteristics, including language, nationality, country of origin, and custom, to

make sense of others and create social groups. While the physicality of sport rightly directs attention to issues of race and racism, the relationships between ethnicity and sport afford keen insights into the formation of identity, community, and society.

ETHNIC IDENTITY

Through sport, ethnic groups define who they are or aspire to be, the values that matter to them, and what distinguishes them from other people. In a very real sense, sport has facilitated the creation of imagined communities: athletic performance and circulation of it through print, visual, and electronic media encourage individuals to identify and connect with others, seeing themselves as part of a common people, or ethnic group. The capacity to play and watch sport has proven to be especially meaningful for ethnic minorities, particularly when great performance offers a foundation for pride and celebration.

In many instances, a particular sport becomes emblematic of a people. Baseball, for example, is said to be America's pastime and as American as mom and apple pie. Similarly, hockey has come to be closely associated with Canadian identity and rugby with what it means to identify oneself as a New Zealander. And ethnic groups, particularly native peoples, increasingly have sought to revive historic sporting practices as a means to reinvigorate heritage and culture.

In other cases the style of play becomes a means to claim or refuse a particular ethnic identity. In the US, the flamboyance, creativity, individuality, and flair associated with the black urban culture has transformed contemporary sport and society, providing African American and Euro American athletes and fans an important reservoir for the presentation of self and the nurturance of social networks. Negative public perceptions of this style of play and its association with urban blackness have also caused gatekeepers to affirm the values defining whiteness through controlling transgressive expressions. Similarly, the hard and fast style of cricket cultivated in the West Indians not only radically changed the sport, but it also became a powerful affirmation of ethnic identity. Increasingly, corporations and sport teams, mindful of ethnicity

and style, have capitalized upon ethnicity to attract fans and sell products.

Increasingly, over the course of the twentieth century, sporting spectacle offered important occasions for ethnic and national groups to present themselves. The opening ceremonies of the Olympic Games provide an excellent illustration of this pattern. In 1936 the Nazi regime used the Summer Olympics in Berlin to articulate a muscular, romantic vision of Germanness, while giving material expression to its anti-Semitism. The Summer Olympics in Mexico City in 1968 witnessed a much more oppositional statement when African American athletes raised their fists in a black power salute on the award stand, affirming an ethnic identity too long marginalized and demonized. The Calgary Winter Olympics in 1988 were also the scene of ethnic protest. The Lubicon Lake Cree Band used the ceremonial torch run passing through Saskatchewan in advance of the games to bring attention to their ongoing land claim disputes and the destruction of their culture.

It would be a mistake, however, to think of the assertion of ethnic identity through sports to be a matter of choice free from the constraints of history or power. In fact, a range of factors, including cultural expectations, political access, social location, and education, delimit the capacity of ethnic groups to articulate an identity audible to all. Making matters worse, stereotypes, bias, and misconceptions often influence public understandings of athletes and athletics. Indeed, research shows that media coverage, beginning with the emergence of modern sport in the nineteenth century, has displayed a propensity to frame players in ethnic terms. In the US, Canada, Australia, and Great Britain, for instance, the media have lamented the minimal work ethic and discipline of athletes of color, while emphasizing their natural abilities, and in turn, have praised white athletes for their hard work, intelligence, and leadership abilities.

In many ways, Tiger Woods offers a striking example of the limits and possibilities of ethnic identity in sport. The celebrated golfer has sought to be identified and accepted as *Cablinasian*, a term he created to encapsulate his multi ethnic heritage. Supporting Woods's hybridity, Nike ran a series of ads in which kids from a number of distinct ethnic groups proclaimed, "I'm Tiger Woods." Most journalists,

commentators, and fans, however, worked hard to assign a singular identity to Woods. Many observers sought to claim Woods, taking him as an example of African American or Asian American excellence and a source of ethnic pride. Media coverage, in turn, frequently presented the golfer in terms that broke with conventional understandings of blackness, but when Woods was not successful, stereotypes of the black athlete became more common.

ETHNIC RELATIONS

While many commentators and fans have pointed to sport as a prime example of multiculturalism and social progress, athletics actually is a much more complex arena of ethnic relations, at once highly visible, saturated with power, and often very contentious. Sport often emerges as a borderland or middle ground that has promoted efforts to assimilate ethnic minorities, encouraged ethnic groups to challenge the precepts and practices of mainstream society, and prompted countless cultural borrowings and social reinventions.

Sport socializes. Sport teaches. It conveys important ideas about the social order. When incorporated into school, physical education and extracurricular athletics have proven important to the efforts of multi ethnic states to deal with perceived social problems. Through sport societies seek to nationalize those deemed foreign – immigrants, indigenous peoples, and other ethnic minorities. In the US (and Canada), boarding schools were established in the late nineteenth century for Native Americans. Over time, athletics became increasingly important to efforts to Americanize indigenous peoples, or as it was often put at the time, "kill the Indian, to save the man." Educators hoped to instill a competitive spirit, discipline, morality, and manliness. In time, they would come to see sports as a powerful public relations tool that might elevate public perceptions of Native Americans, easing the process of assimilation as it eroded misconceptions and prejudices. As Native American boarding schools began to fall out of favor in the 1920s, the post revolutionary Mexican government sought to use physical education for similar ends, namely to unify a multi ethnic country around shared values.

In contrast to its northern neighbor, the effort was not focused on eradicating Indianness. Instead, it amplified ethnic difference, incorporating indigenous practices into the physical education curriculum to forge the hybrid, *mestizaje* nation it envisioned Mexico becoming. Importantly, in both of these examples, athletics in education target ethnic minorities, affixing the problems of broader society on their backs.

In neither case did sport ease ethnic tensions or misunderstandings; however, in both instances sport proved to be especially transformational precisely because the play of sport simultaneously changes individuals and invites differently situated players in turn to change it. Encouraging interaction among different ethnic groups, sport offers a space in between, a meeting ground in which ideas, practices, games, pleasures, and possibilities can be shared, exchanged, and borrowed. Ethnic minorities often adapt individual sports to their own ends. In addition to the play of cricket and basketball previously discussed, the introduction of cricket to the Trobriand Islands is instructive here. Missionaries hoping to acculturate Trobrianders and offer them a substitute for warfare taught them to play cricket. Much to the missionaries' chagrin, however, the islanders rewrote the rules of the sport and used matches as occasions to perform traditional rituals and magic. Dominant ethnic groups remake games played by marginalized groups as well. After watching and playing it for years, Canadians appropriated lacrosse from Native groups, taking a traditional sacred cultural complex and turning it into a rationalized and secular sport that looked quite different. Later, lacrosse organizations in Canada banned First Peoples from participating in sanctioned matches. At the same time, sport has allowed marginalized ethnic groups to survive in hostile social environments. On the one hand, many immigrants play games brought with them. Latino soccer leagues in urban areas in the US allow participants to establish important social networks, find work and community, and maintain connections with homelands. On the other hand, ethnic groups often turn to sport in unbearable social circumstances, such as Japanese Americans in internment camps during World War II.

In highly stratified societies, where the distribution of rights and resources turns on

ethnicity, there are limits to the creativity and freedom afforded by sport. Indeed, as in other social domains, sport has long exhibited pronounced ethnic inequality. Ethnicity has been the basis for exclusion from competition. It is common knowledge that indigenous peoples were barred from lacrosse in Canada, African Americans could not participate in baseball, football, and myriad other sports in Jim Crow America, Jews were marginalized in athletics under the Nazi regime, and Asian immigrants could not play as equals in Great Britain. Even more commonly, ethnic minorities have endured discrimination in position assignment and coaching opportunities, while suffering persecution as they have taken the field and played the game. At the same time, the marginalization and underdevelopment of ethnic communities frequently translates into extremely limited social and economic opportunities. Ethnic minorities regularly turn to sport as a means to achieve a better life. In fact, the history of sport in virtually every country throughout the world parallels its history of immigration; successive waves of immigrants enter into particular sports, only to be replaced a generation later by a subsequent, more newly arrived ethnic group. Only a small fraction of athletes ever achieve their dreams of playing professional sport, suggesting that it is an uncertain path to upward mobility which misdirects energies and aspirations and in turn furthers the underdevelopment of marginalized communities.

Finally, sport is a site of social struggle and ethnic resistance. The ongoing controversy over the use of American Indian names, images, and symbols in sport provides an excellent example. For nearly a century, Native American mascots have reflected and reinforced dominant notions of masculinity, citizenship, and history. Over the past 35 years, a multi ethnic coalition, led by American Indians, has challenged such symbols, asserting that they misappropriate, misuse, and misunderstand indigenous culture and history. They have protested and petitioned, pressing educational institutions and professional teams to change their mascots. In many ways, the controversy has derived in part from efforts to defend traditional formulations of identity in the US, especially its foundations in ethnicity (whiteness), gender (masculinity), nation (Americanness), and history (the myth of the

frontier). It also reflects deep interpretive differences. Whereas supporters insist that mascots foster respect and are meant to honor Native Americans, opponents assert that they denigrate Native Americans, perpetuating historical patterns of discrimination and dispossession. Moreover, supporters stress text (honor, intention), while opponents emphasize context (history and racism).

Ethnicity has been central to athletics since the emergence of modern sport in the nineteenth century. It has proven particularly important for the articulation of ethnic identity and the shape of ethnic relations. As sport becomes increasingly global and mass mediated, the relationships between ethnicity and sport undoubtedly will become more intense and intricate.

sport, professional

Jim McKay

According to the ideal type suggested by Freidson (2001), sport does not exhibit all of the characteristics of a profession. Unlike

archetypal high status professions (e.g., medicine) in which the practitioners rather than governments or markets exert significant control over their labor, professional athletes work in cartels and oligopolies where they must respond to the demands of owners, managers, coaches, sponsors, consumers, and the media. Thus it is more appropriate to say that like many institutions, sport exhibits particular *professionalizing tendencies* (e.g., specialization, relying strongly on expert knowledge). However, these professionalizing propensities can only be understood if they are located in a complex of five other interdependent and mutually reinforcing processes that have shaped modern sport from youth leagues to the international level: commercialization, commodification, bureaucratization, globalization, and governmentalization (Gruneau & Whitson 2001; Miller et al. 2001; Ingham 2005).

Modern sport has been transformed into a multibillion dollar global industry that employs millions of professional athletes, administrators, coaches, scientists, and lawyers. Paying this labor force would be impossible without the income that sporting organizations generate from gate receipts, the sale of media rights, and contracts with sponsors from the business world. It is crucial to emphasize that commercialization, commodification, and mediatization are not simply economic phenomena. For instance, commercialization and commodification simultaneously both constitute and are constituted by discourses in the sporting media. At a more general level, Rowe (2004: 95–6) refers to the *culturalization* of all institutions, noting that despite being progressively more commodified and commercialized, “sports events have become the most important, regular manifestations of . . . national culture.”

Commercializing and commodifying sport occurred in tandem with the replacement of part time volunteers in informal community organizations by national and international bureaucracies administered by full time professionals holding degrees in business, economics, marketing, public relations, and management. Thus sport has gone from being discussed around the kitchen table to being managed by the executive office (McKay 1997). For example, virtually all private and public sporting organizations now have an executive director

overseeing managers who monitor their business, operational, and strategic plans.

The Olympics, various World Cup events, and the Super Bowl are some of the most popular entertainment events in the world. One outcome of the integration of sport into the global entertainment industry has been the creation of "celebrity athletes," in whom multinational corporations invest vast sums of money in the form of endorsements and sponsorships. Like other sought after and mobile professionals, elite athletes and coaches have become "flexible citizens" who switch nations and even nationalities for commercial purposes. Like most global processes, this one is based on the capacity of powerful nations to exploit disadvantaged ones.

The commercialization, commodification, bureaucratization, and globalization of everyday life have been facilitated by governmentalization, the process by which capitalist states have steadily calibrated and managed the conduct of their citizens. Citizens today are the objects of myriad private and public strategies that frame health, well being, lifestyle, fitness, quality of life, and "at risk" behavior as a matter of individual responsibility (Rose 2001: 5–7). This important shift in biopower means that professional experts have become increasingly authoritative in spheres that were not traditionally subjected to direct intervention by private and public agencies. Thus most nations now have government departments responsible for the national planning and funding of "amateur" sport, which are often linked with health, lifestyle, and physical education programs (McKay 1997; Howell & Ingham 2001).

In this regime of biopower, professional athletes have become classic "somatic individuals": both participants in and targets of "molecular politics," with their technologies of self government articulating favorably with the emphasis by professional experts in both the private and public spheres that individuals must accept responsibility for managing their lives (Rose 2001). Thus cyborg athletes gradually subject their bodies to a plethora of legal and illegal performance enhancing techniques. Moreover, all of the above processes have transcended their origins in capitalist states and now pervade virtually *all* formal organizations worldwide.

There are immense qualitative and quantitative differences between organized sport when

it was the pastime of mainly Victorian gentlemen amateurs and the current hegemonic "power and performance model" (Coakley 2004: 110–12), which features the professionalizing developments outlined above. Although these professionalizing trends cannot eliminate all other forms of sport, alternatives seemed destined to occupy a marginal status, given that they exist in a context in which there is heavy reliance on the knowledge of professional experts who continually try to improve athletic performance by the tiniest fraction. Like life in effectively all formal organizations, the tradeoff for the rewards that flow from submitting to this professionalizing regime is the unremitting "government of the soul" (Rose 1999).

sport and race

Ben Carrington

Sport and race have been in complex articulation since the nineteenth century, yet a *critical* sociology of sport and race has only developed substantially since the 1990s. In the 1960s a few academic studies and journalistic accounts examined segregation and racial discrimination in sport, but these were largely descriptive. Two exceptions to this were C. L. R. James's critical reading of the role of cricket in shaping West Indian political identity in the anti colonial struggles of the 1950s and 1960s, and Harry Edwards's important account of the radicalization of the black athlete in the context of America's Civil Rights Movement of the 1960s and black nationalist politics of the 1970s. In the 1970s and 1980s sport sociologists began to investigate continuing racial discrimination in sport with a liberal focus on issues of equity and opportunity, normally using quantitative methods to measure the degree of meritocracy in sports. More recently, scholars have used cultural studies approaches to examine questions of representation and ideology in sport media texts, and ethnographic methods to understand racial identity construction in sport and its intersections with class, nation, gender, and sexuality.

SPORT AND RACE AS SOCIAL PHENOMENA

"Sport" and "race" are sociologically problematic because, at first sight, both appear to be aspects of human life that are immediately knowable and products of a natural physicality that precedes socialization. "Race," the division

of humanity into biologically discrete groups based on phenotypical markers, is commonly believed to be the result of an inherent, fixed, and natural distinction between actually existing groups. But sociologists and biologists alike have demonstrated that the supposed "natural" division of humanity is unrelated to underlying genotypical distinctions. Instead, racial distinctions are based on arbitrarily chosen physical features, such as skin color and hair texture, that are used to demarcate people into groups. Thus, "race" is a complex system of representation learned through socialization, and then acted upon as if these distinctions were "real." In short, "race" appears to be a biological fact of absolute physical difference when it is actually a socially constructed and culturally reproduced set of ideas and beliefs.

Similarly, "sport" appears to be a purely physical activity that is separate from the wider divisions and structures of society. Although we might immediately recognize the social conditions of education, cultural capital, and aesthetic discernment that frame the production and consumption of other cultural forms, sport is commonly seen as an activity that is "simply" physical and open to all regardless of class, gender, race, or sexuality. Barriers in sports, it is believed, exist only in connection with the physical abilities and motivation of individuals. This view of sport as "free" from structural constraints means that sport's role in maintaining and reproducing power relations is underestimated.

Sociologists of sport have sought to explain how the sports we choose to play, the ways that we play them, the meanings we give to and take from them, and the material and social rewards associated with participation and success are intimately related to the structure and organization of societies. Given this, it requires great sociological imagination to go beyond such everyday understandings to reveal how both race *and* sport, far from being universal, naturally occurring phenomena, are actually the result of temporally bound and historically specific human action. In short, the interrelationship between race and sport is a deeply sociological articulation with profound political consequences for how we generally understand racial difference and who has access to sport itself.

RACIAL SCIENCE AND EMPIRE

There is an interesting historical parallel between the emergence of the scientific foundation for ideas of racial difference and the formation of organized, codified, competitive sport. Racial science – the scientific belief in the inherent superiority of white Europeans – developed into a coherent set of ideas during the nineteenth century. In Britain this was the period when sports such as rugby football, cricket, and soccer were institutionalized, as emerging governing bodies formalized rules and assumed authority over how these sports should be played.

The nineteenth century was also the high point for European imperialism, when the idea of race emerged to justify conquest and exploitation. Countries such as Britain sought to maintain their power over their colonies in Africa, South and East Asia, and the Caribbean by a twin process of undermining and destroying local cultures while attempting to “civilize” native peoples by the imposition of British customs and ways of life. In this context of imperialist expansion, buttressed by notions of inherent white European supremacy, sport came to be seen as a way of educating and socializing colonized peoples into more civilized forms of modernity. Cricket served this purpose in the English speaking Caribbean, South Asia, Central and Southern Africa, and in the white settler colonies of New Zealand and Australia. The notion of “cricket, the classics, and Christianity” was seen by British Victorian elites as a way to bring order and civilization to the British Empire – at once a form of control over the masses and a way to inculcate them into the values and norms of an imperial notion of Britishness.

Elsewhere, soccer was “exported” by Europeans to Africa, Asia, and Central and South America. In this context, indigenous games and pastimes, suppressed since the first European expeditions overseas in the fifteenth and sixteenth centuries, faded away or were gradually replaced with new sporting imports. For example, the game of *ulama de cadera*, or hip *ulama* – *ulama* meaning “ball game” – was once popular throughout Mesoamerica, but began to die away after the Spanish outlawed what they perceived to be a pagan game with inappropriate rituals,

such as decapitation for the losers. The game itself, which is similar to volleyball but requiring the use of the hip rather than the hand, dates to around 1500 BC. Although it still survives in parts of Mexico, it is no longer central to Mexican culture, except as a focus for anthropologists, archeologists, and tourists. Soccer is now the national sport of Mexico, as it is throughout most of Central and South America, and most Mexicans have no idea of what *ulama*, one of the world’s oldest sports, actually involved.

SPORT, RACE, AND THE STRUGGLE FOR FREEDOM

At the start of the twentieth century notions of white European supremacy were simply assumed to be an objective, unquestionable fact. While Africans were often seen to be “animal like” in their nature, it was still assumed that whites were intellectually and physically superior to all other “races of man.” The newly emerging international sports arenas were one public space where this obvious superiority was seen to be confirmed. Given the importance of sport in reproducing dominant forms of hegemonic masculinity, it is not surprising that boxing, and heavyweight boxing in particular, came to be regarded as one of the prime avenues for demonstrating the attributes of white male strength, power, and courage. The symbolic significance of black and white athletes competing against each other in public *as equals*, and the fear of black success in the sporting arena, was such that sporting encounters began to take on wider political significance.

In this context Jack Johnson’s successes in the boxing arena heralded a pattern of racial contestation that was to structure relations on the world’s sporting fields for over a century. In 1908 Johnson became the first black World Heavyweight Champion. Given the racial politics of the Jim Crow era, Johnson’s victory caused widespread consternation within wider white society and jubilation among blacks. The search then went out for a “great White hope” to reclaim the mantle of masculine supremacy from the black Texan. In order to prevent such threats to the symbolic racial order, the so called “color line” was redrawn when Johnson

eventually lost his title which once again prevented black boxers from competing against whites. The later achievements in the 1930s, 1940s, and 1950s of African American athletes such as the boxer Joe Louis, the athlete Jesse Owens, the baseball player Jackie Robinson, and the tennis player Althea Gibson, were subsequently seen by black people throughout the African diaspora as victories in the struggle for freedom from racial oppression.

Sport as a form of political resistance can be seen in the example of cricket in the Caribbean. While the imposition of European sporting forms led to both the extinction of indigenous games and an attempt at colonial governance over local populations, these very same conditions led to sports becoming a site for cultural contestation and ideological struggle. Campaigns for equality within the game of cricket thus paralleled wider struggles for freedom and emancipation from colonial rule. Thus, the campaign to allow a black player to captain the West Indies national cricket team – previously only white West Indians were deemed intelligent enough to assume such leadership roles – was achieved in 1960 when the captaincy was finally given to Frank Worrell. Increasingly, from the 1950s onwards, former colonized countries gained their independence, giving further impetus to the symbolic significance of international sporting competitions, especially against their former colonial masters.

The politics of protest through sport continued into the 1960s and 1970s as sport became an important vehicle through which racial oppression and injustice could be highlighted. The “black gloved” protest at the 1968 Mexico Olympics by Tommie Smith and John Carlos similarly drew attention to the human rights abuses that were taking place in America and elsewhere. Their simple but powerful protest also portrayed the ideological role of black athletes who were now able to compete in international arenas for western countries; when athletes succeeded on the field they were hailed as heroes at the same time that black people were denied full rights as citizens. The radical black athletes of the 1960s, best personified perhaps in the figure of Muhammad Ali, revealed the previously ignored racial politics of sport. This enabled a generation of black athletes to speak out, as previous generations dared not do,

against discrimination in sports and society at large.

Nowhere was racial oppression more explicit than in the apartheid regime of South Africa, where a minority white population held complete power and control over the country’s majority black African population. The 1977 Gleneagles Agreement led to a sporting boycott of the regime. This called attention to the suffering of South Africa’s black population and it assisted the anti apartheid movement by exerting political pressure on the South African government. By further isolating South Africa from normal international relations, the boycott contributed to apartheid’s eventual collapse in the early 1990s. Thus, sport – in Caribbean cricket squares, American sporting arenas, and South African rugby pitches, among other sites – has been central to the wider story of black diasporic struggles for freedom throughout the twentieth century.

STEREOTYPES AND THE RETURN OF RACIAL SCIENCE IN SPORT

A persistent legacy of nineteenth century racial science is the ideology of absolute racial difference and its alleged effects on human behavior. While notions of a direct biological link between race, intelligence, and the propensity to commit criminal acts has been effectively critiqued, the belief that a person’s “race” is linked to abilities on the sports field remains strong. For example, using limited and often contradictory evidence, it continues to be asserted that “West African blacks” are genetically predisposed to power and speed events such as sprinting and jumping, while “East African blacks” are meant to have special properties that allow them to dominate endurance events like long distance running.

Stereotypes attributing to black people natural advantages compared to whites when it comes to running and jumping have affected structural and strategic dimensions of sports. Sociological research since the 1970s has shown how “stacking” – the disproportionate placing of black athletes into certain positions assumed to be more suited to their “natural” abilities – has occurred in many sports from American football to rugby league and rugby union. Linked to stacking is the concept of “centrality,” which

suggests that certain positions are more important to a team's chances of winning as these require players to make cognitive decisions, as opposed to merely reflexive or instinctive physical reactions to opponents' movements. These "central" positions are thus seen to be more suited to white players who have a greater ability to "read the game," thus relegating black players to positions believed to require pure physical ability and little if any cognitive ability. In American football, for instance, this supported a stacking pattern in which there was a disproportionate number of white quarterbacks and black wide receivers. This pattern reproduced a racial ideology focused on innate biological differences and led people to overlook socially produced conditions in which coaches and school teachers selected and encouraged players from different racial backgrounds to play in certain positions. Even when stacking patterns have become less apparent, the race logic used in the sports media recategorizes players by, for example, suggesting that "new" black quarterbacks are somehow more "athletic" than their white counterparts, and play in a more "physical" way.

Black success in certain elite sports is often "explained" by these alleged natural differences, further reifying the idea of race. This undermines black athletic excellence by implicitly linking it with an inherent genetic disposition shared by the entire "black race" and ignoring the dedication, hard work, and ability of individual athletes who happened to be racialized as black. Such stereotypes persist in the face of evidence to the contrary. For example, the record breaking times of British long distance runner Paula Radcliffe or the "super human" achievements of the American cyclist Lance Armstrong are often seen by scientists and journalists in terms of dedication and their almost fanatical commitment to training to compete at the highest level. Rarely is white achievement in sport explained by biological or genetic racial attributes. This preserves the myth of black athletic superiority as well as ideological notions of "natural" racial difference. This illustrates the power of hegemonic racial ideology in framing how people interpret success or failure in the world's sporting arenas and how the discredited legacy of racial science continues to inform sports science discourse today.

SPORT AND RACE TODAY

Success in sport has been one way for subordinated racial and ethnic minority groups to register protests and fight discrimination in the wider battles for recognition and inclusion. In the 2000 Sydney Olympics, for example, Cathy Freeman became the first Australian Aborigine to win an Olympic gold medal, and was widely seen as a symbol of Australia's attempts to come to terms with its racist treatment of Aboriginal peoples. A century after Jack Johnson's arrival on the international boxing scene, black athletes now compete successfully in sports such as tennis and golf that were previously the preserve of whites only. The achievements of sportsmen and women of color have only recently been recognized as part of the wider struggle for racial justice and equality.

A danger is that the perceived level playing field of sport can serve an ideological function by leading people to assume that western societies in particular have achieved a meritocracy that transcends the structural correlates of a racialized social order. Similarly, rather than using their position to speak out on issues of racial injustice and social inequality, contemporary millionaire black celebrity athletes often align themselves with commercial programs bringing them monetary rewards. However, research continues to show that, despite diversity on many playing fields, the power positions in the structure of sport organizations are controlled by white men who coach, manage, and own teams. Similarly, the abuse of athletes of color by spectators and occasionally by fellow players and managers continues to be a feature of domestic and international competitions in sports such as soccer. The myth of race is sustained by the apparent "obviousness" of racial difference in sports performance, while the continuance of racism is often disavowed.

The centrality of sport as a cultural practice in many nations and the pervasiveness of ideas about racial difference mean that the complex articulation of "race" and "sport" will persist well into the twenty first century. Critical research on the ways that sports serve as sites for "race related" identity formation for all racialized minorities as well as majority white populations is needed in order to develop more nuanced and effective anti racist strategies.

Research into non English speaking contexts is also required to explain the many forms of racism that exist alongside the local and national context of particular sporting cultures.

sport and religion

Tara Magdalinski

Sport and religion have a conflicted relationship. At times, sport has served the objectives of religious authorities and has been imbued with a morality and philosophy derived from religious doctrine. At others, it has been rejected for its secular, corporeal emphasis and its capacity to divert attention from godly activities. Sport has been utilized as a means to evangelize and to convert non believers, and yet it has also represented a threat to the social and moral order. As such, religion has had an indelible impact on modern sport, and sport has been both embraced and rejected by religious authorities across the centuries.

The Ancient Greek Olympic Games is perhaps the most renowned example of the inclusion of physical contests in a religious festival. The Ancient Olympics emerged from the ritual celebration of Zeus, the king of the Ancient Greek pantheon of gods, with the first event, the stade, recorded as part of the festivities in 776 BC. In other regions, religious or ritualized practices influenced athletic contests, including the ancient Mayan culture in Central America, where priests presided over ball games on playing grounds adjacent to their temples. In Japan, the ritualized aspects of sumo wrestling borrow extensively from the national religion, Shinto. Christianity, however, has most influenced modern conceptions of sport.

The relationship between Christianity and physical activities has not always been congenial. The Christian church has regarded sport with suspicion, owing to its emphasis on the profane body and its potential to lure its followers away from their godly responsibilities. While the Catholic Church included many popular

physical activities into its religious and festive occasions, the rise of Puritanism in the sixteenth and seventeenth centuries heralded an era where many sporting activities were regarded as sinful. While the Puritans did recognize the political and military utility in many physical endeavors, recreations popular among the peasant classes were prohibited as they were invariably accompanied by drinking and gambling and other dubious pursuits. Nevertheless, since the mid nineteenth century, there has been a shift in the relationship between the two institutions, beginning with the incorporation of games in the education of the elite classes in the English public schools. The inclusion of a physical education curriculum to complement the intellectual and moral training already in place elevated sport from a mere corporeal activity to one with a moral and ethical philosophy. In short, sport was employed specifically to teach boys qualities that would transfer to other aspects of life, and as such became a training ground to produce morally and physically competent civic leaders.

Using sport to construct generations of strong, fit, Muscular Christians was the mission of many organizations that feared the feminization of the male youth as a result of industrialization and urbanization. The closer relationship between religious and sporting ideologies was in part responsible for the reconfiguration of Jesus from effeminate and fragile to strong and robust, a more inspiring athletic figure. This mission is apparent in both early Christian organizations that provided sporting opportunities for its members, such as the Young Men's Christian Association, as well as in contemporary evangelism that utilizes sport and sporting organizations as a means to preach to and/or convert adherents.

Since the rapid expansion of the sports industry through the twentieth century, it has not been uncommon to hear popular commentators refer to sport *as* a contemporary religion. In this conception, stadia are said to be *ersatz* cathedrals, while athletes fulfil the role of modern deities. Harry Edwards (1973) pointed to the close structural relationship between sport and religion, identifying saints and gods, ruling patriarchs, high councils, scribes, shrines, houses of worship, symbols of faith, and seekers of the kingdom as features of both. His typology is, on one level, appealing, though he himself

regarded sport as quasi religious rather than an outright religion. Yet the similarities he identified have inspired a number of authors to declare categorically that sport is a religion, though this controversial statement is not without its opponents.

In arguing that sport is an actual religion, researchers have examined the emotional and devotional aspects of sport and suggest that sport holds meaning for fans in a way that traditional religions are unable to do. The structural similarities between sport and religion, as identified by Edwards, are not solely what define sport as a religion, but rather the passion, commitment, agony in defeat, and elation in victory reveal a transcendent experience in followers that provides sacred, communal moments between players and fans. For them, a religion delivers a sense of ultimacy, and sport is capable of providing a means of ultimate transformation that alters people's lives.

Others are not convinced, but recognize that there is more than a coincidental relationship between sport and religion. These researchers argue that sport is similar in structure to a revealed religion and that the two share many ritualized and sacred aspects. But sport itself is also regarded as religious as it represents in tangible form epic human and spiritual struggles, the quest for perfection, an intrinsic drama, and the explication of moral attributes. The ritualized engagement with and in sport, it is argued, serve to deliver a religious experience to their participants, feeding a "deep human hunger" (Novak 1976).

Sport may also be considered a folk religion, which can be understood as the result of shared moral ideals as well as behaviors, and emerges from daily life experiences to provide a means to integrate society, legitimate national values, and communicate societal ideologies. In this conception, sport is accepted as a product of its social, political, and economic context and as an institution that is complicit in reproducing these ideologies. In declaring sport to be a folk religion, researchers recognize its mythic, collective, and historical elements, without necessarily suggesting it is a transcendental experience.

By contrast, those who challenge sport's elevation to the status of a religion argue that the objects of each institution are not consistent, and

thus to equate the two would be to ignore fundamental philosophical differences. Religion, they suggest, is derived from the divine realm, while sport is firmly located in the human experience. One offers truths about life beyond our own experience; the other is simply a corporeal activity embedded in the profane. There is concern that to equate the two might secularize religion and diminish its value.

Essentially, the argument that sport is not a religion rests on the recognition that the intentions underpinning the two institutions vary significantly. Rather than examining sport and religion in terms of structure, it is perhaps more revealing to analyze each from the inside out. Such an analysis reveals the key difference to be the role of religion to proffer answers to, or explanations about, the mysteries of human existence. Sport has no such stated purpose, and even the most ardent sports fan would disagree that devotional activities will reveal anything about people's lives, destinies, or significance. Sport may well embody and reflect social values and ideologies, they argue, but it does not offer any deeper meanings about this world beyond the activity itself.

For others, the contention that sport is a religious experience is problematic. The mere physical act of playing or watching sport, they suggest, has little relationship to rituals of worship. At the same time, they identify a difference between having a religious experience when playing sport and playing sport for the actual purpose of glorifying a god. While these researchers may recognize that many of the rituals, passions, and even myths within sport can take on a religious like significance for participants, they maintain that the actual sporting performance is not a religious act. Thus the symbolic links between physical movement and the expression of a religious doctrine are questioned. As such, some have suggested it is best to examine the moments when sport and religion serve each other's interests rather than trying to define one as the other.

A final way of examining this phenomenon is to regard sport as a cultural vehicle through which religious communities may disseminate their faith or reinforce their beliefs to their existing members. This approach suggests that sport may not be divine in and of itself, but as an institution that reproduces cultural

meanings and values, it might also serve the interests of religious groups. Cultural activities that rest upon ritualized performances are significant ways to reproduce hegemonic ideologies, and sport is no exception. There are numerous examples where sport has been used as one of a number of cultural means to reinforce the collective identity of a religious community. In South Africa, the Muslim population of Cape Town used rugby as an avenue through which their religious and cultural identity could be consolidated. While not using sport as a direct means to proselytize, rugby nevertheless provided social opportunities for members of the community to interact and reaffirm their sense of belonging. Similar outcomes can be seen among Jewish Americans who used physical recreations as both a means to maintain their faith and cultural heritage, and also to integrate themselves into a new national community. In this way, sport contributes to the reproduction of the religious community's social arrangements, particularly in new or rapidly changing cultural contexts as members engage in repetitive, ritualistic cultural practices.

The use of sport has not been as pronounced in Eastern or traditional indigenous religions as it has in the Judeo Christian religions, though there is certainly much evidence that movement cultures are incorporated into religious or sacred practices. The primary point of divergence for many Eastern philosophies, such as Hinduism and Buddhism, is a rejection of the material world in preference for the attainment of a higher spiritual order. An emphasis on the body merely for the sake of gaining material rewards in the secular world is antithetical to the quest for enlightenment, and as such, modern, rational, quantified sport does not serve a purpose in the transcendence of the material world and the development of spiritual awareness.

The relationship between sport and religion has been influenced by differing perceptions of the body, the significance of sporting practices in the expression of religiosity, as well as the structure of both institutions. Christianity has had the most pronounced impact on the philosophy of modern sport, though the various Christian churches have not always regarded sport as a suitable activity for their followers. The emphasis on the corpus was thought to be at the expense of the spiritual, a division that

remained until the rise of the Muscular Christian movement in the nineteenth century, which provided a new model of the sport/religion nexus, one that led to the proliferation of evangelist practices in sport throughout the twentieth and early twenty first centuries. The popularity of modern sport and the devotion that fans display to their teams has led some to regard sport as a contemporary religion, one that holds more meaning for their followers than traditional religions; however, this standpoint has been challenged by those who regard the inherent natures of sport and religion to be fundamentally different.

sport and social capital

Jean Harvey

The literature on sport and social capital is scarce and discussions are fragmented because there are disagreements about the definition of social capital, the role of sport in contributing to social capital, and the forms of social capital that may be generated in the sphere of sport.

Three major approaches to social capital exist in the social science literature. The most

dominant is the functional approach, as represented in the work of political scientist Robert Putnam. For Putnam (1993: 167) social capital consists of "features of social organization, such as trust, norms, and networks, that can improve the efficiency of society by facilitating coordinated action." Putnam (2000) argues excessive individualism in the US has reduced civic engagement and participation in the electoral process, both of which are marks of declining social capital. This, in turn, undermines the efficacy of public institutions. In the case of sports, declining participation in sport clubs and volunteerism is a sign of declining social capital.

Within Putnam's framework, three forms of social capital are distinguished: (1) bounding, referring to the relations within homogeneous groups, like sport teams or clubs; (2) bridging, referring to relations across horizontal social divisions, such as across teams within a league; and (3) linking, referring to ties between different strata of society, for example citizens from all social classes who are fans of their local pro football club. Putnam's work has been criticized (Dyreson 2001), especially by those who argue that the evidence on aggregate measures of social capital and civic engagement may obscure "a more complex reality" and that "the overall picture is of shifts in civic engagement more than losses, and of only moderate net losses at worst" (Curtis et al. 2003).

A second approach is based on the work of Pierre Bourdieu. For Bourdieu (1986: 249), social capital is "the aggregate of the actual or potential resources which are linked to the possession of a durable network of more or less institutionalized relationships of mutual acquaintance and recognition or, in other words, membership in a group." Moreover, Bourdieu explains that the amount of social capital possessed by an agent depends on a combination of the number of network connections one can mobilize, plus the economic, cultural, and symbolic capital possessed by those comprising the network connections. Bourdieusian studies of sport and social capital are rare, although several scholars who use the two other approaches often refer to his work.

The third approach regroups a wide variety of network based approaches to social capital. Those who use this approach build on

Bourdieu's emphasis on social capital as a resource. For example, Lin (2001: 25) defines social capital as "the resources embedded in social networks accessed by actors for actions." Within this general social network approach, some researchers are more interested in the networks themselves (the structure of relations within the networks), whereas others focus on the relational aspects of the networks (the resources available and accessible).

Most sport scholars use the functional definition of social capital, although they do not all adopt a functionalist theoretical framework. Jarvie (2003), Maguire et al. (2002), and Smith and Ingham (2003) have focused on the role of sport in the regeneration of community social capital. They argue that there are ways in which sport can positively contribute to community social capital, although it cannot be assumed that sport always increases social capital all the time.

Smith and Ingham (2003) highlight this situation in their exploration of public discussions (i.e., town meetings) over the development of professional sport stadia in the US. Their findings demonstrate that the public subsidization of professional sport stadia does not contribute to or re/generate the sense of a "community as a whole, but indeed may further divide residents depending upon their situated interests." Dyreson (2001) also notes that there are situations in which sport can promote division, excessive competition, and unhealthy practices among people and communities.

Some scholars are examining sport through the lens of network based social capital. Alegi's (2000) study of soccer in Africa illustrates Bourdieu's theory of social capital as resources grounded in network connections, namely with people who are in positions of power or in a position to change things. Alegi examined the importance of soccer to the social experiences of black African workers, entrepreneurs, and political leaders and analyzed how people subject to systemic discrimination and without political rights used soccer as a site for developing social networks based on community identities at a national, regional, and local level. Specifically, while black African workers and youth were generally not interested in seeking personal mobility in the political sphere, they often turned to soccer for self advancement

combined with the "charitable uplift of their community." Litwin (2003) used a network based approach to confirm that physically active older adults are more socially connected. Furthermore, the older adults in diverse networks consisting of connections across the spheres of friends, neighbors, and family were most likely to engage in physical activity.

Overall, research on social capital supports the notion that sport can enhance social capital as well as erode it. Future research will explain the circumstances under which these outcomes occur.

sport and social class

Alan Tomlinson

Sport is a significant contributor to relations of social class in that people in elite groups have the resources to organize and maintain games on their own terms and in spaces inaccessible to others. This ultimately serves to reproduce social and economic distinctions and preserve the power and influence of those who control resources in society. The growth of modern sports cannot be fully understood unless this key influence and core dynamic is fully recognized.

In its most general sense, social class refers to the social and cultural expression of an economic relationship. Classes are made up of individuals located and identified by (1) their contribution to economic production, (2) their access to and control over resources, and (3) their distinctive class cultures and lifestyles. In modern societies social classes are based on the individual's and the group's place in the industrial and economic process, with the most significant measures of class distinction being wealth and occupation. Explaining the relationship between these indices of class position and other sources of status and identity has long been a focus of sociological theory and research. For example, at the end of the nineteenth century, Veblen (1953) stressed that people in the ruling class recreated imagined lifestyles of the elites from previous times and constructed a life of leisure that set themselves apart from lower classes and less privileged groups. Veblen explained that the accumulation of wealth and conspicuous consumption in sport and leisure were inextricably linked. As the leisure and consumer economies of the twentieth century consolidated and expanded, this link would

become increasingly important for social classes that could balance work–leisure choices, and not just for those who could afford to dispense with paid work or employment altogether.

HISTORICAL CONTEXT

Forms of inequality and exploitation characterized the civilizations of the ancient world, where participation and spectatorship in Greek festivals and Roman games were based upon position and rank in the social and economic order. In the European Middle Ages, when the military rationale of the jousting tournament receded, it was maintained by despotic rulers as a spectacular public display of power and a form of theater in which participation and spectatorship were based on social status and class position.

In comparable ways, a structure of social differentiation based on class characterized the emergent social order of the West's early modern period as industrialization and urbanization reshaped the basis of society and culture. Ascribed status, leaving little option for social mobility, was superseded by achieved status that, in theory, held the promise of a change in status, according to the individual's economic position and potential. Social standing came to be defined in terms of what people did to make a living and how they publicly displayed their acquired economic status rather than in terms of inherited status and prescribed opportunities (Sugden & Tomlinson 2000). Yet, in practice, social class, defined in terms of economic status and its associated cultural dimensions, reproduced the status quo and contributed to the consolidation of power relations and cultural distinctions.

Seminal social histories of sports in Britain – association football/soccer (Mason 1980), rugby football (Dunning & Sheard 1979), and cricket (Birley 2003) – have vividly demonstrated how the emergence and the evolution of modern sports forms were rooted in class relations. Association football in its amateur form was championed by the middle and upper classes, and developed in its professional form by the working class and lower middle classes. The attitudes and beliefs embodied in the ethos of particular sports expressed class based status and values. The middle classes, for instance,

believed that the amateur code of the game built character, strengthened the body, discouraged drinking, and unified social classes (Mason 1980: 229). Rugby football's "Great Schism" of 1895 saw the split between the Northern English mass spectator form of the game, and the amateur, Southern English based Rugby Football Union (Dunning & Sheard 1979: 198–200). Class patronage shaped many forms of sports provision, in the US and advanced societies generally. Marxist influenced accounts have had a widespread impact upon how such class dynamics and relations have been theorized.

NEO MARXIST ACCOUNTS

Miliband (1977) noted that the development of a Marxist sociology of sport was not an outstandingly urgent theoretical imperative, but added that neither was it the most negligible of tasks. Marxist and neo Marxist analysts of sport have been concerned mainly with two themes: sport's ideological role and sport's potential as contestation and resistance.

Marx said nothing about sport or its relationship with social class, but neo Marxists have explored the nature and histories of class dynamics and class struggles. Thompson's (1968) historical interpretation of the making of the English working class describes how sport and leisure often were sites for class struggle, as the social forces that pioneered the development of capitalism emerged and sought to shape the ideological and cultural production of the new age. The establishment of capitalism and the inexorable rise of an industrial and commercial bourgeoisie demanded a disciplined and reliable labor force. A priority for the new ruling class was the reformation of the working rhythms of those whose experience of labor was based in rural rhythms past and seasonal cycles. Necessarily, the non work habits of the masses formed part of the equation of reform, for what people did in their spare time had implications for how they related to the process of production. Thompson showed how an emergent bourgeoisie in England used its influence both in government and within the church to carry out a legal and moral crusade against the recreational habits of the lower orders. He also explained that new

labor habits were established through the imposition of time discipline, a division of labor, the supervision of labor through the use of fines, money incentives, and bells and clocks, the words of preachers and teachers, and the suppression of fairs and sports (Thompson 1967). The incipient working class did not willingly surrender long established customs and leisure practices. Such reforms succeeded only through processes of resistance and struggle between classes and class fractions. For example, Delves's (1981) study of the decline of folk football in the English city of Derby illustrated how new cross class alliances – the emergence of newly dominant class fractions with common interests in commerce, change, and reform – accounted for the demise of the traditional form of folk football, and the rise of horse racing – a more regulated, enclosed, civilized, and profitable form of sport.

SPORT CULTURES: CLASS, HABITUS, AND REPRODUCTION

Bourdieu (1978) notes that sports emerged in exclusive English public schools, where the sons of wealthy, powerful, and aristocratic families appropriated popular games and changed their function to suit their interests. He connects the rationalization of games into modern sport forms with a class based philosophy of amateurism that expressed the moral ideal and the ethos of the most powerful segments of the bourgeois class. To play tennis or golf, to ride or to sail, was, as Bourdieu argues, to bestow upon the participant what he called gains in distinction. Sports in which lower middle class or working class people participate develop as spectacles created for the people as mass commodities. Sports, therefore, are not self contained spheres of practice, and it is class habitus that defines any meaning conferred on sporting activity, and any social value that is associated with the sporting practice. From this perspective, then, sports participation is not a matter of personal choice or individual preference; it depends upon the financial resources available to the potential participant, the social status of those prominent in that activity, and the cultural meaning of a sport and the individual's relationship to those meanings.

Far from being an open sphere of limitless possibilities, sport is a social phenomenon and cultural space that operates in Weberian terms as a form of social closure, in which potential entrants are vetted and excluded to suit the incumbent gatekeepers. At the same time, the inner world of the sports culture is tightly monitored and controlled, as in golf or tennis club membership committees, and in other sports institutions in which formal or informal entry requirements are barriers to open participation. The recruitment and induction processes into such clubs are operational expressions of and examinations in cultural capital. For example, entrance into a tennis club requires that newcomers must communicate competently with the gatekeepers of a club; read the social interactions and etiquette and conventions of a club; comply with the dress code; be equipped with relatively sophisticated technology; and have the ability to play at an acceptable level of competence. This apparently open choice is in reality a possibility or trajectory based upon what Bourdieu recognizes as the power of economic and cultural capital, so that class variations in sporting practice can be understood as shaped by not just the basic financial costs of an activity, but also by the perceived benefits that will accrue, either immediately or later, to the participant. Sporting practices, and associated physical and body cultures, are therefore aspects of the class habitus. Practices, in the Bourdieuan framework, are articulations of habitus.

Bourdieu is sensitive to the fact that classes are not monolithic. He argues that there can be divisions within classes and these too can be reflected in sports. An interesting example that he uses is that of the gender dimension of the class habitus that produces a sexual division of labor that in turn affects participation in particular sporting activities. But in general, for Bourdieu, the analysis of sport is a form of class analysis. Sport acts as a kind of badge of social exclusivity and cultural distinctiveness for the dominant classes; it operates as a means of control or containment of the working or popular classes; it is a potential but unlikely source of escape and mobility for talented working class sports performers; it articulates the fractional status distinctions which exist within the ranks of larger class groupings; and it reveals the capacity of the body to express social principles

and cultural meanings, for physical capital (Wacquant 1995) to connect with forms of economic and cultural capital. Bourdieu described his study *Distinction* (1986) as an attempt to think through Marx and Weber's rival conceptions of class and status, and his major achievement was to connect the study of class position and concomitant lifestyles and statuses. The lesson here for the sociologist of sport is to recognize the need for a complementary and integrated analysis of both the class dimensions of a sport and its associated lifestyle dimensions.

CONCLUSION

Studies of sport continue to pose the question of how important social class is as an influence upon participation and/or spectatorship. A Canadian study (White & Wilson 1999) reports the primary influence of socioeconomic status upon sport spectatorship; a Scandinavian study (Thrane 2001) questions this, disputing any linear influence of household income upon spectatorship, and claiming a further complexity by seeking to measure the influence of education, cultural capital, and sport participation. Unsurprisingly, the more that is measured, the more confusing the picture gets. However, analyzing data from the US General Social Survey in 1993 and drawing upon Bourdieu's concept of cultural capital, Wilson (2002) is much more analytically unequivocal: cultural capital enables people to do more sport, and social class provides the knowledge, tastes, skills, and preferences that motivate individuals towards particular types of sport consumption.

An overemphasis upon the potential of sport to offer social mobility to a few can distort this picture of sport's reproductive capacity. It is often thought that working class males take up boxing in order to get out of the ghetto. Some do; a few more may. But Sugden's (1987) insightful ethnography of the Burnt Oak boxing gym shows how for the majority who will not graduate to the professional ranks, boxing is a form of exploitation, giving them little more than survival skills, honing skills and fueling hope, but confirming their ghetto culture.

In societies such as Britain sport participation in a general sense has demonstrated a relative stability. National participation figures

are notoriously difficult to unravel in completely reliable ways, but it is clear that there was no boom in participation during the 1990s. In fact, sport participation rates and the patterns of participation between different social groups have remained largely unchanged since the early 1970s, with the exception that more women now participate in fitness activities (Rowe 2003). The 2002 General Household Survey in Britain showed enormous differences between groups classified by socioeconomic criteria: 20 percent of adults in the higher occupational cum economic groupings did keep fit; for those not working, or long term unemployed, it was 4 percent; 59 percent of the former group took part in at least one physical activity in the 4 week reference period compared with 30 percent of those in routine jobs. One in 10 of the top occupational group had played golf, the same figure for running/jogging; only 1 in 50 of those in routine jobs had participated in these activities (Fox & Rickards 2004).

National studies confirm such persisting patterns of class based inequality; local and regional studies provide parallel confirmation, as in analyses of urban space and sport and leisure consumption. Twenty first century consumer society without doubt offers numerous opportunities for the expression of experimental identities, for a kind of project of the self to which sport can be one contributing source, as work on lifestyle and extreme sports has shown. Cultures can and do change, but as Williams (1977) noted, in subtle ways in which the dominant, residual, and emergent elements sometimes intermesh. Dominant cultures resist transformation though, and in this wider context sport, at its various levels of performance, participation, and spectatorship, continues to show how class habitus and cultural capital remain major determinants of everyday practices and cultural institutions.

sport and social resistance

George H. Sage

Social resistance is a social phenomenon in which disadvantaged, exploited, and dominated groups contest the dominating practices that nation states, social institutions, social organizations, and traditional cultural practices have constructed. Resistance and acts of agency – meaning the capability of individuals to construct and reconstruct their world – against abuses of power, discrimination, inequality, social injustice, and autocratic control are pervasive features of human history. There are always ongoing struggles against domination through various forms of social resistance. As British social theorist Robin Williams (1977) asserted, dominance “does not just passively exist . . . It has continually to be renewed, recreated, defended, and modified. It is also continually resisted, limited, altered, challenged by pressures not at all its own” (p. 112).

Individual resistance and human agency are the means through which individuals change social processes and structures and build alternatives. When social resistance is carried out under the auspices of an organized group, this is referred to as a social movement. Research on social movements most often focuses on the social and psychological characteristics of those who participate in the movement, the relations between the leaders and other participants, and the social and political outcomes of the organized resistance.

Resistance movements use violent and/or nonviolent tactics. Several of the most common forms of resistance are boycotts, civil

disobedience, guerrilla warfare, and passive resistance. Social scientist James C. Scott (1990) asserts that opposition and resistance of subordinate groups is frequently “found neither in overt collective defiance of powerholders nor in complete hegemonic compliance, but in the vast territory between those two polar opposites” (p. 136).

Sporting practices have typically been vehicles of cultural reproduction, but they have also been avenues for the expression of various forms of social resistance and agency. Athletes and others associated with sport have resisted dominant models of sport in subtle and not so subtle ways. In doing so, they have contradicted, modified, and transformed definitions and modes of control in sporting practices. Several areas of research in which social resistance struggles have taken place in sport are illustrated in the following selected examples.

Issues of race and gender have given rise to social resistance in sport. African American athletes have challenged the sport establishment over racism in sport in a variety of ways. For almost a century after the abolishment of slavery, blacks were excluded from participation and attendance at most mainstream American sports. As one form of resistance to being barred from mainstream sport, blacks formed their own teams and leagues. The so called Negro baseball leagues flourished for more than 40 years in the first half of the twentieth century. All black basketball teams and leagues succeeded in many cities of the Northwest and Midwest during this same era. Black boxers resisted formidable barriers to their boxing careers and several, such as Jack Johnson and Joe Louis, became world champions. More recently, heavyweight boxing champion Muhammad Ali refused to serve in the military and participate in the Vietnam War, saying that he didn’t have anything against the North Vietnamese.

In the 1990s, black and white athletes and coaches boycotted several sport events because of racist policies or practices of the sponsors. They also increased the pressure on the sport establishment for greater African American representation in coaching and managing. Sport has become a medium for demonstrating black pride through hairstyles and handshakes and other rituals carried out in connection with sport events, thus affirming black capabilities,

and challenging the subordination imposed by the politically and socially powerful within American society.

Gender differentiation has been powerfully constructed through sport and the culture of sport. Historically, one of the most persistent and widespread forms of discrimination was the lack of access to sport opportunities for females. Social attitudes and conditions made female athletes an anomaly until the 1970s. Before that, girls and women who participated in competitive sports faced social isolation and censure. Even into the late 1980s, public attitudes supported sport as a male preserve in most nations around the world.

With the women's movement as an ideological foundation, resistance to traditional restrictions to female involvement in sport began in earnest in a few nations. At the youth sports level, girls and their parents began to question the rules and regulations of youth sport organizations. In the United States, for example, they challenged baseball's Little League "boys only" policy by registering to play on Little League teams. They challenged policies of public recreation departments that sponsored only boys' sports teams, and insisted that girls be allowed to play on these teams or that an equal number of girls' teams be created.

Women were a major force resisting the sport inequities for females in US high schools and colleges that were conspicuous and widespread before the 1970s. They were successful at securing the passage of the Education Amendments Act of 1972. A key provision in this act, Title IX, required that educational institutions receiving federal funds must provide equivalent programs for males and females. Similar forms of resistance have occurred internationally and in other nation states.

In recent years sport related political protests have been waged on behalf of various causes. Between 1970 and the overthrow of the white government in South Africa in the early 1990s, unpopular American government and corporate support for South Africa and its apartheid policies led many sport groups to successfully resist the participation of South African athletes in sporting events in the US. Indeed, sport resistance was one of the most important sites for condemning the South African apartheid government.

Athletes and activist groups, even nations, have occasionally chosen sporting venues for social resistance to demonstrate against political policies and practices. In the 1968 Summer Olympic Games in Mexico City, African American Olympic medal winners Tommie Smith and John Carlos raised their gloved fists during the playing of the national anthem to protest racism in the US and racial oppression around the world.

In the 1970s and 1980s, nation state boycotts plagued the Olympic Games. African nations boycotted the 1976 Olympics because New Zealand's rugby team had played in South Africa. The United States and several other western nations refused to compete at the Moscow Olympics in 1980 because of the Soviet invasion of Afghanistan. The Soviet Union and its Eastern Bloc partners countered by boycotting the 1984 Olympics in Los Angeles.

In the United States protesters have used major sporting events to stage protests against war, racism, sexism, nuclear proliferation, and environmental pollution. Speeches, distribution of literature, and placard displays typically take place outside the sports venue, while demonstrations occur inside during pre game or half time. Intercollegiate athletes themselves have engaged in a type of resistance that James C. Scott calls low profile resistance and infra politics. Because they do not receive a salary or wage for their labor – they receive an "athletic scholarship" – they have forged an underground economy, frequently accepting under the table payments and improper benefits from coaches, boosters, and sports agents. Although their actions are not intended to have structural ramifications, they are struggles for social justice in the distribution of wealth that is generated from their labor.

One form of social resistance involves with drawing or evading the dominant canon of a social practice, which in contemporary sport is a highly competitive organized sport culture. Outdoor activities such as hiking, rock climbing, rafting, hang gliding, skydiving, skateboarding, scuba diving, and so forth where participation has priority, have boomed among a clientele seeking alternatives to organized, commercial, and corporate forms of sport. This phenomenon is worldwide. Many participants create alternative norms and relations that

emphasize participant control of the physical activity and open participation rather than rule bound, high level competition.

There are several categories of these alternative sports forms – “action” sports, “whiz” sports, “adventure” sports – often overlapping into a rather ill defined category called extreme sports. Most of these activities do not attract masses of spectators, so the fanfare associated with mainstream sports is not missed. One sport sociologist claims these forms of sport “are about sharing the experience and about community” (Rinehart 2000: 504) – characteristics that attract many of the participants.

Social resistance represents an important precursor for social transformation. This can occur when groups of people use sport to resist certain social attitudes, practices, and laws in an effort to raise public consciousness and bring about social change. For example, to call public attention to prejudice and discrimination against homosexuals and to improve public attitudes about them, in 1982 leaders of the gay and lesbian community planned to create and hold a Gay Olympic Games in San Francisco. The event was quickly crushed by a lawsuit from the United States Olympic Committee (USOC), claiming that the use of the word Olympics violated a trademark the USOC was granted under the Amateur Sports Act of 1978. Nevertheless, resistance quickly emerged within the gay and lesbian community. The name of the event was changed to the Gay Games and the first Gay Games were held in 1982. They have been held every four years since then in different cities throughout the world. The Gay Games have helped to transform the attitudes of many “straight” people towards homosexuals, and have had a transformative effect for many members of the gay community, giving them a sense of empowerment, enhanced self esteem, and opportunities to display socially valued physical skills in a visible context.

Social resistance has extended to apparel and equipment used by sports participants. In the global economy, product manufacturing is a major driving force. A key aspect of the global economy is a system of manufacturing and division of labor known as the export processing system. In this system, product research, design, development, and marketing take place in industrially developed countries, while the

labor intensive, assembly line phases of product manufacture are relegated to developing countries. The finished product is then exported for distribution in developed countries of the world.

Sporting goods manufacturing is one of the most flourishing export processing industries, and Nike was one of the pioneering sporting goods corporations in foreign export processing. During the 1990s, 16 major investigations were made of factories producing Nike footwear in Asian countries. The reports uniformly found appalling working conditions in Nike’s factories: local industrial safety laws were violated and workers’ rights were nonexistent. Between 1992 and 1996, as global understanding and consciousness grew about Nike’s Asian factories, a mass chord of horror and outrage spurred collective actions and launched what became the Nike social movement. This resistance movement was composed of an international coalition of organizations. Their goal was to create enough public outrage against Nike that governments, businesses, unions, religious organizations, and human rights groups would bring pressure on Nike to change its labor practices and improve conditions in the factories. The Nike social movement severely damaged the Nike brand name and reputation for millions of people throughout the world. In 1998 the Nike CEO announced plans for what he called New Labor Initiatives, which was a plan for significant reform in the company’s labor practices. These reforms likely came about as a direct result of the Nike social movement campaigns.

sport as spectacle

David L. Andrews

The spectacle, in the form of an imposing public display, is not simply a benign cultural form, because it can seldom be separated from “non coercive strategies of power and persuasion” (Cary 2005). This is often overlooked when considering contemporaneous high profile sporting events staged for the entertainment of spectating publics (e.g., the NFL Super Bowl, Olympic Games, or FIFA World Cup), which, despite their celebratory sporting veneer, routinely communicate the values and ideologies of the dominant corporate capitalist order. The sport spectacle has, of course, long been a vehicle for the expression and/or performance of dominant cultural practices and sensibilities. This can, at least partially, be attributed to the fact that the visceral intensity of competition based physical culture possesses an almost unrivaled capacity to capture the interest and imagination of publics located within divergent historical and social contexts. Moreover, the very practice of bearing witness to (or spectating) particular displays of competitive physicality has played an important role in establishing the sociocultural import of

some physical activities over others. Thus, the Olympic festivals of ancient Greece, the gladiatorial contests of ancient Rome, and even the folk football rituals of pre industrial Europe (such as the Florentine *calcio*) were only fully constituted as socially, culturally, and indeed politically significant practices through the presence and involvement of massed ranks of spectators, whose numbers dwarfed those of active participants.

As resonant focal points for popular identities, desires, and fears, physical cultural spectacles have frequently become appropriated by particular social groupings looking to advance their own political and ideological agendas. This is perhaps best exemplified in what Juvenal famously described as the “circuses” of violent entertainment staged within Rome’s vast amphitheaters as a means of appeasing the baser sensibilities of the Roman populace. As well as providing a diversion for the underworked (due to the presence of an extensive slave populace) yet disenfranchised (due to the nature of the Republic’s constitution) Roman masses, these games also constituted a highly visible site for the Roman elite to exhibit their economic and political power. Roman luminaries thus regularly sponsored ever more extravagant, blood thirsty spectacles (including gladiatorial combat, elaborate and voluminous human sacrifices, the mass slaughter of animals, and even carefully staged naval battles) as a means of securing the popular approval of Rome’s excitement seeking plebian classes.

While the emergence of modern spectator sport in the late nineteenth and early twentieth centuries incorporated considerably less savage forms of competitive physicality than their ancient antecedents, they did nonetheless perform similar sociopolitical functions. By codifying sporting practice (regulated participation) and sanctioning cathartic release (mass spectatorship), the patrician industrialist power bloc ensured that sport helped constrain working bodies to the demands and discipline of the industrial workplace, while simultaneously contributing to the commercialization of what was a burgeoning urban leisure culture. Thus, within the modern industrial era, and specifically its newly defined realm of leisure time, institutionalized sport became an increasingly important site of “surveillance, spectacle, and profit”

(Miller & McHoul 1998). As Brookes (2002) reiterated, the instantiation of modern sport during the nineteenth century both disciplined and commodified popular physical culture, through the standardized regulation of sporting "time, space, and conduct," which provided opportunities for aspirant participants, entrepreneurs, and spectators alike.

While most industrializing nations began developing their own inventory of spectacular sporting events at this time, the modern Olympic Games, originating with the 1896 Athens Olympiad, rapidly became sport spectacle of truly global proportions. The global spectacularization of the Olympic Games was expedited through successive phases of technological advancement in the mass communications industry (i.e., news reel, radio, television, and Internet innovations) that allowed the Olympic spectacle to engage, and inform, both internal and external audiences alike. Initially advanced as a festive celebration of sporting excellence, fair play, amateurism, and internationalism, the modern Olympic Games soon became appropriated by, and an expression of, the prevailing power structure within the host nation. Thus, the Games have become forums for the (inter)national display and attempted validation of specific political economic orders, such as those associated with British imperialism (London, 1908), German fascism (Berlin, 1936), USSR communism (Moscow, 1980), US capitalism (Los Angeles, 1984), and US neo imperialism (Salt Lake City, 2002). Interestingly, within many recent Olympic celebrations (Salt Lake City, 2002, excluded), the Games have been spectacularized – particularly through the performance of defining national cultural characteristics within Olympic opening ceremonies, and the utilization of specific national geographies as event locations and facilities (Hogan 2003; Tomlinson 1996) – as mechanisms of place marketing for potential tourist visitors to the host cities. In this manner, Barcelona (1992), Sydney (2000), and Athens (2004) are all illustrative of the commercial processes through which the Olympic Games have become implicated within, and veritable motors of, what are the overdetermining forces and networks of global (consumer) capital.

In the second half of the twentieth century sport was conclusively and apparently

irreversibly integrated into the commercial ferment of the dominant consumer capitalist order. Of course, many sporting entities, such as Major League Baseball (MLB), the National Basketball Association (NBA), the National Football League (NFL), and the National Hockey League (NHL), originated as professional, putatively commercial, ventures. However, until relatively recently, most occupied a space at the periphery of the commercial marketplace, with utility maximization (sporting performance) routinely taking precedence over – frequently to the exclusion of – profit maximization (financial performance). The commercialization and commodification of sport – what Walsh and Giulianotti (2001) describe as a continuing process of converting "the social meaning of a practice or object into purely financial terms" – reached a heightened level of intensity with the contemporaneous advancement of the profit driven corporation as the naturalized, and largely unquestioned, model of social organization. Sporting *bodies* (sport organizations, events, leagues, teams, athletes, etc.) thus became incorporated into the structures, values, and directives of late capitalist culture. Put simply, a conjuncture within which "everything . . . has become cultural; and culture has equally become economic or commodity oriented" (Jameson 1998). Within this context, an expansive economy of highly managed and marketed sport spectacles has become an important "correlative" to a consumer society in which consumption (of commodities and services) has become the generative core (Kellner 2003: 66). Since contemporary capitalism's culturally inflected regime of accumulation is prefigured on the operationalizing of the mass media (simultaneously as both core commercial product and commercializing process), sport's evolution has become inextricably tied to the rhythms and regimes of an expanding media industrial complex. Thus, from the mid twentieth century onwards, the emergence and rapid diffusion of commercial television has played a crucial role in the enlarging presence, and intensifying influence, of mass mediated, mass entertainment oriented, commercial sport spectacles. Moreover, the relentless rise of commercial television as a major conduit to both the *commercialization of culture* and the associated *culturalization of the economy* has revolutionized the sport economy:

escalating fees from the selling of broadcast rights and media sponsorships having become, for many professional sports, teams, and events, the single most important source of revenue generation (Bellamy 1998). Thus, there is a growing tendency for media organizations and corporate sponsors/advertisers to exert monopoly like control over sport organizations (Jary 1999). In other words, there has been a conclusive "institutional alignment of sports and media in the context of late capitalism" (Real 1998).

Of course, the demands of understanding the spectacular economy of contemporary sport culture lead, somewhat predictably, to Debord's (1990, 1994) theorizing on the society of the spectacle. However, as Tomlinson (2002) warned, all too frequently Debord's provocative treatise on the transformations in relations between capitalism, technology, and everyday life is the subject of little more than superficial invocation. Within examinations of sport, this is routinely done through reference to the proliferation of mass mediated spectacular sporting events as if they, in and of themselves, encapsulate the complexities of spectacular society. In Tomlinson's terms, this trite appropriation belies an "interpretive shorthand" used by academics, whose passing references to Debord signify an acknowledgment of the mediated spectacle "without any fully developed sense of the conceptualization of the spectacle." The tendency toward reifying the spectacle is soon eviscerated through actual recourse to Debord's theses which exhume the layered complexity and multidimensionality of the spectacle, and its position and function within spectacular society: "The spectacle appears at once as society itself, as a part of society and as a means of unification" (Debord 1994: 12). According to Debord, the upper case Spectacle (mediated mega event) and the lower case spectacle (relentless outpourings of the corroborating and/or parasitic culture industries and processes) provide both the monumental and vernacular architecture of a spectacular society, in which the spectacle as capitalist product and process realizes a situation in which the "commodity completes its colonization of social life" (p. 29). Kellner (2003: 66), this time with specific reference to the dualism of the sport spectacle, similarly observed that "postindustrial sports have transformed traditional (and in some cases, non traditional) practices into

media spectacles in such a way that exemplifies the broader processes of cultural commodification associated with the rise of a mass media driven consumer society."

sport and the state

Jacques Defrance

Since the end of the nineteenth century the dynamics of the sport–state relationship are best understood by taking into account (1) the dramatic growth of sport relative to other forms of physical activity (gymnastics, traditional games, etc.) and (2) socially significant changes in the operation and status of the state.

Sport is a competitive form of physical activity, codified to ensure equal opportunities of victory to competitors and guarantee physical security in contests. This mode of physical game, a unique feature of industrial and parliamentary societies, emerged first in England during the eighteenth and nineteenth centuries (Elias & Dunning 1986). Between 1880 and 1900 it had become common in western industrial societies and territories controlled by the British Empire (Mangan 1985) and it became worldwide after the era of decolonization in the 1950s and 1960s.

The British state, under which modern sport was invented, was also the first to adopt a parliamentary form of government. As these developments occurred, British society also was characterized by relatively stable internal social relationships (i.e., during the eighteenth and nineteenth centuries). However, as organized forms of competitive sports spread during the twentieth century, they were appropriated and incorporated into diverse social formations and different state structures, including those that were socialist, fascist, corporatist, liberal, etc. These recent historical developments raise a series of questions about sport and the state. Through what processes did states acquire power over sports (Harvey et al. 1993)? What functions were fulfilled by sports in different political systems? How are institutionalized forms of sports shaped and developed as autonomous activities in different types of states? What relations are formed between institutionalized versions of sports and public powers?

Scholars in the social sciences have raised these questions only since the 1960s. Although research on the state is common among scholars in political philosophy, law, sociology, and political science, it has only recently been undertaken by scholars in the sociology of sport.

There have been English, French, and German speaking scholars with interests in political economy and the sociology of sport who have published research and theoretical essays on the relationship between sporting institutions and the state. This work varies with the underlying conception of the state used by scholars. Some have employed a Marxist or neo Marxist definition of the state and focused attention on the nature of the state, domination by the bourgeois classes (employers, capitalist class, leisure class), and the role of class power in the reproduction of the social order in general and institutionalized forms of sport in particular. This approach is structural and theoretical. Other scholars have done empirical analyses of the state, including its agencies and policies related to sport. They have provided sociohistorical accounts of the making and transformation of the contemporary state through the twentieth century (Houlihan 1991; Callède 2000). They have focused on nationalism, imperialism, and the form of the nineteenth century state, and then on the forms of the state that emerged in connection with advanced capitalism and the formation of public welfare policies during the twentieth century. Less functionalist than Marxist analyses, these studies have revealed a less monolithic state and produced typologies of state forms.

Among sociological traditions that deal with relations between sport and the state, only figurational theory produces specific insights on the making of the modern state and the place of sport in this process (Elias & Dunning 1986). The civilizing process that occurred during the fifteenth through nineteenth centuries in Western Europe assumed an associated process of state formation and the state's monopoly over the exercise of legitimate violence. Norbert Elias's analysis of the civilizing process in eighteenth century England shows that the English inner political space was pacified through a civilizing spurt, in which political elites agreed to challenge each other for access to governmental offices by using non violent strategies. Two factions of the upper classes struggled to gain power through the use of rhetoric and persuasion in a parliamentary system, rather than using coercive force. At the same time, political elites transformed their pastimes into sports, that is, into rule governed competitive games in which opponents, regulated by the norms of civility,

compete for victory without destroying each other. Elias uses historical data to show that the quest for domination in the realm of the state and on playing fields is grounded in a competitive disposition shared by those elites attracted to both political involvement and sporting activity. This theory also takes into account that as social space has divided into separate spheres through the twentieth century, it has broken the direct class based links between political activity and sporting practice. Chris Rojek addressed this divergence and proposed a complementary analysis to the work done by Elias and Elias and Dunning (Dunning & Rojek 1992).

Scholars using forms of critical theory have studied the growing involvement of political bodies in capitalist and socialist industrial nations/states in sport since the beginning of the Cold War. The sociology of culture and political sociology have been used as frameworks for developing explanations of the ways that government involvement have influenced sporting practices and the development of elite level sport in the USSR, the US, Japan, and Europe. A "pluralist" sociological model is employed by some political scientists who analyze diverse management methods across the nations, and the social functions that sport fulfills for contemporary political powers (Meynaud 1966).

Work based on a Marxist model defines the state as an apparatus dominated by the bourgeoisie, whose control is gained through a struggle among different groups competing for power (hegemony theory). This work shows the ways that sport fits into state policies, market mechanisms, and commercial entertainment regulated by the state (Cantelon & Gruneau 1983; Hargreaves 1986). It highlights the similarity between the sport related values of physical efficiency and competition, and capitalist norms of productivity and economic competition, all of which are fostered by the state (Brohm 1978). Much of this work is conceptually limited, but it has pointed out the contradictions between (1) the development of a sporting culture which attracts popular classes (soccer in Europe, football in the US, hockey in Canada), (2) the domination of bourgeois values in the sporting ethic and the control exercised by dominant classes over sport organizations, (3) the state, and (4) the corporations that sponsor sport.

In England and North America, hegemony theorists, inspired by Gramsci, and sociologists using cultural studies frameworks, have studied the ways that the working classes construct and interpret sporting practices according to their ideological and material interests. Similar work has been done by sociologists analyzing the sporting field and habitus; they identify the historical circumstances in which members of lower classes have succeeded in using the symbolism of sport to support protest and opposition to dominant economic and political norms. The state usually assists mainstream sport organizations in condemning protesters and marginalizing grassroots sport forms. However, in the US, for example, there have been cases of collective protests, such as those by African Americans in the 1960s and women in the 1970s, when the state enacted legislation to make discrimination by race and sex illegal in sports (e.g., in 1972, Title IX of the Equal Education Amendments to the Civil Rights Act made discrimination by sex illegal in schools receiving federal funds).

When scholars have analyzed sport and its functions in international political relationships they have focused on the ways that the state promotes or restricts international sporting relationships. They examine the autonomy of sporting powers and the degree of politicization in the sphere of sport. This work has examined foreign affairs and diplomacy, but has ignored other aspects of relations between sport and the state.

The material support given by the state to sport, mostly during the 1960s, enhanced the legitimacy of sport in many societies. As a result, sport and sport related values were introduced into the school curriculum in several European countries and Canadian provinces such as Quebec. The sociology of education and culture, therefore, has focused some attention on the conditions under which a bond is established between the state and sports organizations in order to impose a sporting culture in school. Some research has tried to identify the ways that state agencies are influenced by sport related lobbying interests that work in and through committees for school reform, with representatives of sport industries, or under the leadership of coaches' associations and elected representatives. The receptiveness of public officials to sporting

interests indicates a spurt of "sportization" in connection with the state. Conversely, the situation in some countries shows state interference in sport in the form of government control and a corresponding lack of autonomy in the sporting field. This was the case in the USSR with the socialist sporting system (Riordan 1977), in the Fascist regime in Italy and Germany in the 1930s, and it is still the case in nations with authoritarian regimes and military dictators (e.g., some African nations and Western Asian kingdoms). Partial forms of government control exist in strongly centralized democracies like France, where the state manages sporting centers (e.g., the National Sporting Center in Paris established in 1942), creates state guaranteed diplomas (state certificate for sporting educators established in 1962), and employs and finances technical staff in sporting federations, among other things.

In the US there is another type of articulation between the (federal) state and the sporting field dominated by men's professional leagues (such as the National Football League and Major League Baseball). Until the 1960s, the state seldom intervened in sports, except when a dispute between officials or other parties threatened the system, or when a scandal or unsavory events occurred and received public attention. The state then played a regulatory role in reconciling conflicting interests and providing equal opportunity to practice sports; it also mediated conflicts that interfered with winning medals in international competitions such as the Olympic Games. When the economic stakes associated with sports increased dramatically during the 1960s and 1970s, and when a dispute subverted the process of selecting athletes for national teams, the federal government intervened and restructured the organization of amateur sports. Like other states, the US government has influenced sports through its economic and fiscal policies (Johnson & Frey 1985).

Studies on sport and the state increased through the 1970s and early 1980s, when public sports policies reached their peak. They decreased afterwards, when neoliberal policies reduced state interventions in all social and cultural domains, including sport. At that point,

research in the sociology of sport began to focus on the professionalization and commodification of sport, and other issues in which public policies do not play a major role.

The revival of state theory in political science served as an incentive for research based on Marxism during the 1960s, and research focusing on welfare policies as state funded social programs were reduced during the 1980s. Functions of the state, as a normalizing, regulating, and repressive agent, were reexamined during the 1990s and 2000s.

The concepts used to study the state have come from the political sciences, history, and the sociology of social relationships and conflicts. Although scholars need to clarify concepts such as "the state," (sporting) "ideology," "public policy," and "domination," they have used the theories of Marx, Weber, Durkheim, Elias, Giddens, and Bourdieu in their research on sport and the state. Some research has helped us understand details in decision making processes and the financing of sport, but many questions remain unanswered. A clear definition of a frame of analysis for the "world of sports," conceived as precisely as the models of the state, would permit the development of a more coherent body of research, as it is proposed by the theory of "fields," borrowed from Pierre Bourdieu (Defrance 1995). Comparative studies are needed to explain the relationships between sport and various state forms, such as those organized around religious power, those established alongside a strong industrial capitalist sector, those that have been militarized for a long time, and others.

Questions related to the culture of the state personnel (qualified occupations in public administration) and their perception of sport should be examined to understand the public administration of sport, as well as when and where it prevails over private administration. The specific transformations of the neoliberal state since the 1980s form a new topic in the analysis of sports policies. During this period, the issue of controlling sport doping practices has become a topic that enables scholars to study alliances and oppositions between public and private powers in the governance of contemporary sports.

sport as work

Peter Donnelly

If work and sport are referred to in the same breath, it is usually as opposites. Although it is now commonplace to refer to professional sports as a business, perhaps some resentment about the salaries of some professional athletes in some sports (as opposed to, for example, a more

widespread acceptance of corporate salaries/bonuses, and incomes in the entertainment industry) is related to this sense that sport is not work. Along with leisure, recreation, games, and play, sport is usually considered as part of the non serious side of social life. However, there are many ways that sport is and has become work like, and a number of ways that sport is related to work.

Consider, for example, how sport has become a metaphor for work. Even in children's sports we continually find references to "work out," "work rate," "hard work," and "getting the job done." Taylorism, the scientific management and measurement of work, found its way into coaching and training principles in sports in the twentieth century, as coaches emphasized discipline, routine, and repetitive systems of training. As sports became both ideologically and commercially important following World War II, the emphasis on outcome (product) in the form of "win at all costs"/ends justify the means approaches became widespread. By the 1980s a system of early talent identification and intensive and specialized training for young athletes was widespread, making the experience of sports work like for many children, and leading some sociologists to refer to such involvement as "child labor" (Donnelly 1997).

The utilitarian idea that sport for its own sake was not justification enough and that sport and recreation ought to have a rational purpose first became evident in the nineteenth century, when it was assumed that the function of sport was to build character. Eventually, sport took on a larger socializing purpose. Riesman (1978) highlighted this when he observed: "The road to the boardroom leads through the locker room." Seeley et al. (1956) described how sports prepared upper middle class boys in a Toronto neighborhood for the "career." The somewhat contradictory, but career necessary skills of individual achievement and teamwork were exemplified in sports, and sports created opportunities for bonding and networking. Berlage's (1982) corporate socialization research involved a series of studies of boys' sports in upper middle class suburbs of New York City. However, feminism added a new interpretive dimension to her research, highlighting the relationship between the "glass ceiling" and sport participation. Lacking experiences in team sports,

Berlage noted, prevents women from being more successful in the corporate world.

The socialization theme was also evident in the work of several European neo Marxist sociologists of sport in the 1970s. They argued that sport in capitalist societies was practiced in such a way as to enculturate work discipline in participants and spectators. However, their argument went further, pointing out that in the relations of production of sport, working athletes (amateur and professional) were alienated from both the process and the product of their labor (Rigauer 1981). As with alienated labor more generally, sport participation held no intrinsic satisfaction for athletes who did not own the profits of their labor. These ideas were picked up in North America, where similar arguments were made with regard to college athletes (in the US) and professional athletes.

Occupational analyses of sport have addressed both direct involvement – athletes, coaches, and officials – and the numerous ancillary occupations associated with sport.

Some of the earliest studies in the sociology of sport were of professional wrestling and horse racing. Subsequent studies focused on careers such as university coaches and referees. These studies used an interactionist/interpretive approach and often focused on “career contingencies.” A critical and cultural shift in the field of subcultural research in the late 1970s led to a combination of interactionist and more critical sociologies (e.g., Ingham 1975), leading to a cultural studies approach to occupational subcultures in sports.

Ancillary occupations (e.g., sport agents, sport lawyers, sport scientists, and those engaged in the administration and marketing of sports) have received less sociological attention. However, there are growing bodies of research on clinicians involved in sports medicine; and on sports journalism, including newsroom studies, television production ethnographies, and the struggles of female journalists to cover sports. Another set of ancillary occupations involves those who work in the manufacture of sporting goods and clothing, and the construction of sports facilities. The manufacturing group has been the focus of research deriving from the anti Nike campaigns (Sage 1999) and more recently the focus has returned to child labor in the sporting goods industry, and to the

trafficking of child athletes (Donnelly & Petherick 2004). However, the majority of work in sports is carried out by unpaid volunteers – without them, a significant number of organized sports events would not occur. Although research on volunteers is just beginning, there is a small but important body of research on the ways in which women’s unpaid labor facilitates the sport participation of men and children (Thompson 1999).

The final form of work that has generated interest in the sociology of sport has been termed identity work. Research shows how individuals becoming involved in sports actively work to construct appropriate athletic identities (Donnelly & Young 1988). More recently, interest has shifted to class and gender, and to studies of racial, ethnic, and national identities, exploring the relationships between sport and attempts to produce, reproduce, and maintain relevant identities.

The Beijing Olympics may provoke more interest in fair labor practices in sports; there is growing interest in the work of sports clinicians, and in workplace health and safety/injury issues related to sports; research has begun to focus on sport volunteers and ideas of social capital and community; and studies of identity work will continue as researchers turn to Bourdieu’s theories to analyze the ways that individuals work to maintain class distinctions through sports.

sportization

Joseph Maguire

The sportization process involved a shift towards the competitive, regularized, rationalized, and gendered bodily exertions of achievement sport that, in turn, connected to wider changes at the level of personality, body deportment, and social interaction. This process entailed regulating violence, developing formalized sets of rules and governing bodies, and shifting body habitus. Despite the existence of European rivals in the form of German and Swedish gymnastics, and although some older folk pastimes also survived, it was male achievement sport, emerging out of England, that was to affect people's body habitus on a global scale. Resistance to and reinterpretations of this body culture have been evident throughout the ongoing sportization process.

The initial sportization of British/English pastimes occurred in phases. There was a seventeenth and eighteenth century phase in which the principal pastimes of cricket, fox hunting, horse racing, and boxing emerged as modern sports. A second, nineteenth century phase followed in which soccer, rugby, tennis, and track and field assumed modern forms and during

which school based sport developed (Elias & Dunning 1986). A third sportization phase during the late nineteenth and early twentieth centuries paralleled wider globalization processes and was shaped by a series of global flows. Modern sport rapidly diffused globally along the lines of the formal and informal British Empire. At this stage, the content, meaning, and control of sport reflected British/European male values. The fourth phase lasted from the 1920s through to the 1960s, when sportization processes, though still powered by western values, increasingly reflected "American" notions of sport and was further consolidated across the non western parts of the globe. Beginning in the late 1960s, there emerged a fifth phase of sportization containing two seemingly contradictory features: the increasing standardization of what counts as sport – through media sport and the Olympic movement – combined with new varieties of body cultures and movements that challenge the hegemony of modern achievement sport (Maguire 1999).

There is a series of structured processes that have permeated the five phases of sportization (Maguire et al. 2002). While the reach and spread of each of these structured processes has varied over time and across space, they now constitute modern achievement sport – the context within which people experience global sport (Guttmann 1994; Van Bottenburg 2001). The pattern and development of these structured processes also reflects and reinforces prevailing established/outsider relations and the power geometry within specific societies. These structured processes involve the following.

First, there is the emergence and diffusion of achievement sport accompanied by the decline of both western and non occidental folk body cultures. Modern achievement sport has marginalized indigenous games. Although such practices have not disappeared, and may, in some societies, be undergoing revival, the overall trend is for folk games to become residual features of body cultures (Renson 1998).

Second, global sport reflects a gendered ideology and content, making it a "male preserve" whose levers of power are still handled by men (Hargreaves 1994).

Third, sportization involved the development of physical practices that entail schooling the body. There have been shifts from

nineteenth and twentieth century forms of “drill,” European forms of gymnastics and dance, Physical Training, and Physical Education to late twentieth century practices associated with Human Movement Studies, Sport Science, and Kinesiological Studies. The state, through its compulsory schooling policies, has thus played an active role in the reinforcement of global sport (Maguire 2004a).

Fourth, from its inception through its current high tech manifestations, modern achievement sport has reflected and reinforced the medicalization, scientization, and rationalization of human expressiveness. The athlete is increasingly seen as an enhanced, efficient machine, adhering to a sport ethic associated with the “ultimate” performance. The logic at work may well be leading the athlete towards genetic modification and a cyborg coexistence (Hoberman 1992).

Fifth, global sport has impacted the habitus of people across societies and the habitats in which they live. Over time, as sport practices moved from small to large scale, from low intensity to high intensity forms, and from “natural” materials to synthetics, the athlete, spectator, viewer, and employers became consumers of scarce resources and threats to the environment (Maguire et al. 2002).

Sixth, the global diffusion of sport has reflected the ongoing balance of power within and between nations, and today the sport power elite have maintained their grip on power and been joined by a range of representatives from large media and sponsoring corporations (Miller et al. 2001). Demands for democratic control and transparency and accountability in decision making remain unfulfilled, while academic stakeholders are frozen out of the sport policy process.

Seventh, both in the making and ongoing formation of global sport we see the reinforcement and enhancement of global inequalities within the West and between the West and non occidental societies. Here, questions concerning cultural power, civilizational struggles, and wider globalization processes arise (Maguire 1999; 2004b).

sports heroes and celebrities

Steven Jackson

The terms hero and celebrity have increasingly become used interchangeably, but they are fundamentally different. According to Daniel Boorstin, “*The celebrity is a person who is known for his well knownness ... The hero was distinguished by his achievement; the celebrity by his image or trademark. The hero created himself;*

the celebrity is created by the media. The hero is a big man [*sic*]; the celebrity is a big name" (1992: 57, 61). Thus, there are some clear distinctions between the two concepts and the challenge is to ascertain how and why they have become conflated. First, we must examine the meaning, significance and types of heroes and why sport remains such an important site for their identification and development. In turn, we need to understand how changes in wider society have tended to shift attention, status, and rewards from heroes to celebrities.

Heroes/heroines have existed throughout human history. From ancient Greece and Rome through the Middle Ages and the Renaissance to the twenty first century, societies and cultures have created, defined, bestowed, and otherwise recognized what is known as a hero (Klapp 1949). In Browne's (1990) view, heroes highlight the potential and possibility of humans by expanding and/or conquering the physical, psychological, social, spiritual, and altruistic limits of human beings.

And while there are many cultural arenas in which individuals have emerged as heroes, sport has always been one of the key sites. There are likely many reasons for this, but in particular sport, as a cultural practice and institution, offers the opportunity for the demonstration of physical superiority in a system with clear rankings and rewards, the display of courage, commitment, and sacrifice, and the chance to represent a particular group, community, or nation. In a contemporary commercial context the latter point is quite important, given that "Only sports has the nation, and sometimes the world, watching the same thing at the same time, and if you have a message, that's a potent messenger" (Singer 1998; cited in Rowe 1999: 74).

Even a cursory look at the diversity of sport heroes, both historical and contemporary, indicates that they emerge from a wide range of personal achievements, social backgrounds, and cultural contexts. In effect, there are different ways by which heroes emerge. Although the typology that follows is not exhaustive, it may aid in understanding the process of how different individuals became heroes. Although the categories are not mutually exclusive, one becomes a hero in one of four ways (Ingham et al. 1993). First, a person can perform an extraordinary superhuman feat. In actual fact

heroes are often people who perform ordinary things but at a much higher level and with much greater consistency than the average. A few people who fit this category might include Sir Donald Bradman, Babe Didrikson, Jessie Owens, Paavo Nurmi, Pelé, Nadia Comaneci, Michael Jordan, Wayne Gretzky, Carl Lewis, Tiger Woods, and Lance Armstrong.

Second, one can become a hero by being the first to achieve a particular and unexpected standard. Such a category would include people like Sir Roger Bannister who, in 1954, was the first person to break the 4 minute mile; or Sir Edmund Hillary who, along with Tenzing Norgay, was the first to climb Mount Everest, the highest point on earth, in 1953.

Third, one can become a hero through risk taking, personal sacrifice, and/or saving a life. There may be no better example of this type of hero than Canadian Terry Fox. Diagnosed with cancer and with part of his right leg amputated, Fox set out to run across Canada in what he called the Marathon of Hope. Sadly, his run ended after 3,339 miles because the cancer spread to his lungs. Terry Fox died at age 22 on June 28, 1981. Still his life and mission are celebrated annually. Each September 13 marks the Terry Fox Run and to date his foundation has raised over \$360 million.

Fourth, a person can become a hero by virtue of a particular performance within a specific sociohistorical context: being the right person at the right time (see Ingham et al. 1993). One example of this type is John Roosevelt (Jackie) Robinson, who, facing enormous racial discrimination and other social barriers in 1947, became the first "black" athlete to play Major League Baseball.

The world still has heroes, but something has changed in terms of the type of people that society celebrates and rewards. Increasingly, status appears to be something that is *manufactured* versus *achieved* and heroes are being marginalized by celebrities, stars, and idols (cf. Andrews & Jackson 2001; Dyer 1979; Gamson 1994; Rojek 2001). While there are no simple answers to explain this transformation, consideration must be given to the emergence of the society of the individual, a greater scrutiny of private lives embodied in an exploitive tabloid culture, and a world driven by consumption, advertising, and marketing. As a consequence,

“everyone is involved in either producing or consuming celebrities” (Rein et al. 1997: x). Arguably, the most powerful vehicle in this shift are the media, whom Leo Braudy (1997: 550) calls the “arbiters of celebrity.” The media are global, immediate, and increasingly interconnected, resulting in a virtual saturation of celebrity culture linked to sport, music, fashion, movies, and reality television.

Ultimately, we are left with a challenge to gain a better understanding of the social and political function of contemporary heroes and celebrities. In part, this will require an examination of who has the power to define heroes and celebrities, under what conditions, and in whose interests.

sports industry

Dominic Malcolm

Sport became an industry at the point at which events (matches, races, bouts) ceased to be oriented solely toward participants and became largely organized so that they could be consumed by spectators. In perhaps the earliest sociological analysis of this process, Gregory P. Stone (1955) argued that consequently “play” (unscripted, spontaneous) became overshadowed by “display” (prearranged, staged, spectacular); that is to say, in some respects industry or commercialism is the very antithesis of sport. This critique still lingers amongst those who might be termed “purists,” but it must now be recognized that whilst on the one hand sport has become an industry just like any other, on the other hand, and particularly in terms of the demand for sport, it has a number of distinctive or peculiar features.

Contemporary analysis of the sports industry can be subdivided into four mutually interdependent parts: sports teams and leagues; the media; sponsors and manufacturers; and sports celebrities. A brief initial examination of the development of the sports industry, however, will be used to demonstrate the long lineage of these commercial processes, and therefore to correct the prevalent, false, assumption that they are unique to contemporary sport.

Aspects of a sports industry can be seen in the “sports like” activities of ancient Rome, but it is more useful to trace the development of the sports industry back to eighteenth century Europe, and England in particular. At this time, tavern owners and innkeepers started to exploit existing sports events to increase trade. The more entrepreneurial would provide facilities for playing cricket, quoits, horse racing, cock fighting, and so on. As the eighteenth century progressed, tavern owners started to charge admission fees to supplement the profits made through the sale of refreshments and lodgings. Subsequently, the emergent ruling bodies of sport (e.g., the Jockey Club, the Marylebone Cricket Club) established their own permanent facilities (i.e., Newmarket Race Course, Lords Cricket Ground) to contain the 10,000 plus

spectators that could be attracted to the major sporting events of eighteenth century England.

The development of the sports industry in England progressed relatively unrestricted until the advent of amateurism in the middle of the nineteenth century. Boxers, cricketers, and jockeys were often sponsored by a wealthy aristocrat who would employ talented sportspeople, nominally as household servants or for work on his estate but, in fact, principally on account of their sporting skills. The first professional sports team was William Clarke's All England XI, a cricket team which toured England playing "exhibition" matches from 1846 to 1870. A number of imitators soon followed. Churches and factories were subsequently influential in establishing works teams. These teams came to represent towns and cities and thus became key sites of identity formation in a time of industrialization led geographical mobility. Public demand for regular and meaningful fixtures, fueled by the emerging publishing industry that grew up around sporting contests, led to the establishment of the Football Association (FA) Challenge Cup in 1871 and the English Football League, consisting of 12 clubs from the English Midlands and the north, in 1888. In 1895, rugby clubs in the north of England broke away from the staunchly amateur English Rugby Football Union (RFU), ultimately forming a professional version of the game, rugby league. English counties first competed for a cricket championship in 1873 (Holt 1989).

Whilst the emergence of a sports industry in America was initially slower, the lack of a strict adherence to amateurism enabled it to subsequently develop rather more rapidly. During the 1860s sports entrepreneurs enclosed grounds, assembled "all star" teams, and charged entry fees. Initially, baseball was strongly influenced by the amateur ethos, but by the time the National Baseball League (NBL) was formed in 1876, commercialization and covert professionalization were well established. Albert Spalding, a significant driving force in the development of the NBL, had the year before moved from the Boston Red Stockings to the Chicago White Stockings because he was offered a well paid job in a grocery which entailed minimal duties and thus the chance to play regular baseball. Spalding subsequently went on to organize

promotional baseball tours to England and develop baseball related merchandise such as balls, uniforms, and bases. The antecedents of today's sports industry were well established in nineteenth century Britain and America (Wiggins 1995).

SPORTS TEAMS AND LEAGUES

The appeal of sport, and therefore the economic viability of the sports industry, is said to depend on "uncertainty of outcome," i.e., its unpredictable, unscripted nature. It is on this basis that anti competitive practices (the draft system, collective merchandising, and revenue sharing agreements) and legal exemptions from antitrust laws exist in many US sports (and to a lesser extent under EU law). US leagues are organized as monopolies – or cartels – with no automatic mechanism for the removal of weaker clubs and their replacement by stronger teams. By limiting the extent to which the individual teams compete against one another for fans, media revenues, and merchandise sales, the league is in a stronger position to eliminate competition from rival leagues. The peculiar feature of sport in the US is that competitions are oriented toward the economic benefit of all the teams in the league, rather than forwarding the interests of individuals and individual teams (Gratton & Taylor 2000).

Somewhat ironically, after decades in which team sports have not been particularly profit oriented (economists have traditionally described English professional football clubs as utility maximizers rather than profit maximizers), the leagues and sports clubs of Europe have, in some regards, "out commercialized" their American role models. Pyramids of leagues exist to enable weaker teams to be replaced by stronger ones. Leading clubs have successfully sought to consolidate their own economic position, at the expense of teams with less popular support, using as leverage the threat of withdrawal from existing competitions and the establishment of their own private league and cups. Recently developed European football competitions (e.g., the European Champions League in football) structure prizes and revenue sharing to favor the clubs from the wealthiest leagues. Currently,

broadcasting rights are sold by the league or competition as a whole, but if clubs were to negotiate individually, some, and Manchester United in particular, would be likely to profit considerably. To this end, some clubs (e.g., Manchester United) have established their own television stations. Whereas most American sports organizations are privately owned but reliant on publicly funded or owned stadia, mainland European (football) clubs have traditionally been membership clubs owning their own facilities (though an increasing number have established commercially oriented, more streamlined, executive boards in the last decade). Traditionally, English sports clubs have been privately owned but in an attempt to release capital and increase spending power, many have become publicly listed companies on the London Stock Exchange. A consequence of this is that clubs now have a legal obligation to prioritize the interests of shareholders, and inevitably this leads to a more direct pursuit of profit.

THE MEDIA

It is often said that the relationship between the media and sport (but strictly speaking the sports industry) is symbiotic. Media companies pay large amounts for the right to broadcast particular sports events because the programs are cheap to produce, attract relatively large audiences, and because the demographics of the viewers they attract (e.g., young males with large disposable incomes) appeal to sponsors who, in turn, are willing to pay large fees for the right to advertise during the broadcast. The sports industry needs the media both as a source of income and as a means of publicity. The balance of power between the sports industry and media companies varies from sport to sport and between countries. However, certain common patterns of the ways in which the media have shaped sport in recent years are identifiable (Wenner 1998).

First, media companies request that events are scheduled at particular times in order to appeal to the largest viewing audience. The establishment of Monday night football in the US is a classic example. Similarly, whilst

English football matches have traditionally been held on Saturday afternoons, increasingly television has (successfully) requested matches to be rescheduled to Sundays, Monday nights, and Saturday mornings in order to maximize viewing figures (which itself has led to the expansion of the phenomenon of sports consumption based around bars and inns). International sporting events, such as the Olympics, are most heavily influenced by the media of economically dominant countries, i.e., the US. Second, it has been claimed that media companies have forced changes to the structure of the sports themselves. Boxing contests were reduced from 15 to 12 rounds, it has been argued, to enable television companies to more conveniently package bouts within a 1 hour time slot. Rule changes have increasingly protected quarterbacks in American football to encourage a more open passing game. Free throws in basketball have been minimized to speed up the action. Third, accompanying these structural and timing changes have been changes in presentational style. The use of loud music, video, cheerleaders, and mascots all serve to make the behavior of sports crowds more orchestrated, and thus more amenable to broadcasters' desires and production needs. Whilst there is a tendency to exaggerate the media's influence (sports are not fixed in time, and rules are not inherent or unalterable but have continually been refined for various purposes), commercial interests currently play a larger part in rule reformation than at any stage in the past (Sewart 1987).

Some sports events combine some or all of these characteristics and essentially become "TV made" (e.g., Kerry Packer's cricket "circus" in Australia, indoor soccer leagues in America, professional wrestling competitions). Television programs such as *Gladiators* illustrate the media's ideal format for sports but, tellingly, as Stone earlier argued, the demands of spectacularization are sometimes entirely antithetical to play, for they destroy the uncertain element that is the basis of the appeal of sport. This has led television companies to pursue a new strategy, the purchase of sports clubs, for this is now seen as the most effective way in which broadcasters can exert control over "genuine" sporting events which enjoy enduring and widespread popularity.

SPONSORS AND MANUFACTURERS

Sponsors of sport can be divided into two groups, those whose products are intrinsically sport related, and those whose aren't. For the latter group, sport is seen as a useful tool through which to promote products because of the supposedly health promoting and character building qualities of sport. The mass and youth appeal of sport is similarly attractive to sponsors and the male dominance of sports spectatorship has led numerous beer manufacturers to sponsor leagues and teams. In recent years tobacco companies have used sports sponsorship (most notably motor racing) to overcome legal restrictions on their ability to advertise. A classic example of what has been called the "sport-media-production complex" is the coalition of the National (American) Football League (NFL), Anheuser Busch (makers of Budweiser beer), and British television company Channel 4 (Maguire 1990). Their mutual interests converged in an attempt to increase the popularity of American football in the UK, overcome the British perception of American beers as unmasculine, and aid a newly established broadcaster to develop a distinct profile and market. Despite the triumvirate's success in the 1980s, the subsequent decline of American football in the UK again shows the limits of the industry's ability to manipulate popular demand.

There is, however, a more natural link between sport and companies producing sports related products, but it is only since the 1980s that the demand for sports related goods – such as sports shoes – has become big enough (i.e., as high performance sports gear has become high fashion) to justify the levels of expenditure required to sponsor major sports events. Nike are thought to have changed the rules for sports marketing by paying huge endorsements to tie athletes to using their equipment (\$90 million for basketball's LeBron James, \$450 million for the right to run Manchester United's merchandise and kit operation) and "in your face," aggressive advertising linking their products to the athletic success of a few high profile individuals. Nike, more than most, have had to deal with accusations about their dependency on exploited Asian labor, but this seems to have had little impact on sales and profits (Sage 1999).

SPORTS CELEBRITIES

It is the convergence of the interests of sponsors such as Nike, media/television companies, and sports organizations that means that when we look at the sports industry we must recognize the role of sports celebrities (Andrews & Jackson 2001). The sports industry idealizes images of sports celebrities so that they become general objects of glamour and fantasy in popular culture. Nike's endorsement deal with basketball superstar Michael Jordan led the "Air Jordan" sports shoe to become the highest selling sneaker of all time, and helped bolster the popular appeal of the NBA. But these interdependencies also fed Jordan's celebrity status, which in turn served as a site for the production of particular (largely racial) ideologies. Sociologists have also highlighted how, in tennis, the Anna Kournikova sports industry produces ideologies relating to gender and how Nike's work with self starred "Cablinasian" golfer Tiger Woods has sought to promote a color blind, multicultural America of the future, which in turn has helped open up lucrative new markets for golf equipment in Asia.

But perhaps at the pinnacle of this sports celebrity industry is English footballer David Beckham, about whom an increasing quantity of academic literature has appeared (Cashmore 2004). Beckham ties all these themes of the sports industry together: a sport which has in the last decade exploited satellite television technology to increase exposure and generate ever increasing income; a player for the wealthiest soccer clubs in the world (Manchester United, Real Madrid); huge endorsement contracts with Adidas, Brylcreem, and others; and, underlying his success and celebrity status, the production of various class and sexuality discourses. But more than this, unlike Michael Jordan whose celebrity was a largely North American phenomenon, Beckham, by virtue of playing the only truly global sport, is perhaps the most globally recognized sports celebrity.

The sports industry started as a local financial venture, with locally based sports celebrities like Albert Spalding. As the Beckham case shows, the contemporary sports industry has expanded to be global in scale, hunting out new audiences and markets for merchandise, filling increasing amounts of television airtime, and creating new

sources of revenue for sports teams, sports media, sports sponsors, and sports celebrities.

sports stadia

John Bale

Sports do not require stadia, but in their modified form they have come to be seen as necessities. In contemporary discussions of the sports stadium two broad themes have attracted the attention of both sports scholarship and public opinion: (1) activity and organization

within the stadium, and (2) extra stadium effects and implications. Academic approaches to these themes are considered in turn.

The sports stadium is an ambiguous architectural form. It has been read and written from various perspectives. With its rows of numbered seats, its geometrically segmented form, and the all prevailing video surveillance equipment, the modern stadium has been read as an example of container architecture analogous to a prison. Such a reading draws on the ideas of Michel Foucault. It is undoubtedly a secure place to house large numbers of bodies and, in times of unrest, stadia occasionally have been used as places of incarceration. The gaze of the police and video camera is, at the level of the “playing field,” matched by the gaze of the referee or umpire. The controlled character of stands and bleachers is matched by the spatial positioning and constraints on those who entertain the entertained. The spectators and the players each have defined positions in stadium space. The stadium, then, is a facility for displaying dominance and power. A Marxist view would add that it is a modern site of “bread and circus” (Brohm 1974) in the production of “docile bodies.” This is not to say, however, that resistance from both spectators and players has been eliminated, as numerous studies of deviance and hooliganism testify (Dunning et al. 2002).

The Foucauldian model can be read as a malign, pessimistic view of power. An alternative, slightly more benign perspective is to see the stadium as a theater. Elias and Dunning (1986) write that the drama as a game of soccer unfolds has something in common with a good theatrical play. The play has a script; sports have their game plans. A major difference, however, is that the modern theater crowd remains passive compared with that of the sports stadium, though this was not always the case. And there is a logical case for making the sports crowd more like that of the theater. After all, it is well known from studies of the home field advantage that the crowd has an impact on sporting performance, hence contributing to an unfair advantage. Some postmodernists have suggested, therefore, that crowds should be excluded from stadium sports events (Bale 2003).

A widely used third metaphor is that of the garden: a stretch of grass (nature) in the middle of the city (culture). This view is encouraged

by the notion that there is more to the stadium experience than watching a game (Raitz 1995). The color, the playfulness, the noise and smell are said to make the stadium visit a sensory experience or a carnival. Of course, there is nothing "natural" about a football, baseball, or cricket field. Indeed, the progress of "turf science" has produced grass surfaces that are often almost indistinguishable from nylon carpets. Nevertheless, the garden metaphor is revealing in that, like the garden, the stadium is a melding of horticulture and architecture, and of dominance and affection. Arguably the prime advocate of the stadium as garden is Bartlett Giamatti (1989), who sees the stadium as an adult version of the kindergarten. And it worth recalling how many stadia are still called gardens and parks, despite the absence of flowers, trees, and foliage.

It is also possible to read the stadium as a reduced mirror image of the city (Bromberger 1995), with its segmented spectator space and sense of community. Different research, then, reads and writes the stadium in different ways.

A second broad approach to "stadium studies" is to explore the wider impact that the stadium has on urban or rural space. The social, economic, and geographical impact of stadia in urban areas has been the subject of considerable research. Residents and business in close proximity to stadia may receive both indirect benefits and disadvantage from such proximity. Quality of life can be reduced for such residents on game days as noise, crowds, and various forms of pollution may be imposed upon them. These are the stadium negative externalities. Contrariwise, some businesses such as bars and vending depend greatly on stadium events for revenue. From a social perspective the presence of a local stadium and its occupants can generate bonding and place pride (Bale 2001).

Stadium relocation – implying the migration of the clubs and teams that play in them – has become a widespread phenomenon in the United States. It is widely believed that the construction of such new stadia adds to urban image, status, and economic regeneration. It is further argued that the new spending associated with such facilities creates an economic multiplier effect that boosts local or regional wealth. The evidence for such positive effects of stadium development is mixed, but the general

view is that the benefits of such developments are often negative (Baade 1995).

Stadia are increasingly becoming multifunctional facilities or "entertainment centres" rather than monofunctional spaces, dedicated to a specific sport. The diversity of stadium activities is driven by the need for revenues and profits, hence the need for intensive use of space. The ambiguous nature of domed stadiums, for example, with retractable roofs, and associated banqueting, hotel, conference, and restaurant facilities, makes it clear that these places are not just for sport. The Toronto Skydome (Kidd 1995) represents an early example of such a structure, and Ritzer (2005) has identified recently constructed, large stadiums as "cathedrals of consumption."

stalking

Emily Finch

No single definition of stalking exists. This is probably because, despite certain commonalities, there is no prototypical case upon which a definition could be founded. Although some types of behavior are common in many stalking cases – silent/abusive telephone calls, unwanted gifts and letters, surveillance – each case involves an idiosyncratic combination of these and other diverse types of behavior that renders a definition based on the conduct involved somewhat nebulous. Other than this, definitions have isolated factors such as the relationship between the parties or the motivation behind the behavior, but again, these are so diverse and wide ranging that it is impossible to formulate a definition that captures the full spectrum of stalking cases. Although the various attempts at definition differ, a common theme exists that facilitates the identification of core characteristics: repeated and unwanted intrusions into the life of another that engender a negative reaction in the recipient.

Stalking emerged as a pressing and prevalent social problem during the 1990s. Its emergence was incremental as stalking developed through a series of manifestations before becoming embedded in the public consciousness. Initially, stalking rose to prominence in the United States as a problem experienced by celebrities as over zealous fans resorted to desperate measures to make contact with the object of their affections. Gradually, it became apparent that stalking was not just a celebrity problem but something that affected “ordinary people” too, although this was generally viewed as occurring in the context of a turbulent or terminated domestic relationship. It was for this reason that stalking became viewed for a time as inherently associated with domestic violence. It underwent a further metamorphosis as non relational stalking

rose to prominence. This manifestation of stalking, in common with celebrity stalking, had connotations of irrational obsession and mental illness as it became clear that stalkers could develop an obsession based on only tenuous contact with the victim. Although the evolutionary period of stalking gave rise to some divergent constructions, it finally emerged as a problem that was based upon repeated, unwanted, and unwelcome intrusion into the victim’s life irrespective of the identity or relationship of the parties involved.

Even after the emergence of stalking as a social problem and the development of a shared social understanding of its nature, there were impediments to the formulation of an appropriate and effective legal response. Definitional difficulties thwarted some of the earliest attempts at the introduction of stalking legislation due to the formidable challenge of creating legislation that differentiated between stalking and lawful conduct. It became clear that an unfortunate paradox existed in relation to a legal regulation of stalking. If stalking involved conduct that was inherently unlawful such as damaging property or causing harm/injury, for example, the police were able to intervene without the need for reliance on stalking legislation. Frequently, however, the stalker would engage exclusively in lawful conduct such as sending gifts or waiting for the victim in a public place, so any attempt at the criminalization of stalking needed to find a means of distinguishing between such conduct undertaken for lawful reasons and that undertaken as part of a campaign of stalking. How is the law to encapsulate the amorphous distinction between the single minded pursuit of the object of desire that occurs in stalking cases and which mirrors the socially acceptable pursuit of one’s true love in a way that criminalizes the former without undermining the legitimacy of the latter?

Ogilvie (2000) attributes this definitional dilemma to the “paradoxical status of stalking as simultaneously being an exemplar of conformity and criminality.” This acknowledges that stalking frequently involves behavior that would not be regarded as deviant or unacceptable if it were to occur in a different context. Sending flowers to a loved one can be distinguished from sending flowers to a total stranger, but even this is not unacceptable if it is welcomed by the

recipient as a romantic gesture. Context is every thing in stalking cases. Unlike the majority of criminal offenses, stalking frequently involves no breach of normative conventions; rather, it often involves lawful conduct that engenders a negative reaction in the recipient. As such, the response of the recipient of the conduct is legally transformative; a positive or indifferent response allows the conduct to retain its lawful nature whilst an adverse response brings the conduct within the remit of stalking and hence within the reach of the regulation of the law.

Stalking is particularly problematic in the complex context of sociosexual relationships in which pursuit and persistence is socially acceptable, even desirable. Mullen et al. (1999) believe that the apparent increase in stalking in the late twentieth century can be attributed in part to the more transient nature of relationships, which can leave individuals feeling isolated and rejected and thus engender desperation to find a partner. The intensity of these feelings and the pressure to achieve social acceptability by the formation of a romantic relationship can lead individuals to engage in overexaggerated or excessive romantic gestures; what Ogilvie (2000) describes as an "amplification of normative conformity." If this coincides with an anxiety induced inability (or reluctance) to recognize the often subtle social cues that delineate the parameters of acceptable behavior at the early stages of a sociosexual relationship, then the initiator of the conduct may be unaware that his attentions are unwelcome. Differential understanding and interpretations of the same events by different actors are frequently the basis of accusations of stalking. In a culture in which the authorities play an increasing role in what was previously considered to be the private realm of interpersonal relationships and in which there is an expectation of the state's protection from all that is adverse and unpleasant in society, the primacy of the recipient's interpretation and the consequent criminalization of such events were an almost inevitable development.

standardization

Darin Weinberg

Standardization is a procedure used in science to increase the validity and reliability of research. It is predicated on the principle that truly objective scientific findings ought to be non contradictory and replicable and that the most efficient technique for facilitating both internal consistency and replication is to ensure that the various aspects of research design and conduct (e.g., measurement instruments, methods of data collection, methods of analysis) do not clash either within the confines of a particular study or from one study to the next. Standardization is thought to fortify scientists against the biases that may otherwise be introduced into research by things like their own personal characteristics and/or the characteristics of the particular social contexts within which research is conducted. The concept of standardization is used in two distinct but related senses in science. In a purely descriptive sense, the standardization of research methods secures uniformity in the scientific enterprise by establishing a certain lingua franca within which to conduct meaningful and productive dialogue and debate. Standardized methods facilitate confidence among researchers conforming to them that they and others who also conform are gathering new knowledge about the same empirical phenomena. In the second sense, standardization is less descriptive than prescriptive. Hence one seeks to standardize scientific research methods not

only to make them uniform among scientists studying the same things, but also to ensure that a certain level of excellence is maintained. In this sense, scientists seek to standardize research methods not only to keep standards uniform but also to keep them “high.” In the social sciences, the concept of standardization has become particularly important in survey research. Considerable efforts are made to both promote the uniform adoption of particular question formats and other kinds of measurement instruments across studies and to ensure uniformity of procedure amongst interviewers working on the same study. Critics of standardization sometimes argue that procedures that ensure scientific findings can be replicated, or reproduced at different times and in different places, are not the same as procedures that might ensure that those findings are in fact valid. These critics argue that the preoccupation with replicability can easily mistake reliable findings for valid ones. Other critics suggest that standardization inevitably entails a level of veiled coercion as proponents of different standardized procedures wrangle with one another for supremacy. Still others suggest that standardized research methods impose an artificial framework on the collection of data that can introduce distortions into our data. These critics suggest that a more naturalistic and spontaneous approach to data collection may facilitate a more nuanced sensitivity to the nature of phenomena under investigation. More recently, sociologists of science have shown that standardized procedures must inevitably be applied in real world research situations that require discretionary assessments as to whether those procedures have been implemented properly. Because these discretionary assessments themselves can never be fully reduced to standardized protocols, we must remain cognizant of the fact that standardization can never completely eliminate the influence of specific individuals and specific social contexts on the conduct of scientific research.

standardized educational tests

Mark Berends and Albert Boerema

Standardized tests are tests that are administered under controlled (or “standardized”) conditions – specifying where, when, how, and for how long test takers may respond to questions. The test questions provide a way to gather, describe, and quantify information that assesses performance on particular tasks to demonstrate knowledge of specific topics or processes. Standardization is important to compare individuals or groups and involves a consistent set of procedures for designing, administering, and scoring the test. The aim of standardization is to ensure that test takers are assessed under the same conditions, assuring that their test scores have the same meaning and are not influenced by differing conditions. Such standardized tests occur over the life course, with a range of uses including determination of school readiness, achievement throughout the schooling progress for students, accountability for districts, schools, teachers, and students, capabilities for college, and achievement as employees in the workforce.

Standardized tests, as a part of the wider educational, psychological, and sociological testing and assessments, have a long history within the United States. They represent one of the most important contributions of behavioral and social science to society, even though tests have been used in a myriad of proper and improper ways (AERA 1999). Their history is deeply rooted in a United States culture that is: empirically oriented and data driven; focused on change, which is assumed to be progress; embraces a belief that evidence can provide general guidance for efficient action; and straddles the choices that give individuals certain advances versus choices that serve the larger society (Baker 2001).

As described by *Standards for Educational and Psychological Testing* (1999) – an authoritative document on standards for measurement – there are four important facets of testing standards: (1) technical standards for test construction and evaluation; (2) professional standards for test use; (3) standards for particular applications; and (4) standards for administrative procedures. For a standardized test to be technically adequate, it should meet standards of validity and reliability, whether the test is norm referenced or criterion referenced.

Reliability is the degree to which the results of an assessment are dependable and consistently measure particular student knowledge and/or skills. Reliability also refers to the consistency of scores over time, across different performance tasks or items intended to measure the same thing, or consistency of scores across different raters. That is, reliability statistics can be computed to measure (1) *item reliability* – the relationship between individual test items intended to measure the same knowledge skills; (2) *test/retest reliability* – the relationship between two administrations of the same test to the same student or students; or (3) *rater reliability* – the extent of agreement between two or more raters. If assessments are not reliable, they cannot be valid.

Validity refers to both the extent to which a test measures what it is intended to measure and the appropriate inferences and actions taken based on the test scores. If a math test can only measure a subset of the domain of math skills, how confident are we that students are good at math if they perform well on a math test? How

confident are we that the proficiency level accurately portrays proficiency in mathematics? Within the current policy environment of the United States, if an assessment is to be valid, it should be aligned with the standards it is intended to measure and it should provide an accurate and reliable estimate of the students' performance relative to the standard.

In addition to the importance of standardized tests being reliable and valid, they can be either norm referenced or criterion referenced. A *criterion referenced* test is linked to specific performance standards or learning objectives. One interprets scores on criterion referenced tests based on the degree to which students demonstrate achievement of the specific learning standards and not how students perform compared to other students. On a criterion referenced test, it is possible that all students (or no students) will perform well on the specific learning objectives or standards. Of course, the percentage of students who will perform well on specific learning objectives depends on how ambitious those performance standards are (Linn 2003).

In contrast to criterion referenced tests, *norm referenced tests* are tests that compare student performance to a larger group. Typically, this larger group, or norm group, is a national sample representing a large and diverse cross section of students that allows comparison of a particular student's performance to the performance of others. The scores on norm referenced tests allow comparisons between the norm group and particular students, schools, districts, and states. All of these tested groups can be rank ordered in relation to the norm group. Thus, norm referenced tests are typically used to sort students rather than measure proficiency of specific learning objectives or standards.

Standardized testing has played a number of important roles in educational settings. These tests have been used for placement in instructional groups (e.g., ability groups or tracks), measuring achievement, assisting in making career and postsecondary educational choices, determining acceptance of applicants to colleges and universities, and monitoring the performance of educational systems.

Intelligence testing to guide ability grouping was one of the early uses of standardized testing (Cronbach 1975). The perceived need for ability grouping arose as two factors – students

staying in school longer and the large waves of immigration to the US at the turn of the twentieth century – created a wider range of student ability in high school classrooms. These changes had an impact on college bound students whose progress was held back, according to some ability grouping proponents, by the large number of students who did not seem to be academically gifted.

Following from the work of Binet in development of what were called “mental tests,” Terman developed a screening tool to identify students who were viewed as not prepared for the intellectual challenges of typical schooling with such labels as “feeble-minded” or “retarded” (Resnick 1982). These early tests were administered individually to students to determine whether they should be removed from normal instruction. Wholesale use of intelligence testing was introduced by the military during World War I, when tests were developed to identify potential officers. The successful use of standardized testing by the military encouraged further development of tests and non military use, such as determining placement of students in homogeneous instructional ability groups (Resnick 1982). In the 1950s, there was a resurgence of intelligence testing for the purpose of grouping as a result of implementing the comprehensive high school with differentiated tracks (Linn 2000).

A second use of standardized testing has been the measurement of student achievement levels in a variety of academic domains. Examinations had long been used to determine student progress and set standards for high school graduation, but as the number of students increased it became necessary to establish standardized criteria. The National Education Association adopted recommendations to standardized evaluation in 1914. At the time of World War I, there had been a rapid increase in the number of achievement tests, numbering more than 200 available for use in the primary and secondary schools (Resnick 1982). Later, a related use of achievement testing was the implementation of minimum competency testing for high school graduation in the 1970s and early 1980s (Linn 2000, 2001).

Standardized testing played a third role as it was used by school guidance departments to assist students in job or career selection and in

making decisions about attending postsecondary institutions. Testing in this area included assessing student aptitudes, interests, and skills to guide decision making between career and educational options. One aspect of this innovation was the move to keeping cumulative student records to document continued individual development (Resnick 1982; Linn 2001).

Determining whether students were academically prepared for college and university entrance is a fourth use of standardized tests. In 1899, the College Entrance Examination Board was created to “establish, administer, and evaluate examinations, in defined subject areas for entrance to participating colleges” (Resnick 1982: 187). After World War I, the Scholastic Aptitude Test (SAT) was developed to provide a standardized test that was not based on a specified curriculum, such as one from a college preparatory school. The focus on aptitude rather than curriculum was seen as being more equitable. In addition, the SAT introduced the use of multiple choice rather than essay type questions. Performance on the SAT and the American College Test (ACT), which was introduced in 1957, became a major component in the decision to accept students into most postsecondary institutions in the US.

A final important role of standardized testing, and possibly one of the earliest, was to compare schools and monitor their performance. As early as the 1840s a set of common questions was used in Boston to determine student progress. The result of this testing had little effect on students or teachers, but provided the Superintendent with a way to hold schools within the district accountable to common standards of student and teacher performance (Resnick 1982). This practice of using student achievement tests to hold schools accountable grew and continued through the rest of the nineteenth century, and is certainly prevalent today (Linn 2001).

New interest in the use of standardized testing occurred as a result of the 1965 federal Elementary and Secondary Education Act (ESEA). Standardized achievement tests became the means of monitoring and evaluating the use of these funds (Linn 2000; Koretz 2002). The 1983 *A Nation at Risk* report on the state of American education added a new impetus for the use of standardized testing in evaluating the performance of schools. While the testing arising

from the ESEA focused on educational equity, the new emphasis after *A Nation at Risk* was overall performance of the American educational system relative to international education systems.

Most recently, the 2001 ESEA reauthorization, the No Child Left Behind Act (NCLB), increased the importance of standardized testing to new levels in the US. This wave of standardized testing has moved the focus to establishing content standards, the setting of performance (or proficiency) standards for all students, and the addition of high stakes assessments for schools, educators, and, in some jurisdictions, students (Linn 2000, 2003; Linn et al. 2002).

In the foreseeable future, there are several avenues of research that are currently underway or likely to be carried out.

First, research should continue to examine reasonable projections for schools making adequate yearly progress toward learning objectives. The current federal law of NCLB increases the testing requirements and establishes accountability standards for states, districts, and schools in that they need to make measurable adequate yearly progress (AYP) for all students and subgroups of students defined by socioeconomic background, race/ethnicity, English language proficiency, and disability. There is currently wide variation in the rigor of both standards and tests so that students measured to be proficient vary widely from state to state. Over the next few years, researchers could continue to analyze data from different states to examine which schools make large gains on state assessments to understand what ambitious, yet reasonable, goals might be established for AYP (see Koretz 2002; Linn et al. 2002; Linn 2003).

Second, research needs to focus great attention to the tradeoffs that schools and teachers deal with under NCLB by examining how instructional resources are devoted to students at different points in the achievement distribution. For example, by focusing educators on the task of bringing all students to a minimum level of proficiency, it is possible under NCLB that schools will divert attention and resources from students who already meet this standard. In addition, schools may divert resources away from students who are so far below the standard because schools perceive little chance of

bringing them to the proficient level. However, such consequences are not inevitable. It may be possible to avoid negative distributional effects if schools instead make more efficient use of their resources, but additional research is needed to address this important issue.

Third, researchers should continue to examine how school principals and teachers actually use test score results for improvement (Goldring & Berends 2006). Schools are typically inundated with data and many teachers and principals are not trained in statistics and measurement to thoroughly understand how to use test score results for improving the conditions of schools and classrooms. Further research into the capabilities and capacity of schools to use data in effective ways for improving students' test scores would be beneficial for accountability systems that require shared responsibility (Linn 2003).

Finally, researchers should explore different ways to use tests to hold schools accountable. The current research suggests that test based accountability does not always work as intended, but there is no adequate research base to offer a compelling alternative to policymakers and educators. Koretz (2002: 774) describes the current situation as one in which "the role of researchers is like that of the proverbial custodian walking behind the elephant with a broom. The policies are implemented, and after the fact a few researchers are allowed to examine the effects and offer yet more bad news." Alternative accountability approaches would expand beyond just tests to examine a mix of incentives for teachers, changes in instructional practice, quality of examining standardized test score gains and growth for students in addition to proficiency levels, and alignment of instruction to standards to tests (see Porter 2002). Together, empirical analyses of these elements incorporated into various programs, policies, and interventions may provide not only alternatives, but also better information about the system of student learning.

state

Boris Frankel

Few concepts are as central to social analysis and political practice as the state. Many assume that the state is synonymous with the elected government. All the non elected state administrators, coercive apparatuses, and sociocultural institutions that constitute modern states are often ignored. Despite the crucial nature of state power, major political and methodological

disputes remain over the nature and role of the state and how to acquire and maintain state power. Some argue that state institutions are interwoven with social and economic relations in society. Others view the state as distinct from non state institutions because they perform coercive, taxing, judicial, and other administrative roles that private institutions cannot perform. Despite the privatization of various state industries and services, there is little prospect that the state will be abolished and that all its current roles will be performed by private businesses. Sociologically and politically, Marxists argue that class and power relations in society hold the key to understanding state institutions and the way states maintain ruling class power, ideology, and cultural practices. Conversely, liberals and conservatives claim that society is made up of rich and poor individuals rather than a ruling class dominating other classes. Hence, they see the state as independent of class divisions in society. Weberians also argue that states are autonomous of class relations in society and have their own bureaucratic rationality and political and military agendas. Regardless of the political perspective, state theorists are also divided between those who formulate ideal types and models such as the “feudal state,” the “capitalist state,” or the “advanced liberal state,” and those who reject ideal types and stress the historical uniqueness of each state.

Without a notion of state institutions it is difficult to explain how stateless societies (such as indigenous communities) differ from societies with elaborate forms of military, fiscal, and administrative state power. Revolutions, imperialism, world wars, welfare states, and numerous other developments would be unintelligible if the vital roles played by state institutions were ignored. State theory has always been intimately related to particular historical and political developments. Political philosophers from Aristotle to Machiavelli analyzed political power in city states and empires. Between the fifteenth and eighteenth centuries, religious conflict and secular opposition to religious authority led to a redefinition of church–state relations. Absolutism gave rise to liberal ideas about state sovereignty and property rights, constitutional checks on tyranny, and the belief in a “social contract” between rulers and citizens. Hobbes, Locke,

Rousseau, and Hegel produced differing conceptions of the relationship between civil society and state institutions. States were either conceived as embodying the highest spiritual, legal, and political values, or as a constant threat to the freedom and privileges of citizens. The eighteenth and nineteenth century political economists – from Adam Smith to Karl Marx and J. S. Mill – helped lay the foundations of contemporary liberal and Marxist analyses of the role of states in developing capitalist societies.

By the late nineteenth century, two parallel trends were evident in state theory. The formal legal constitutional state theorists produced numerous books outlining national constitutions and various laws (Dyson 1980). However, little was written by these nineteenth and early twentieth century constitutional formalists on the *informal* structures of state power, such as “backroom” machinations and bureaucratic processes. By contrast, between the 1880s and the 1930s a combination of new political movements and academic analyses established the foundations of contemporary state theory. Politically, the rise of labor, socialist, and communist parties on the one side, and various conservative and fascist parties on the other, thrust the whole issue of state power on to center stage. From an anti socialist and anti liberal perspective, the “new Machiavellians” or elite theorists Mosca and Pareto celebrated the cunning of foxes and the brute force of lions as necessary to winning and holding state power (Bottomore 1964). The elite theorists later became admirers of Italian Fascism, which made a cult of state power. Lenin (1917) also criticized parliamentary road strategies favored by socialist and labor movement parties as naïve. According to Lenin, socialists should not place too much faith in formal liberal constitutional processes and ignore the power of state repressive apparatuses (the army, police, and bureaucracy). Repressive apparatuses can defend capitalism by obstructing or overthrowing a socialist party should it win a parliamentary majority. The Italian Communist leader Antonio Gramsci (imprisoned by the Fascists in the 1920s) analyzed the complex relationship between capitalist states and civil society. Capitalist hegemony required both coercion and consent via an elaborate set of cultural and educational practices, values, and socioeconomic

relations. The visible state in the industrial capitalist West, Gramsci (1971) argued, could not be captured by revolutionaries (as Lenin had done in the largely agrarian Russia of 1917) if the less obvious “earth works” (shoring up the state) of cultural and social hegemony remained largely intact. Fifty years later, neo Marxist state theorists used Gramsci’s work to reconceptualize contemporary state–civil society relations.

State coercion and consent were also central in the work of Weber. He differentiated between traditional forms of spiritual and princely authority or legitimacy and the development of an impersonal legal rational authority that underpinned modern organizations – especially bureaucracies of the modern state. Weber defined the modern state as an organization that has “a monopoly of the legitimate use of physical force.” Although state authorities do not like sharing armed power with other groups in nation states, Weber’s definition is limited in that many state officials tolerate both non state criminal organizations and illegitimate coercion and corruption within state armed forces and police. Various state administrations and secret police have practiced state terrorism and illegal torture without the knowledge of citizens or other branches of government, thus mocking the notion of a monopoly of “legitimate violence.” The legitimacy or illegitimacy of a whole state system (rather than the popularity or hatred of a particular party or individual in government) requires an understanding of how state power is maintained. Some states rely heavily on repressive power, while others prefer voluntary adherence to the law and social norms. Anarchists and other anti statist regard all states as illegitimate and advocate a non hierarchical stateless society. Freedom for the individual or community from abusive hierarchical state power may be desirable, but it remains unclear whether cooperative stateless societies can carry out complex administration, production, and distribution at local, national, or global levels.

Between the 1930s and 1950s liberals became increasingly divided over theories of democracy and the modern state. Conservative liberals continued to favor a *laissez faire*, “minimal state” that primarily defended private property rights against demands for social equality.

The Great Depression of the 1930s, followed by the defeat of fascism in 1945, led various Keynesian liberals and “social market” liberals to champion new interventionist welfare states and international economic steering bodies such as the International Monetary Fund. Nevertheless, most liberals believe parties or individuals in government might pursue sectional interests, but view the state as neutral, serving all citizens impartially. Marxists, however, argued that it was impossible for the state to be a neutral umpire in a class divided society. Despite their differences, Marxists agreed that without capitalist state institutions private market forces would be unable to manage society, sustain profitability, or, equally importantly, defend capitalism against working class and other opposition. In the US a new generation of liberal pluralist theorists had fused the insights of the elite theorists, Weberian sociology, and neoclassical economics into a redefinition of democratic government. The two party system, they argued, was a choice between competing elites. Liberal representative democracy was no longer based on a relationship between the state and the rational individual. Instead, the mass media and interest groups helped frame policy agendas. The “new class” of managers, bureaucrats, and technocrats now ran private corporations and government, rendering obsolete the world imagined by both classical liberal individualism and Marxian class analysis (Bottomore 1964). Paradoxically, the new political science dominant in American and other western universities during the Cold War resulted in state theory almost disappearing between the late 1940s and the late 1960s. While western modernization theorists wrote many works on how newly decolonized or “undeveloped” African, Asian, and Latin American countries could take the correct path to “state building,” few scholars paid attention to state institutions in the West. It was widely assumed that state power was crucial in totalitarian communist societies. However, in the West, systems theory and American pluralism reduced states to neutral structures akin to a black box, with inputs (interest group pressures) that produced outcomes (policies and decisions). What happened inside the box or the state was not entirely clear. Yet American pluralists vigorously asserted that there was no ruling class or power elite as

claimed by orthodox Marxists and radical critics such as Mills (1956). Against a background of mass protest movements in the late 1960s and 1970s, a renaissance in state theory occurred as new state theorists broke the deadlock between pluralists and radicals by refocusing on state institutions.

The various Althusserian, Frankfurt School, Gramscian, capital logic, and other schools of neo Marxist state theory rejected both elite theory and the liberal claim of a classless society and state neutrality by documenting the pro capitalist material and immaterial roles played by state institutions. The *material* roles ranged from vital infrastructure (roads, ports) through to numerous state subsidies for industry and other state funded contracts and benefits without which private businesses could not function or earn high profits. The *immaterial* roles included everything from states undertaking the education and training of labor, research, and development necessary for new products, through to promoting and securing pro market values and ideology in the public sphere. Capitalist states were also defined by what they could not do. Private capitalists strongly opposed replacing market competition with state planning or nationalizing private companies. The neutrality of the state was also challenged by pointing to the inequity of taxation and budgetary allocations at the expense of workers and those dependent on state benefits. State repressive apparatuses constantly protected private property and maintained commodity production and capital's dominance over labor, while little was done to protect workers, consumers, and the environment from abuses perpetrated by businesses and government departments.

Most neo Marxists rejected simple orthodox Marxist mechanical notions of the state as a superstructure determined by the economic base. Poulantzas's (1969) critique of Miliband's (1969) work on the capitalist state highlighted the “relative autonomy” of the capitalist state from market forces and the structural role state officials had to perform. Individual office holders or managers in state apparatuses may have bourgeois or working class family and school or economic backgrounds. What counted were the structural roles each had to perform as part of the capitalist state, regardless of social

background. Marx and Engels's definition of the capitalist state as "the executive committee of the bourgeoisie" or the "ideal collective capitalist" was seen as simplistic by many neo Marxists (Frankel 1979). The idea that the capitalist state embodied the *collective will* that eluded capitalists because of perennial conflicts and competition was replaced by neo Marxist emphasis on the *contradictory* nature of state institutions. Capitalist states were arenas of class struggle. If labor movements and other social protest movements were strong, parties sought electoral support and state officials implemented policies to placate demands for better welfare services or such things as environmental pollution regulations. O'Connor (1973) and Habermas (1975) analyzed the economic and social contradictions flowing from the capitalist state promoting the private accumulation of wealth while simultaneously trying to disguise or legitimate this class based set of policies. Poulantzas (1973) emphasized the divisions between the finance, industrial, merchant, and other fractions of capital and how these ongoing divisions among capitalists gave rise to particular state policies that antagonized sections of business depending on which fraction or fractions were dominant. Offe (1975) stressed the formal methods of acquiring state power via election or appointment to office as opposed to the informal bases of power exercised by private capital upon which state administrators depended for fiscal revenue and the smooth running of society. If governments pursued policies designed to redistribute wealth to non capitalists or other social justice strategies, they risked investment strikes by capitalists, destabilization, and other hostile reactions. Reform governments encountered obstacles ranging from obstructive behavior by hostile senior state bureaucrats through to military *coups d'état*, as happened to the Allende government in Chile in 1973. The extensive growth of state activity in all spheres of socio economic life during the twentieth century meant that state institutions were not just political administrative structures separate from, or intervening in, "the economy." State institutions at local, regional, and national levels employed up to a third of the workforce, sustained millions of pensioners, the sick, and unemployed on state income, and generally accounted for a significant proportion of investment and

economic life in capitalist societies. According to Offe (1975), where state officials are preoccupied with "allocating" state resources in a routinized manner – that is, any activity that involves fixed rules and sanctions – then the Weberian notion of bureaucracy has a degree of applicability. But where state officials are involved in "productive" state activity – administering and creating policies and practices in a whole range of areas such as health, education, and so forth – then the Weberian notion of bureaucracy as "routinization" is grossly inadequate and inappropriate. Most state employees also do not conform to the Weberian notion of independent bureaucrats standing between capital and labor. Instead, millions of state workers lack power and share many characteristics with white and blue collar workers employed by capitalists, such as poor work conditions and insecurity of employment (Frankel 1983).

The neo Marxist renaissance in state theory also stimulated interest in the state by feminists who focused on the *patriarchal state*, which reproduced male dominance and worked against the interests of women in all spheres of social policy and power relations (Chappell 2003). Environmentalists also analyzed the absence of a *green state* or an *ecological state* (Eckersley 2004). Like Marxists and feminists, environmental theorists rejected the liberal notion of a neutral state and highlighted the manner in which capitalist and communist states endangered ecological sustainability. The demise of Keynesian policies and the rise of neoliberalism since the late 1970s ushered in analyses of changes from the *corporatist state* (tripartite agreements between capital, labor, and government) to the *contract state* of privatization and the importation of market practices into state institutions and services. Ascendant market values and greater global corporate power have ironically coincided with the unpopularity of Marxist theories of the capitalist state. Post Marxist followers of Foucault (1991), for instance, reject class analyses of the capitalist state in favor of studies of "governmentality" and "advanced liberal" technologies of power. The Foucauldians often appear more concerned with surveillance and accountability rather than explaining how neoliberal states sustain social inequality and pro market policies.

Despite numerous state theories, many misconceptions and problems remain. It is common for radicals, liberals, and conservatives to speak of complex state institutions as if they were a homogeneous actor or subject, like Machiavelli's Prince, capable of moral, immoral, or amoral behavior and having a "collective mind" or political will. Similarly, others simplistically conceive of state institutions as instruments that can be wielded by a ruling class or elite outside the state (Frankel 1983). Despite numerous cases of cronyism and corruption and the complicity of state officials and presidents in corporate collapses or the promotion of special favors, the complex sociopolitical relations embodied in state institutions make them more than mere instruments. Economistic Marxists conflate the political with the economic. Yet state institutions also embody residues of pre-capitalist legal, religious, racial, and sexual values and practices, as well as contemporary cultural and social policies that are not derivative of the conflict between capital and labor (Frankel 1983). Capitalist relations currently coexist with republics, monarchies, communist states, military dictatorships, theocracies, and federalist, unitary, and other state institutional forms. Boundary problems are also very confusing, as no two Marxists or liberals, for instance, can agree on what constitutes the state, "civil society," or "the economy" and whether they overlap or are separate spheres. Althusser (1971) placed almost all the institutions of "civil society," such as family, media, and school, inside the "ideological state apparatuses," thus making the notion of the state all inclusive. Blurred state/society boundaries are also evident in the "party state" of fused political and state officials, or the "para corporatization" of non-state associations to provide social welfare services on the cheap, or expensive public-private partnerships of combined state and capitalist economic and social activity that earn businesses high profits. The orthodox Marxist notion of capitalist repressive apparatuses also fails to explain how the military led revolutions or staged *coups d'état* ranging from Egypt to Portugal. Moreover, there is no agreement among state theorists on how large a state-run public sector can become in a capitalist society and how many egalitarian reforms are possible before the capitalist state ceases to defend and reproduce capitalist social relations.

Finally, state institutions are not equivalent to a particular nation state. Globalization and the emergence of supra states such as the European Union exacerbate the confusion over state-society "boundary problems" and raise questions about the future power and role of existing state institutions (Jessop 2002).

state and economy

John L. Campbell

The literature on the relationship between states and economies is vast. This entry focuses exclusively on states and economies in advanced capitalist societies. In this context, sociologists tend to follow Max Weber in viewing nation states as organizations consisting of administrative, legislative, judicial, and military apparatuses that govern a finite territory, ultimately through the use of force if necessary. They tend to view economies as systems of material production that are organized around market exchange and the pursuit of profit, and that are embedded in a variety of surrounding institutions, including political ones. Research in the area of state and economy has focused on several questions. How does the economy affect the state? How does the state affect the economy? How are state–economy relations organized? How are state–economy relations changing?

HOW DOES THE ECONOMY AFFECT THE STATE?

To address this question, sociologists have often researched why government promulgates the regulatory, macroeconomic, and other business related policies it does. For example, pluralists argue that a wide variety of economic actors, including representatives from business and labor, but also consumers, environmentalists, and others, struggle to influence the policymaking process. Policymakers tend to respond most favorably to those groups who have the most resources, organizational skills, and access to policymakers. If labor is strongest in this regard, then states pass legislation protective of workers; if business is strongest, then states pass

legislation that is protective of corporate interests; if consumers are strongest, then states pass legislation that regulates product safety and quality.

However, some scholars maintain that the business community has a significant advantage in this political competition because it has more resources than other groups in society and so is generally able to capture, dominate, or otherwise influence the policymaking process to its advantage. For instance, according to this view, business leaders are able to make comparatively large contributions to politicians' electoral campaigns. This affords them greater access to politicians and therefore greater opportunity to influence the policymaking process than other groups enjoy, who have less money to contribute.

Taking a view that focuses more on the structural constraints imposed on states by economies than on the influence of instrumentally oriented economic actors per se, other researchers claim that policymaking is inevitably biased in favor of business interests. This is because policymakers have little choice but to promote continued business investment and economic growth. For instance, regardless of how much pressure the business community or others put on policymakers, states must ensure that the economy continues to operate smoothly, that unemployment remains relatively low, and that inflation remains in check. Otherwise, political leaders will be voted out of office, tax revenues will dry up, and the state will suffer political and fiscal crises.

Still other observers argue that states enjoy far more autonomy over economic policymaking than any of these other perspectives acknowledge. Some go so far as to suggest that states are predatory in the sense that their rulers are driven to maximize the revenue their states extract from the economy in order to increase their own power. In the extreme, self interested rulers may extract so much revenue that it saps the vitality of the economy altogether.

These debates have provoked an enormous amount of empirical research (e.g., Evans et al. 1985). Much of this has focused on the development of welfare states insofar as they provide the social policies upon which economies depend, such as unemployment compensation, pensions, health care, job training, and education (Hicks 1999). Less attention has been paid to identifying the determinants of tax policies

(but see Campbell 1993). This oversight is surprising because welfare spending would be impossible without sufficient revenues to finance it and because tax policy itself has significant effects on the economy, as we shall see later. And sociologists have largely ignored the formation of general macroeconomic and monetary policy, subjects that have traditionally been the province of economists and political scientists.

HOW DOES THE STATE AFFECT THE ECONOMY?

Regardless of who or what influences state policymaking, the state always influences the economy in several ways (Lindberg & Campbell 1991). First, governments provide and allocate *resources* to business through direct subsidies, infrastructure investment, and procurement, which create incentives for firms to engage in many kinds of behavior. As noted earlier, welfare and tax policy also affect the economy. For instance, welfare spending can affect the availability and quality of labor in the labor market and the amount of money firms need to spend on health insurance and pension benefits for their workers. State spending can also affect the sorts of research and development in which firms engage and the types of products they manufacture.

Second, states establish and enforce *property rights* and regulate firms in ways that affect not only their behavior, but also their organization. Anti trust law, for instance, influences whether firms form cartels or merge to create vertically and horizontally integrated firms. Similarly, dairy cooperatives were commonplace in many European countries during the early twentieth century, but were illegal under anti trust law in the US and were therefore relatively rare until Congress passed legislation in 1922 legalizing them. Tax law is another form of property rights insofar as it determines the amount of profit firms can retain and the amount of earnings workers can keep. Tax policy also influences, among other things, whether consumers buy or save, whether firms invest or return profits to stockholders, and whether workers seek to improve their skills through education.

Third, the *structure* of the state apparatus affects business. For example, decentralized

states provide different opportunities for firms to relocate their operations within national borders than do centralized states. In decentralized states like the US, where there is wide variation across subnational governments in tax, labor, and other types of business law, these variations may create incentives for firms to relocate their operations from one part of the country to another. Different laws of incorporation were one reason why US firms tended to incorporate in New Jersey during the late nineteenth and early twentieth centuries. And differences in labor law were one reason why US textile manufacturers moved from their mills from the northeast to the southern part of the country later on. Variations like these are less common in more centralized states like France or Japan.

Fourth, nation states engage other nation states in *geopolitics*. Such international activity often impacts national economies. Notably, when war breaks out, economies can be devastated or revitalized, as occurred in Western Europe and the United States, respectively, during World War II. But even during peace time, geopolitics can have significant effects. The development of common markets, such as the North American Free Trade Agreement and the European Union (EU) are two important examples. In both cases, the states involved agreed to open their borders to increased levels of trade, capital mobility, and labor migration. In the EU, this eventually led to the adoption of a common European currency that replaced several national currencies. It also led to hundreds of EU directives that were designed to harmonize the business environment across member countries.

HOW ARE STATE-ECONOMY RELATIONS ORGANIZED?

The complex relationships between states and economies take different institutional forms in different societies. Generally speaking, scholars recognize three types of state-economy relationships in capitalist countries (Katzenstein 1978). First is the *liberal* model where the state tends to maintain an arm's length relationship from the economy, grants much freedom to markets, pursues relatively vigorous anti trust policy to ensure market competition, relies heavily on

broad macroeconomic and monetary policies to smooth out business cycles, and tries not to interfere directly in the activities of individual firms. The US is often cited as the typical example of the liberal model.

Second is the *statist* model. Here countries like Japan, France, and South Korea come to mind. In these countries the state is much more involved in the economy and exercises much greater influence over individual firms, such as by providing finance and credit directly to them. Occasionally, the government owns and runs firms in key infrastructural industries such as railways, telecommunications, and energy, although since the 1980s statist countries have privatized many of these firms.

Third is the *corporatist* model, typically found in the Scandinavian countries, Germany, Austria, and Switzerland. In this model the state promotes bargaining and negotiation among well organized social partners, notably centralized business associations and labor unions, in order to promulgate economic and social policies that benefit all groups in society. In Germany, for example, national legislation passed after World War II ensured that labor would be represented on corporate boards of directors and would be able to establish works councils that would facilitate bargaining between managers and workers over issues like investment, plant closings, shop floor relations, and the introduction of new production technologies. The state also organized centralized bargaining between employers' associations and unions over wages, benefits, and in some cases prices.

In sum, government can be an arm's length regulator, a strong economic player, or a facilitator of bargained agreements. But regardless of which model we refer to, it is important to understand that the state and economy are *always* connected in important and complicated ways. And this has always been true, even in the most *laissez faire* examples. For example, in the US during the nineteenth and early twentieth centuries the state was pivotal in providing corporate charters, infrastructure, subsidies, property rights, and a variety of other supports for the economy's development. Furthermore, during the early days of industrialization when capitalism was first emerging in Europe, the state played an important (albeit rudimentary) role in defining property rights, regulating

business, and providing at least minimal protection to workers. According to Karl Polanyi (1944), this was necessary in order to prevent capitalist self interest and the pursuit of profit from getting out of hand to the point where it hurt workers, consumers, and the environment so much that it would have led eventually to capitalism's self destruction.

Variations in how state–economy relations are organized matter in terms of the ability of firms to compete successfully and the ability of states to manage macroeconomic problems, such as inflation and unemployment. However, there is much disagreement as to which variation is best. Many economists and conservatives maintain that the liberal model is the best because it ensures relatively unbridled market activity, which, following neoclassical economics, is the most efficient and surest way to achieve positive economic performance. Many political scientists and sociologists tend to favor the other two models, reasoning that coordinated economic activity will more effectively mitigate market failures and social ills like inequality and poverty.

Recently, some scholars have shown that each variety of capitalism has its own strengths and weaknesses. For instance, liberal economies enable firms to compete by making decisions quickly, keeping costs low, and moving capital rapidly from sector to sector and region to region. The other varieties enable firms to compete by producing high quality products and by ensuring a high degree of cooperation between labor and management. Why? Because governments in statist and corporatist countries tend to provide a well educated labor force, ensure bargaining and negotiation between business and workers, and offer generous welfare supports to facilitate the sort of economic restructuring that enables business to be competitive internationally (Hall & Soskice 2001).

HOW ARE STATE–ECONOMY RELATIONS CHANGING?

Since the mid 1970s, economic activity has become increasingly globalized. In particular, capital has gained the ability to move from one country to another faster than ever and in greater volume than ever. This has generated much concern that the ability of firms to shift

investments rapidly from one country to another has undermined the institutional differences associated with the three models of capitalism discussed earlier. Many have warned that states will need increasingly to compete against each other to retain and attract capital investment. To do so, it is argued, they will have to realign their institutional arrangements with the liberal model. In other words, they will have to grant firms more autonomy to do as they please without having to worry about the interests of government, labor, or other actors. As a result, states will have to reduce taxes, welfare spending, and the regulatory burden on business. If they fail to do so, then capital flight will result and precipitate a host of economic problems, including plant closings, job loss, unemployment, and poor economic growth. Ultimately, according to this view, state sovereignty is at risk to the extent that the only way to control capital in such a globalized environment is for nation states to relinquish some of their powers to regulate economic activity to international organizations, such as the World Trade Organization, the European Union, and the like.

During the 1990s this became a popular argument among politicians who sought to roll back business regulation, welfare spending, and taxes. Nevertheless, researchers have shown that there is little sign of institutional convergence on the liberal model, or that serious economic problems result for countries that fail to adopt it (Hicks & Kenworthy 1998; Swank 2002). Instead, the relationship between state and economy and the institutional basis by which business competes continue to evolve along a variety of trajectories. There are several reasons why.

To begin with, states are not helpless in the face of increased global economic pressures. After all, states are partly responsible for the rise in international trade and capital mobility because they have deliberately lowered barriers to trade and investment. As such, they can surely reverse these trends if they want. States can also block these sorts of reforms if political forces are strong enough to resist change. This happens, for example, when well organized labor unions and social democratic parties defend welfare spending from its political opponents. And even when states make concessions in one area, such as by lowering corporate profit taxes, they can compensate in other areas,

such as by devising new taxes on Internet commerce or cross national financial transactions (Campbell 2003).

Second, institutional change tends to proceed in path dependent ways. Even when governments try to mimic institutional practices observed elsewhere, they typically translate them into local contexts in ways that do not fully supplant current practices (Campbell 2004: ch. 5). So, for example, even though the Japanese state privatized its national telephone company in 1984, it also developed a powerful regulatory ministry to supervise many aspects of the new private firm's operations, including pricing and technology development. These state capacities were much more in line with Japan's traditional statist model than the alternative liberal model. In other words, Japan *reregulated* rather than *deregulated* the industry.

Third, firms do not compete just on the basis of costs. Even if they can find cheaper labor or lower taxes somewhere else, they do not automatically move their operations there if they recognize that they enjoy other competitive advantages where they are currently doing business. For instance, firms operating in the Scandinavian countries may face much higher taxes and labor costs than their competitors elsewhere, but they enjoy other offsetting advantages like a well educated workforce, peaceful labor-management relations, excellent infrastructural support, and more. The point is that even though capital may have become increasingly mobile internationally, firms recognize that they can compete on the basis of comparative *institutional* or *cost* advantage. Thus, when firms recognize this they will often defend against attempts to undermine these institutional advantages. Although German firms pay relatively high wages and benefits to their workers as a result of the institutionalized bargaining described earlier, they have resisted recent calls to dismantle these arrangements precisely because they understand the advantages that accrue from them, such as very cooperative labor-management relations that facilitate high quality production and the ability to be flexible in the face of the rapidly changing market demands that are associated with globalization. These are things that have bolstered Germany's international competitiveness for decades and many firms want to preserve this.

This is not to say that state–economy relations will not change in the face of globalization. As noted earlier, the point is that the institutional environments within which economic activity takes place – including the institutionalized relationships that link state and economy – will continue to evolve as they have for decades. But variation among institutional types of capitalism will likely persist for a very long time.

state and private sector employees

Rolf Becker

Public employment is a significant characteristic of modern welfare states. After the building of nation states, professional employment in the state sector has become for an increasing share of citizens an indicator of modernization and democratization in most of the western countries (Weber 1920–1). While in the early phases of industrialization and modernization public employment has been characterized in terms of bureaucratization and the privileged status of a minority of the labor force, employment in the state sector became the pioneer of the post industrialization of social stratification (Esping Andersen 1990). In the twentieth century, the dominance of traditional tasks of the state sector such as military, police, public administration, and production of common goods (electricity, railway, and water supply) has shifted to social services and welfare production. As in any large scale organization in the private sector, a division of labor and well defined areas of competencies are basic characteristics of the state. A segmentation of specific welfare programs as well as segmentation within state employment is brought about (Mayer & Schoepflin 1989).

This development arising in the nineteenth century has been accelerated by the expansion of the welfare states in the post war era of the twentieth century. The rapid increase of public employment is the most visible direct effect of the welfare state expansion in the post war era (Table 1). In the modern western nations, in particular during the “golden era of the welfare state” from the 1960s until the end of the 1970s, at least 20 percent of employed individuals are public employees (Rose et al. 1985). After 1980, political changes in the government, economic crisis, and declining ability to finance labor intensive welfare programs led to decreasing shares of public employment over total employment. In most contemporary mixed economies, the welfare state is still one of the largest employers: public employment grew faster than private employment during the post war decades and

contemporary public employees make a major claim upon tax revenues.

The social democratic welfare states (e.g., Sweden, Finland, Norway, Denmark) have expanded their labor intensive welfare programs (education and health) and are followed by the state corporatist welfare states (e.g., Germany, France, Austria) in which economic programs dominated until the 1960s and 1970s. One of the major aims of the expansion of the social democratic welfare state was the reduction of social inequality by the guarantee of long term employment and income in the state sector. In state corporatist welfare states, the generous alimentionation of civil servants is a significant tradition in such systems. The rationality of this alimentionation is the exchange of political loyalty of employees and the maintenance of their privileged social status and position in the social stratification. In this respect, this exchange between the modern state as employer and public employees results in the maintenance of existing social inequalities to the advantage of civil servants. Liberal welfare states (e.g., US, UK, Canada, Australia, Switzerland) as well as rudimentary welfare states (e.g., Italy) provide a minimum of public support of individuals and their families, and social welfare is oriented toward market processes. These countries employ citizens mainly in the state defining programs including police, law enforcement, and military defense.

The growth of public employment is linked to political decisions related to several programs and the shift of public employees to these programs (Table 2). In terms of the type of welfare state, most of the public employees produce

goods and services in the social welfare program. The number of public employees producing common goods in state defining programs has been diminished to a greater degree than the number of public employees in economic activities. The byproduct of this shift among the state programs is the increase in female employment in the state sector (almost 50 percent of the employees are female) and the recruitment of qualified employees offering skilled services. In most of the western welfare states, the state sector employs a higher proportion of educated personnel than the private sector. Government can even employ a majority of highly educated graduates. The post war expansion of labor intensive social programs is the chief cause of a high level of public employment of qualified manpower and reflects the self consumption of the output of educational expansion initiated by the state itself.

As a side effect, the expansion of the welfare state and increase of public employment has had an important impact on the careers of state employees and their position in social stratification compared to employees in the private sector (DiPrete & Soule 1988). In particular, the employment and career prospects of qualified women have been advanced by the state as employer (Becker 1993). Similar to private employees in the internal labor market of large scale firms, for the state employee there are privileged working conditions with special occupational status and labor contracts, guarantee of employment, early recruitment in hierarchical systems of career lines, formal regulations of careers by certificates and seniority, rigid and stable structure of careers and mobility patterns

in career lines, and more independence from individual characteristics (Grandjean 1981). In the course of increasing the importance of internal labor markets in the private sector, the differences between the private and state sectors in terms of such organizational and institutionalized working conditions (DiPrete & Soule 1986; Erikson & Goldthorpe 1992) are probably diminishing. However, studies of career and income trajectories in the private and public sectors demonstrate remaining differences (Visser 1984; Carroll & Mayer 1986; Becker 1993). On the one hand, there is less empirical evidence for the self selection of individuals with a specific personality and habitus (rule orientation, unconditional obedience, dogmatism, risk avoidance, need for security) into the state bureaucratic sector (Grunow 1991), but some indications that there is an intergenerational reproduction of state employees (Becker 1993). For Norway and Germany, we have empirical evidence for consecutive birth cohorts that the relationship between social origin and entrance into the state sector has become closer in the course of educational expansion and expansion of labor intensive service in the state sector. On the other hand, because of their privileges, state employees are not interested in job shifts from the state sector into the private sector during their working life (Becker 1993). However, in contrast to the employees in the

private sector, they have lower rates of upward mobility and remain longer in their jobs and in the same organization.

state regulation and the workplace

Holly J. McCammon

Workplaces are highly regulated spaces. As Edelman and Suchman (1997) state, they “are immersed in a sea of law.” In regulating the workplace, the state attempts to control the behaviors of employers, managers, and workers using a system of incentives and penalties and a variety of policy tools. In the US, the government has at least some say – and often much say – over discrimination in the workplace, union activities, workplace safety, wage levels, hiring practices, work hours, employee leaves, plant closings, and compensation for injuries at work. The two main areas of workplace regulation in the US are employment law and labor law. Employment law encompasses anti discrimination law, affirmative action policy, and equal pay law. Labor law, on the other hand, regulates trade union organizing, collective bargaining between workers and employers, and

strike action by workers. Both areas have received substantial attention by researchers in sociology as they try to make sense of the law’s development over time and its impact on employment relations.

EMPLOYMENT LAW

The 1960s were a watershed in US employment law. In 1963 the Equal Pay Act was passed, requiring employers to pay men and women equally for equal work. And in 1964, in response to the Civil Rights Movement, Congress enacted the Civil Rights Act, which greatly broadened the state’s ability to restrict race and sex discrimination, including in the workplace. Prior to this time, workplace discrimination against women, African Americans, and other minorities was commonplace. Employers routinely refused to hire blacks, ethnic minorities, and women for a variety of jobs, and even when hired these social minorities were segregated into occupations and jobs deemed culturally “appropriate” for them (Hodson & Sullivan 2002). Title VII of the new law made it unlawful for employers to treat employees differently because of their “race, color, religion, sex, or national origin.” The law also established the Equal Employment Opportunity Commission (EEOC) to oversee the law’s enforcement. Title VII fundamentally altered the cultural environment of workplaces by instituting due process rights. But as Reskin (2001) points out, enforcement of Title VII has often depended on the perseverance of the victims of discrimination to carry their cases forward. This stems primarily from underfunding of the EEOC. In addition, the nature of Title VII and of EEOC procedures obscures the intersectionality of discrimination by requiring that plaintiffs choose among their social identities when filing cases (Crenshaw 1989). The unique experience of a black woman, for instance, can be overlooked if, as the law requires, she must identify herself as *either* female or African American to file her case.

Another key development in anti discrimination law in the 1960s was the passage of Executive Order 11246 in 1965 by President Lyndon Johnson. This affirmative action policy, as it has come to be known, requires that a company doing business with the federal government

“take affirmative action to ensure” that employees and applicants for jobs are not discriminated against with regard to “race, color, religion, or national origin.” In 1967, Executive Order 11375 included “sex” in its affirmative action provisions. Affirmative action policies are thus proactive workplace regulation, mandating that companies with governmental contracts establish workplace policies that give preference, particularly in hiring, to qualified female and minority applicants in order to address the effects of past discrimination. The policies, however, have been controversial and support for them has declined over time among whites (Sears et al. 2000). Moreover, many workplace policies have called for only minimal adjustments in hiring and promotion practices and thus have had a limited impact in reducing occupational race and sex segregation (Reskin 1998). But research indicates that the policies have helped some workers, particularly women and minority men seeking professional and managerial positions, where most affirmative action programs have been targeted (Tomaskovic Devey 1993). Research also shows that the effectiveness of affirmative action depends on the organizational resources devoted to the programs, the commitment of company leaders, and the duration of the programs’ existence within a business (Konrad & Linnehan 1999).

Research on anti discrimination law has also explored the impact of these policies on race and gender wage inequality. Wage data document that an earnings gap continues to exist between men and women and among racial and ethnic groups, with white men being substantially advantaged (Padavic & Reskin 2002). Various studies, however, indicate that the 1960s shift in employment law helped to narrow the disparity. McCrone and Hardy (1978) find that the racial wage gap declined significantly under Title VII. Burstein (1979), using indicators of EEOC funding and the number of lawsuits decided in favor of the plaintiff, shows that women’s and minority wages increased with greater agency enforcement, resulting in greater equality. A number of US states have enacted comparable worth or pay equity laws that go beyond the 1963 Equal Pay Act and stipulate (for public employers but as yet not for private employers) that compensation systems must pay workers equally for comparable, and not just

identical jobs. The US federal government, however, has not yet enacted comparable worth legislation. Instead, federal comparable worth law has developed as a result of wage discrimination suits filed within the courts (Guthrie & Roth 1999).

A more global perspective finds affirmation of equality in the workplace in both the United Nations’ Declaration of Human Rights and its International Covenant on Economic, Social, and Cultural Rights (see especially Article 7). The International Labor Organization as well states in its Declaration of Philadelphia that “all human beings, irrespective of race, creed or sex, have the right to pursue both their material well being and their spiritual development in conditions of freedom and dignity, of economic security and equal opportunity.” Most western countries today have adopted such principles in their body of law. Some recent developments include Northern Ireland’s Fair Employment Act of 1989 (which places restrictions on discrimination based on religious affiliation) and Germany’s *Frauenförderungs gesetz* of 1994 and Israel’s Civil Service Act of 1995, both of which provide for fair gender representation in government service (Ben Israel 2001). Other nations have also made important strides in establishing equal employment law. China enacted a law to protect women’s right to employment, and India and Belize now have policies to prevent sexual harassment in the workplace (United Nations Office of Public Information 2000).

US LABOR LAW

If the decade of major change in US employment law was the 1960s, in labor law it was the 1930s. In 1935 during the Depression, Congress passed the National Labor Relations (Wagner) Act, which institutionalized a system of collective bargaining and provided workers with a legal right to organize unions and to strike. The law also established the National Labor Relations Board (NLRB) to adjudicate workplace disputes. The US Supreme Court upheld the constitutionality of the new law in 1937. Prior to this time and largely through the courts, the government had regularly impeded attempts by workers to organize unions and mount strikes.

Both state and federal judges routinely issued labor injunctions to end strikes and enforce "yellow dog" contracts or contracts which a worker signed to gain employment but in which he or she was also compelled to agree not to join a union. The courts' use of injunctions significantly restricted the collective activities of labor (McCammon 1993b). In 1932, just before enactment of Wagner, the Federal Anti Injunction Act was passed. The anti injunction law was a response to labor and legal reformers who called for an end to the courts' constraints on labor's actions. The anti injunction act barred the federal courts from issuing injunctions to halt strikes; however, it did not go so far as to protect the right of workers to strike. This came with Wagner. The Wagner Act, a New Deal law, was passed in a period of acute unemployment and economic stagnation, but also one of increasing labor militancy. Workers struck to force employers to recognize their unions. But even with passage of Wagner, strikes continued, largely because employers ignored Wagner, refusing to recognize unions and participate in collective bargaining. Not until the Supreme Court affirmed the law in 1937 did employment relations gradually begin to calm.

The 1937 decision of the Supreme Court redirected the actions of employers away from attempts to repeal the law and away from open resistance to unionization in the workplace and instead toward establishment of bargaining relations with organized labor. In short, a new legal regime of employer-labor relations was instituted (Bowles & Gintis 1982). Prior to the New Deal era, the government's legal policy concerning worker collective action was generally one of "repressive intervention," as it wielded the injunction to halt worker actions (McCammon 1993a). With passage of Wagner and the Supreme Court's affirmation of it, however, the state's legal policy became one of "integrative prevention." The law granted workers legal rights in their interactions with employers, viz., the right to organize, bargain, and strike. But the law also constrained these rights. The subsequent development of labor law after passage of Wagner, with the enactment of the Labor Management Relations (Taft Hartley) Act of 1947 and a number of pivotal Supreme Court decisions (e.g., *Lincoln Mills*, 1957; "Steelworkers Trilogy" cases, 1960; *Boys*

Markets, 1970; *Buffalo Forge*, 1976), meant that unionization and collective bargaining were increasingly regulated and the circumstances in which workers could strike became particularly limited (Wallace et al. 1988). While strikes over wages between labor contracts were legally permissible, strikes over issues that challenged employer control in the workplace were typically defined as illegal.

Moreover, the developing law provided employers with important tools for resisting worker organizing and collective action (Gross 1995). During union certification elections, for example, the law grants long delays between the filing of a petition for a union and the actual election, and whereas employers have free speech rights to communicate their opposition to a union with employees while employees are at work, union access during working hours is greatly restricted (Bronfenbrenner 1994). The law also allows employers to hire permanent replacements for striking workers, so that strikers may not be able to retain their employment. And although the law does not permit employers to discharge workers for attempting to unionize, the law's minimal penalties for such action can make the strategy viable for some employers (Comstock & Fox 1994). Surveys suggest that employer intimidation of unionizing workers is more common among low wage, minority, and female workers (Comstock & Fox 1994). A number of researchers provide evidence that these provisions in labor law are at least in part responsible for the decline in the labor movement in the US today (Sexton 1991). Given that unions have played a significant role in increasing working class wages and augmenting the size of the middle class in the US, their decline and the role of state regulation in that decline are likely to be important contributors to rising economic inequality in the US today.

Antagonistic labor-employer relations are not limited to the US, but most Western European nations generally have a history of more harmonious relations. Collective bargaining exists in the UK and France similar to that in the US, although strikes are more common in France when bargaining breaks down (Hodson & Sullivan 2002). In Germany, Norway, and Sweden, workers have greater power in workplace decision making, through works councils (composed of workers and management) in

unified Germany and autonomous work groups in the Scandinavian countries (Servais 1998). Arthurs (1998), however, suggests that in most western nations collective bargaining laws are no longer being strengthened as these countries' economies adapt to competitive pressures in the global economy. He points out that only in "newly reconstructed states," such as South Africa, South Korea, and in Central and Eastern European nations, have labor's legal rights been augmented in recent years.

statistical significance testing

Andrew Poggio and John Poggio

The act of reasoning from factual knowledge or evidence is a process ubiquitous in the lives of individuals. In order to make good decisions and function effectively, one must make distinctions between events that are likely to occur and those that are not. If the morning sky is dark and threatening, one logically concludes that the forecast is for rain and thus one carries an umbrella. A student attends class on the assumption that the professor will be there. Most of the decisions a person makes involve subjective estimates of the probability of various events occurring based on specific observations. Statistical inference uses probabilistic reasoning in a more objective and precise fashion and allows the researcher to account for chance error in drawing inferences from a small set of observed data to a larger set of unobserved data.

Suppose a researcher is interested in the attitude of taxpayers toward the use of state dollars for subsidizing a federally mandated education program. It would not be possible to question every taxpayer in the country, therefore the researcher would want to survey the attitudes of a random sample of taxpayers to infer characteristics about the population. The fundamental goal of statistical inference is simple: based on information obtained from a sample of elements, the researcher draws conclusions about a population by inferring that what is observed in the sample reflects what one might expect to be true in the population. While convenient, when one deals with sample data and not data from the entire population,

one cannot describe the population characteristics with complete certainty so any statement about the population is somewhat risky. Had the investigator only surveyed a group of five citizens, for example, the ability to generalize the findings from these few individuals interviewed would be low as the observed difference in attitudes could be due to chance alone with such a small sample.

The adequacy of statistical inferences depends on how well the sample represents the population. If one is uncertain of how representative a sample is, then the individual should be equally uncertain about inferring any results to a specific population. The key to solving problems of statistical inference is to answer the question, "How likely is the occurrence of sample events when the sample is assumed to be representative of the population?" Or, stated another way, "What kind of sample results can be expected from chance alone?" These are questions of probability that are pertinent to the statistical inference process. Thus, one assigns probabilities to the inferences. Probability allows the researcher to make decisions with predetermined levels of confidence.

A hierarchical relationship exists between the research process and the statistical inference process. The research process is all encompassing and provides the framework for general research activities. Statistical inference imposes a logical reasoning methodology on the research process, resulting in inferences about population characteristics based on sample data. Statistical reasoning and procedures for making inferences about populations from sample data are defined by the hypothesis testing process and confidence intervals. Statistical hypothesis testing, also known as significance testing, is the most widely used statistical inference approach by behavioral and social science researchers.

HYPOTHESIS TESTING

The goal of statistical inference is to be able to infer something about the truth of a hypothesis without collecting data from an entire population. Hypothesis testing allows the researcher to make this inference, but one must start with some hypothesized value of a population characteristic. In hypothesis testing, the statistical

hypothesis identifies an *assumed* value or relationship about a population. The exact population characteristic value is not known, so a hypothesis is formulated about it. One assumes that the hypothesized population value is correct (null hypothesis) until the sample data provide contradictory evidence. The null is rejected if an event can be shown to be *highly unlikely* to occur if the hypothesis is assumed true. That is, if the sample result is contrary to what is expected when the hypothesis is assumed true, then the hypothesis is rejected as a possibility. “Highly unlikely” refers to a specified statistical significance level, or *alpha* (α) level. As one will not be able to be certain of any inferences when sampling from a population, probabilities are assigned to the inferences. The level of significance is set prior to data analysis and is the probability criterion level for rejecting the null hypothesis. For example, if the difference between the sample value and the hypothesized parameter is due to random chance fewer than five times in a hundred (i.e., $\alpha < .05$, or a 5 percent level of significance), then the results are statistically significant. Researchers in the social and behavioral sciences typically select low alpha values (e.g., .01 and .05, most commonly) to protect against concluding that an observed result is true when it could have occurred by chance.

Hypothesis testing is a sequential process that typically involves five steps. Illustrative examples, definitions of certain terminology, formulas, and other discussions regarding the logical aspects of the process facilitate understanding and appreciation of the procedure but are beyond the scope of this entry. Further treatment of the topic is available in many sources as standard statistics texts discuss hypothesis testing in detail (see Blalock 1979; Glass & Hopkins 1996; Shavelson 1996; Levin & Fox 2006).

The hypothesis testing steps outlined below are described through references to the simple situation of testing differences between group means. It should be noted, however, that the thinking and reasoning behind the steps are the same whether one is dealing with these types of situations or very sophisticated multivariate problems. Hypotheses will differ depending on a particular study (e.g., one may want to

hypothesize differences in group means, variances, and proportions, or in terms of correlations), yet the same general steps are employed and the logic guiding the process is the same.

Step 1: Identification of the hypotheses, which are represented statistically using population parameter symbols such as the mean, proportion, indices of variability, and correlation, for example. The convention of labeling the statistical hypothesis to be tested (the null) is H_O . Possible alternative hypotheses are labeled H_A . A null hypothesis is a statement of equality, that is, no difference or no relationship exists between population parameters. The alternative hypothesis, or research hypothesis, is the null’s complement, a statement of inequality. The alternative is formed by specifying a direction of the difference from the hypothesized value, so H_A is formed by using the symbols for “does not equal” (\neq), “less than” ($<$), or “greater than” ($>$). The alternative does not state a specific alternative value for the population parameter as the process does not test a hypothesized alternative. The following illustration translates a simple research question into verbal and symbolic hypotheses:

Research question: Does assertiveness training help make people more assertive?

Verbal H_O : There exists no difference between the mean level of assertiveness between persons who have received training and those who have not

Symbolic H_O : $\mu_{\text{training}} = \mu_{\text{no training}}$

Verbal H_A : The mean level of assertiveness is greater for people who have received training than for those who have not.

Symbolic H_A : $\mu_{\text{training}} > \mu_{\text{no training}}$

The alternative hypothesis in this example specifies the direction of the difference between the means. This is a one tail hypothesis, whereas an alternative in which the direction of the difference is not specified is called a two tailed hypothesis, meaning it can be significant in either direction.

Step 2: Specification of the a priori level of significance (α) to be used, that is, the criteria

for rejecting H_0 . The extent to which the sample value coincides with expectations is defined by the probability of the sample value occurring as a result of random sampling from the hypothesized population. The researcher can set any probability level as a criterion for rejecting H_0 . As decisions based on probabilities will not be correct 100 percent of the time, it is always possible that an error has been made in the statistical inference resulting from the decision on whether to reject H_0 . The level of significance defines the degree of improbability deemed necessary to cast doubt on the null hypothesis to warrant its rejection. The probability level chosen as a criterion for rejecting H_0 directly affects the potential for making specific kinds of errors in the inferential process. When a criterion level is set for rejecting the null, one is actually identifying the *potential* probability of committing a Type I decision error. For a discussion of these potential errors and a consideration of factors influencing the choice of significance level, see below.

Step 3: Determination of the region(s) of rejection by identifying the critical value resulting from the α level set for testing H_0 . The critical region is an area under the normal probability distribution; thus, critical values (z) are obtained from the normal distribution. The area of the curve to the left of the lower critical value and to the right of the upper critical value is the region of rejection. Consistent with the level of significance adopted, it is chosen so that if the obtained value of the statistic (test statistic, *step 4*) falls within the region, rejection of the null hypothesis is indicated. For example, for a two tailed hypothesis ("does not equal"), a z must exceed 1.96 or be less than -1.96 to be significant at the $\alpha = .05$ level. The critical value for a one tail test ($\alpha = .01$) is 2.33 or -2.33 depending on the direction of the alternative hypothesis.

Step 4: Calculation of the sample statistic value needed to test the null hypothesis. The term *test statistic* refers to the statistic employed in the testing of H_0 . In conducting research and engaging in hypothesis testing, a sample is drawn from a population and a summary statistic, such as a mean, is obtained. Direct comparison between the sample value and the hypothesized population value is not an appropriate procedure as the sample data will deviate

somewhat from the population characteristics. Rather, one must convert the sample value to a standard test statistic. Common test statistics include z , t , F , and χ^2 . The framework for testing statistical hypotheses is similar for each of these tests. While a discussion of each test statistic is beyond the scope of this entry, examples as well as formulas for computing various tests of significance can be obtained from the same sources listed previously.

Step 5: Decision regarding the null hypothesis. The decision process in hypothesis testing is straightforward as it involves a comparison of the observed sample standard score to the critical value determined by the α level. If the test statistic falls in the region of rejection, the null hypothesis is rejected and the inference is made to accept the research hypothesis. If the test statistic does not fall in the critical region, the null fails to be disproved and no inference can be made.

CONFIDENCE INTERVALS

Statistical inference under the significance testing paradigm uses a sampling plan to select a single representative of some population, or a point estimate, which is often a mean. However, there is another approach to statistical inference: interval estimation. Rather than using a single value as a direct estimate of a parameter, interval estimation establishes a range or interval to which a level of confidence (typically 95 or 99 percent) can be attached that the interval contains the parameter. Establishing a range for the population mean based on the sample data with an upper and lower bound intuitively provides more information about the mean; however, in terms of accuracy of the estimate, interval estimation and point estimation are identical as both are based on the same information.

When the value specified by the null hypothesis is not contained in the confidence interval, the result is statistically significant. Standard notation for confidence intervals is to let the confidence level equal the quantity $1 - \alpha$. Thus, if $\alpha = .01$, the confidence level is .99 or 99 percent. To construct the interval, the upper and lower limits are found using the formulas (when σ is known):

$$\text{Upper limit} = \bar{X} + (z_{1-\alpha/2}) \sigma_{\bar{X}}$$

$$\text{Lower limit} = \bar{X} - (z_{1-\alpha/2}) \sigma_{\bar{X}}$$

$$\text{where } \sigma_{\bar{X}} = \sigma/\sqrt{n}$$

The proper interpretation of a confidence interval reflects the sampling concept of the sampling distribution (discussed in the next section): over repeated random samplings of size n , the probability is that $(1 - \alpha)$ percent of all of the confidence intervals that could be constructed around the sample means will contain the population mean. Interval size relates directly to estimate precision: the smaller the range, the more precise the interval estimate of the population mean. Additionally, with greater confidence comes a wider interval, meaning that a 99 percent interval will encompass a wider range than a 95 percent interval. Sample size and the amount of variability in the population affect the precision of interval estimates by affecting the size of the standard error. Both factors improve estimator precision by making the standard error smaller.

SAMPLING DISTRIBUTIONS

Inferences are made from a single event, single experiment, or single set of sample results. Assuming a model of randomness, one is usually interested in determining how probable a result is by chance for the single event or sample. To make this determination, the researcher needs to know something about how the sample outcomes are distributed in general. A *sampling distribution* is the relative frequency distribution of a statistic of all possible samples of size n that could be selected from the population. Fortunately, the characteristics of sampling distributions for various sample statistics have been derived by statistical theory. Sampling distribution characteristics describe theoretical models to indicate a sample statistic's precision in estimating a population parameter of interest.

Different sampling distributions are possible; every sample statistic has one and each is defined by its shape, mean, and standard deviation. Characteristics of a sampling distribution of means, for example, are expected and predictable from mathematical theorems. One such theorem, the *central limit theorem*, identifies

these three characteristics that describe fully the expected distribution of sample means resulting from random samples of size n .

Shape: The sampling distribution approaches normality as sample size increases and for a very large n is approximately normal.

Measure of central tendency: The mean of a sampling distribution of means ($\mu_{\bar{X}}$) for samples of any size n equals the population mean (μ).

Measure of variability: The standard deviation of means ($\sigma_{\bar{X}}$) in a sampling distribution is known as the standard error of the mean, which reflects the amount of variability among the sample means.

Figure 1 illustrates distributions of various sized random samples. Suppose one were drawing random samples of size 16, 49, and 100 from a population with $\mu = 50$ and $\sigma = 10$. Figure 1 shows how the theoretical sampling distribution of means would appear. As n is increased, the standard error becomes smaller and the more closely the sample means cluster around μ ; that is, the sampling distribution approximates a normal curve more closely.

TYPE I/TYPE II ERRORS AND POWER

Earlier, it was said that the α level selected directly affects the potential for making specific kinds of errors in the inferential process. Examining the consequences of one's decisions resulting from hypothesis testing, it is clear that only two decisions regarding H_0 can be made: one can reject it or not. Consequences of this decision relate directly to the true state of affairs concerning H_0 – whether H_0 is true or whether it is false as a description of the population characteristic. Table 1 identifies the consequences (correct decision or error) of rejecting or not rejecting H_0 given the truth about the null.

A Type I error – a decision to reject H_0 when H_0 is true – can only occur when the null hypothesis is true. When α is set as the criterion for rejecting H_0 , one is actually identifying the potential probability of concluding that a difference exists where really one does not. Type II error (β) refers to a decision to not

Figure 1 Distributions of various-sized random samples.

Table 1 Consequences of the hypothesis test

	<i>True State of Affairs</i>	
	<i>H₀ True</i>	<i>H₀ False</i>
Decision:	Type I	Type II
Reject <i>H₀</i>	Decision Error (α)	Correct Decision (1 - β)
Do Not Reject <i>H₀</i>	Correct Decision (1 - α)	Decision Error (β)

reject H_0 when H_0 is false. In many instances, Type I error is the more severe error as change is likely to be implemented upon finding a significant result. Therefore, one usually sets the probability criterion level for rejecting H_0 by chance quite low (typically .05 or lower) in social science research.

If one decides to reject H_0 , one of two potential consequences results: an error (Type I) or a correct decision. The α probability level is only relevant and applicable if H_0 is really true. If one decides to reject the null and H_0 is really false, this is a correct decision. The probability of this outcome is called the *power* of a statistical test (rejecting H_0 when the null is truly false) and equals $1 - \beta$. Manipulating several design factors can increase the power when testing the null hypothesis so that if H_0 is false, the probability of rejecting it is high. Factors affecting power include: increasing sample size and sampling from a more homogeneous population (reduces standard error resulting in a more precise estimate), using a one tailed test (a directional hypothesis results in greater power than a two tailed test), and using a larger α level. The latter factor will result in greater power in testing H_0 when H_0 is false; however, when

H_0 is true, the Type I error rate is larger due to the increased α . Therefore, many researchers are reluctant to use a larger significance level in an attempt to increase power.

MEANINGFUL DIFFERENCES: STATISTICAL VS. PRACTICAL SIGNIFICANCE AND EFFECT SIZE

Statistical significance is often confused with practical or substantive significance. When a null hypothesis is rejected, a difference between two means has been found, but the magnitude or importance of the difference does not necessarily follow. Given large samples, any difference will likely be significant in statistical terms. A misconception of significance testing is that a smaller significance level (α) indicates a stronger treatment effect or that somehow this indicates a more important result. However, a statistically significant outcome does not imply that a difference is large or of substantive importance. To determine if a difference is substantively trivial, researcher judgment (simply examining results) should play a role in addition to available empirical procedures.

In recent years, *effect size* reporting has become a popular empirical method for reporting the magnitude of a difference between means: that is, the size of a statistically significant result. In comparing distributions, the researcher will typically find the standard deviations to be similar, though not identical. In such situations, the standard deviations can be pooled for the purposes of appraising the magnitude of the difference between two means. Effect size (d) is the index that quantifies a mean difference in terms of pooled standard deviation units. One convention defines effect sizes $d = .20$ as small, $d = .50$ moderate, and $d = .80$ large (Cohen 1988). The need for judgment regarding practical significance should not be abandoned at this point as any sample difference is subject to sampling variation, especially in the cases of small sample size.

statistics

Wayne Gillespie

Censuses are used to enumerate a population and its characteristics. Statistics are mathematical calculations derived from this information or

data that are collected and recorded in a numeric or quantitative format. Quantitative methods such as these have been used to describe human populations for hundreds, even thousands, of years. Censuses, or the numbering of people, occurred throughout the ancient world. For example, the Romans conducted censuses in order to determine household income for political (i.e., voting) and taxation purposes. The Han dynasty census from 2 CE China is the earliest, intact census surviving from ancient times; it shows that the population of this dynasty exceeded 57 million. Another notable census is the *Doomsday Book*, which was compiled in 1086 after the Norman invasion of England to determine the amount of wealth obtained from the conquest. Sometimes censuses are conducted on the dead as opposed to the living. In 1662, John Graunt reported the number of deaths in London over the preceding 30 years. He even analyzed mortality trends by gender, season, and location. Graunt eventually published the first "life tables," used to compute life expectancy. In 1693, Edmund Halley refined Graunt's calculations to correctly compute life expectancy (Heyde & Seneta 2001). Censuses of human populations are still conducted throughout the modern world. The first census in the United States was taken in 1790, and censuses are done every 10 years in the US (US Census Bureau 2005).

Censuses are useful in describing an entire population, but they can be costly and time consuming. Probability sampling and statistical analysis allow for information to be generalized from a smaller group of people to the general population from which the group was selected. The primary advantage of statistical analysis is that compiling information on entire populations is not necessary. Rather, by drawing from probability theory, statistics allow researchers to estimate the attributes of populations from the characteristics of samples.

Statistics is an applied mathematical science, but not necessarily a subfield of mathematics; as Moore and Cobb (2000) noted, statistics values mathematical understanding but only as a means to an end, not as an end unto itself. Indeed, statistics has application in many seemingly disparate fields such as biology, education, public health, and sociology. In their text on statistical reasoning in sociology, Mueller

et al. defined the concept of statistics in two related manners: “(1) the factual data themselves, such as vital statistics, statistics on trade, production, and the like; and (2) the methods, theories, and techniques by means of which the collected descriptions are summarized and interpreted” (1970: 2).

The discipline of sociology emerged in tandem with the development of the field of statistics in the nineteenth century. Adolphe Quetelet (1796–1874) was a Belgian astronomer who became deeply interested in the application of statistical principles to human populations. He used probability theory to explain the consistency in the number of crimes from year to year, as well as to describe the characteristics of the “average” man (Mueller et al. 1970). For example, Quetelet used statistics to devise the first body mass index, known as the Quetelet Index, which is still used today as an indicator of obesity. Quetelet even organized and presided over the First International Congress of Statistics in 1853 (Heyde & Seneta 2001). According to de Heer et al. (1999), Quetelet’s two important contributions toward social statistics were his concept of the average man and his fitting of the normal curve to social phenomena.

Positivism was the first major paradigm in sociology, and it relied on statistical methods, such as those advanced by Quetelet, combined with Auguste Comte’s (1798–1857) positive philosophy and later Émile Durkheim’s (1858–1917) structural functionalism. This variant of early sociology was concerned with patterning social science after natural science and identifying laws of human behavior and social facts. The positivist approach is inherently quantitative, and it has been criticized for reducing complex social behavior to statistical probabilities and undermining human free will (Mueller et al. 1970). It is this penchant toward determinism that is the greatest criticism of both positivism and statistics.

Current statistical methods rely on laws or rules of probability. The estimation of population parameters from sample statistics is possible through probability theory. Probability is the numerical representation of the likelihood of an expected outcome occurring over multiple trials. It is the ratio of the number of expected outcomes (i.e., successes) to the total number of possible outcomes (Blalock 1972). There are at

least three rules of probability that inform statistics (Ritchey 2000). The first rule notes that probabilities are bound between 0 and 1, or between 0 percent and 100 percent. The second rule is called the addition rule. When two mutually exclusive outcomes are expected, then the probability of either of these events occurring is equal to the sum of the probabilities of the individual outcomes. However, when these events are not mutually exclusive, the probability of either the first or second outcome occurring is equal to the sum of their separate probabilities with the probability of their joint occurrence subtracted. The third probability rule is known as the multiplication rule. When two outcomes are statistically independent, the occurrence of the first event does not influence or predict the second. When two outcomes are statistically independent, the probability of both events occurring at the same time is equal to the product of their separate probabilities. However, when two outcomes are not statistically independent, the probability of both events occurring simultaneously is the same as the product of the probability of one event and the conditional probability of the other.

These rules of probability are important to statistics because many statistical tests assume that there is independence between events or outcomes, and that conditional probabilities do not need to be used. As Blalock pointed out, “it is assumed that there is independence of selection within a sample – the choice of one individual having no bearing on the choice of another individual to be included in the sample” (1972: 142). Random sampling, where every subject has an equal chance of being selected into the sample, is required to meet the assumption of independence.

Probability theory is used to produce sampling distributions. Sampling distributions are infinite since they involve repeated sampling (i.e., random samples repeatedly drawn from a population). A sampling distribution is another mathematical representation derived from repeated sampling that describes all possible event outcomes and the probability of each one (Ritchey 2000). It is important to note that sampling distributions are hypothetical, theoretical distributions, and researchers never attain a sampling distribution through empirical trials. Yet, when statistics are calculated for

each of these samples and then graphed, it results in a bell shaped or normal distribution. The normal distribution is one of the fundamental concepts in statistics, and it is expressed as the central limit theorem. According to this principle, regardless of the shape of the raw score distribution of a characteristic measured at an interval or ratio level, the sampling distribution of means will be more or less normal in shape as the sample size increases.

Probability and sampling provide the theoretical basis for statistics from a mathematical perspective. However, many of these rules and laws are implicitly assumed. The field of social statistics, in practice, is probably more concerned with the levels of measurement and the various types of statistical tests rather than the laws and rules that make such analysis possible in the first place (Blalock 1974). Indeed, the level at which social phenomena are measured dictates the type of statistical test that can be calculated. Once a characteristic is measured, and the characteristic shows variation, then it is called a variable. Variables are measured at four levels: nominal, ordinal, interval, and ratio. Ratio measurement is the most precise because the distance between values is both equal and known, and variables measured at the ratio level may contain a true zero, which signifies the total absence of the attribute. As with variables expressed at the ratio level, interval level variables are continuous, and the distance between values is also both known and constant. However, for variables measured at the interval level, no true zero point exists; the zero in interval level data is arbitrary. Variables measured at the nominal and ordinal levels are categorical. With ordinal level data, the response categories are both mutually exclusive and rank ordered. The categories of a variable measured at the nominal level have no relationship with one another; they simply signify the presence or absence of a particular quality. It is important to note that these levels of measurement are cumulatively related to one another; for example, a ratio scale possesses all the properties of an interval scale, included in an interval scale are all the properties of an ordinal scale, and the ordinal scale has all the properties of the nominal level.

Blalock (1972: 21) observed that "the use of a particular mathematical model presupposes

that a certain level of measurement has been attained." Statistical tests are generally univariate, bivariate, or multivariate in nature. Univariate statistics involve the description of one variable. If the variable was measured at a nominal level, then it is possible to report the mode (i.e., the most commonly occurring value), proportions, percentages, and ratios. When the variable is measured at the ordinal level, it becomes possible to calculate medians, quartiles, deciles, and quartile deviations. Then, at the interval and ratio levels of measurement, univariate procedures include means (i.e., the arithmetic average), medians (i.e., the midpoint), variances, and standard deviations. Measures of central tendency include the mode, median, and mean; measures of dispersion or the spread of the values for a given variable are typically reported as a quartile, percentile, variance, or standard deviation.

Bivariate statistics involve tests of association between two variables. Again, the level of measurement determines the appropriate bivariate statistic. For example, when both the dependent variable (i.e., the effect or the characteristic that is being affected by another variable) and the independent variable (i.e., the cause or the characteristic affecting the outcome) are measured at a nominal level, then the chi square statistic is most commonly used. Unfortunately, the chi square test only reveals if two variables are related; in order to determine the strength of a bivariate relationship involving two nominal variables, other statistics such as lambda or phi are used. When the dependent variable is measured at an interval or ratio level, and the independent variable is categorical (i.e., nominal or ordinal), then it becomes necessary to compare means across the categories of the independent variable. When the independent variable is dichotomous, the t test statistic is used, and when the independent variable contains more than two categories, an analysis of variance (ANOVA) must be used. When both variables are measured at an interval or ratio level, then statistical tests based on the equation for a line, such as Pearson's correlation and least squares regression, become appropriate procedures. Multivariate statistics often test for the relationship between two variables while holding constant a number of other variables; this introduces the principle of statistical control.

Examples of multivariate techniques include multivariate analysis of variance, multiple linear and logistic regression, factor analysis, path analysis, structural equation modeling, hierarchical linear modeling, and meta analysis (Grimm & Yarnold 1998).

Blalock (1972) identified five steps that all statistical tests have in common. First, assumptions concerning the population and the ability of the generalizations from the sample must be made. The assumptions also influence the formal stating of hypotheses (e.g., the null hypothesis is a statement of no association, and the research hypothesis is the alternative to the null). Then, the theoretical sampling distribution must be obtained or the probability distribution of the statistic must be rendered. Next, an appropriate significance level and critical region for the statistic must be selected. Fourth, the test statistic must be calculated. Lastly, based on the magnitude of the test statistic and its associated significance, a decision about the acceptance or rejection of hypotheses must be made. In many ways, hypothesis testing is the apex of statistical methods because it combines statistical theory with empirical, mathematical calculations to describe social phenomena and determine relationships between social facts.

status

Vasiliki Kantzara

Status, originally a Latin word, means state of affairs, condition of a person as defined by law and in social sciences; it denotes standing in society. In sociology, the notion of status or social status designates location and position of collectivities – communities, groups, or strata – in the social hierarchy of honor and prestige. Positions are distinguished from one another in terms of differentiated duties and rights, immunities and privileges, and usually are associated with a lifestyle or a consumption pattern. In their turn, these distinguishing traits are attributed a hierarchical value that generally represents the scale of social worth in society.

Status as a concept denotes both the evaluation process entailed in achieving a position and the granted location in the social hierarchy. Individuals attain status mainly in two ways: status is achieved and is ascribed (Linton 1936). It is achieved on the basis of personal effort, which is represented in educational titles and income earnings. Status is ascribed on the basis of characteristics that seem given, such as a person's age, ethnicity, or gender. In addition, status has an interrelational aspect, that is, the honor or prestige achieved needs to be granted

or attributed so that one may argue that a high status is truly attained. Groups and individuals strive to maintain or increase their acquired status, while they may strongly resist status loss.

THEORETICAL FOUNDATION OF STATUS

The term status captured the imagination of social scientists and particular sociologists, for they thought that the term could explain the constitution of social order and the position and relation of individuals to this order. The latter is emphasized in Linton's approach, the former in Weber's.

Ralph Linton, a social anthropologist in the US, employed the term status in the 1930s, referring to status as "a position in a particular pattern" (1936: 113). The status of an individual is, for Linton, the "sum total" of all the statuses a person occupies. A status is distinct from the person and it is defined as a collection of duties and rights, which form the static aspect of a position. When duties and rights are put into effect, they constitute the "dynamic" part of status, that is, the role involved in a position. These obligations and rights derive primarily from custom rather than law. Until about that time, the term status was largely employed in a legal sense, that is, rights and duties conferred to a person by law. Status in Linton's sense departs from this definition as the social position of an individual is viewed in terms of the degree of attributed prestige, esteem, and respect rather than in terms of possessing wealth and power (Zelditch 1968: 250).

Max Weber defined status as "a quality of honor or a lack of it" (1974: 405). Honor is furthermore differentially attributed, constituting a system of social stratification that is based on custom and communal values. In Weber's view, status groups differ in an important respect from classes. Classes are based upon the economic order, being an essential part of this order (pp. 180–1), and status groups are based on and are part of the social order, which is formed by customs and legal arrangements.

Status groups may be tight or less tight – "amorphous" – communities and are distinguished entities, as they are characterized by a

common consumption pattern and a lifestyle. These social groups, furthermore, claim rights and privileges for their members and strive to increase their status, while defending acquired rights. In this, status groups may come into conflict with other social groups or may exercise a closure strategy by controlling, for instance, the admission of new members to their ranks.

Status groups are in Weber's view part of the stratification system and are "knitted" into the economic order. In the long run, status groups and classes are interlinked and interconnected: a highly valued status group will acquire wealth and power, and a wealthy class will eventually acquire a high status (Weber 1974: 180–94; Scott 1996). Later, Benoit (1966), drawing on Weber, described this tendency as a "status conversion mechanism."

Weber's approach has been significant for the social stratification paradigm in social sciences. In the US, his approach has been influential, albeit without the social conflict component of his theory (Turner 1988). Linton's approach is important in that it has laid the basis for approaching status at the level of individuals. Subsequent theorizing and research on status throughout the twentieth century focused on varied aspects and dimensions of the term. From these researches and theories three broad areas can be discerned. First, a considerable amount of research has investigated the importance and relevance of social status to stratification by exploring the status of occupations. Second, status has been examined in relation to interaction and its outcomes within groups, exploring inequality in face to face interaction. This approach is known as the expectation states theory. Third, status consistency or inconsistency has been the focus of some approaches that sought to explain variation of holding different statuses at an individual level.

SOCIAL STATUS AND OCCUPATIONAL STRATIFICATION

In social sciences, it is viewed that in modern western societies the status of an individual derives primarily from one's occupation, as it is considered the main avenue of acquiring immunities, privileges, honor, and wealth, and

is an indicator of authority and power. Its significance becomes evident in some studies that relate achieved status and occupation to levels of self esteem.

The significance of occupation in determining an individual's position in the social hierarchy underlies the paradigm that focuses on occupational stratification. In this paradigm, it was thought that measuring the standing of occupations would provide an answer to questions and issues relating to social stratification and upward social mobility (Bendix & Lipset 1966). It has been largely assumed that achievement in western societies can overcome ascription and barriers posed, for instance, by social origins or gender (Treiman 1977). Ideally, in an open society, supposedly even the highest positions are open to every aspiring individual worthy of such a position.

Research in this area was directed to exploring occupational status or prestige (Reiss 1961; Treiman 1977) by measuring the standing of occupations. The terms status, social status, occupational status, and occupational prestige are used interchangeably and sometimes synonymously (Kantzara 2001). Research has been mainly quantitative and the main criteria or "variables" employed are education, occupation, and income, best known as the socioeconomic index.

The occupational stratification paradigm has produced numerous indices that depict the "images" and the hierarchy of occupational status as well as the changes it undergoes. This variation within a country as well as in comparative studies has made it difficult to sustain the main argument that social stratification is "invariant," obeying "laws" that the sociologist has only to uncover. Certain tenets and arguments of this paradigm have been criticized and challenged (Burawoy 1977), while research from this perspective continues to this day.

STATUS AND GROUP INTERACTION

Status order within groups is the primary focus of the expectation states theory or status characteristics theory. This theory constitutes a theoretical program comprising different but related research programs. It is based on the

work of Bales and others, who found that in small task oriented groups, inequalities could be observed in relation to members' participation and influence (cited in Berger & Zelditch 1998: 97–8). Expectation states theory sought to elaborate on these findings and explore some of the conditions in which a status order emerges or is maintained. Concepts such as status characteristics, status organizing processes, and path of relevance are employed in order to analyze patterns of evaluation and status order in small task oriented groups (Berger & Zelditch 1998; Ridgeway 1992).

Research has focused more particularly on the status characteristics of individuals, such as their age, ethnicity, and gender and the relation of these traits to judging individuals' degree of competence, quality of work performance, or the degree of influence these actors exercise in making decisions in small groups. The research results are based on experiments conducted in these groups. There is sufficient evidence that the assumed status of individuals plays a major role in the evaluation of competence and the quality of one's work performance; that is, the higher the status, the higher the positive evaluation of work performance regardless of whether it is qualitatively better. States expectation theory is an ongoing research project that has already passed through various stages within the disciplines of social psychology and sociology (Berger & Zelditch 1998).

STATUS CRYSTALLIZATION OR CONSISTENCY AND INCONSISTENCY

Focusing on an individual level, some authors have referred to the phenomenon of status consistency or inconsistency. These terms broadly denote that an individual's achieved status in one area converges or on the contrary may differ from ascribed or achieved status in another area.

In cases where status in one area converges with status in another, some authors suggest that an individual's status is crystallized or consistent. Lenski's approach attempted to formulate this proposition with a mathematical equation (cited in Smith 1996). The equation has been challenged to a great extent, but not the content of the argument. Lenski's work is

based on that of Benoit, who discusses status equilibration and status conversion mechanisms, drawing on Weber's approach. The terms denote that different "types" of status tend to reach a common level; that is, an individual's high status in the economic hierarchy will match the achieved status in the "political hierarchy" and this in turn will be equivalent to the status in the "hierarchy of prestige" (Benoit 1966: 80).

Merton (1966), who takes up Linton's definition of status and role, suggests that when an individual puts into effect different roles that have conflicting obligations, we witness a status inconsistency. Merton suggests that society usually develops adaptive mechanisms to mitigate these conflicts. In addition, individuals may avoid role conflicts by exercising "self selection," which means that they usually avoid occupying positions that cause role conflicts.

Hughes, on the other hand, discusses status contradictions and dilemmas people face when they interact with those who are in a status inconsistent position. Such cases, Hughes suggests, can be seen in occupations where the expected traits of professionals do not match with those in reality: a "black" doctor and a woman engineer were common examples in his time of status dilemmas. The solutions given include segregation, in two ways: (1) the individuals who differ are "put out of sight," so that, for instance, clients or co workers do not come into contact with them; (2) the individuals in question are directed to occupations that are thought to suit best their race and gender, that is, a "black" sociologist will eventually teach "race studies" and a woman engineer will design household appliances (Hughes 1971: 142–9). This approach also touches upon the issue of the interrelational aspect of status – to attain it, it needs to be granted (Kantzara 2001) – and "status passage."

CURRENT RESEARCH

Status both in Weber's and in Linton's sense has in a variety of ways greatly influenced theorizing in social sciences in general and in sociology in particular. Since the 1970s, the concept has also been increasingly employed to document the position and relative ranking or standing of disadvantaged social groups on the basis of gender

or ethnicity. In sociology of education, for instance, studies from a Weberian perspective explore and explain the changes in educational systems as an outcome of conflicts between rival status groups aspiring to control education and access to certain benefits. Additionally, the term status is employed to explain advantage or underachievement in education. Currently, however, status is mostly employed descriptively as shorthand for social position, as for instance women's status, or indicating a current state of affairs, as in the term health status.

It seems that status as a term has ceased to be at the center of theorizing in social sciences. However, the relevance of the concept for investigating the constitution of society has not diminished in importance. Status could be employed as an analytic concept in exploring and explaining social hierarchy, stratification, or inequality, which is still very relevant in the face of such social tendencies as increased diversity on the one hand and homogenization on the other. The relation of status to social identity and citizenship is a promising area of research as well. The latter relation is apparent in cases where various or competing social groups pursue and demand equal rights, and most importantly demand the application of equal rights for their members. In practice, it is witnessed that depending on context, prestige and standing still largely define the unequal distribution of rewards, whether financial, political, or cultural, and unequal access to social goods and services.

status attainment

Claudia Buchmann

Status attainment research begun by sociologists in the United States more than three decades ago laid the foundation for the study of the transmission of socioeconomic advantage from one generation to the next (also called intergenerational social mobility). Status attainment research seeks to understand how characteristics of an individual's family background (also called socioeconomic origins) relate to his or her educational attainment and occupational

status in society. It developed a methodology – usually path analysis and multiple regression techniques with large survey data sets – to investigate the intergenerational transmission of status.

In the classic study, *The American Occupational Structure* (1967), Peter Blau and Otis Dudley Duncan used national level data obtained from the 1962 Current Population Survey from the US Census Bureau and presented a basic model of the stratification process in which father's education and occupational status explain son's educational attainment, and all three variables, in turn, explain son's first job and subsequent occupational attainment. They found that the effect of son's education on son's occupational attainment was much larger than the effect of father's occupation on son's occupational attainment; thus they concluded that in the United States in the mid twentieth century, achievement was more important than ascription in determining occupational status.

David Featherman and Robert Hauser replicated the Blau and Duncan study in their book *Opportunity and Change* (1978), and found many of the same results. They found evidence of mobility both within generations (intragenerational mobility) and between generations (intergenerational mobility). Most mobility was rather short in distance and occurred primarily in the middle of the occupational hierarchy. They also found more upward mobility than downward mobility. Combining the findings of Blau and Duncan, Featherman and Hauser, and follow up studies, status attainment research has determined that there has been a long term decline in the importance of family background in determining an individual's occupational status.

Around the same time that Blau and Duncan were writing *The American Occupational Structure*, William Sewell and colleagues at the University of Wisconsin began publishing papers that addressed questions regarding the relative impacts of family background and schooling on subsequent educational and occupational attainments (Sewell et al. 1969). A notable aspect of the "Wisconsin model" of status attainment was its focus on social psychological factors, such as aspirations and motivation, in conjunction with family socioeconomic status in determining student achievement. In this regard, the Wisconsin

model attempted to specify the mediating mechanisms by which family origins influenced individual educational and occupational outcomes. The Wisconsin model of status attainment demonstrated that "significant others," including parents, friends, and teachers, strongly affect the educational and occupational expectations of male high school students. Subsequent research found that peers and parents help shape students' ambitions and attitudes toward schooling, both of which are mediating factors in later educational attainment and achievement. Generally, parents are more influential as definers of behavior while peers are important as both modelers and definers of behavior. Most of these studies include controls for socioeconomic status, parental education, and the student's academic ability or achievement, all of which have the effect of increasing aspirations. While Blau and Duncan specified father's occupation and education as separate influences, the Wisconsin researchers usually combined these measures, along with mother's education and family income, into a single measure of socioeconomic status. Despite these measurement differences, both models concluded that socioeconomic status strongly determined educational attainment.

The now classic research by Blau and Duncan and the Wisconsin model of status attainment established a framework for the study of family background on educational and occupational attainment in a wide range of contexts. By the early 1980s, more than 500 papers had attempted to replicate or extend their basic findings (Campbell 1983).

Human capital models in economics, in which family background and schooling decisions determined education and earnings outcomes, also contributed to this growing field.

While some studies applied the status attainment model to nationally representative samples in the United States, others examined status attainment processes in very different countries and contexts. Building on the foundation laid by status attainment research in the United States, studies have examined the role of social origins in determining educational and occupational status and mobility in a range of countries; other research has investigated how intergenerational mobility changes over time with large societal changes, such as the expansion of formal

schooling, the industrialization of society, or the transition from socialism to capitalism.

Some comparative status attainment research sought to examine another hypothesis offered by Blau and Duncan. On the basis of their findings from the United States, Blau and Duncan predicted that as societies industrialize, achievement processes become more important and ascriptive processes become less important in determining educational and occupational attainment. They tested this hypothesis for the United States by comparing the experiences of different birth cohorts but they found no clear trend over time. Donald Treiman (1970) expanded upon these ideas to provide a detailed explanation of the mechanisms by which industrialization should promote greater mobility. As societies develop, urbanization, mass communication, and industrialization should lead to greater social openness and a shift from particularistic to universalistic bases of achievement. As a result, the direct influence of father's occupational status on son's occupational status, as well as father's educational and occupational status on son's educational attainment, should decline, while the direct influence of son's educational attainment on his occupational status should increase. During the 1970s and 1980s, researchers set out to test these propositions. Most studies examined historical or regional differences within a single society and few found support for the industrialism thesis. To date, the evidence regarding how the impact of social origins on educational and occupational attainment varies with industrialization remains inconclusive, largely due to the lack of cross national survey data for a wide range of countries.

International studies of social mobility have contributed greatly to our understanding of how family socioeconomic status shapes educational and occupational outcomes. The influence of the Blau-Duncan model is clearly evident in this international research; most studies conceptualize socioeconomic status as either father's education and occupation or a composite measure of these and other family background factors. Some researchers have had to alter this approach due to data limitations or considerations of the local context, but still, the systematic approach to the measurement of family background is striking. As a result of these efforts, status attainment models now

exist for many nations in all regions of the world.

In status attainment research, occupational status is typically measured via scales that have been developed to generalize the prestige associated with occupations across a wide range of societies. The earliest of these was the Socioeconomic Index (SEI) scale formulated by Duncan for the United States and subsequently modified by other researchers for other countries. Comparative stratification researchers have devoted considerable effort to developing internationally comparative scales of occupational prestige and testing their reliability cross culturally. Two of these scales, the Standard International Occupational Prestige (SIOP) scale and the International Socioeconomic Index (ISEI) of occupational status, have been used extensively in international research. Although most prior research relied on paternal occupational status in constructing this measure, recent empirical evidence indicates that mother's occupational status has a strong impact on educational outcomes, independent of father's education and occupational status. Such findings, combined with the increasing prevalence of women's full time labor force participation throughout the world, suggest that mother's occupational status should be included as a measure of family background in future status attainment research. The inclusion of mother's education has been more common, perhaps because early status attainment research indicated that mother's education had positive effects on children's schooling, net of father's education and occupational status. In many cases, maternal and paternal education are highly correlated and researchers use one or the other as a measure of parental education. In contexts where mothers spend more time with their children or where males are typically absent from the household, it is reasonable to expect that mother's education should have a stronger impact than father's education, and researchers have used mother's education as the measure for parental education. Another strategy has been to use the sum of both parents' schooling.

As in the case of occupational status, scales have been developed for measuring educational attainment with the goal of ensuring comparability cross nationally. CASMIN and ISCED are two such scales. The International Standard

Classification of Education (ISCED) was originally developed by UNESCO and is regularly used by UNESCO and other international organizations for reporting national education statistics. The CASMIN categories were developed as part of a project known as "Comparative Analysis of Social Mobility in Industrial Nations." Walter Mueller and his colleagues at the University of Mannheim, Germany developed CASMIN with the express purpose of facilitating comparative research on social stratification and mobility. ISCED and CASMIN are similar in that they focus on the levels of education completed: elementary, secondary, and tertiary education, and specify some subdivisions at each level. The CASMIN scale goes a step further to distinguish general or academic credentials from vocational credentials. These scales have facilitated international comparisons of educational systems and educational stratification.

Status attainment research constitutes one of the largest bodies of empirical research in the study of social stratification. It reshaped the study of social mobility by focusing attention on how aspects of individuals' socioeconomic origins relate to their educational attainment and occupational status in society. Nonetheless, critics have noted several limitations with this line of research. First, status attainment research does a better job of explaining the social mobility for white males than females or minorities. Second, this line of research has limited explanatory power because, even for white males, status attainment models can explain only about half of the variance in occupational attainment. This indicates that even the most complex status attainment models still do not get very close to approximating the even more complex reality of the attainment process. Third, in its focus on individual characteristics, status attainment research has tended to neglect the role of structural factors in determining individual educational and occupational outcomes. Changes in the economy or changes in the opportunity structure of occupations caused by large scale policy changes (e.g., equal employment opportunity policies) are just two examples of factors that create societal shifts that can impact status attainment processes at the individual level. Since the 1990s, more research has expanded status attainment research to account for such

social structural or organizational factors that may play a role in individual mobility.

status construction theory

Cecilia L. Ridgeway

Status construction theory focuses on the collective development of widely shared status beliefs about apparently nominal social differences among people, such as sex or ethnicity (Ridgeway 1991; Webster & Hysom 1998; Ridgeway & Erickson 2000). Status beliefs associate greater respect and greater competence at socially valued tasks with people in one category of a social difference (e.g., men, whites) than with those in another category of that difference (women, people of color). A typical reaction to the recognition of social difference is for people in each category to assume that their own group is “better.” When status beliefs develop about a recognized social difference, however, they transform simple difference into an evaluative hierarchy so that the distinction

becomes a status characteristic in society. The distinctive aspect of status beliefs is that those in the social category that is favored by the status beliefs and those in the less favored category both come to hold similar beliefs that “most people” view the favored group as better than the other group. Status construction theory describes one set of processes by which such beliefs could come to be accepted as a matter of social reality by those they disadvantage and by those they advantage. In this way, beliefs become roughly consensual in society. The theory claims that the processes it describes are sufficient to produce widely shared status beliefs but are not the only way such beliefs might develop in a society or collectivity.

Status construction theory developed in the 1990s in the context of two well established bodies of theory and research. Several decades of research on status hierarchies among individuals in groups, especially research associated with expectation states theory, had documented that interpersonal influence and deference are largely driven by differences in the status characteristics of the individuals involved (Berger et al. 1977). How social differences became status characteristics, however, was unknown.

While this micro tradition of theory and research examined status between individuals, macro approaches to status, beginning with Max Weber, focused on status as a relationship between social groups in society. Status between individuals and status between groups are linked by the widely held status beliefs that both represent the social standing of groups in society and cause group differences to manifest as status characteristics in interpersonal settings. Status construction theory attempted to connect these two bodies of work by offering an account of the development of status beliefs about social differences.

The theory is a micro–macro theory that focuses on the aggregate effects that emerge from interpersonal encounters between socially different actors when these encounters have been framed and constrained by macrostructural conditions. The theory takes as a starting point the existence of a socially recognized but not yet consensually evaluated categorical distinction. An assumed scope condition is that members from the groups created by the distinction are to some degree interdependent in that they must

regularly cooperate to achieve what they want or need. Under these conditions, status construction theory, drawing on its roots in expectation states theory, argues that the local contexts in which people from different categories encounter one another become arenas for the creation, spread, and maintenance of status beliefs about categorical difference.

The theory's basic arguments can be summarized as follows (Ridgeway & Erickson 2000). In interdependent encounters between categorically different people, interpersonal status hierarchies are likely to develop among the participants just as they do in most cooperative, goal oriented encounters. Such interpersonal influence hierarchies develop implicitly, through multiple small behaviors that the participants rarely scrutinize. Since the actual origins of their influence hierarchy are obscure to them but their categorical difference is salient, the theory argues that there is some chance that the participants will associate their apparent difference in esteem and competence in the situation with their categorical difference. If the same association is repeated for them in subsequent intercategory encounters, the theory argues that it will eventually induce them to form generalized status beliefs about the categorical distinction.

Once people form such status beliefs, they carry them to their next encounters with those from the other group and act on them there. By treating categorically different others according to the status belief, belief holders induce at least some of the others to take on the belief as well. In effect, they "teach" the others the beliefs by acting on it. This in turn creates a diffusion process that has the potential to spread the new status belief widely in the population.

Whether the new status belief does in fact spread widely and which categorical group it casts as higher status depend on the structural conditions that shape the terms on which people from each group encounter one another (Ridgeway 1991; Ridgeway & Balkwell 1997). Of central interest is whether structural conditions result in an unequal distribution between the groups of some factor such as material resources or technology that is helpful in gaining influence in intercategory encounters. The unequal distribution of such a "biasing factor" means that in intercategory encounters, there

will be a systematically greater likelihood that people from the group with more of the factor will emerge as the influential actors in the situation compared to people from the group with less of the factor. As a consequence, the set of intercategory encounters in the population will continually foster more status beliefs favoring the structurally advantaged group than favoring the other categorical group. As these beliefs spread and diffuse through future encounters, beliefs favoring the structurally advantaged group will eventually overwhelm counterbeliefs and become nearly consensual in the population. From this reasoning, the theory argues that if a biasing factor is unequally distributed between categorical groups, status beliefs favoring the structurally advantaged group will emerge and spread to become widely shared in the population.

As this description shows, the theory consists of two sets of arguments. The first addresses processes through which participants form status beliefs in micro level encounters between categorically different actors. The second set of arguments addresses the role of structural conditions in determining the aggregate consequences of belief formation in micro encounters.

In its initial formulation, status construction theory focused on one specific structural condition, a correlation between superior material resources and membership in a particular categorical group (Ridgeway 1991). Since Max Weber, sociologists have observed that a common precondition for the development of status beliefs about two social groups is that people in one group become, on average, richer in material resources than those from another. In its first statement, the theory delineated a set of processes through which this precondition gives rise to status beliefs about the group distinction. This statement brought together Peter Blau's (1977) theory of how social difference affects the likelihood that people encounter one another with expectation states theory's arguments about the influence hierarchies that would be likely to develop in encounters of various social composition. The analysis shows that "doubly dissimilar" encounters between people who differ in both material resources and the categorical distinction are especially important for the systematic development of status beliefs.

Although other intercategory encounters may induce status beliefs, it is only in doubly

dissimilar encounters that material resources systematically bias the development of influence hierarchies so that these encounters reliably produce more status beliefs favoring the materially advantaged group. Doubly dissimilar encounters are the least common type of intercategory encounter according to Blau's association arguments. However, through the diffusion process, these encounters feed a steady surplus of beliefs favoring the materially advantaged group into the population. Such beliefs overwhelm the cultural confusion of conflicting local beliefs, allowing widely shared status beliefs to emerge.

Two sorts of evidence support the initial formulation of the theory. Laboratory experiments suggest that people do form status beliefs favoring the materially advantaged group after two repeated doubly dissimilar encounters, as the theory predicts (Ridgeway et al. 1998). In these experiments, participants formed beliefs that most people would see the typical member of the materially advantaged group as higher status, more respected, and more competent, but not as socially considerate, as those in the other group. Participants formed these beliefs even when the beliefs cast their own categorical group as less respected and competent, although more considerate, than the other group.

In addition, computer simulations of the diffusion process provide logical support for the theory's arguments about how structural conditions shape the aggregate consequences of encounters. These simulations show that the emergence of nearly consensual status beliefs would be a logical consequence under a variety of assumptions about the strength of the correlation between categorical membership and superior resources, the strength of homophily bias in associations, and the relative sizes of the categorical groups (Ridgeway & Balkwell 1997).

Subsequent developments revealed that the theory's initial focus on the effects of inequalities in material resources was unnecessarily narrow and that the theory could account for the development of status beliefs under a broader range of structural conditions. The logic of the theory was shown to imply that an inequality in the distribution between two categorical groups of any factor, not just material resources, that biases the development of influence hierarchies in encounters will lead to the emergence of status beliefs about the categorical distinction

(Ridgeway et al. 1998; Webster & Hysom 1998). Webster and Hysom (1998) used this more general formulation of the theory to show how the social distribution of moral approval based on sexual orientation acts as a structural biasing factor that fosters the formation of status beliefs about homosexuality.

The viability of this more general formulation of the theory depends on the assumption that people form status beliefs simply from the repeated, consistent association of categorical difference with participants' relative influence in intercategory encounters. Further laboratory experiments showed that this does occur and that participants form these status beliefs even when the beliefs represent their own group as lower status and less competent than the other group (Ridgeway & Erickson 2000).

The above studies offer evidence that people form status beliefs about salient social differences from their cooperatively interdependent encounters with different others. For widely shared status beliefs to emerge about a categorical distinction, however, people must also be able to spread their newly acquired status beliefs to others by acting on those beliefs in subsequent encounters with those who differ on the distinction. Two laboratory experiments have examined this aspect of the theory (Ridgeway & Erickson 2000). The first showed that when participants had two repeated experiences of being treated in a status evaluated way, i.e., either deferred to or treated assertively, by a nominally different other, the participants formed status beliefs about the nominal distinction that corresponded to the way they were treated. A second study showed that participants acquired status beliefs not only when they were directly treated according to such beliefs themselves, but also when they witnessed the status evaluated treatment of someone like themselves by someone different. These studies suggest that intercategory encounters have the potential to propagate newly forming status beliefs widely through the population.

Status construction theory and the research that supports it suggest that interactional contexts are relatively powerful contexts for transforming nominal social differences into status differences. Yet despite this, not all socially recognized differences become status differences. Recent developments in status construction theory

examine in greater detail the processes of belief formation in encounters in an effort to discern how the processes of belief formation can sometimes be interrupted and undermined in local contexts so that widely shared beliefs do not emerge.

This recent elaboration of the theory argues that for participants to form status beliefs, not only must the influence hierarchies in their encounters be consistently juxtaposed with a salient categorical distinction, but the apparent correspondence between influence and difference must also seem socially valid to the participants (Ridgeway 2006). The stronger the appearance that the correspondence between difference and influence is consensually accepted by others, rather than resisted or challenged, the more socially valid it will seem, and the more likely it is that clear status beliefs will form. Legitimated authority will also make the correspondence seem socially valid, facilitating the formation of status beliefs. Supporting these arguments, experimental evidence shows that challenges to consensus undermine the formation of status beliefs, while the support of authorities strengthens status beliefs. These results suggest that widely shared status beliefs are most likely to emerge about a categorical distinction when structural conditions not only advantage one categorical group in gaining influence in intercategory encounters, but also constrain the ability of those in the structurally disadvantaged group to display resistance to that influence.

Status construction theory has framed its principal arguments in terms of the creation of new status beliefs. The theory also claims, however, to speak to the maintenance of existing status beliefs, particularly over changes in the initial social conditions that created them (Ridgeway 1991). According to the theory, if structural conditions described by the theory, such as an inequality in resources between the categorical groups, are currently present, then status construction processes will be sufficient to maintain status beliefs about that categorical distinction. This will occur whether or not these processes played a role in the actual historical origin of the status beliefs. Status construction processes, then, may cause status beliefs based on race, gender, or other social differences to persist in contemporary societies even though the original historical cause of those status

beliefs has disappeared. This aspect of status construction theory has been used in combination with other arguments to account for the persistence of gender status beliefs in western societies over major transformations in the socioeconomic organization of gender relations in those societies, such as those associated with industrialization or the movement of women into the paid labor force.

status passages

Michael J. McCallion

The term status comes from the Latin word meaning “to stand,” which helps to clarify how the term has come to be used in sociology as

constituting a basic analytic unit in a social system (society), denoting a *position* that an individual holds (stands) in a particular institution or social structure. The concept of status had wide currency in the post World War II heyday of structural functionalism (Parsons 1951), and generally referred to a collection of specific institutional rights and duties (Linton 1936). The enactment of these rights and duties, on the other hand, was considered an individual's "role," the more dynamic aspect of status. Status passages, therefore, refer to persons passing from one status to another (e.g., from being single to married).

Gennep (1960) enduringly inscribed in the social scientific community's consciousness the phenomenon of status passages, in particular, age based status passages (e.g., adolescence to adulthood). Although Gennep was an anthropologist, sociologists used his work to explain various societies' methods for moving people from one status to another. Although sociologists have studied these transforming procedures, it could be argued that they have been overly influenced by Gennep's work in assuming that most status passages are regularized, scheduled, and prescribed. Certainly, many status passages have these characteristics and sociologists have spent considerable effort in studying these within occupations (careers) and organizations (mobility), as well as how these status passages affect self identity. But it was not until Strauss published "Some Neglected Aspects of Status Passages" (1968) and Glaser and Strauss's book *Status Passage* (1971) that various other properties or characteristics of status passages were theorized and studied. Among the other properties of status passages, Glaser and Strauss list the following:

- The passage may be desirable or undesirable (getting married or becoming a prisoner).
- The passage may be inevitable (birth to childhood).
- The passage may be reversible to some degree (job demotions).
- A passage may be repeatable or nonrepeatable (being sick).
- The person "passing" may do so alone or collectively (with any number of persons).
- It follows that when people go through a passage collectively, they may not be aware

that they are all passing through together (large school classes).

- Persons involved may or may not be able to communicate with the others (junior executives being simultaneously demoted).
- The person making the passage may do so voluntarily or have no choice in the matter (commitment to a mental institution).
- Degree of control during the passage by the one making the passage and others who oversee it (father not allowing his son to obtain a driver's license).
- The passage may require some special legitimation by one or more authorized agents (a physician and being sick).
- The clarity of the signs of the passage may vary from great to negligible (a con man turning one into a mark or parents not knowing their daughter is getting married).
- The signs of passage may be clear or disguised by relevant parties (which are also signs of control).
- The centrality of the passage to the person, that is, how much difference it makes to him or her (similar to desirability, above).
- The length of time or duration of a status passage.

Glaser and Strauss admit this is an incomplete list of properties. Nevertheless, these properties sensitize the researcher to the broader and more dynamic nature of status passages. Indeed, Glaser and Strauss argue that they have developed a formal theory of status passages, which is a theory developed for a formal or conceptual area of sociological inquiry which transcends any one substantive or empirical area of investigation.

Since the work of Glaser and Strauss, status passages have come to be viewed as dynamic, constantly shifting, changing, and in motion rather than as static. This dynamism is evident in the fact that status passages involve not only the "passagee" but various "agents" who assist or hinder the passage. These agents are sometimes called coaches, sponsors, teachers, guides, gurus, parents, and so forth who assist the passagee particularly during the transitional or liminal phase of the status passage, for this is when the passagee is betwixt and between statuses and, consequently, most vulnerable. For example, an individual passagee has left the single life

status (engaged to be married), but has not yet been fully initiated into married life. Equally important is the fact that the relationships involved and developed during the status passage underscore the social nature of such passages, that is, they are not traversed alone.

Accordingly, from a sociological perspective, status passages reveal the fundamentally social nature of human life. Successfully or unsuccessfully negotiating a status passage assumes that agents/others have been integral to the status passage (whether bane or blessing). The status passage can vary in terms of how much individuality or collectivity is involved, but there is always some degree of the "other" involved in a status passage. Although status passages are most often researched at the social psychological level, the broader social dimension is evident as well in the fact that society at large legitimates certain statuses into which one may pass. Individuals do not make up statuses and then passages to go through to obtain them without "others" recognizing and legitimizing them as such (Stone 1970).

As indicated above, most recent studies have been at the social psychological level in that they have focused on how individuals have completed the passage into a host of professional occupations (MacNeil 1997; Bradby 1990), been converted to a particular religion (Snow & Machalek 1984; McCallion & Maines 2002), pass through the life course (Glaser & Strauss 1968), attain the status of deviant (Becker 1963), and many others. What have been under researched are the broader levels of the social and cultural. For example, do various societies have more or less extensive status passages, more or less opportunity to undergo a status passage, and, if so, why? If more extensive, for example, does this indicate that the particular society is more rigid and closed or flexible and open – a question sociologists and historians have examined for years. And if there are more opportunities, are the status passages strong or weak, short or long? The basic sociological question that still needs further research is under what social conditions are there more or less, weak or strong, long or short, fewer or more opportunities for status passages? Why are some churches (Catholic), for example, maintaining lengthier status passages than others (Protestants)?

Status passage research can reveal much about a society and its culture, especially in terms of socialization, social mobility, social structural arrangements, and identity salience. Further research on status passages, therefore, could advance sociological theory about these matters, as well as how societies work at the more macro level.

steering, racial real estate

Gregory D. Squires and Jan Chadwick

Racial real estate steering occurs when home seekers are guided by housing providers to communities where their race is already highly concentrated. So as racial minorities are channeled to integrated or predominantly non white neighborhoods and whites are shown homes primarily in white communities, steering contributes directly to the segregated housing patterns that have long persisted in urban communities and the many costs associated with that separation.

Steering can take several forms. Information steering occurs when minority homeseekers are shown or given information on fewer homes or neighborhoods than non minority homeseekers. Segregation steering occurs when minorities are shown homes in areas with larger minority populations than areas shown to non minorities. And class steering occurs when neighborhoods shown to minority homeseekers are of lower socioeconomic status than those shown to non minorities. Several actors in the housing industry engage in steering. Mortgage lenders and insurance agents often provide less information and offer fewer, more expensive, and lower quality products to non white households or residents of non white communities than they do for whites and predominantly white communities. These practices influence the location and range of housing options for minority families. However, racial steering is most closely associated with the practices of real estate agents who are often the gateway to housing opportunities, which often differ for white and non white families.

Historically, steering was virtually required by law and widespread industry practice in many communities. Early in the twentieth century steering took the form of restrictive

zoning laws that apportioned particular city neighborhoods for different racial groups. Blacks and other minorities were prohibited by law from living in certain neighborhoods of several cities, North and South. When these policies were ruled unconstitutional by the Supreme Court in the 1917 case of *Buchanan v. Warley*, they were replaced by the racially restrictive covenant. These covenants generally took the form of deed restrictions stating that the property could not be occupied by members of certain ethnic groups. They were promulgated and often instigated by real estate agents and mortgage brokers who would encourage entire neighborhoods to participate. The National Association of Real Estate Boards (NAREB) promoted this practice by stating in its code of ethics up until 1950 that "a realtor should never be instrumental in introducing into a neighborhood . . . members of any race or nationality . . . whose presence will clearly be detrimental to property values in that neighborhood" (Massey & Denton 1993: 37). While judicial enforcement of racially restrictive covenants was declared unconstitutional in 1948, and the words "race" and "nationality" were eliminated from NAREB's code of ethics in 1950, the practice of steering between already established segregated neighborhoods has continued.

Racial steering has been motivated by several factors. Real estate agents generally serve selected neighborhoods within metropolitan areas and rely heavily on word of mouth advertising to recruit new clients. Many fear loss of business if they introduce a minority family into a white neighborhood. Historically, some agents feared strong reprisals from area residents if they introduced a household that could have a "detrimental" effect on the neighborhood. Some maintain they are simply responding to the preference of renters and buyers who prefer to live in homogeneous neighborhoods. And others no doubt still assert that they are helping to maintain property values by steering homeseekers to such communities.

A combination of statutes, court cases, and regulations has declared racial steering to be unlawful. In 1968 Congress passed the federal Fair Housing Act (Title VIII of the Civil Rights Act of 1968), prohibiting discrimination on the basis of race, color, national origin, sex, or religion, and in 1988 persons with disabilities

and families with children were added as protected classes. While the law does not specifically use the word "steering," case law has generally found steering to be in violation of section 3604(a) of the Act, which states that it is unlawful "to otherwise make unavailable" housing because of a protected class status. Both rental and sales steering have been successfully challenged in court, and not always by actual homeseekers who were steered. In *Trafficante v. Metropolitan Life Insurance Co.* (1972), the white plaintiffs claimed that they had been injured because they had lost the social benefits of living in an integrated community; they had missed the business and professional advantages which would have accrued if they had lived with members of minority groups; and they had suffered embarrassment and economic damage in social, business, and professional activities from being stigmatized as residents of a "white ghetto." Other significant steering cases included *Gladstone, Realtors v. Village of Bellwood* (1979) and *Havens Realty Corp. v. Coleman* (1982) where the court gave standing under the Fair Housing Act to other local residents and investigators with fair housing centers who claimed that steering by real estate agents was destroying the racial balance of their neighborhood or community and denying residents the benefits of integrated living. In the 1985 case of *Heights Community Congress v. Hilltop Realty, Inc.*, the Sixth Circuit held that a real estate agent who engaged in intentional racial steering violated the Fair Housing Act. Perhaps more significantly, the court held that even if the statements made by the agents about the racial makeup of the neighborhoods were truthful, if the effect of the statements was to discourage people of particular races from considering those neighborhoods, it violated the Act.

In addition to the statutory and case law, when the Fair Housing Act was amended and strengthened by the Fair Housing Amendments Act of 1988, the US Department of Housing and Urban Development (HUD) promulgated regulations prohibiting steering, which it defined as any effort to "restrict or attempt to restrict the choices of a person by word or conduct in connection with seeking, negotiating for, buying or renting a dwelling so as to perpetuate or tend to perpetuate, segregated housing patterns, or to discourage or obstruct choices in a community,

neighborhood or development." These regulations state that unlawful steering includes but is not limited to: (1) discouraging any person from inspecting, purchasing, or renting a dwelling because of the minority status of the person, or the minority status of the persons in a community, neighborhood, or development; (2) discouraging the purchase or rental of a dwelling because of a protected class reason by exaggerating drawbacks or failing to inform any person of desirable features of a dwelling or of a community, neighborhood, or development; (3) communicating to any prospective purchaser that he or she would not be comfortable or compatible with existing residents of a community, neighborhood, or development because of a protected class reason; or (4) assigning any person to a particular section of a community, neighborhood, or development, or to a particular floor of a building, because of a protected class reason.

Even with the passage and strengthening of the Fair Housing Act, studies have shown that racial steering continues. These studies generally take the form of a housing audit and utilize "matched paired testing" where white and minority testers posing as homeseekers are identically matched on all relevant housing related characteristics (e.g., income, occupation, housing preference) and sent to visit real estate offices. While many local housing audit studies have been conducted, the most comprehensive national audits have been sponsored by HUD and conducted by the Urban Institute. In 1979, 1989, and 2000, national paired testing studies were conducted. Due to methodological differences, it is not possible to draw comparisons between the 1979 research and the two subsequent studies. But the latter two studies, each of which covered more than 20 metropolitan areas, do permit some conclusions about the changing nature of housing discrimination.

The key finding from the 1989 and 2000 studies is that overall discrimination has dropped considerably, but still remains a central feature of the nation's urban and metropolitan housing markets. The share of black and Hispanic homebuyers and renters experiencing discrimination dropped from approximately one third of all homeseekers in 1989 to about one out of every five in 2000. However, these studies understate the actual level of

discrimination, for several reasons. The studies included only housing units that were advertised in major daily newspapers. Homes in minority neighborhoods are less likely to be advertised in these outlets than are homes generally. This is also the case for homes in exclusively white neighborhoods where racial discrimination may be the most explicit. And testers did not follow up their initial contact with housing providers, so the study did not capture behavior that occurs during subsequent visits, after an offer is made, or when insurance or mortgage loans are applied for in the homebuying process. Consequently, the 2000 study reports a conservative estimate of the actual level of discrimination that occurs in the housing market (Turner et al. 2002).

Despite the lower incidence of racial discrimination overall in 2000 compared to 1989, the frequency of racial steering actually increased. For example, the percentage of tests in which whites were shown homes in communities that had a higher white population than the communities in which black testers were shown homes increased from 7.5 percent in 1989 to 11 percent in 2000. When whites and Hispanics were paired, the share of white favored tests on this measure increased from 7.4 percent to more than 14.7 percent. However, steering most commonly occurred through informal, unsolicited comments directed to white home seekers about the racial composition of selected neighborhoods. Among these comments were the following:

"I would not recommend (area), it's totally black. And I don't like (area), it's pretty mixed."

"There are lots of Latinos living there ... I'm not supposed to be telling you that, but you have a daughter and I like you."

"(Area) is very mixed. You probably wouldn't like it because of the income you and your husband make. But I don't want to sound prejudiced."

"(Area) is different from here; it's multi-cultural ... I'm not allowed to steer you, but there are some areas that you wouldn't want to live in." (Galster & Godfrey 2003: 19, 23).

If racial discrimination has declined in recent years, it persists at very high levels in the nation's urban and metropolitan communities.

And steering has increased. Steering, along with other forms of discrimination, contributes to the ongoing segregation of American cities and its many social costs. Segregation nurtures the concentration of poverty, and particularly the concentration of poor minorities. Housing values and the wealth accumulation associated with homeownership are undercut for racial minorities because of their continued isolation from more favored neighborhoods. Consequently, racial minorities are disproportionately trapped in neighborhoods where school achievement is lower, crime rates are higher, and most public services and private amenities are of lower quality or not available at all.

But fair housing enforcement appears to be working. Reductions in discrimination during the 1990s suggest that the efforts of HUD and other law enforcement authorities, along with the work of non profit fair housing organizations around the country, are having the intended effect. During the 1990s lawsuits filed by non profit housing centers generated more than \$180,000,000 for plaintiffs. But the fair housing agenda remains unfinished. Racial steering is clearly one of the issues that should be the focus of future enforcement efforts. Persisting high levels of discrimination (even if lower than in previous years) indicate that equal housing opportunity, though the law of the land, is not yet the reality.

stepfamilies

Marilyn Coleman and Lawrence H. Ganong

Stepfamilies are common throughout the industrialized world. In the US nearly everyone marries, and about half of the marriages include at least one previously married partner (US Census Bureau 2000). Most divorced people in other western countries also either remarry or cohabit, but at lower rates than in the US. About half of the remarriages involve adults who have children.

Because not all remarriages involve parents, remarriages and stepfamily formation are not the same. A stepfamily is a cohabiting or legal union of two adults, at least one of whom has a child or children from previous relationships. According to Fields (2001), about 17 percent of all children in the US live in a stepfamily household, usually with a stepfather and mother. An estimated 30 percent of children in the US will live in a stepfamily household before they become adults. A large number of children who live primarily with a single mother also visit a remarried or cohabiting father.

Although stepfamilies have been common throughout history, they have not been studied until relatively recently. Until past the midpoint of the twentieth century, remarriage was considered the solution to a social problem. When divorce rather than bereavement became the

most common precursor to remarriage and step family formation (around 1974), stepfamily formation became viewed as a social problem. This view appeared to stimulate both research and clinical work (Ganong & Coleman 2004). Most stepfamily research has been done since 1990 (Coleman et al. 2000). These studies offered marked improvement over previous work: samples were more representative, large scale longitudinal studies were launched that allowed us to examine family process, more observational research was conducted, measurement was greatly improved, and there was increased use of theory. However, little attention has yet been paid to racial, ethnic, or SES diversity.

The most frequently studied phenomena have been the effects on children of living in stepfamilies. These studies generally have reported that stepchildren, on average, are slightly more at risk for externalizing and internalizing behavior problems, do less well in school, and are less likely to form stable couple relationships as adults than are children who grow up living with both parents. However, the differences between stepchildren and children in first marriage families tend to be small, and most stepchildren (about 80 percent) function normally on psychological, cognitive, and interpersonal outcomes. The research emphasis primarily has been on documenting problems in stepfamilies – sometimes called a *deficit comparison* approach. In recent years, more researchers have begun to explore how and why some stepfamilies function well and others do not, using what has been called a *normative adaptive* approach.

Numerous reasons for problems in stepfamilies have been offered, but one of the more widely known is Cherlin's (1978) seminal work that described families formed after remarriage as *incomplete institutions*. Cherlin argued that stepfamilies lack institutionalized guidelines and support in solving family problems, and as a result they have more problems than do first marriage families. Research in general has lent some support for this hypothesis. A contributing factor to the incomplete institutionalization of stepfamilies is *nuclear family ideology*. This means that there are strong cultural biases that families *should* live in nuclear families, and those who do not conform to this model are deficient and/or deviant. The nuclear family ideology

creates social stigma that appears to result in many stepfamilies attempting to hide their status and to act as if they were a nuclear family (e.g., stepchildren using their stepfather's surname even though it is not their legal surname), which may only further contribute to their feelings of isolation or being different. Negative media images and language negatively stereotyping stepfamilies and stepfamily members (e.g., "the parks system is the stepchild of city government") continue to be a problem as well. Stepparents are motivated to adopt stepchildren, in part, to convert a step relationship legally into a parent-child relationship, thereby avoiding stigma and acquiring norms for guiding their relationship.

People who remarry differ from those in first marriage families in several ways. For example, individuals who remarry are older, engage in shorter courtships, and are more likely to have children from previous relationships. They also are more likely than couples in first marriages to marry someone who is different from themselves in various ways (age, race, religion, SES). In the US, whites are more likely to remarry than other racial groups, divorced adults tend to remarry other people who have been divorced, and men remarry more quickly and at a higher rate than women. On average, people in the US remarry within 4 years of divorce. Additionally, individuals cohabit or remarry quickly, often within months of beginning a relationship. Approximately 75 percent of remarried couples cohabit before legally remarrying; increasingly, couples in all western cultures are cohabiting in lieu of legal remarriage. We know little about how decisions to remarry or cohabit are made.

Until the late 1970s, clinicians basically treated stepfamilies as though they were the same as first marriage families, which, perhaps not surprisingly, resulted in stepfamily members reporting that therapy was not helpful. Early work by clinicians such as Goldner, Sager, and John and Emily Visser identified a number of ways in which stepfamilies are different from first marriage families. For example, stepfamilies are more complex than nuclear families and this complexity either can be exciting and challenging or it can be overwhelming to family members. Contributing to this complexity is the fact that children often belong to two

households. They typically have their primary residence with their mother and stepfather, but increasingly also are likely to spend significant amounts of time with their father and stepmother. Because of this often legally mandated sharing of children between the two households, if stepfamilies are to function well, they need to have permeable boundaries that allow children to move in and out of the household comfortably.

Stepfamilies' histories differ from those of nuclear families. In nuclear families the parents have been together from the beginning and over time they have developed roles, rituals, family rules, and other patterns of behavior to which children are socialized. Stepfamilies, however, can form any time in a child's lifetime, from infancy to adulthood. Adults in stepfamilies do not have the luxury of gradually developing family routines and rituals together before they socialize children. Instead, adults and children in stepfamilies find they must negotiate their new household rules and routines while they are learning how to live together. Without clear and frequent communication, the opportunities for hurt feelings and oppositional behavior are great. Children seldom appreciate new rules, especially if they come from the stepparent. They also may miss the rituals from their previous family household and be unenthusiastic about developing new ones, especially when the stepfamily household is first formed.

Still another way that stepfamilies differ from first marriage families is that the parent-child bonds are older than the spousal bonds. This means that at least during the early formation of the stepfamily, the parent-child bond is likely to be the closest one. As a result, it is often difficult for the stepparent to feel a part of the family early in the stepfamily's life. Fortunately, over time, most stepparents develop step relationships and find functions that they can fulfill in the household. For example, a stepparent may become the math homework expert or the tennis teaching expert in the family. Stepparents who try to fill more traditional parental roles such as disciplinarian are more likely to find their efforts meet with resistance. Clinicians suggest that the genetic parent should be the main disciplinarian for quite some time and that the stepparent should enforce household rules, such as bedtime, in much the

same way that a babysitter might enforce them. If the stepparent takes on the role of disciplinarian too soon, without a relationship being formed with stepchildren, coalitions are likely to form between the children or between the parent and the children. Such coalitions weaken the couple bond and seriously hamper stepfamily functioning and stability.

Finally, legal relationships between stepparents and stepchildren either do not exist or are ambiguous. This means that a stepparent does not have the legal authority to check a child into the emergency room if there is an accident. It also means that if the parent and stepparent divorce, the stepparent no longer has any rights regarding the stepchild. If the parent does not want the child to see or keep in touch with the stepparent, the stepparent must abide by the parent's wishes. The effect that the lack of a legal relationship has on the stepparent-stepchild bond has not been fully explored, but some scholars have speculated that it might hinder efforts by stepparents to develop close relationships with stepchildren.

Evolutionary scholars posit that it is not the lack of a legal relationship that contributes to stepparents investing less emotionally in their stepchildren, it is the lack of a genetic tie that results in low investment. Their view is that men who treat their stepchildren well do so only to impress the children's mother rather than out of an interest in the children's well being. Evolutionary scholars propose that individuals want to protect and invest in their own offspring, so stepchildren are at much greater risk of child abuse and neglect than children living with both parents. There is evidence that children who live in a household that includes an adult who is not their genetic parent are at greater risk of abuse than those who live with their genetic parents only, but stepparents (usually stepfathers) are categorized with mothers' boyfriends, uncles, grandfathers, and a host of other adults who share the mother's home. There also is speculation that there are fewer barriers to reporting a stepfather or other household member for child abuse than for reporting a parent. Regardless, some stepchildren are abused by stepparents, and this has caused a few social scientists to accuse parents who remarry of engaging in child abuse by placing their children at risk! This argument is an

extreme overreaction that perpetuates harmful stereotypes that may negatively contribute to stepfamily process. Other, perhaps more plausible reasons for stepchildren faring slightly less well than children in first marriage families have to do with stress (the cumulative effect of multiple family changes and transitions), poor quality parenting by parents who are too stressed to competently monitor their children, and conflicts (between divorced parents and within stepfamily households).

In addition to differences between nuclear families and stepfamilies, there are numerous differences among stepfamilies. Stepfamily configurations are diverse. For example, stepfather families are different from stepmother families, and they both differ from complex households in which both adults are stepparents to each other's children. Additionally, it makes a difference if a stepfamily is formed following the death of a parent, following parental divorce, or if the parent had never been married. The sibling configuration within stepfamilies makes a difference as well. Some stepfamily households contain only full siblings, often the children of the mother. Blended stepfamily households contain children from previous relationships of both adults. These children are stepsiblings that share a residence but have no genetic ties. Many stepfamily households have at least one half sibling. These children are a product of the remarried couple, and they share one genetic parent in common with the other children in the household. To add further complexity, some stepfamilies may have children living with them as well as with the other parent. If a stepfamily adult has shared physical custody of children from prior relationships, children move in and out of the stepfamily household. Stepfamily variations seem almost endless and this complexity has created tremendous research challenges.

In spite of the challenges, there has been an increase in studies in the past decade. However, more longitudinal studies are needed to explore how stepfamily processes change over time. We also need more within group studies to replace the deficit comparison approach so that we gain a better understanding of how strong stepfamilies function. Additionally, we need qualitative studies that provide in depth understanding of stepfamily members' experiences. We lack information about family processes in

cohabiting stepfamilies. Although there has been a large number of studies on residential step father/stepchild relationships, stepmothers and nonresidential stepparents have received little attention from researchers. Stepsibling relationships, relationships between stepchildren and stepgrandparents, and mother–child relationships in stepfamilies have been overlooked as well. Finally, researchers need to continue to develop more innovative designs that capture the complexity of remarriage and stepfamilies.

stepfathering

Rosalind Edwards with Lucy Hadfield

Stepfamilies are becoming increasingly common in contemporary developed societies, with the vast majority (in heterosexual families) comprising a stepfather who has partnered and formed a (married or cohabiting) household with a biological mother and her resident children. The rise in stepfather households,

however, occurs in an institutional context where legislation in many countries has shifted towards the view that bringing up children, and financial responsibility for them, primarily and unchangeably rests with biological parents. In contrast, and despite their prevalence, the institutional position of stepfathers is largely one of invisibility, or at least ambiguity, with few defined rights and responsibilities.

Stepfamilies are usually considered to involve particularly complex family forms and relationships. Work that has developed typologies of different forms of stepfamilies, focusing on gender of the stepparent, marital status, step and biological children's residence and access patterns, and so on, draws attention to the diversity of stepfamilies. As a body of literature, however, the evidence on the implications of this diversity, in terms of stepchildren's development and relationships between stepfathers and stepchildren, is equivocal. Further, a continuous theme of work on the topic is that there is normative uncertainty around the practice of stepfathering, focusing on how much of a father figure stepfathers can, are, or should be. This is especially the case because stepfathers now often have to negotiate their practice alongside the involvement of a nonresident father. In this respect, issues of context, including gendered expectations of fatherhood in general over time and social class, are coming increasingly to the fore.

One key preoccupation of studies is the effect of stepfathers on children's behavior and attainment. This usually draws on survey data, and has largely been conducted within the psychological and therapeutic fields, drawing on clinical inventories or family systems theories, as well as cohort based social studies. Family structure is examined in relation to the outcomes for children's psychological adjustment, educational achievement, "transition" points such as leaving school and home, sexual activity and parenthood, and involvement in criminal activity. The age of the child when a stepfather enters the household and the child's gender in relation to the stepfather are often highlighted as factors. The evidence, however, provides equivocal messages. For example, boys are said to be especially affected negatively by having stepfathers, but there are also problematic issues of sexuality in stepfathering girls in early

adolescence (for assessments of the literature, see Gorell Barnes et al. 1998; Hughes 1991). Another inconclusive facet is the issue of whether or not stepfathers are more likely than biological fathers to abuse their stepchildren (Daly & Wilson 1998).

Overall, the relationship between stepfathers and their stepchildren is seen as a difficult one to manage, primarily because it is built on a third person, the mother. On the one hand, stepfather-stepchild relationships are characterized as ones of conflicting loyalty. Stepfathers are said to be subject to resentment and jealousy about the time and attention children require impinging on their own time and relationship with their partner, as well as on the part of the children over sharing their mother (Robinson & Smith 1993). On the other hand, there is also some evidence that stepfathers can understand their coupledness with the children's mother as a foundation for building relationships with their stepchildren (McCarthy et al. 2003). The mother's involvement in facilitating the mode of stepfathering practice, and the stepchildren's own perceptions and reactions, are also issues here.

Another potential cause of conflict of loyalties relates to the fact that many stepfathers have their own biological children, either from a previous relationship and with whom they have contact, or in their stepfamily household from their current relationship. Again, the evidence is contradictory, with some concluding that stepfathers feel more commitment to their biological children and others concluding that having their own biological children enhances stepfathers' ability to take on a fathering identity in relation to their stepchildren (Marsiglio 1995).

This leads into another key preoccupation of the literature: the extent to which stepfathers are father figures to their stepchildren. In turn, this raises issues of the historically situated constitution of fathering. Lack of clarity in quite what stepfathering consists of is often related to a shift towards a less clear formulation of norms concerning fathering in general, in particular whether or not it is ascribed and status bound or achieved and socially constructed. Ascribed fatherhood is rooted in the biological tie and its accompanying social status as a father, which in itself is seen to constitute the essence of fatherhood. Within this status, fathering practice is

related to the gendered division of labor between married parents wherein fathers are breadwinners, disciplinarians, and emotionally distanced, and mothers are nurturing carers. In contrast, fathering as an achieved relationship is rooted in what are considered to be new expectations that fathers should actively engage with their children as physically and emotionally involved carers. The emphasis has shifted from fatherhood as an institutional status to fathering as an engaged relational form; a transition from ascribed to achieved.

Stepfathering is not necessarily captured in this idea of a transition from ascribed to achieved fathering because both concepts are underpinned by the biological tie. For this reason, researchers often make a distinction between biological and social fathering, with stepfathers falling into the latter category in that they act as fathers in the social sense. This does not tell us about the content of social fathering, however. For example, the practice of stepfathering may work towards ascribed fatherhood in all but biology.

There are two main strands of work attempting to throw light on this issue, using different methodologies but both working within a constructionist approach to stepfathering practice. The first and dominant strand comprises survey data. This can examine stepfathers' identity and the extent to which they seek and maintain "affinity" with their stepchildren, with the evidence here equivocal again. On the one hand, nonresident fathers are said to impinge on stepfathers' ability to take on a fathering identity, in that they have the ascribed breadwinner and authority role undermined by the nonresident fathers' input. On the other hand, there is also evidence that stepfathers can take on a father identity alongside the biological father rather than feeling in competition with or undermined by them (Marsiglio 2004). Survey data is also used to assess stepfathers' behavior, focusing on patterns of parental employment, family activities, and practical involvement in childcare and child rearing. Here shifts over time can be detected, from a social practice akin to ascribed fatherhood towards one that represents more involved achieved fathering (Ferri & Smith 1998).

The second strand is relatively small, but comprises grounded qualitative studies that

provide a valuable insight into the subjective aspects of stepfathering. A feature of this work is the extent to which stepfathers feel their step children to be “their own.” Some research, taking a developmental approach, attempts to posit “timescales” governing stepfathers’ integration into, and involvement in, their stepchildren’s lives, but again the evidence for a distinct pattern is contradictory, and in some views the search for it is misplaced (Gorell Barnes et al. 1998). More interpretive work attempts to draw out the images and factors informing step fathers’ orientation towards their stepchildren. In this respect, several studies across different national contexts indicate that working class stepfathers are more concerned with a social practice in which they can feel and act the same as biological fathers, while middle class step fathers are more likely to place an emphasis on the primacy of biological fatherhood, meaning that they cannot take on a full fathering role (Edwards et al. 2002). The interplay between economic and material circumstances, and culture over time, may well be an issue here, and is one that deserves further attention, including in relation to ethnicity.

stepmothering

Marilyn Coleman and Lawrence H. Ganong

Stepmothers are women who marry or cohabit with partners who have children from prior unions. This broad definition of stepmothers includes women from a variety of roles and who live in diverse family constellations – those who have children of their own as well as women that are childless or childfree, women in lesbian relationships, and it includes step mothers who reside with their stepchildren all of the time, some of the time, or never. Women who live with their stepchildren are called *residential* stepmothers and those who do not live with their stepchildren, or who spend only part of each year living with their stepchildren, are called *nonresidential* stepmothers. Some women that fit the broad definition of stepmothers, such as women cohabiting with fathers whose children live elsewhere, and some lesbian partners, do not see themselves as stepmothers, and, in fact, are seldom included in studies of step mothers. Given the diversity of stepmothers’ situations, it is unfortunate that the majority of studies have been limited to married step mothers and most researchers have not distinguished between residential and nonresidential stepmothers.

Anyone who is familiar with children's fairy tales such as Cinderella and Hansel and Gretel knows that stepmothers are not a new phenomenon; there have always been large numbers of stepmothers. However, throughout most of human history, stepmothers were women who moved in with a father and his children after the death of the children's mother. In the past, stepmothers often were considered mother substitutes; in fact, fathers often were motivated to wed because they needed help with childcare after the death of their wives. In the last century, better control of disease, especially infections related to childbirth, resulted in fewer early deaths of mothers and less need for stepmothers as substitute mothers. Fewer early maternal deaths, combined with increases in divorce, resulted in divorce replacing death as the precursor to remarriage in the 1970s, a trend that continues (Ganong & Coleman 2004). Consequently, stepmothers now are not replacements for deceased mothers, but are additional family members.

In western societies fathers are seldom awarded physical custody (at least, sole physical custody) of their children after divorce, so the vast majority of stepmothers do not live with their stepchildren on a daily basis. These nonresidential stepmothers may have adult stepchildren whom they barely know, they may have minor aged stepchildren who visit them on occasion, or they may have stepchildren who visit regularly and frequently. According to Nielsen (1999), over 90 percent of the estimated 13 million stepmothers in the US are nonresidential, and it is reasonable to expect similar percentages of nonresidential stepmothers in other western societies.

Because mothers most often have physical custody of their children after divorce, there are about five times more residential stepfathers than residential stepmothers. Not surprisingly, the majority of stepfamily research has focused on stepfathers and stepfather-stepchild relations, in part because they are easier for researchers to find (Coleman et al. 2000; Ganong & Coleman 2004). As a result, a lot more is known about stepfathers than is known about stepmothers.

Clinicians (Bernstein 1989; Visser & Visser 1979) and some researchers (MacDonald & DeMaris 1996; Sturges et al. 2001) have

indicated that stepmothers struggle more with their roles within stepfamilies than do stepfathers. Clinicians and the few researchers who have studied nonresidential stepmothers have found that these women are involved in the lives of their stepchildren, but they struggle with ambiguous expectations and feel frustrated with the lack of support from their partners (Ambert 1986; Church 2004; Morrison & Thomson Guppy 1985; Weaver & Coleman, in press).

Stepmothers are stressed by not knowing how they should interact with their stepchildren. As additional adults, nonresidential stepmothers report actively avoiding acting as if they were the mother to their stepchildren out of fear of usurping the inviolate role of the biological mother (Church 2004; Weaver & Coleman, in press). One nonresidential stepmother in Weaver and Coleman's study described herself as enacting "a *mothering* but not a *mother*" role. However, when she described her behaviors in the stepfamily (taking care of the stepchildren, cooking for them, helping them with homework) it was difficult to tell how these behaviors differed from what a mother would do. Nonetheless, this stepmother was typical of others in her efforts to distinguish what she did from what her stepchildren's mother would do for them. Because of cultural expectations that women should be responsible for the quality of their family's relationships, stepmothers are in a difficult position. They are not the mothers of their stepchildren, yet to be a good woman, they are responsible for their stepchildren's well being, at least during the time they share a household. This is an ambiguous position at best, and one that many stepmothers report feeling ambivalent about. Church (2004) found that one way stepmothers deal with this is by identifying more strongly with their spousal/partner role than with their parenting role. This enables them to avoid competing with the mother and attempting to meet the nearly impossible expectations that assuming the mother role would require.

Stepmothers who reproduce with the father of their stepchildren are not as close with their residential stepchildren as are stepmothers who do not produce a half sibling for the stepchildren (Ambert 1986) and they are less satisfied with being a stepmother (MacDonald & DeMaris 1996). The role of mother is so

important (Hayes 1996) that it likely predominates over the stepmother role in stepfamily households.

Women who become stepmothers to grown (adult) stepchildren struggle less with issues about how to relate to their stepchildren. They often attempt to be friends with stepchildren or take a peripheral position to that of the father. Vinick (1998) found that women who became stepmothers later in life often played an important role in promoting the reestablishment of relationships between their husbands and their stepchildren. Nonresidential fathers often lose contact or maintain only minimal contact with their children after divorce, a situation that their new wives try to remedy. Vinick referred to these women as "carpenters" because they "repair" relationships between their husbands and their children.

In addition to problems determining their roles within stepfamilies, stepmothers have been demonized across cultures for centuries (Church 2004). In fact, no other family position has been held in such low regard. Stepmothers are stereotyped as "evil" and "wicked." Young children have an early introduction to this stereotype through many old and beloved fairy tales. Because of the stigma surrounding stepmothers, the chief goal of many of them is to avoid the "wicked" label. Unfortunately, there are no clear guidelines for doing so.

It is evident from the research that stepmothers have quite different experiences, depending on whether or not they share a residence on a daily basis or only see their stepchildren occasionally. There are also differences depending on the age of the stepchildren, and whether or not the stepmother shares a mutual child with her partner. Unfortunately, clinicians and most researchers do not distinguish between the various types of stepmothers. To understand the nature of stepmothering, far more attention needs to be paid to these variables in stepfamily research. Considering the difficulties that clinicians and researchers identify that stepmothers have in negotiating their roles within stepfamilies, it is unfortunate that we have so little empirical evidence to guide them.

stereotyping and stereotypes

Michael Pickering

STEREOTYPING DEFINED

Stereotyping is a way of representing and judging other people in fixed, unyielding terms. These revolve around an alleged characteristic of the category to which they are assigned. They are reduced to the stereotype that results from this, rather than being viewed as individuals with their own personal features and qualities. Instead of being considered and treated as particular and distinctive, they are represented simply through their category assignment and the essentialized and naturalized attribute this is made to carry. The force of the stereotype is strongest when it is commonly held to be irrevocable.

In countering stereotypes, individuality can be exaggerated. The fallacy of individualism lies in its conception of personal uniqueness. For social, cultural, and historical reasons, all individuals share in the characteristics of certain groups, such as those of their social class or status, or their gender or ethnicity; people have group memberships and possess the insider knowledge required to operate efficiently within those groups and the milieux associated with them. The question is where to strike the line between group membership and individuality. Stereotypes involve refusing this distinction. Those who wield them see the people they represent entirely in terms of prescriptive assumptions about their biology, nationality, sexual orientation, disability, or whatever. Such assumptions fix on what is putatively most characteristic of broad, indiscriminate categories. Stereotypes make categories seem categorical. Since they are unconditional and not amenable to qualification, we could say that they are individualism in reverse. Anyone assigned to a stereotype is perceived primarily, if not solely, through the alleged characteristic that is considered to be definitive of who they are and what they do. Their identity and conduct is seen as the

natural – and therefore necessary and unchangeable – consequence of this one key element. That is the fallacy of essentialism.

There are certainly cases where people adapt themselves to the alleged characteristic, at least in certain circumstances. They internalize the stereotype of them under the pressures of social conformity, censure, or fear of what will happen if they buck the stereotype. This may appear to confirm and validate it. All it does is conceal and possibly confuse or hedge in the subjectivity of the person stereotyped, along with the capacity of self determination upon which subjectivity depends. Stereotyping denies this capacity in others. It is important here to distinguish stereotyping from the way we operate all the time with preconceptions and mental schemas as a means of cognitively mapping the world and negotiating different situations and circumstances, including those with which we are not necessarily familiar. These help us in our encounters and interactions in everyday life; they can be modified, updated, and flexibly used as our lives develop and move on. Stereotyping is by contrast a rigid form of cultural representation that creates barriers between people. It attempts to place and fix other people – who they are and what they represent – once and for all. The fact that this is not possible increases the effort to make it seem so, to make stereotypes seem absolute, not relative. That is why they are in the first place inflexibly based on homogenous, naturalized features regarded as integral to members of a specific group or category. Resisting stereotypes involves contesting the necessity of this in the name of self determination. Three questions follow from this: who does the stereotyping; what purpose does stereotyping serve; and has stereotyping always existed?

PRACTICE, PURVEYORS, AND PURPOSES OF STEREOTYPING

Those who generate and perpetuate stereotypes of others are usually in positions of greater power and status than those who are stereotyped. Stereotypes not only define and place others as inferior, but also implicitly affirm and legitimate those who stereotype in their own position and identity. That has, for example,

usually been the case with anti Semitic stereotypes. For this reason stereotypes say far more about those who stereotype than about their stereotypical targets. This is usual, but not invariable. There are times when stereotypes may speak to a sense of deficiency in people's own identities or a sense of alienation from their own mainstream cultures. The stereotypes may involve selective idealizations of others, as for instance with the way some white men have regarded black jazz, blues, or rap musicians. They may then appear more positive as images, but they are still one sided projections and may have negative consequences for the other, as for example in confining them to a set role or ability. Other stereotypes have figured as a juncture of both disavowal and desire on the part of dominant groups or nations; various Orientalist stereotypes have operated historically in this way. It is also the case that stereotypes are held by those with relatively little power and status in society. Those who are stereotyped may then serve as scapegoats for the feelings of frustration, disaffection, or anger connected with this lack of power and status. Travelers, foreign workers, and refugees (or so called asylum seekers) are examples of people who have suffered from this displaced aggression, not least when it is given vent by a commercially driven press. The aggression is projected negatively onto whoever is targeted by the stereotype, and the stereotype then acts as a source of consolation for those who are relatively powerless or low in social status and esteem.

This is closely related to the various purposes which stereotyping can have. It may not only bolster the sense of superiority of those among whom the stereotype circulates, but also act as a means of validating elements of an existing social order or cultural hierarchy. Stereotyping creates symbolic boundaries between peoples and cultures, as for instance in the nineteenth century when Africans or people of African descent were considered socially and culturally backward, or when women were confined to certain functions (such as carers and house keepers) and excluded from certain activities (such as participation in certain "higher art" genres like history painting and musical composition). The symbolic boundaries which stereotypes patrol strategically exclude those who are targeted by them. This is the political dimension

of stereotypical representation. It is the focus of much of the struggle that goes into contesting stereotypes. We should remember and take heart from the successes of such struggle, for they tell us that stereotypes are not, of necessity, historically unchanging. Both women and black people have over time challenged the negative closure of their stereotypical representations; they have achieved, even if as yet incompletely, a greater inclusiveness within society, an expansion of opportunities and scope, and a more positive social identity. As the content of stereotypes diminishes and recedes, so the targets of stereotyping change historically, across different times and conjunctures. This brings us to the issue of whether stereotyping itself has always existed.

Prejudiced attitudes and hostility towards collectivities different to one's own are problems that stretch back a long way in time. They have occurred in many societies and cultures, and because of this it seems that stereotyping can be conceptually applied to various social contexts and circumstances, over both time and space. The difficulty here is that it has only been developed as a concept in modern times, with particular reference to modern societies or societies becoming modern. In various ways it is specific to such times, and may even be said to be characteristically modern in the problems it addresses. Its historical or anthropological application outside the context of these times is possible, but transposing a period related formulation as a tool for interpreting phenomena beyond its usual social and cultural range requires care and caution. The concept is perhaps strongest when used with reference to specifically modern conditions, though of course these conditions have not been realized to the same extent, or in the same invariant combinations, across time and space.

MODERNITY AND LIPPMANN'S DILEMMA

That is why we need to remember that in the first place the concept arose specifically in western societies during the process of their becoming modern. Conceptual thought often develops through a metaphorical amplification in the semantics of an existing term. This was

the case with the stereotype, which was initially used in printing to describe the process of type setting: fixing characters and text in rigid form for the sake of their repeated use without subsequent modification or change. During the nineteenth century it was figuratively adapted as a synonym for commonplaces or over-conventionalized diction, but its conceptual power was only realized later when it became, metaphorically and then in its own right, a term of reference for reductionist forms of social and cultural representation – fixing and perpetuating such categories as “woman,” “foreigner,” “native,” or the “undeserving poor” in their pejorative forms. The same applies to any of the stereotypical variants of these broad categories, such as “blonde bimbo,” “wops,” “chinks,” or “welfare scroungers.”

The American political columnist and social commentator Walter Lippmann is generally acknowledged as the first person to elaborate the term in this way, particularly in his book *Public Opinion* (1965). Lippmann not only offered the initial formulation of the concept – from which point it became a key term in the social and human sciences – but was also the first to link it to the problems of modernity. In this respect, he conceived of stereotyping as a dilemma attendant on living in the increasingly differentiated formations characteristic of modern urban societies, along with the expansion of encounters with cultural difference and of contact with multiple social groups which they have entailed.

The dilemma can be summarized in the following way. On the one hand, it can be argued that the difficulties of understanding and response that accompany our proliferating social and cultural relations under conditions of modern life create the need for informational short cuts, readymade devices of discourse and representation that help us process the otherwise overwhelming data of daily social realities. We may turn to the modern media as sources of information and knowledge, and we may find that at their honest best they help us build mental bridges and enrich our experience of the complex world around us. On the other hand, this modern social need provides a fertile bed for the cultivation of stereotypes, as for instance in media such as film, advertising, and tabloid journalism. Once established and

widely accepted, stereotypes diminish or block our appreciation and understanding of other social groups and categories because of the stunted, fixed manner of their representations. As already noted, stereotyping works by making these representations seem natural and absolute, and when it is successful the resulting view of others becomes entrenched and difficult to shift, even in the face of empirical evaluation or conflicting experience. The media are certainly not the only sites in which this process occurs, but media stereotyping attains influence and power beyond that of every day conversation and interpersonal exchange because of the broad distribution and circulation of the products of modern communications, and the extent to which they are accredited as sources of authority or truth. Media accreditation increases the rhetorical force of stereotypes, whether this involves young people reading teen magazines or adults watching the news on television.

The dual sense of stereotypes as both necessary and undesirable modes of representation encapsulated for Lippmann an endemic contradiction of modernity, a simultaneous product of the imperatives of development, expansion, and change *and* the drive to order, control, and the enforcement of social norms. A key line of response to this contradictory combination involves a hardening and entrenchment of people's mental schemas or cognitive structures, converting aspects of them into stereotypes or making people more receptive to stereotypes already in circulation. Lippmann's resolution of the problems thrown up by these opposed imperatives was to side with the need for order, stability, and control in producing a consistent view of the world and securing public opinion on this basis. This was a diminution of conceptual vision. It undermines the need to critique stereotypes as ideological forms of representation which strive to repress both politics and history by injecting into social and cultural processes the fixity of their naturalized forms.

CONCEPTUAL REFINEMENTS AND CRITICAL ISSUES

There is a strong temptation to adopt some form of stereotyping when people are faced

with ambivalence, uncertainty, loss, or bewilderment change. They may also then be more vulnerable to influence from the media use of stereotypes. In these circumstances, the fast frozen figures of stereotypes promote an intolerance of social and cultural difference on the basis of their categorical, unbending views of particular ethnic, gender, sexual, or other categories. In the face of these undesirable views and their various consequences, we should not lose sight – as Lippmann did himself – of the epistemological dilemma we face in modernity of embracing complexity and contingency without resorting to reductive simplification, either/or forms of thinking, and the absolute judgments of others that go with the territory of mediated and situated stereotyping.

All too often, this is what has happened in the subsequent application and development of the concept. It is as if those concerned with stereotyping in the social and human sciences see only one side of the dilemma, and not the other. For example, there is a strong tendency to see stereotyping as a problem associated only with other people, a critical distanciation that sets off “us” against “them” in a process which is akin to stereotyping itself. Stereotyping creates and maintains rigid boundaries between “us” and “them.” Ironically, this is what happened after Lippmann’s initial formulation of the concept, when stereotyping became widely conceived as a pathological process, an abnormal and irrational way of responding to others conveniently set apart from normal and rational forms of categorization. It could then be seen as entirely the product of deficient schooling, damaged personalities, or extreme beliefs – such as the anti Semitic views of mid twentieth century Fascists – and the propagandist dissemination of these in contemporary media. Partly because of the dominance of behaviorism in both mid twentieth century psychology and communications research, this response to stereotyping was common to both from roughly the 1930s to the 1960s. The us/them dichotomy it set up between stereotyping and the rational coming to terms with difference may have appeared to resolve the dilemma identified by Lippmann, but it did this by all too cleanly separating the (rational) researcher from the (irrational) acceptance and use of stereotypes.

The model had no way of explaining the wide spread social prevalence of stereotypical views – as for instance in the Nazi period of the Third Reich or the apartheid era in South Africa.

What followed from this unsatisfactory resolution was that the opposed senses of stereotyping in Lippmann’s formulation became split off from each other. In late twentieth century psychology, for instance, social cognition and social identity theory reacted to the pathologization of stereotypical prejudice by questioning the rigid divide between irrational (“false”) and rational (“correct”) thinking. However, in pointing up its wider social occurrence, they turned the pathological model on its head and began to conceive of stereotyping as a necessary component of ordinary human cognition, vital for the way we process and utilize information. The question of ideology was repressed, not because it is overburdened with all sorts of past intellectual baggage, but because stereotyping itself was normalized. This occurred around another binary opposition, that of ingroups and outgroups. The dichotomy distinguished between the assimilation of people into their own social groups and categories where their similarities are exaggerated, and the division between such social groups and categories and others where their differences are blown out of proportion and heavily biased. In this simplistic conception of culture, association, and belonging, stereotypes are vital to positive group identities, so being a member of any group inevitably leads to bias, distortion, and denigration of others. Stereotyping comes to appear as cognitively universal and natural whereas, from a critical sociological perspective, it is stereotyping which naturalizes its own universalized definitions of others.

More recently, the emphasis on just one side of Lippmann’s epistemological problem has been redressed by other psychologists who have attended more fully to the social dimensions of stereotyping and other forms of representation or to the cultural models they involve, though these developments have occurred with cognition as their general informing background, and with the media being almost completely ignored. Social psychologists who pay explicit attention to the issues of power and ideology and their discursive accomplishments remain

exceptional. For example, Augoustinos and Walker's (1995) definition of stereotypes as "ideological representations which are used to justify and legitimize existing social and power relations" is made against prevailing traditions within their discipline. Media and cultural studies, along with many areas of sociology, have moved mainly in the other direction to these traditions, opting to focus only on ideology and power at the expense of the psychological dimensions of experience, perception, knowledge, and belief. Much of the work that has resulted has been of enormous significance for sociology and other disciplines – the conceptual formulation and analysis of representations of the stereotypical Other in postcolonial and historical studies is just one example of this – but again there has been a tendency to lose sight of Lippmann's dual conception of stereotyping. The benefit of this is that it offsets the academic split between cognition and culture, or psychology and politics, and reminds us of the dilemma underlying stereotyping which stereotyping seeks to annul: the dilemma of how "we" are going to go about getting to know "you." Is this to be accomplished in terms of one dimensional representations that help maintain existing structures of power, order, and control, or should we treat these representations critically for the way they help to produce and perpetuate inequality and oppression, and so try to develop a more complex vision characterized by its openness, flexibility, and tolerance?

Critical sociological commentary on stereotypes needs to focus not only on the pernicious images of public stereotyping and their discursive properties, but also on the broad relational dynamics of power and conflict that are always present in stereotyping as a social process. It has certainly proved fruitful to apply philosophical, feminist, and psychoanalytical theory to these dynamics, but we should remember that they are always definite and contingent, which means that methodologically the relations between identity, representation, and difference need to be historicized, understood within specific social and cultural contexts in time and space, across the different periods and formations of modernity and late modernity. These relations are fluid and changing, and

although the belief that they are not may itself be the result of stereotyping and its underlying self assertions, it is important to see how stereotypes have been historically situated within such modern constellations of identity and discourse as sexual politics, nationalism, militarism and war, colonialism and postcolonialism, imperialism and neoimperialism, crime, normality and deviance, race and ethnicity, disability and disease. This may be something of a wish list for further research, but such research is necessary wherever the relations of identity, representation, and difference generate the production or reproduction of those tight knots of symbolic figuration we refer to as stereotypes.

stigma

Abdi M. Kusow

The term stigma refers to a social or individual attribute that is devalued and discredited in a particular social context. As Goffman (1963) noted, however, this definition requires an important qualification, one that defines stigma in terms of “a language of relationship” that can link attributes to particular stereotypes, rather than a priori objectified attributes. The language of relationship between attributes and stereotypes is extremely important because an attribute, in and of itself, does not carry an inherent quality that makes it credible or discreditable outside the nature of the stereotype that corresponds to it.

Link and Phelan (2001) defined stigma in terms of the presence and convergence of four interrelated components. First, people distinguish and label human differences. Second, members of the dominant cultural group link labeled persons with certain undesirable attributes. Third, negatively labeled groups or individuals are placed in distinct and separate categories from the non stigmatized. Fourth, as a result of the first three components, labeled individuals experience status loss. Finally, the process of stigma placement, and therefore management, is dependent on the degree of one's access to social, economic, and political power.

Regardless of how stigma is defined, however, in order for an attribute to be designated as a mark of stigma, two conditions must be present. First, the designation of stigma must be informed by a collectively shared understanding

by all participants of which attributes are stigmatizing in the available pool of socially meaningful categories in a particular social context. This statement is important because an attribute that is stigmatizing in one social context may not be stigmatizing in another. The second condition relates to the degree to which a mark of stigma is visible. The degree of visibility determines the stigmatized person's feelings about themselves and their interactions and relationship with non stigmatized groups and individuals, particularly in situations perceived as potentially stigmatizing encounters.

There are two general categories of stigma attributes. The first category refers to attributes that are immediately or potentially visible upon social encounters. Three types of stigma attributes can be outlined within this category. The first relates to outward and clear physical deformations. The second relates to what Goffman described as “the tribal stigma of race, nation, and religion.” The latter is transmitted through lineage, and affects all members of the stigmatized group. This type of stigma can be characterized as collective or group stigma, while the first, physical deformities, affects only individuals, and can therefore be referred to as individual stigma.

The second broad category relates to stigma attributes that are not clearly and outwardly visible, but may or may not become visible upon social interaction and where the stigmatized person believes that their stigma is not known to those with whom they interact. The distinction between whether or not a particular stigma attribute is visible is important because it determines the nature of social interaction between those who are perceived as stigmatized and the normals. More importantly, it situates the nature of the reactions and information management by stigmatized individuals that appear to reveal their stigma attributes. In the case where the stigma attribute is readily and clearly visible, the process of information management involves attempts to minimize tensions generated during social interactions.

If the stigma attribute is visible, the process of information management shifts from mere tension management to information management about one's feelings of having a spoiled identity. The concern of the stigmatized in this

case becomes one of whether or not to display discrediting information, and ultimately leads to what Goffman described as information management techniques.

There are a number of information management techniques employed by stigmatized individuals. One common technique is “covering.” Covering refers to attempts by stigmatized individuals to conceal signs commonly considered stigma symbols. Another strategy is “distancing,” where stigmatized individuals or groups disassociate themselves from those roles, associations, and institutions that may be considered as stigmatizing. Still another strategy is “compartmentalization,” where individuals divide their worlds into two social worlds: a small and intimate one to which the stigmatized reveals their identity, and a larger group from which the stigmatized individual conceals their identity. Finally, individuals may engage in “embracement” through the expressive confirmation of the social roles and statuses associated with stigma (Snow & Anderson 1987).

A recent criticism of the nature of stigma, however, pertains to the uncritical assumption of the existence of a normatively shared understanding of the distribution of stigma symbols (Kusow 2004). The conventional literature on the distribution of stigma divides a society into stigmatized and normals. This distinction is less tenable than before, however, because the current demographic, social, political, and economic context in which stigma symbols are distributed is radically different from those when Goffman’s seminal essay *Stigma* first appeared. Due to changes in the political and social climate, particularly as a result of the impacts of multiculturalism and the embracement of wider social identities in the US, we are approaching a situation or an era in which who and what is normal, and therefore the question of who stigmatized whom, is under constant revision. Given this situation, future scholars must also consider how stigmatized individuals disavow dominant perspectives regarding the distribution of stigma, instead of merely concentrating on information management on the part of the stigmatized.

strain theories

Robert Agnew

Strain theories argue that strain or stress is a major cause of crime. Individuals engage in crime to reduce or escape from their strain (e.g., theft to reduce monetary strain, running away to escape abusive parents), seek revenge against the source of their strain or related targets, or cope with the negative emotions caused by strain (e.g., illicit drug use). There are several major versions of strain theory in sociology, distinguished in terms of the types of strain they examine and their description of the factors that influence or condition the effect of strain on crime. This entry describes the major versions of strain theory, beginning with Durkheim and ending with Agnew, whose general strain theory builds on previous strain theories.

DURKHEIM

Durkheim presented the first modern version of strain theory in his book *Suicide* (1951). Durkheim argues that healthy societies set limits on individual goals, such that individuals

have a reasonable chance of achieving their goals. During periods of rapid social change or turmoil, however, societies may lose their ability to limit individual goals. Individuals, lacking the ability to limit their own goals, come to pursue unlimited or ever escalating goals. The despair that inevitably results from the pursuit of unlimited goals was said to be a major cause of suicide and was also linked to other directed violence. Durkheim's view of strain as the pursuit of unlimited goals, however, never had a significant effect on the study of crime, in part because it was overshadowed by Merton's version of strain theory (see Passas & Agnew 1997).

MERTON

Like Durkheim, Merton (1938) focuses on that type of strain involving the inability to achieve one's goals, particularly economic goals. Merton departs from Durkheim, however, in two important ways. While Durkheim focuses on the pursuit of unlimited goals, Merton focuses on the inability of lower class individuals to achieve more limited economic goals. This difference may reflect the fact that Merton's theory was developed during the height of the Depression. Further, while for Durkheim the failure of society to regulate individual goals is the source of strain, the opposite is the case in Merton. Merton argues that society encourages individuals to pursue the goal of monetary success, but prevents large segments of the population from achieving this goal through legitimate channels. In particular, Merton argues that all individuals in the US – regardless of class – are encouraged to strive for monetary success. Many individuals, however, particularly those in the lower classes, are prevented from achieving such success through the legitimate routes of educational and occupational advancement. Such individuals experience much frustration and, according to Merton, they may respond in one of five ways.

Conformity is the most common response: individuals continue to strive for monetary success through legitimate channels, living with their frustration. Innovation involves the attempt to achieve monetary success through illegitimate channels, like theft, drug selling, and prostitution. Ritualism involves lowering

the desire for monetary success to the point where it can be achieved through legitimate channels. Retreatism involves rejecting the goal of monetary success and the means to achieve it. Retreatists, according to Merton, include skid row alcoholics, drug addicts, and in the most extreme case, those who commit suicide. Rebellion also involves rejecting the goal of monetary success and the means to achieve it, but individuals substitute new goals and means in their place. While rebellion may assume political forms, it can assume criminal forms, as illustrated in the discussion of Cohen, below.

It is of course critical to understand why some people adapt to strain in ways that involve crime while others do not. Merton provides some guidance here. He states, for example, that lower class individuals are more likely to employ criminal adaptations because they are less committed to legitimate norms due to their inadequate socialization. The revisions in Merton's theory by Cohen and by Cloward and Ohlin shed additional light on the ways in which individuals, particularly lower class juveniles, adapt to strain.

COHEN

Cohen (1955) drew on Merton's theory in an effort to explain lower class gang delinquency. According to Cohen, lower class boys do not simply desire money; rather, they desire middle class status more generally – including respect from others. Such boys, however, have trouble achieving this status through legitimate channels. Most notably, they are often frustrated and humiliated when they compete with middle class students in the school system and try to meet the expectations of middle class teachers.

There are several ways to cope with this frustration, but the response of innovation is not a viable option. Middle class status is not easily achieved through illegitimate channels. Many lower class boys, however, cope through the response of rebellion. They reject the goal of middle class status and set up an alternative status system in which they can successfully compete. Their hostility toward the middle class leads them to set up an oppositional status system which places high value on criminal acts like theft and fighting. Cohen's description of this

oppositional subculture has been challenged as extreme, but Cohen's use of strain theory to explain the origin of delinquent groups is a fundamental contribution to criminology. Most contemporary researchers view delinquent groups as an adaptation to the strain experienced by group members.

CLOWARD AND OHLIN

Cloward and Ohlin (1960) also apply strain theory to the explanation of lower class gang delinquency. Drawing on Merton, they argue that lower class people want to achieve monetary success, but are often prevented from doing so through legitimate channels. Drawing on Cohen, they argue that if conditions are right, adolescents sometimes adapt to their strain by forming or joining delinquent groups like gangs. These delinquent groups facilitate law violation; among other things, they provide rationalizations or justifications for delinquency. But Cloward and Ohlin go on to argue that there are different types of delinquent groups; some specializing in fighting, some in theft, and some in drug use. The type(s) of delinquent group available depends, in part, on the characteristics of the individual's community.

Cloward and Ohlin have been criticized because research suggests that most gang members do not specialize in particular types of delinquency. Their work is nevertheless important because it makes the point that explanations of crime must not only consider the factors that predispose individuals to crime, like strain, but also the opportunities that are available for crime – referred to as illegitimate opportunities.

CRITIQUES OF CLASSIC STRAIN THEORIES

The classic strain theories of Merton, Cohen, and Cloward and Ohlin were perhaps the dominant explanations of crime during the 1950s and 1960s. They were also part of the inspiration behind the War on Poverty, which was designed to make it easier for individuals to achieve economic success through legitimate channels. Certain of the programs that were part of the War on Poverty (like Head Start and Job Corps) are still in existence. Classic strain theories came

under heavy attack in the late 1960s and 1970s, however. Self report surveys showed that delinquency was common in all social classes. This fact was taken as evidence against classic strain theories, although these theories can explain middle class delinquency if one focuses on relative deprivation (Passas & Agnew 1997). Also, empirical tests provided little support for classic strain theory. Such tests typically examined the individual's educational or occupational aspirations and expectations, in an effort to determine if crime was highest among those who did not expect to achieve their aspirations. Crime, however, was found to be highest among those with both low aspirations and expectations, a finding usually interpreted in terms of control theories (Hirschi 1969).

These tests have been criticized; among other things, they do not focus on the key goal of monetary success. More recent data suggest that dissatisfaction with one's monetary situation is related to crime (Agnew 2001). Further, qualitative studies frequently report that criminals engage in income generating crimes because they have a desperate need for money, but few legal prospects for obtaining it. Nevertheless, classic strain theories fell into decline. There were several attempts to revise strain theory in the 1970s and 1980s, most of which argued that people may pursue a ranges of goals and that goal achievement is a function of more than social class. In 1992 Agnew drew on classic strain theories, the revisions in these theories, and the broader stress literature to develop his general strain theory of crime, which led to a renewed interest in strain theory.

AGNEW'S GENERAL STRAIN THEORY (GST)

Agnew's (1992) general strain theory focuses on a broad range of strains or stressors. Certain of these strains involve the inability to achieve positively valued goals – the type of strain emphasized in previous versions of strain theory. Other strains involve the loss of positively valued stimuli (e.g., romantic partners) and the presentation of negatively valued stimuli (e.g., verbal and physical abuse) – the types of strain emphasized in the stress literature. Hundreds of specific types of strain fall under these broad

categories, but GST argues that those strains most likely to lead to crime are (1) seen as unjust, (2) are high in magnitude, (3) are associated with low social control, and (4) create some pressure or incentive to engage in criminal coping. Specific strains that meet these criteria include the inability to achieve goals such as monetary success, thrills/excitement, autonomy, and masculine status; the experience of parental rejection; discipline that is very strict, erratic, excessive, and/or harsh; child abuse and neglect; negative secondary school experiences like low grades and negative relations with teachers; work in the secondary labor market; homelessness; criminal victimization; and experiences with prejudice or discrimination based on ascribed characteristics.

These types of strain lead to a range of negative emotions, including anger, frustration, and depression. These negative emotions in turn create pressure for corrective action. Crime is one possible response, since it may allow individuals to reduce or escape from their strain (e.g., running away from abusive parents), seek revenge, or alleviate negative emotions through illicit drug use. Whether strained individuals turn to crime is influenced by a range of factors which affect the individual's ability to engage in legal coping, the costs of crime, and the individual's disposition for crime. Such factors include coping skills and resources (e.g., intelligence, financial resources), level of conventional social support, parental supervision, personality traits like low constraint and negative emotionality, beliefs regarding crime, and association with delinquent peers.

GST has some empirical support, with studies suggesting that the above strains increase the likelihood of crime and that their effect on crime is partly mediated by negative emotions (Agnew 2001). Evidence on the extent to which the effect of strain on crime is influenced by the above factors is mixed, although some recent studies provide support for GST. Recent work has applied GST to the explanation of group differences in crime, including age, gender, community, and race/ethnic differences in offending rates. It is argued that some groups are more likely to experience those types of strain conducive to crime, react to strain with strong negative emotions, and respond to such strain and negative emotions with crime. Strain

theory, then, is once again playing an important role in the explanation of crime and deviance.

stranger, the

Terri LeMoyné

Simmel defined the field of sociology as the study of social forms, or the assorted patterns that people impose upon social interaction to give it coherent meaning. Social forms are the structured features of interaction, and Simmel argued that the sociologist should ascertain these social forms because actors typically create them unconsciously. In addition, he maintained that "social types," or general character traits, are based upon social forms and are dependent upon social interaction. Therefore, individualisms, or qualities that we oftentimes assume to be uniquely personal, are really rooted in social interaction. "The Stranger"

(1971 [1908]) is but one illustration of a social type.

The notion of distance is important to Simmel in his typology of the stranger, whose social position involves a synthesis of both attachment and detachment. The stranger is someone who can be located within any social environment at any point in time. He is both remote from us while still being close; he is simultaneously a part of the group as well as outside of it.

Simmel utilized "the trader" as an exemplar of the stranger, and more specifically, the European Jew as the classic example of it. By definition, the trader obtains a range of goods for his community from outside groups. Because he is the middleman for trade, he is mobile and is not tied to the group through kinship, locality, or occupation. As a result, he is not completely enmeshed within the group. Because of his unique position, members of his group view him as both far and near.

Because of this unusual social position, others assume that the stranger possesses an objective attitude regarding social matters; he is both involved in and indifferent to the community. Therefore, group members are more inclined to divulge private information to the stranger that they often keep hidden from intimates.

The stranger is also viewed as possessing greater individual autonomy. Simmel writes that the stranger is less apt to distort information because of his differences from the group. This allows him to reach conclusions that more easily deviate from those members who are more entrenched within the collective.

This objective stance provides the stranger with a greater freedom than that experienced by those enmeshed in the group. His attitudes and perceptions are less likely to be distorted because he is not as closely attached to the group. His atypical social position allows him to assess more accurately situations, even close ones, from a distance. This unique freedom allows him to examine a variety of situations with minimal personal bias. As a stranger, he possesses standards that are more general and objective, and his actions are less constrained by customs, religion, or established community practices.

In determining the qualities of the stranger, Simmel writes that group members tend to highlight the general abstract traits that they

share with him. In contrast, when people share a close relationship to someone, they attend to those attributes and qualities that are specific to their relationship. While a focus on general qualities unifies people as a whole, they do not lead particular individuals toward one another. This approach results in a lessening of the bond between people coupled with their awareness of the tenuousness of the relationship. In these cases, the stranger is close to others based upon general similarities like nationality, social position, or occupation, but these same universal attributes make him remote because they also pertain to many others.

Because there is an emphasis on these common general human qualities, they also tend to stress the individual characteristics that they do not share with the stranger. This approach results in a relationship that is characterized by tension. For example, if one is a stranger in terms of nationality or race, these differences are not viewed as individual, but are seen instead as qualities that the stranger shares with other strangers. It is here that strangers are viewed as types rather than people. As types, their nearness is no more specific than their remoteness. Simmel cites the taxation practices of the Middle Ages as an illustration of the Jew as a social type. Where the Christian population was taxed according to their individual assets, all Jews were charged an identical tax no matter what their income. A fixed tax was levied upon the Jews because they were treated as a social position rather than as separate, distinct individuals, with separate, distinct incomes.

In an effort to make this social type more universal, Simmel claims that there is a level of strangeness in all relationships, even the most intimate ones. When entering into romantic relationships people tend to concentrate on what is unique and distinctive about the association, while ignoring any general similarities. This occurs because they believe that no other relationship is comparable to theirs. This love has never existed before. As time passes, each participant will come to question the validity of their relationship when they realize that it is not particularly unique. In fact, relationships just like this one occur with great frequency and each partner could have just as easily met someone else who would have fulfilled this romantic void. All close relationships must endure this

assessment because what they all share is never exceptional to them. The outcome of this new found awareness is an overall level of strangeness within the relationship.

Simmel argues that although varying degrees of remoteness and nearness are present in all relationships, there is a “special proportion and reciprocal tension” between farness and nearness that produce the unique social type of the stranger (Simmel 1971 [1908]: 149). But, Simmel warns, we cannot define or quantify this special proportion with great certainty. All we know is that there are certain amounts of nearness and farness that must be present for this social type to exist.

strategic decisions

David C. Wilson

Theoretical and empirical studies of decision making pervade organization theory. They have done so for over six decades. James March and

Herbert Simon suggested in 1958 that managing organizations and decision making were virtually synonymous. From this broad perspective, decision making has maintained its centrality to the field of organization theory and is one of the most active areas of current management research, particularly in the field of strategic management. The dynamics of organizing brought with them the need for understanding decision making. As organizations grew and became more complex, decision making became a central activity. Managers, in particular, were expected to make choices amongst often uncertain alternatives and to choose wisely – benefiting the organization and its many stakeholders. Scholars were expected to uncover the characteristics of decision processes and to explain ways in which we might, ultimately, improve the ways in which decisions were made in organizations.

The scholarly study of decision making covers many levels of analysis (from individual cognition to the cultural characteristics of nation states), and many disciplines inform our knowledge (from mathematics to behavioral theories of social science). The term strategic decision making is usually used to indicate decisions made in organizations, as opposed to individual choice activity (such as choosing where to go on holiday). Organization includes any collective social, economic, or political activity involving a plurality of human effort. Strategic decisions emphasize the social practice of decision making as it is carried out amongst and between a group of such individuals. It is the organizing of decision activity as a collective phenomenon which takes center stage, rather than the cognitive processes of individual choice makers.

Equally, strategic decision making is not primarily concerned with computation in the field of judgment and choice. Various branches of mathematics can inform us about risk, options, game theory, and choice. All have their utility in understanding choice processes, but are less useful when considering how organizations full of people make decisions. For example, the most well known variant of game theory (decisions between two players) is the prisoner's dilemma, where two criminals are in separate cells and have to decide whether or not to betray each other (having agreed not to betray in advance of the game). The greatest payoffs come from both

prisoners sticking to their agreement, but most betray each other and the payoffs are significantly reduced. The lesson is that computational mathematics could help the players maximize their returns. This is choice theory (rather than strategic decision making).

Why *strategic* decisions? These decisions are usually large, expensive, and characterized by high levels of uncertainty (no one has done this before). Once implemented, they set the course of many operational (everyday) decisions that follow in their wake. A further characteristic of strategic decisions is that they are difficult to reverse once resources (human and financial) have been committed to their cause. A more robust list of the characteristics of strategic decisions would include the following:

- They are difficult to define precisely (the nature of the problem is elusive).
- Understanding the problem is also part of understanding the solution.
- There is rarely one best solution, but a series of possible solutions.
- Each solution is associated with different tradeoffs and priorities.
- They are difficult to assess in terms of performance, since they tend to continue through the organization without a clear final end point against which performance can be judged.
- They are highly interconnected with other problems in the organization.
- They have high levels of uncertainty associated with them.
- They require strategists to accept fairly high degrees of risk in making decisions.
- Once made, they are difficult to reverse.
- They are likely to be discontinuous and political, with different competing interests trying to influence the outcome in line with their preferences.

At its simplest, strategic decision making may be considered an instantaneous action, a choice between two or more known alternatives. However, this “point of decision” approach is unable to capture the richness and complexity of:

- the influences that impact upon putting the decision into action;
- assessing the ultimate performance of that decision.

Decision making from this choice perspective also assumes that managers have full agency and control over decisions. Sometimes they may have very limited discretion to make decisions or choose amongst alternatives. This could be the case, for example, where strategic decisions in organizations are heavily constrained by interventionist government policies (such as privatization or deregulation), where all strategic decisions are framed and shaped by this wider context. Nevertheless, managers still have some degree of strategic choice even if the wider context (e.g., privatization) is firmly set in place. Managers can still make strategic decisions, for example, concerning such key topics as organizational design, choice of suppliers, choice and sophistication of information systems, and general product or service portfolios.

Theorists such as Drucker (1974) and Weick (1995) showed how decision making processes in organizations were as much about *defining the question* as they were about *providing an answer*. The important aspects of understanding strategic decisions are deciding whether there is a need for a decision and, if so, what that decision should be about. Weick likens this process to those of boards of inquiry following a disastrous event. Such boards have a number of roles. They are historians – reconstructing the past to allocate responsibility and to prevent future disasters happening through the same processes. Essentially, they take an outcome and interpret it to be the result of a series of decisions (which were often not seen as discrete decisions at the time by those involved). Much of strategic decision making is about this kind of social reconstruction.

There are many other views of strategic decision making. You could view strategic decisions as a *plan*: the decision is a consciously intended course of action. In the same way that you might intend to catch an airplane to a specific destination at a particular time, decision making is a process which is carried out in advance of the action that follows and is developed with a clear purpose. Or you could view strategic decisions as a *ploy*: a decision from this

- the processes that lead up to the point of decision;

perspective is a set of actions designed to outwit the competition and may not necessarily be the “obvious” content of the decision. For example, a decision to build a new building in order to expand may not be the overt strategy, but is more concerned with increasing barriers to entry for potential competitors. Here, there are connections with strategic decision making as conceived in its military roots, where the plans of campaigns may have similar characteristics to those of a ploy to outwit the “enemy.” You could view strategic decisions as a *pattern*: decisions are not necessarily taken with a planned purpose and decision makers do not always have access to the range of knowledge required to plan wholly in advance. What happens is that multiple decisions taken over time form a pattern. It is this pattern of resulting (emergent) behavior that we call the strategy of the firm. Strategy is therefore characterized as a pattern that emerges from a stream of decisions.

Strategic decision making can also be seen as achieving a *position*: decisions are less about the dynamics of planning or gamesmanship and more about trying to achieve a match between the organization and its environment. This position can be one of alignment, so that the organization matches its environment (e.g., highly decentralized structures to match a turbulent and unpredictable environment), or one of trying to secure competitive advantage (where the organization achieves a unique position in the market for some time). Positions, of course, can be planned, emerge, or be a combination of both emergent and planned processes.

Finally, strategic decision making can be viewed as a *perspective*: decisions are characterized as being a reflection of how strategists in an organization see and perceive the world and their organization. For example, the strategic perspective of Nokia is one of continuous and sometimes radical change (Nokia began as a paper and pulp company); IBM favors a dominant marketing perspective, whilst Hewlett Packard favors an engineering excellence perspective. This perspective, if pervasive enough, can influence the kinds of decisions taken, in respect of their content and their processes. We can see the effects of this embedded view of decision making by observing that organizations in similar industries often choose similar strategic decisions. They

become institutionalized. Universities tend to follow broadly similar strategies, as do large retailers or service organizations.

Over the last 50 years there have been radical changes in the ways in which strategic decision making has been researched. For example, the 1950s and 1960s saw an emphasis on the planning approach to decision making. The focus was on tools and techniques to help managers make informed decisions about future business directions. Such tools included industry structure analyses and portfolio matrices (e.g., the Ansoff matrix or the Boston Consulting Group’s Box). Strategic decision making was mostly about planning. The 1970s onwards saw a different emphasis. Decisions were now supposed to emphasize the payoffs to organizations that may accrue if they pursued different strategic directions. Typical options were diversification decisions, but this was also the era of innovation (R&D), acquisition, joint venture, and internationalization decisions.

The 1980s saw a move away from examining the content of strategic decisions (that is, what they were about) to examining them more as processes. The question now became whether we could map the progress of a strategic decision and make any inferences about why such processes might occur. David Hickson and his colleagues characterized such processes as sporadic (discontinuous), fluid (continuous and smooth), or constricted (restricted to a small group of stakeholders and highly political). This work also underscored the importance of such processes since they underpinned the recognition amongst managers for strategic change. The 1990s onwards have seen a continuing interest in unfolding the characteristics of decision processes, but the emphasis has changed to focus on whether or not there are any links between decision making activity and performance (did the decision succeed or fail – and do a number of failed strategic decisions lead to failed organizations)? Finally, very recent approaches to strategic decision making have started to concentrate upon the more micro aspects of how managers think, act, and interpret strategic decisions. This approach has been termed the *strategy and practice* perspective (Whittington 1996).

Strategic decision making has encountered many attacks on its theoretical and empirical claims to be a discrete field of study. It has not

only survived these attacks, but has also prospered in recent years with many established authors returning to some of the original ideas in decision making (we can see this, for example, in the more recent works of Karl Weick and James March), and there are many newer researchers joining the field. The major criticisms of the field were:

- The decision itself is an inappropriate level of analysis.
- A lack of large scale empirical studies (too many assumptions based on too few cases).

The first critique argues that studying decisions as the primary unit of analysis “gets in the way” of what is really important. That is, actions occur in organizations where decisions may not have been taken and to isolate and study “the decision” is to miss that process. The counter argument says that deciding and implementing are matters of degree in quite diffuse processes. Since then, the decision as a unit of analysis has become the firm focus of many theoreticians, with general agreement that in order to understand “strategy” in organizations one has to understand the processes of the handful of decisions which make up that strategy. Key authors in the field (including Henry Mintzberg, James March, Karl Weick, Paul Nutt, David Hickson and colleagues) are today focusing on the decision as the appropriate unit of analysis.

The second critique was more robust until the large data sets of Paul Nutt and Dean and Sharfman in the US and David Hickson and colleagues in the UK began to emerge from the late 1980s onwards. After this empirical work, it was no longer necessary to base the interpretation of decision making on a few key in depth cases, but the comparative empirical study of decisions was possible using multivariate tools for analysis. It became recognized in the social science community that strategic decision making could be argued to be a robust field of study and that it remained theoretically (and empirically) distinct from other related cognate areas such as corporate strategy or individual choice theories such as consumer behavior.

Overall, strategic decision making research has informed the general field of organization theory in distinct ways. For example, the

notion of *incrementalism* (piecemeal attention to small steps in any process) arose from Charles Lindblom’s research into how decisions were made. The notion of *problemistic search* (managers only seek information when they have to, or when there is a pressing problem) came out of work by Richard Cyert and James March. The concept of *enacted environments* (managers only see and interpret the bit of the operating environment they focus upon) came out of research by Karl Weick. All of these concepts were developed in the field of strategic decision making and have become more generically applied to organizational processes in recent years. Strategic decision making has proved a rich ground for the emergence of such concepts.

The processes of making strategic decisions can appear deceptively simple. Actions are formulated toward the solution of a particular problem. The problem with this approach is that there may be discernible actions and there may be observable outcomes, but they need not necessarily be wholly related to one another. Problems may be solved by factors other than strategic decisions and, sometimes, taking a strategic decision can create a whole new set of problems (without solving the initial problem the decision was supposed to address).

These polar views can be represented as the *planning* versus the *chaotic* processes of strategic decision making. They are extremes and, although most decisions lie somewhere between the planned and the chaotic, both perspectives are useful for understanding the processes of strategic decision making. Viewing processes as basically a set of planning tools allows *actions*, *procedures*, and *measurement* to be explicitly addressed. Planning facilitates decision makers in analyzing and codifying what appear initially as complex problems. Planning simplifies complexity and helps reduce uncertainty. Because of this, planning can also help decision makers examine current planning practices in their organization and assess their utility in light of current problems. From a behavioral perspective, planning can ensure that others in the organization are involved and are communicated with as fully as possible. Note that although involvement and communication can be explicit parts of the plan, this may not endow those participants with any influence over the process or its eventual outcome. Finally, planning

processes help decision makers identify key performance indicators by which progress of the decision can be monitored and judged.

Chaotic processes mean that organizations can be viewed as an “anarchy” or as a system with chaotic tendencies. Hence decision makers can neither understand fully nor control decision processes. Means and ends are unlikely to be coupled, which implies that actions do not lead to expected outcomes and are swayed one way or another by other decisions, other actions, and unforeseen circumstances. The main components of a strategic decision making process (problems, solutions, participants, and choice situations) interact in an apparently haphazard way, a stream of demands for the fluid attention and energies of managers. Participants move in and out of the decision making process (every entrance is an exit elsewhere), and this can create discontinuity. At other times, participants fight for the right to become involved and then never exercise any influence they may have.

Viewing decision making processes as chaotic also has some advantages for decision makers. Unlike the planning approach, the chaos perspective does not seek to simplify and to reduce uncertainty. It avoids any oversimplification of the process and allows decision makers to appreciate and expect the role of politics and influence to be a natural part of the decision making process. In theory, the chaos perspective should encourage decision makers to think creatively around complex problems and help them to avoid thinking solely in linear sequences.

Creativity and innovation may be enhanced by decision makers being encouraged to take actions that seem unrelated to the decision under consideration. On the other hand, we should bear in mind that the distinction between creativity and madness is a rather fine line. From a decision making perspective, this means that no one will know whether the tangential explorations were useful or folly until a long way down the track of the decision process.

The work of James G. March characterizes and summarizes many of the basic features and debates in strategic decision making. The basic decision process can be illustrated as in Figure 1.

The major contribution of this simple flow diagram was that its very simplicity could be misleading. The cycle can be broken or can malfunction at each stage of the process and between stages. James March taught us to beware of assumptions of rationality both in individuals and in organizations. Actions can be taken for a variety of reasons which correspond to the ways in which organizations are structured (each specialized function developing its own view on what should happen). This was added irrevocably to the vocabulary of organizational decision making in the form of “local rationality” (Cyert & March 1963).

March was later to refine this concept by emphasizing local preferences (rather than rationality). His argument was that in organizational decision making, the main thing was in forming *interpretations* rather than in making choices. Here, interpretations cover a wide arena

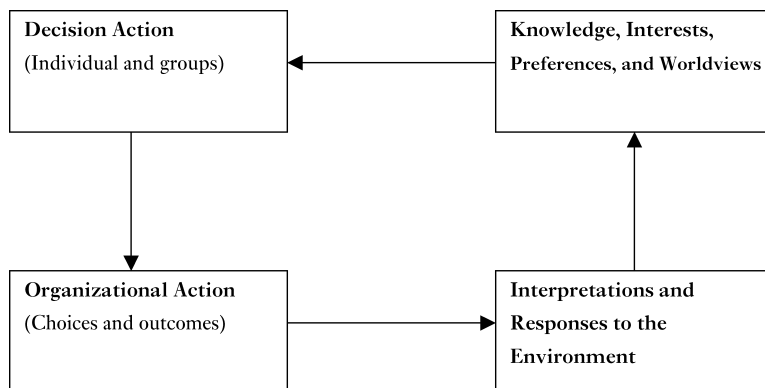

Figure 1 Strategic decision-making processes (James March).

of examining organizational decision making. In particular, March was keen to show the differences between decisions that were choice based or rule based. The main distinction was whether decision makers pursue a logic of consequences, making choices amongst alternatives and evaluating their consequences in terms of prior preferences, or do they pursue a logic of appropriateness, fulfilling identities or roles by recognizing situations and following rules which match appropriate behaviors to the situations they encounter? In this respect, organizations provide the context in which such interpretations are formed, sustained, and sometimes changed.

March also alerted our attention to the fact that organizations could engender two very different types of decision behavior. One may be characterized by clarity and consistency and the other by ambiguity, inconsistency, and chaos. In the former case, organization is all about coherence and reducing uncertainty to avoid equivocality. In the latter case, organization is anarchic and acts as a background for decisions which may not be linear in process, may not be logical in a consistent sense, and where solutions may precede outcomes (in the sense that organizations by their very nature are collections of solutions already made – waiting for new decision opportunities to which they can become attached).

Finally, March argued that decision outcomes can be seen as primarily attributable to the actions of autonomous actors in organizations, or can be the result of the systemic properties of organizations as an interacting ecology. Here, the links between organization and decision are made explicit. Is it possible to describe decisions as emanating from the intentions, identities, and interests of independent actors? Or is it necessary to emphasize the ways in which individual actors, organizations, and societies fit together?

There is unlikely to be any resolution of the above theoretical disjunctures. Future work in strategic decision making may have to try and seek a synthesis – not to force choices amongst epistemologies – so that one can weave together both approaches in ways that allow one to highlight or illuminate the other. Whatever the outcome of this process, it is certain that strategic decision making will remain at center stage of

the sociology of management and organization for many years to come.

strategic essentialism

Kristina Wolff

The concept of strategic essentialism is a “strategic use of positivist essentialism in a scrupulously visible political interest” (Fuss 1994: 99).

It utilizes the idea of essence with a recognition of and critique of the essentialist nature of the essence itself. It is a means of using group identity as a basis of struggle while also debating issues related to group identity within the group.

Strategic essentialism emerged out of Gayatri Chakravorty Spivak's critique of the Marxist, historical collective called the Subaltern Studies Group. The collective's main project was to operate as a counter movement, working to expose elitist representations of South Asian culture, particularly within Indian history. Subaltern studies performed the rewriting of the history of colonial India from the position of subordinated social groups or the *subaltern*. The *subaltern* is often used as a word for the oppressed or "Other" in society. Spivak's usage is based on Antonio Gramsci's definition, which consists of subordinated or non elite social groups. These groups occupy a space of difference with no or extremely limited access to the culture of the elite. The goal of the Subaltern Studies Group was simply to provide access or space for the subaltern to speak. The subaltern is a product of the network of elites, of differing understandings of what the subaltern *is*, as defined by the elites.

Strategic essentialism recognizes the complexities of occupying a subject object position, of the subaltern, whether it is a movement, group, or individual. They are working from within a structural position of subordination in society, while also embodying and critiquing that position. For example, a movement for immigrant laborers' rights would be challenging the elites in their definitions of and practices of domination over the workers, while also recognizing the complexities of what it means to be an *immigrant laborer*. The fundamental nature of this concept is that it deliberately suits a particular situation and does not serve as an overarching theory.

Spivak combines the techniques of deconstruction with Foucault's theory of power in the foundational pieces of strategic essentialism. *Deconstruction* as a method of critique provides a means to examine something that is important to how we understand society, perhaps something that is defined as an "essence," while also investigating the complexities of that

essence. Power is examined where it occurs, as a place of domination and of resistance.

Strategic essentialism as applied to feminism serves to utilize essentialist definitions of *woman* while also continually critiquing the concept itself. For example, one of the main goals of liberal feminism is the political struggle to gain equal rights for men and women. This includes providing equal pay for equal work. When arguing for this change in status, the concept of "woman" is used as being as able as men to complete tasks and uphold responsibilities in the working world and therefore they should be judged equally. There is no critique of what being a woman is, but there is a critique as to women's subordinated status in society due to their gender as well as the effects of this on the availability of jobs for women. Strategic essentialism also recognizes that women exist in positions of power within the working world, thus placing them in a position where they may be using female traits that are understood as inherent to all women. This concept moves beyond basic liberal feminist understandings, recognizing that women may be seen as rejecting these "natural" traits in order to fit into a "man's world" of work so that they can be successful. Here women are embodying and rejecting essentialist qualities of being a woman in a calculated manner.

Within the liberal feminist movement, discussions and debates occurred surrounding the ways in which they were utilizing their status as women to fight for their rights. This included the way they fulfilled their expected roles as wives and mothers, as well as using these roles as points of resistance. Additionally, women began to question essentialist definitions of "woman," thus causing great debate within the movement and the development of alternative forms of feminism based on these critiques and definitions of what being a woman means and the effects this has on identity on the individual, group, organization, and societal levels.

Critiques of strategic essentialism often focus on whether it can account for the complexities of race, class, and gender, specifically if it is to focus on a specific situation, within a certain political, geographic, historical context. Others question if those utilizing the technique are always making a strategic choice, as there is an

assumption of a certain awareness at play. However, the loudest and most constant critic of strategic essentialism is Spivak. She sees it as morphing into a tool for promoting essentialism rather than serving as a means of critique. Many utilizing it stop short of deconstructing essentialist beliefs serving as the foundation of what is considered essentialist. Strategic essentialism has been adopted and used as a theory rather than remaining a technique, a strategy for understanding the complexity and fluidity of subject/object positions, of identity and power, and of the ways in which subordinated groups operate and work for changing their situations, their status. The indiscriminant use of strategic essentialism broadly to all oppressed groups ignores the importance of tactics and in turn becomes a misapplication of the spirit of the concept. Spivak does find that it can continue to be useful through the consideration of how individuals and others are essentialist in different ways, thus embracing the challenge of the relationship of race, class, gender, and other components of identity.

strategic management (organizations)

David Knights

On being asked to define strategic management, the temptation is to respond by asking what is *not* strategic in management. In other words, as soon as the idea of management is addressed, it is necessary to see it as strategic, although clearly much of management is about managing organizational routines. Such a response begs the question of what is meant not only by strategy, but also by management. Some writers on strategy and management have seen the two as coincident, but others perceive the focus on strategy to be contemporary and linked to the emergence and development of large, often multisite and sometimes multinational corporations. Both terms are in need of definition, even though we know that their meanings are tied to the context of their use. Nowhere is this made more obvious than when consulting the Shorter Oxford English Dictionary, where both terms are treated in terms of usage and would seem to share a similar genesis in activities concerned with battle or the military.

Management has its derivation in managing as controlling the affairs of the household or training horses (to be put through the exercises of the *manège*). Alternatively, it refers to the handling of weapons or instruments to serve one's purposes. It is then about directing both animate and inanimate resources toward a particular objective. But the art of managing can also be seen as the use of contrivances for effecting some purpose, often by way of deceit or trickery. On the other hand, it can refer to indulgence or consideration shown toward a person. As with the term strategy, there is a strong association between management and military activities since it is clear that "handling weapons" and the use of horses cannot be separated from the conduct of battle in medieval warfare. The relationship continues even today, with the police use of horses in managing crowds during mass demonstrations. These activities might be seen as the "hard" practices of management, but the term has links with a "softer" meaning in which it refers to "animal

and household husbandry,” where it relates to caring for and maintaining what is under its tutelage.

Strategy has its origin in military history and may be defined as the art of projecting and directing the larger military movements and operations of a campaign. Chandler (1962) defined it largely in terms of long term goals and the means (i.e., courses of action and allocation of resources) for attaining them. In organizations, however, strategy operates at various levels.

- *Corporate strategy* refers to how the corporation defines itself, what business it is in, and its future direction and scope.
- *Business strategy* is concerned with the application of the corporate strategy to a subsidiary, division, or business unit of the corporation.
- *Strategic management* focuses on managers in general acting strategically in order to make the best use of the corporation’s competitive advantages, core competences, and market positioning and to advance the corporate mission, while having due regard for external constraints and opportunities.

While these different levels of strategy need to be distinguished, often the term strategic management is used less technically to refer generically to all three levels.

INTELLECTUAL AND SOCIAL CONTEXT

Insofar as the term management was used within the field of productive work, it tended to be associated with engineering and the military; thus, social class was extremely important in the context of recruitment into, and the pay differentials of, managerial positions during the period of the Industrial Revolution. The transiency of this privilege declined after 1790, when payment became attached to the job rather than to the person and seemed to coincide with an erosion of the differential between proprietors and salaried managers, though the latter were more often than not the relatives of the former (Pollard 1965: 139, 145). At this time, however, management was seen as

restricted to achieving the goals of the organization as laid down by entrepreneurs, who determined the nature and scope of the business, its goals, finance, and markets (Pollard 1965: 3). In effect, proprietors were rightly seen as entrepreneurs and were responsible for strategic thinking (a term not used at the time), whereas managers were simply functionaries translating their ideas into practice.

Once the joint stock company legislation was passed in 1854, those owning capital could invest their funds without being liable for any thing other than the amount invested should the company fail. They therefore took the opportunity to spread risk through owning a portfolio of shares in several companies, thus becoming absentee landlords. Managerial agents were employed to run the business, but they also assumed responsibility for designing strategies against which the owners could evaluate their performance at annual general meetings.

After this institutional separation of ownership from control, the distinction between entrepreneurs and managers began to erode as the latter assumed executive responsibility for both activities, although they were accountable to a board of directors who represented the interests of shareholders. Insofar as managers were clearly beginning to be recognized as of equal, if not greater, importance than the absentee owners, this could be seen as a point of discontinuity between the pre managerial and the managerial world. This, it could be claimed, provided the conditions that made it possible for strategic management to be practiced and eventually for it to become a topic of academic and popular management discourse.

Although some notion of strategy has been a central feature of armies for centuries, Hoskin and Macve (1986) argued that strategic management only became meaningful when writing, recording, and calculation became common practice within organizations. Strategy and management were identified as virtually synonymous since they were mutually interdependent.

Hoskin (1990) sought to pursue this theme with greater precision, suggesting that modern management had its genesis in mid nineteenth century America with the development of the Pennsylvania railroad. By “importing the practices of writing, examination, and grading,” Hoskin (1990: 23) argues, Herman Haupt of

the Pennsylvania railroad changed the “rules of business discourse” in the direction of being “proactive and future oriented,” or what we would now define as strategic. It is this orientation to strategic corporate decision making that Hoskin identifies as synonymous with a concept of modern management. This is seen as coterminous with the development and transformation of the internal discourses and practices of organizations into a written recorded and calculable form.

Modern management, from this point of view, is grounded in the knowledge and power that make it possible to control labor and the organization of production in pursuit of a set of strategic ends such as profit or corporate expansion. It is accomplished through practices that turn everything and everyone into an “object” to be managed (Miller 1987). Case files on employees and customers are written, recorded, and stored, and their behavior is continuously examined so as to render it calculable in terms of both the present and future prospects of the corporation. Examining, quantifying, and grading people and events brings them readily within the disciplinary gaze and the techniques of surveillance of strategic managers who exercise power and constitute knowledge within organizations.

While so far this analysis has been entirely academic in focus, as with many of the concepts in management, the strategy literature is heavily dominated by managerial approaches that see the academic’s role as helping managers to do their jobs more effectively and efficiently in terms of meeting goals presumed to be those of, or defined by, that self same management. This takes us to an examination of the main approaches and dimensions of strategic management.

MAJOR APPROACHES AND DIMENSIONS

The idea of strategy in management did not become standard in academic discourse until the 1960s, when the Master of Business Administration (MBA) was widely introduced. However, an equivalent notion of planning can be traced as far back as 1916 to the writings of Fayol (1949 [1916]: 43), who, in arguing that

“managing means looking ahead,” presumably was reporting on his experience of planning as a practitioner. While business schools were established in the US around the turn of the twentieth century (Wharton, 1881; Harvard, 1908; Stanford, 1925), largely in response to industrialization and the need for “trained managers” (Robinson 1995), it was not until around the middle of the twentieth century that they began to expand dramatically and to begin their development in the rest of the world.

It is possible to identify numerous approaches to strategy (Mintzberg 1994), but these can be contained within two broad perspectives – the rational and the processual. Similarly, there are several levels or dimensions in addition to those of corporate, business, and generic management strategy, but again these can be restricted to issues relating to creation, formation, development, and implementation. It should be noted, however, that these various approaches, levels, and dimensions may differ depending on the area of the business – accounting and finance, customer service, human resource management, information and computer technology, marketing, operations, and so on.

Rational Approach

The rational approach continues to dominate mainstream thinking about strategy, particularly within economics, but also, with some modifications, in organization analysis. One of the most popular rational approaches is Porter’s (1980) competitive forces model. Although broadly based on the economic theory of competition, the model also draws on the marketing theory of product differentiation and the organization theory of corporate power. Porter’s model is illustrated in Figure 1.

If the magnitude of the five competitive forces is zero, the strategic competitive advantage of the company is infinite for it is, in effect, in a monopoly position, although this is rare. The normal situation is for the five forces of competition to be of variable degrees of magnitude, and all will affect the strategic competitive advantage of the company, the price it can charge for its products or services, and hence its profitability. Product differentiation, especially when supported by expensive advertising,

Figure 1 Porter's model of competitive strategy.

helps to reduce, if not eradicate, product substitution and the threat of new entrants, as do highly capital intensive operations. However, high levels of profitability will attract new entrants regardless of capital costs and product differentiation, and high prices will encourage both suppliers and buyers to look for substitutions. Powerful suppliers push up costs, as does the effect of competitors, and powerful buyers will force down prices.

Within organizations studies, the rational approach is most vividly represented by the Design School, which sees strategy largely as being designed and developed by senior executives and then distributed through the hierarchy in a top down, cascade like fashion. Strategic management is informed by a SWOT analysis, which involves developing the strengths and minimizing the weaknesses of the organization as well as exploiting environmental opportunities and neutralizing any threats. Implementation of the strategy is expected to proceed bureaucratically without divergence or disruption.

Process Approach

The process approach considered the Design School to have a naïve view of organizations, since it presumed rather than demonstrated coherence and consensus. From an examination of the processes whereby decisions are made and implemented, it is clear that there is as much conflict as consensus, as much contest as compliance, and as much competition as cooperation within organizations. Implementation cannot therefore be presumed to be a smooth and uncontested process; it therefore makes sense to adopt a more flexible approach toward strategic management (Mintzberg 1994). In order to secure the commitment of those who have to implement strategies, managers need to “find”

strategies lower down the organization rather than simply trying to impose formal plans from above. This approach seeks to remedy the failings of formal strategic planning, which include its inflexibility, its preoccupation with management control, and the problems that these generate for creative and innovative work. If strategies emerge from below, they will not suffer the same problems of implementation since staff will identify with them. Incremental and emergent conceptions of strategy, where design and implementation go hand in hand on a trial and error basis, are more appropriate in contemporary turbulent environments (Mintzberg 1994).

A process approach draws on contingency theories of organization, which reject universal approaches to management in favor of flexibility and responsiveness to the environment, often presumed to be unstable. Scenario planning, in which every aspect of the environment is investigated in order to produce medium and long term forecasts of its development, is a necessary prerequisite for this kind of strategic management.

CURRENT EMPHASES IN RESEARCH AND THEORY

Strategic management has tended to assume a different form and content, not only historically, but also in relation to where it is located within the organization. Generally, corporate strategy is a boardroom discourse and practice, although it will usually also be a responsibility of senior managers who advise the board. Business strategy, by contrast, is invariably a cascaded translation of this corporate strategy to the various divisions, departments, or business units of the organization. However, much depends on how power is distributed in the organization since some corporations operate a strict command

and control system, whereas others may simply distribute budgets and leave their divisions, units, or profit centers to manage themselves. A divisionalized structure usually means that strategy is distributed to the divisions or profit centers, but those corporations that retain strategic thinking at the center have clearly not been influenced by the idea of “emergent” strategy.

Corporate strategy may be understood as having passed through at least five phases from the 1950s until the present (Grant 1998). Financial control dominated in the early period, giving way to a concern for planning, then strategic diversification, competitive advantage, and, most recently, a preoccupation with innovation and guru prescriptions. Insofar as these approaches to corporate strategy have been simply recording the fads and fashions of business practice, they remain descriptive in content but often seek to influence practitioners and thereby follow a prescriptive line that suggests a particular approach is more effective than previous ones. Sometimes those academics (e.g., Gary Hamel, Rosabeth Moss Kanter, Tom Peters, Michael Porter) prescribing the “strategic one best way” entered the bestseller lists through entertaining vast armies of business managers with time to kill in airport lounges and on long haul flights.

Strategy, then, like other aspects of management, is subject to the fads and fashions of managerial thinking. Knights and Mueller (2004) suggested an alternative classification to the rationalist (realist) and processual (social constructionist) approaches, for these are respectively objectivist and subjectivist. A non dualist approach perceives strategy neither as a “thing” nor merely as a “process” to capture but as an ongoing project that reflects and reproduces particular forms of subjectivity. Although closer to the social constructionist than to the objectivist approach, it combines both to theorize a range of rationalities, processes, and politics, but then seeks to delve beneath the surface of discursive practices to explore their dynamic. Whereas the process theory recognizes organizational politics only to seek its eradication on the basis that it is often disruptive to the achievement of strategic objectives, the project theory sees politics as an inescapable but necessary part of securing managerial and staff

commitment to the strategy. Strategy can only be fully accomplished when it coincides with the subjectivity of members of the organization. While strategy clearly is about penetrating existing and new markets, gaining competitive advantage, restructuring, or mergers and acquisitions, an unintended effect is how it transforms individuals into subjects that secure their sense of identity, meaning, and purpose by participating in the activities it invokes (Knights & Morgan 1991). In short, a side effect of strategy is a stimulation of subjective self discipline that secures the management control of employees, enrolls the support of fund managers and shareholders, and facilitates the mobilization and incorporation of consumers as loyal customers.

METHODOLOGICAL ISSUES AND FUTURE DIRECTIONS

The major methodological problem in studying strategy is access, because ordinarily corporations are secretive about their strategy on the basis that it contains competitively sensitive data and material. Few academics have managed to secure access to the boardroom to observe rather than speculate on how strategy is formulated. Consequently, most studies of strategy rely on archival or secondary data that are in the public domain. Rarely does research take place in the boardroom where strategy is enacted (see, however, Knights & Willmott 1992; Samra Fredericks 2000). Only direct observation of boardroom interactions can avoid the selection of material for purposes of impression management, since the ongoing context of seeking to develop or implement a strategy in a boardroom meeting must prevail over any attempt to impress the observer.

The above two studies used the most sensitive of methods – recorded observations – to study boardroom behavior and the data are therefore available for further analysis. They sought to show how strategy was accomplished through, rather than independently of, the boardroom social encounters and that it was both a medium and an outcome of the exercise of power and the concern to secure identity among board members. Samra Fredericks (2000) not only

tape recorded board meetings but also video recorded them, thus providing verbal transcripts as well as the various bodily movements and expressions that often reveal more than the words themselves. Both studies used a range of methods, including non participant observations, work shadowing, interviewing, and documentary investigation.

A fairly limited literature has begun to develop that may be seen as providing some of the missing links on what makes strategy work operationally. Developing a strategy, whether from above or below, does not amount to operationalizing that strategy or translating it into practice. This requires organizational members to be fully conversant with the strategy as well as committed to it. Recent research has used methods that secure access to boardroom meetings where strategy is usually formulated and/or distributed to other members of the organization. Drawing on analytical approaches about subjectivity and self discipline, this research suggests that strategy is less important for its actual content than for the effect it has on subjects, who may begin to secure a sense of themselves – their meaning, purpose, and identity – through engaging in the discourses and practices that the strategy invokes.

stratification, distinction and

Wout Ultee

Behind a lot of research on societal stratification lurks the idea that, if persons are given a choice between a large and a small pay packet, they will opt for the larger one. Yet people in general not only want to have more than they already have, they also want to be more than others around them, particularly others who have about as much as they themselves have. This is the subject of distinction within the field of stratification. It became important in sociology through studies by Thorstein Veblen on conspicuous consumption, Norbert Elias on changing standards about what counts as good manners, and Pierre Bourdieu on distinction

through leisure activities. Also to be mentioned is work by the art historian E. H. Gombrich on "the logic of vanity fair."

Although the tendency for people to distinguish themselves from others may be assumed to be present in most persons, the tendency supposedly is stronger in societies with open stratification systems, that is, systems where a person's station in life is not fixed at birth, but in which social mobility and marriages between societal strata occur. In societies that to a large extent are closed, visible markers of an elevated position often are restricted by custom and law to the persons with these positions. The game of outdoing the other took place among persons on more or less the same rung of the social ladder in European agrarian societies until the beginning of industrialization and was limited by sumptuary laws and similar devices. Their contemporary form in highly developed societies is the rate of value added tax on luxury goods, which is higher than that on the necessities of life.

Of the various sociological contributions to the topic of stratification and distinction, perhaps that of Elias is the most important. By way of a comparison of a series of French books on good manners ranging from the fifteenth to the nineteenth centuries, Elias made clear that the tendency for persons to distinguish themselves from others by following the rules of good manners in gatherings and encounters, if imitation of these standards by persons just below them on the social scale is possible, makes the old rules of civility lose their discriminatory power, leading to more strict rules of politeness, which in turn are imitated, and so on. For that reason the process of distinction shows a particular direction unintended by any of the original persons involved. Gombrich has argued that such processes of devaluation of old signs of distinction through imitation stand behind contemporary phenomena such as rapidly changing fashions. One may think here of shorter skirts and louder pop music. The question of where these inflationary processes end is an important topic for research.

stratification: functional and conflict theories

Paul M. de Graaf

Every society can be characterized by a set of social positions that are related to the access to the scarce and desired goods in that society. Functional and conflict theories of stratification are formulated to provide an answer to the question how are positions distributed across members of a society.

The functional theory of stratification was formulated by Davis and Moore (1945), who refer to the universal necessity which calls forth stratification in any social system. They explicate the functional theory as follows. Every society has a number of positions (occupational structure), which can be ranked by the importance they have for society and by the skill level required. If position A is more important than position B, and if position A requires more skills than position B, then the rewards of position A must be larger than the rewards of position B, otherwise its attractiveness would not be large enough to be filled by able individuals. Individuals who have either the required native abilities or the required training must have an incentive to fill the most important positions. Functional importance and scarcity of personnel both are relevant for a social position to be highly rewarded. If a position is functionally

important but can be filled easily, its rewards do not need to be high to motivate individuals to prepare for it and to acquire the necessary skills. In other words, functional importance is thought to be a necessary but not a sufficient condition for a function to be rewarded highly. Rewards can be diverse, ranging from material rewards like income and wealth, to more symbolic forms of rewards like occupational prestige and admired lifestyles, as long as they motivate individuals to use and develop their talents.

An important element of the functional theory of stratification is that the distribution of social positions varies between societies and between historical periods, mainly because of technological innovation. As a consequence the relevant talents and skills individuals must acquire in order to fill the social position also vary between societies and periods. Examples are the transition from an agricultural to an industrial society, the increasing efficiency in industrial production, and the emerging information technology, which all have changed the occupational structure. Following Blau and Duncan (1967), the modernization process in industrial and post industrial society could have made educational qualifications more important, a process which was labeled a shift from "ascription" to "achievement" and soon as the leading determinant of status attainment.

The functional theory of stratification has been criticized for at least two reasons. First, functional theory lacks an individual basis. It seems to assume that individuals adjust their careers to support society's need for qualified personnel in a given set of social positions. However, individuals cannot be expected to support the interests of society as a whole; instead, they pursue their individual interests and strive for income, prestige, and power. Second, the functional theory is criticized because it has an eye only for the eufunctions of social stratification: the incentive it provides for all individuals in a society to acquire the skills needs for the given set of social positions. Doing this, it neglects dysfunctions of social stratification, mainly the negative consequences for social cohesion.

The conflict theory of stratification stresses that inequality is not a benefit for all members of society, but mainly for the elites. Power differences mean that some groups take more of the scarce goods than other groups. The

privileged groups exploit the subordinate groups. Using their superior resources, elites tend to attempt to increase their share, and to transmit their privileged position to their children. The Marxist interpretation is about economic ownership of the means of production and distinguishes between two *classes*: the bourgeoisie and the proletariat. This Marxian class scheme has been extended in different directions. In international sociology two important class schemes have been developed by Eric Olin Wright and John Goldthorpe. Both are based in the differentiation in the occupational structure, especially on the market situation and employment relations.

The conflict theory of stratification has been developed explicitly by Collins (1971), based on the concept of status groups (Weber). Status groups include persons who share a common culture and lifestyle: behavior and manners, language style, consumption patterns, values, attitudes, and preferences. Status groups are often but not necessarily based on their position in the occupational structure (classes). The struggle for wealth, power, and prestige is assumed to take place primarily between status groups, and education is thought to be the primary battlefield. Schools teach the culture of the dominating status groups, and because education is so important for selection in the labor market, education is the channel of intergenerational transmission of privileged positions. Collins argues that educational requirements for jobs are often not (only) based on technical reasons. Employers select the higher educated because they feel that they are better socialized and more respectable. Bourdieu (1973) adds to this argument that the educational system works in a way that children from the elites feel at home at school. Their parents have provided them with cultural habits and preferences that are parallel to what is expected at schools. The conflict theory of stratification argues that education is serving as a device to transmit social status from one generation to the next. Note that this interpretation of conflict theory can be seen, to some degree, as a conspiracy theory.

Educational expansion is explained by the functional theory of stratification as a logical system answer to technological innovation. The shifts in the occupational structure mean that job requirements have changed and educational

growth is a functional consequence of this change. Conflict theory interprets educational expansion as the consequence of individual choices. When education has become a key factor in the selection process of personnel, it becomes worthwhile to invest in it. If people start to invest in education, the logic of the situation means that it becomes necessary for everybody to invest as well. Empirical tests of the functional and conflict theories of stratification are scarce and not very convincing. Whether in modern society education serves as a meritocratic device or as a reproduction channel remains at issue, and both interpretations are probably valuable.

stratification, gender and

Catherine Hakim

The documentation, interpretation, and explanation of structured social inequality has always been a central focus of sociology. Although social stratification lies at the heart of macro sociology, and is the subject of extensive theoretical and empirical analysis, the study of gender and stratification is comparatively recent, and developed in the 1970s onwards as a result of the second wave of the feminist movement in

modern western societies (Crompton & Mann 1986). The traditional sociological view was that the subordination and oppression of women could be adequately incorporated into class analysis. Feminist theory insisted that in modern societies the class structure, and the oppression of women within patriarchal systems (i.e., women's oppression by men), were separate but interacting social processes.

In conventional class analysis, women generally, and wives in particular, took the social class position of the males in their family or household: initially their father's social class, then later, after marriage, their husband's social class. This was essentially because occupation, or any other status in the public sphere (such as elected politician), was taken as the most obvious indicator of a family's or household's social class/status in modern capitalist societies. The unit of analysis was the cohabiting and income sharing social unit, not the individual. The feminist focus on women's oppression within the patriarchal family, and within patriarchal societies, forced sociologists to look at the class/status position of individuals as well. This led to an extended debate among empirical sociologists on whether the family or the individual is the appropriate unit for class analysis and, more specifically, whether wives should be allocated to social classes on the basis of their husband's occupation or on the basis of their own current (or last) occupation (Dex 1990; McRae 1990).

It is now agreed that women's position in society, and in the labor force, should be studied separately from class analysis. Empirical research has shown that the sex segregation of occupations, and the pay gap between men and women, cut across social classes in ways that vary from one society to another, and vary across time (Hakim 1998). Occupational segregation and the pay gap develop and change independently within labor markets as a result of anti discrimination policies and other social policies (such as family friendly policies) that often have unintended deleterious effects (Hakim 2004). Similarly, women's position in the family can be studied independently of their position in the class structure, and may depend on their property rights (Crompton & Mann 1986: 69–72, 191–2) or their level of education as much as their position within the labor market (Hakim 2000).

The feminist challenge to conventional class analysis was based in large part on the idea that rising female employment rates in modern western societies were leading to a new situation in which all couples would be dual career as well as dual earner, wives would cease to be financially dependent on their spouses, and symmetrical family roles would become the norm, so that it no longer made sense to classify wives by their husband's occupation and social class, especially in the context of serial monogamy and declining marriage rates. Here too, empirical research provided a new perspective and led to the development of preference theory. Hakim (2000, 2004) showed, firstly, that there has in fact been relatively little change in female employment rates in modern societies over the past 150 years and that most of the visible change (in economic activity rates) was due to rising levels of part time employment, and to some women switching from full time to part time employment; in consequence, less than one quarter of all women of working age achieve the male pattern of continuous full time, life long employment by the start of the twenty first century. In most societies, the female full time employment rate remains far lower than that for men, and typically wives remain secondary earners in their household rather than equal earners. Rising female employment was exposed as a myth in most European countries, although it is real in the US. Secondly, Hakim showed that, in most modern societies, in Europe as well as North America, women divide into three distinct groups: a minority of work centered women who follow the male employment profile and are financially self supporting; a minority of home centered women who are entirely dependent on their spouses after marriage; and a majority of adaptive women who are generally secondary earners within their households rather than careerists. This heterogeneity of women's lifestyle preferences, and thus their employment profiles, cuts across social classes, education levels, and income levels. This diversity of female lifestyle choices produces a polarization of female employment profiles over the life cycle, and is a major cause of rising income inequality between households in liberal modern societies – as illustrated by the income differences between dual career childless couples and one earner couples with several children to

support. Similarly, preference theory predicts that occupational segregation and the pay gap can never be completely eliminated – two goals that are underlined by feminist campaigners and by policymakers in the European Commission.

Female social stratification is thus substantially different from male social stratification in modern societies, because women now have two avenues for achieving higher social status and class position – through the labor market, or through the marriage market. Both are still actively used by women, even in modern societies after the equal opportunities revolution of the 1960s and 1970s (Hakim 2000). In contrast, men are limited to using the labor market almost exclusively. All research shows that the vast majority of women resist the idea of role reversal in marriage, with the female as the sole or main income earner (Hakim 2000). Overall, stratification and inequality among women will tend to be larger than among men. For example, in the US and Britain at the start of the twenty first century, there were more female than male millionaires, because some women achieved success and wealth through their own activities in the labor market, and some achieved wealth as rich men's widows or ex wives.

The picture in less developed societies is different, and depends a lot on whether women have independent access to the labor market/market economy, have access primarily through male members of their family (father or spouse), or are expected to refrain from market activities and devote themselves exclusively to homemaking and childrearing activities (reproductive work rather than productive work). In agricultural societies, technology itself has also been an important factor in women's social and economic position, as illustrated by large differences in women's position in economies depending on the hoe or on the plow (Boserup 1970).

The precise importance of patriarchy and male dominance as a cause of women's position in the family and in the social structure continues to be the subject of theoretical debate and empirical research. Feminist theory tends to treat patriarchy as the main cause of women's oppression in all societies, and at all times in history. In modern societies, patriarchy is argued to work through occupational segregation and the pay gap in particular; these are

imposed by men on women in order to restrict women's economic independence, force them into financial dependence on men, and thus keep women subject to male control (Hakim 2004: 8–11). However, new research by historians, political scientists, and sociologists suggests that in reality male desire for control of female reproductive work may be far more important as the catalyst for patriarchal systems than male desire to control female productive work. If this analysis is correct, patriarchy will be eliminated by technological advances in reproduction and fertility control. An extensive review of the historical evidence by Lerner (1986) led her to conclude that male desire to control women's sexuality and childbearing, in order to safeguard the inheritance of private property, was the primary cause of the introduction of patriarchal control of women's activities. The control of women's gainful activities outside the home was an accidental side effect, never the main aim. This conclusion is consistent with the results of analyses of World Values Survey data for 85 countries around the world in all six continents. Inglehart and Norris (2003) and Norris and Inglehart (2004) argue that culture can be viewed as providing a survival strategy for a given society. In subsistence level traditional societies, life is insecure and short, and the culture encourages maximum fertility. Partly through religious beliefs and institutions, and partly through patriarchal value systems, women's primary role is defined in terms of childbearing and high fertility. In rich secular knowledge societies with long life expectancies, the culture changes to accept low fertility levels but with high quality children, and women are encouraged to have more diverse social roles – in public life and the labor market as well as in the family. In short, patriarchal values, along with religious values, are maintained by women as much as men, and then jointly abandoned in prosperous modern societies, according to the importance of high fertility as a survival strategy in a given society.

stratification and inequality, theories of

David B. Grusky

The term stratification system refers to the complex of institutions that generate inequalities in income, political power, social honor, and other valued goods. The main components of such systems are (1) the social processes that define certain types of goods as valuable and desirable, (2) the rules of allocation that distribute these goods across various roles or

occupations in the division of labor (e.g., houseworker, doctor, prime minister), and (3) the mobility mechanisms that link individuals to these roles or occupations and thereby generate unequal control over valued goods. It follows that inequality is produced by two types of matching processes. The social roles in society are first matched to “reward packages” of unequal value, and individual members of society are then allocated to the roles so defined and rewarded. In all societies, there is a constant flux of incumbents as newcomers enter the labor force and replace dying, retiring, or out migrating workers, yet the positions themselves and the reward packages attached to them typically change only gradually. As Schumpeter (1953: 171) famously put it, the occupational structure can be seen as “a hotel . . . which is always occupied, but always by different persons.”

There is a growing consensus among academics, policymakers, and even politicians that poverty and inequality should no longer be treated as soft “social issues” that can safely be subordinated to more fundamental interests in maximizing total economic output. This growing concern with poverty and inequality may be attributed to such factors as (1) the dramatic increase in economic inequality in many countries over the last quarter century; (2) the rise of a “global village” in which spectacular regional disparities in the standard of living have become more widely visible and hence increasingly difficult to ignore; (3) a growing commitment to a conception of human entitlements that includes the right to secure employment and be spared extreme deprivation; (4) an emerging concern that poverty and inequality may have negative macro level effects on terrorism, ethnic unrest, and total economic output; and (5) a growing awareness of the negative individual level effects of poverty on health, political participation, and a host of other life conditions. Although the growth of anti inequality sentiment thus rests in part on an increased awareness of just how unequal and poverty stricken the world is, it may also be attributed to an ever evolving and accreting list of human rights (i.e., a “normative” account), as well as a growing appreciation of the negative externalities of inequality and poverty (i.e., a “consequentialist” account).

CONCEPTUALIZING INEQUALITY

The first task in understanding inequality and poverty is to specify the types of assets that are unequally distributed. It is increasingly fashionable to recognize that inequality is “multidimensional,” that income inequality is accordingly only one of many forms of inequality, and that income redistribution in and of itself would not eliminate inequality (e.g., Sen 2005). When a multidimensionalist approach is taken, one might usefully distinguish between the eight types of assets listed in the left most column of Table 1, each understood as valuable in its own right rather than a mere investment item. It must nonetheless be recognized that the assets of Table 1 are also inevitably “resources” that serve some investment functions. For example, most economists regard schooling as an investment that generates future streams of income, while some sociologists likewise regard cultural resources or social networks as forms of capital that can be parlayed into educational credentials, income, and other valued goods. There is much research and theorizing on the social processes by which inequality in one domain is converted into inequality in another domain.

The core task of the contemporary inequality researcher is to develop evidence on how much inequality there is, whether some countries are more unequal than others, and whether inequality is increasing or decreasing within and between countries. Although the vast majority of research within this fact finding tradition has focused on income distribution, inequality scholars are increasingly examining how distributions of other assets may or may not resemble income distribution. It is now fashionable, for example, to examine the structure of inequality with respect to such outcomes as computer literacy (i.e., the “digital divide”), mortality and health, risks of imprisonment or capital punishment, and lifestyles and consumption practices.

This line of research typically takes the form of an exposé of the extent to which seemingly basic human entitlements, such as living outside of prison, being gainfully employed, freely participating in “digital” culture, or living a reasonably long and healthy life, are unequally distributed in ways that amplify well known differentials of income. The continuing attraction

Table 1 Types of valued goods and examples of advantaged and disadvantaged groups

of such exposés (at least among academics) may be attributed to our collective discomfort with an economic system that generates rather more inequality than is palatable under contemporary cultural standards. That is, capitalist economic systems are not only highly successful in delivering the goods (i.e., high gross national products), but are also great inequality producing machines, and we are hard put to reconcile such extreme inequality with our post Enlightenment cultural commitment to the view that humans are "fundamentally" equal. Although the equalizing reforms of social democracy have historically been a main solution to this tension, the declining legitimacy of such reform (especially in Europe and the US) leaves the tension an increasingly unresolved one.

This tension is only exacerbated by recent trends in income inequality. Arguably, the most dramatic social scientific finding of our time is that income inequality has increased markedly

over the last 35 years, reversing a longstanding decline stretching from the eve of the Great Depression to the early 1970s. According to the classic Kuznets curve (Kuznets 1955), the initial stages of capitalist development will bring about a one time increase in income inequality as capital is increasingly concentrated among a small number of investors, whereas more advanced forms of capitalism entail a growth in the size of the middle class and a consequent reversal of the upward trend. This story aligns nicely with the facts of inequality up to the early 1970s, but then a dramatic, unprecedented upswing in inequality in the post 1970 period (within many countries) made it clear that history does not end with the much vaunted middle class expansion.

We have since witnessed one of the most massive research efforts in the history of social science as scholars sought to identify the "smoking gun" that accounted for this dramatic

increase in inequality. Initially, the dominant hypothesis was that deindustrialization (i.e., the relocation of manufacturing jobs to offshore labor markets) brought about a decline in demand for less educated manufacturing workers, a decline that generated increases in inequality by hollowing out the middle class and sending manufacturing workers into unemployment or into the ranks of poorly paid service work. Although this line of argumentation still has its advocates, it cannot easily be reconciled with evidence suggesting that the computerization of the workplace and related technological change has been a driving force behind a heightened demand for highly educated workers. Because of this result (and other supporting evidence), the deindustrialization story has now been largely supplanted by the converse hypothesis that “skill biased technological change” has increased the demand for high skill workers beyond the increase in supply, thus inducing a short term disequilibrium and a correspondingly increased payoff for high skill labor. At the same time, most scholars acknowledge that this story is at best an incomplete one and that other accounts, especially more narrowly political ones, must additionally be entertained. Most notably, some of the rise in income inequality in the US is clearly attributable to the declining minimum wage (in real dollars), a decline that in turn has to be understood as the outcome of political contests that increasingly favor pro inequality forces (e.g., Levy 1999).

The future of income inequality depends on which of these underlying mechanisms is principally at work. The silver lining of the deindustrialization story is that within country increases in inequality should be offset by between country declines (as poor countries profit from new manufacturing jobs), whereas the silver lining under skill biased technological change is that the heightened demand for high skill workers is presumably a one time, short term disequilibrium that will, by virtue of the higher payoff to high skill jobs, trigger a compensating growth in the supply of high skill workers. There is, unfortunately, no shortage of competing stories that imply more disturbing futures, even futures consistent with a classical Marxian account in which low skill workers are emiserated by virtue of a globalization induced “race to the bottom.” Indeed, accounts that focus on

the political sources of rising inequality often take on this more disturbing character, given that social democratic ideologies have fallen largely out of fashion and no longer provide capitalists with a viable high road of “enlightened self interest” (e.g., support for labor unions, redistribution). As social democratic agendas come to be viewed with suspicion, political support for the minimum wage and other inequality reducing institutions may increasingly falter, and market generated inequality may no longer be much restrained by pre market or after market interventions.

CONCEPTUALIZING SOCIAL CLASS

The claim that inequality takes on a “class form” is one of the few distinctively sociological contributions to inequality measurement and stands as the main alternative to approaches that either focus exclusively on income inequality or analyze the many dimensions of inequality independently and separately. The main advantage of class based measurement, as argued by sociologists, is that conventional class categories (e.g., professional, manager, clerk, craft worker, laborer, farmer) are institutionalized within the labor market and are accordingly more than purely nominal or statistical constructions. The labor market, far from being a seamless and continuous distribution of incomes, is instead a deeply lumpy entity, with such lumpiness mainly taking the form of institutionalized groups (i.e., “classes”) that constitute prepackaged combinations of the valued goods listed in Table 1.

Within sociology, the implicit critique, then, of income based approaches rests not so much on the argument that the income distribution is just one of many distributions of interest (i.e., multidimensionalism), but rather on the argument that measurement strategies based on the income distribution alone impose an excessively abstract, analytic, and statistical lens on a social world that has much institutionalized structure to it. This structure takes the tripartite form of a set of social classes that are privileged under capitalist labor markets (e.g., capitalists, professionals, managers), a set of social classes that are less privileged under advanced capitalism (e.g., routine nonmanuals, craft workers,

operatives), and an “underclass” that stands largely outside of the labor market and is accordingly deeply disadvantaged in market systems. The rise of class models should therefore be understood as a distinctively sociological reaction to the individualism of the income paradigm and other unidimensional approaches to measuring inequality.

The foregoing account, which is a largely consensual rendition of the rationale for social class measurement, nonetheless conceals much internal debate within the field on how best to identify and characterize the boundaries dividing the population into classes. These debates can be conveyed by recounting the three phases through which the field has developed.

Structuralist Phase (1945–1985)

The class models of the postwar period rested implicitly or explicitly on the assumption that classes are coherent bundles of endowments (e.g., education levels), working conditions (e.g., amount of autonomy), and reward packages (e.g., income). The middle class of “craft workers,” for example, comprises individuals with moderate educational investments (i.e., secondary school credentials), considerable occupation specific investments in human capital (i.e., on the job training), average income coupled with substantial job security (at least until deindustrialization), middling social honor and prestige, quite limited authority and autonomy on the job, and comparatively good health outcomes (by virtue of union sponsored health benefits and regulation of working conditions). By contrast, the underclass may be understood as comprising a rather different package of conditions, a package that combines minimal educational investments (i.e., secondary school dropouts), limited opportunities for on the job training leading to intermittent labor force participation and low income, virtually no opportunities for authority or autonomy on the job (during those brief bouts of employment), relatively poor health (by virtue of lifestyle choices and inadequate health care), and much social denigration and exclusion. The other classes appearing in conventional class schemes (e.g., professional, managerial, routine nonmanual) may likewise be understood as particular combinations of scores on the dimensions of Table 1.

For the purposes of illustration, consider a simplified case in which the multidimensional “inequality space” comprises only three individual level variables (e.g., education, autonomy, income), thus allowing the class hypothesis to be readily graphed. Additionally, assume that the class structure can be represented by six classes (e.g., professional, managerial, sales & clerical, craft, laborer, farm), signified in Figure 1 by six different symbols (dark squares, light squares, dark circles, light circles, dark triangles, light triangles, etc.). As shown in this figure, the two main claims underlying the class hypothesis are that (1) the structural conditions of interest tend to cluster together into characteristic packages, and (2) these packages of conditions correspond to occupational groupings. For a class analyst, the multidimensional inequality space is presumed to have a relatively low dimensionality, indeed a dimensionality no more nor less than the number of postulated classes. The individuals falling within the classes comprising this scheme will accordingly have endowments, working conditions, and reward packages that are close to the averages prevailing for their classes. Moreover, even when individual scores deviate from class averages, the conventional class analytic assumption (albeit wholly untested) is that the contextual effect of the class is dominant and overcomes any individual level deviations. This type of contextual effect would appear to be ubiquitous; for example, the full professor

Figure 1 Class regime.

who lacks a PhD is presumably just as marketable as a fully credentialed (but otherwise comparable) full professor, precisely because membership in the professorial class is a “master status” that tends to dominate all other individual level ones.

The postwar period also was notable for a flourishing of gradational measurement approaches that again treated occupations as the fundamental units of analysis, but then assumed that such occupations may be ordered into a unidimensional “socioeconomic” scale. In Figure 1 we assumed that the class structure cannot be understood in simple gradational terms, meaning that the underlying individual level variables did not vary linearly and that at least some classes were formed by combining high values on one dimension with low values on another. It is possible, however, that the structural conditions of interest tend to covary linearly, thus generating a class structure of the very simple type represented in Figure 2. In a regime of this sort, inequality becomes rather stark, as privilege on one dimension implies very reliably privilege on another. There should accordingly be much interest in determining whether inequality indeed takes this form. Unfortunately, inequality scholars of the postwar period did not typically test the linearity assumption, but rather simply assumed that it held and proceeded to develop socioeconomic scales that treated education and income as the main dimensions of interest (and ranked

occupations by averaging scores on these two dimensions).

It may be noted that many neo Marxian scholars during this period also deviated from a strict multidimensional stance by nominating particular dimensions within Table 1 as being theoretically crucial and hence the appropriate basis upon which social classes might be defined. There are nearly as many claims of this sort as there are dimensions in Table 1. To be sure, Marx is most commonly criticized for placing “almost exclusive emphasis on economic factors as determinants of social class” (Lipset 1968: 300), but in fact much of what passed for stratification theorizing during this period amounted to reductionism of some kind, albeit often an expanded version of reductionism in which two or three dimensions were nominated as especially crucial (Wright 1985). When a reductionist position is adopted, the rationale for a class model is not typically that classes are coherent packages of conditions (as represented in Fig. 1), but rather that the nominated dimension or dimensions are crucial in defining interests and will accordingly come to be the main sources of social action. The classic Marxian model, for example, has workers ultimately appreciating that their status as workers (i.e., nonowners) defined their interests.

Culturalist Phase (1985–1995)

In the mid 1980s, Bourdieu (1984) and other sociologists (especially Wilson 1996) sought to develop a culturalist rationale for class models, a rationale that rested on the claim that classes are not merely constellations of structural conditions (e.g., endowments, outcomes), but are also socially closed groupings in which distinctive cultures emerge and come to influence attitudes, behaviors, or even preferences of class members. Throughout this period many sociologists continued to work with more narrowly structuralist definitions of class (Wright 1997; Goldthorpe and Erikson 1992), but Bourdieu (1984) and Wilson (1996) were instrumental in legitimating the claim that class specific cultures are a defining feature of inequality systems. The two main forms of closure that serve to generate class specific cultures are residential segregation (e.g., urban ghettos) and workplace segregation

Figure 2 Gradational class regime.

(e.g., occupational associations). As Wilson notes, members of the underclass live in urban ghettos that are spatially isolated from mainstream culture, thus allowing a distinctively oppositional culture to emerge and reproduce itself. The effects of residential segregation operate, by contrast, in more attenuated form for other social classes. After all, residential communities map only imperfectly onto class categories (i.e., the demise of the “company town”), and social interaction within contemporary residential communities is in any event quite superficial and cannot be counted upon to generate much in the way of meaningful culture. If distinctive cultures emerge outside the underclass, they do so principally through the tendency for members of the same occupation to interact disproportionately with one another in the workplace and in leisure activities. In accounting, for example, for the humanist, anti materialist, and otherwise left leaning culture and lifestyle of sociologists, class analysts would stress the forces of social closure within the workplace, especially the liberalizing effects of (1) lengthy professional training and socialization into the “sociological worldview,” and (2) subsequent interaction in the workplace with predominantly liberal colleagues.

When classes are allowed to have cultures in this fashion, one naturally wishes to better understand the content of those cultures and, in particular, the relationship between such content and the structural conditions (i.e., endowments, outcomes, institutional setting) that a class situation implies. At one extreme, class cultures may be understood as nothing more than “rules of thumb” that encode optimizing behavioral responses to prevailing institutional conditions – rules that allow class members to forego optimizing calculations themselves and rely instead on cultural prescriptions that provide reliable and economical shortcuts to the right decision. For example, Goldthorpe (2000) argues that working class culture is disparaging of educational investments not because of some maladaptive oppositional culture, but because such investments expose the working class (more so than other classes) to a real risk of downward mobility. In most cases, working class children lack insurance in the form of substantial family income or wealth, meaning that they cannot easily recover from an educational

investment gone awry (i.e., dropping out), and those who nonetheless undertake such an investment therefore face the real possibility of substantial downward mobility. The emergence, then, of a working class culture that regards educational investments as frivolous may be understood as encoding that conclusion and thus allowing working class children to undertake optimizing behaviors without explicitly engaging in decision tree calculations. The behaviors that a “rule of thumb” culture encourages are, then, deeply adaptive because they take into account the endowments and institutional realities that class situations encompass.

The foregoing example may be understood as one in which a class specific culture instructs recipients about appropriate (i.e., optimizing) means for achieving ends that are widely pursued by *all* classes. Indeed, the prior “rule of thumb” account assumes that members of the working class share the conventional interest in maximizing labor market outcomes, with their class specific culture merely instructing them about the approach that is best pursued in achieving that conventional objective. At the other extreme, one finds class analytic formulations that represent class cultures as more overarching worldviews, ones that instruct not merely about the proper means to achieve ends but additionally about the proper valuation of the ends themselves. For example, some class cultures (e.g., aristocratic ones) place an especially high valuation on leisure, with market work disparaged as “common” or “polluting.” This orientation presumably translates into a high reservation wage within the aristocratic class. Similarly, “oppositional cultures” within the underclass may be understood as worldviews that place an especially high valuation on preserving respect and dignity for class members, with of course the further prescription that these ends are best achieved by (1) withdrawing from and opposing conventional mainstream pursuits, (2) representing conventional mobility mechanisms (e.g., higher education) as tailor made for the middle class and, by contrast, unworkable for the underclass, and (3) pursuing dignity and respect through other means, most notably total withdrawal from and disparagement of mainstream pursuits. This is a culture, then, that advocates that respect and dignity deserve an especially prominent place in the utility function

and that further specifies how those ends might be achieved.

It should by now be clear that sociologists operating within the class analytic tradition have adopted very strong assumptions about how inequality and poverty are structured. As noted, intrinsic to the class concept are such claims as (1) the space of outcomes and capabilities has a (low) dimensionality equaling the number of social classes, (2) the class locations of individuals become master statuses that dominate (or at least supplement) the effects of individual level endowments, and (3) such class locations are socially closed and come to be associated with adaptive or maladaptive cultures. The foregoing claims have been unstated articles of faith among class analysts in particular and sociologists more generally. In this sense, class analysts have behaved rather like stereotypical economists, the latter frequently being parodied for their willingness to assume most anything provided that it leads to an elegant model.

Postmodernist Phase (1995–present day)

The third phase of conceptual work within sociology has been marked by an increased willingness to challenge the assumptions underlying the class analytic status quo. In recent years, such criticisms of the class analytic enterprise have escalated, with many postmodernist scholars now feeling sufficiently emboldened to argue that the concept of class should be abandoned altogether. Although the postmodern literature is notoriously fragmented, the variant of postmodernism that is most relevant here proceeds from the assumption that the labor movement is rooted in the old and increasingly irrelevant conflicts of industrial capitalism, that political parties have abandoned class based platforms in favor of those oriented toward values and lifestyles, and that class based identities accordingly become ever weaker and more attenuated. The resulting “individualization of inequality” (Beck 1992) implies that lifestyles and consumption practices are becoming decoupled from work identities as well as other status group memberships. The stratification system may be regarded, then, as a “status bazaar” (Pakulski & Waters 1996: 157) in which identities are actively constructed as

individuals select and are shaped by their multiple statuses.

This hypothesis, which is represented in extreme form by Figure 3, has not yet been subjected to convincing empirical test and may well prove to be premature. Moreover, even if lifestyles and life chances are truly “decoupling” from economic class, this ought not to be misunderstood as a more general decline in inequality *per se*. The brute facts of inequality will still be with us even if social classes of the conventional form are weakening. As was already noted, income inequality is clearly on the rise, and other forms of inequality show no signs of withering away. The postmodernist hypothesis speaks, then, to the way in which inequality is organized, not to the overall amount of such inequality.

CONCEPTUALIZING ALLOCATION

Although inequality scholars have long sought to understand how different “reward packages” are attached to different social positions, an equally important task within the field is that of understanding the rules by which individuals are allocated to the social positions so defined and rewarded. The language of stratification theory makes a sharp distinction between the distribution of social rewards (e.g., the income distribution) and the distribution of opportunities for securing these rewards. As sociologists

Figure 3 Disorganized inequality.

have frequently noted, it is the latter distribution that governs popular judgments about the legitimacy of stratification. The typical American, for example, is quite willing to tolerate substantial inequalities in power, wealth, or prestige provided that the opportunities for securing these social goods are distributed equally. If the competition has been fairly run, we are quite willing to reward the winners and punish the losers.

The study of opportunities (or “capabilities”) is no less fashionable among economists. However, the main motivation among economists for studying opportunities is not some intrinsic interest in mobility processes themselves, but rather a concern that standard outcome based measures of inequality are tainted by the confounding effect of differential tastes. For example, an employee with a well developed taste for leisure will presumably opt to work for relatively few hours, leading to low earnings but nonetheless high utility (by virtue of the high valuation placed on leisure). Whenever income inequality is generated through the operation of differential tastes, most economists would argue that it should be regarded as quite unproblematic, given that low income workers are simply choosing, by virtue of their particular tastes, to tradeoff income for some other valuable good (e.g., leisure). This line of reasoning implies that inequality scholars should measure the distribution of opportunities that prevails before differential tastes can express themselves. The main task of an inequality scholar under this formulation is to determine whether “capabilities” (i.e., opportunities to secure rewards) are equally distributed, not whether rewards themselves, which reflect the operation of tastes, are equally distributed (e.g., Sen 2005).

It follows that sociologists and economists have become quite interested, albeit for different reasons, in the study of opportunity and how it is unequally distributed. In most of the resulting research, the liberal ideal of an open and discrimination free system is treated as an explicit benchmark, and the usual objective is to expose any inconsistencies between this ideal and the empirical distribution of life chances. This objective leads, then, to analyses of the net effects of gender, race, and class background on income and other labor market rewards. The size of such net effects may be uncovered

statistically by examining between group differences in income (and other rewards) in the context of models that control all merit based sources of remuneration. Additionally, experimental approaches to measuring discrimination have recently become popular, most notably “audit studies” that proceed by (1) sending employers resumes that are identical save for the applicant’s gender, race, or class, and (2) then examining whether call back rates (for interviews) are nonetheless different across such groups. Although the available statistical and experimental studies all indicate that opportunities are far from equal, there remains some debate about whether or to what extent such inequalities are declining or will continue to decline.

The main reason that long run declines in discrimination might be anticipated is that employers who opt to discriminate (in favor of men, whites, or upper class families) cannot successfully compete against those who select without bias the most qualified and efficient workers (Becker 1957). Furthermore, the spread of egalitarian values renders discriminatory tastes ever more suspect and illegitimate, and indeed some employers now appear to have “tastes for equality” or perhaps even “tastes for reverse discrimination.” The ongoing diffusion of egalitarian values additionally underlies the emergence of equality generating political reform (e.g., affirmative action, anti discrimination law), as well as the rise of bureaucratic labor markets in which hiring and firing is, at least in principle, rigorously merit based. This package of equality generating forces, which is featured in the so called “liberal theory” of industrialism, suggests that economic rationality will ultimately triumph over discrimination and ascription.

At the same time, each of the main forms of unequal opportunity (i.e., race, gender, class) is actively supported by various countervailing forces that make it difficult to predict how quickly, if at all, discrimination will indeed erode away. There are many countervailing forces of this kind, but perhaps the most important ones are (1) the tendency for African Americans to be segregated into ghettos with few jobs and, some would argue, maladaptive cultures (i.e., “segregation”); (2) the continuing cultural presumption that women are best suited

for domestic duties and that men should accordingly invest disproportionately in education, on the job training, and other forms of human capital (i.e., “gender essentialism”); and (3) the presumption that parents have a fiduciary responsibility to their children and should therefore assist them in the competition for good jobs by providing them with economic, cultural, and social resources (i.e., “intergenerational transfer”). These countervailing forces of segregation, essentialism, and intergenerational transfer are seemingly organic features of late industrial stratification rather than simple residues that automatically wither away as economies modernize and rationalize. The key question of our time, and one which remains largely unanswered by the evidence of the last half century, is whether the forces for equality featured in the “liberal theory” are strong enough to overcome such countervailing processes.

stratification: partner effects

Paul M. de Graaf

Partner effects refer to the impact that partners (spouses or partners in consensual unions) have on each other's life chances. In stratification research partner effects especially refer to the ways in which partners affect each other's labor market careers with regard to labor market supply and occupational status. Educational homogamy means that partners are similar with regard to their human capital and thus, *ceteris paribus*, an individual approach would predict a similarity with regard to the labor market careers of partners. However, couples face time budget problems when both partners have full time careers because of the domestic and caring tasks which have to be dealt with, especially when they have children. Couples must decide how to divide the paid and unpaid work, and in this decision process partner effects have proven to be important. The question is: how do partners mutually affect each other's career opportunities?

The notion that stratification research should focus on households and not on individuals has been clear for a long time. However, only recently have the combined status positions of husband and wives, and the interdependencies

in their labor market careers, been the object of research (Blossfeld & Drobnič 2001). Earlier, the status position of male family heads was thought to be decisive for the social status of the family. The status of married women was derived from the status of their husbands, even when the wives held positions in the labor force as well. The traditional family model of a male breadwinner and a female caretaker was dominant, in society just as in social studies. This may have been reasonable in times when most women stopped working when they married or when they had their first child. Since the 1960s and 1970s, however, the number of married women who participate in the labor market has increased dramatically, as has the age at which they enter motherhood. The traditional family model is no longer dominant. The increasing labor market supply of women is the result of a modernization and emancipation process. In this process the educational opportunities of girls and boys have become more equal and the labor market has opened for women.

In many households and families in industrial societies both partners add to the family income, although there is still much cross national variation (Blossfeld & Hakim 1997). In Southern Europe the traditional model is dominant, in Northern Europe many mothers work in part time jobs and some in full time jobs, and in the US dual full time couples are much more common. The possibility of dual careers means that husbands and wives have to decide who is going to work in the labor market and who is going to work in the household, and especially how many hours both partners are going to work inside and outside the household. Economic theory uses an explicit household perspective: it is assumed that decisions are taken by husband and wife together. Exchange theory and bargaining theory argue that individuals pursue their own interests as well, but it is obvious that the household perspective must be taken into account explicitly.

The economic theory of the family (Becker 1981) argues that household and families divide the paid work in the labor market and the unpaid work at home according to the principle of comparative advantage. The partner who has comparative advantage in the labor market will focus on paid work and the partner who has comparative advantage in domestic work

will take care of the home and the children. Although this theory can be seen as gender neutral, it is often believed that wives are more productive in the household and husbands are more productive in the labor market. It is important to note that the human capital investments of young men and women reflect the sex specific division of work in society in the period they are growing up, and thus some continuation of the prevailing division of work can be expected.

Partners affect each other's labor market careers in positive and negative ways. A positive partner effect means that the labor market career of one's partner is a resource to one's own career, and a negative partner effect means the partner's labor market career is a restriction to one's own career opportunities. It is clear that economic theory predicts negative partner effects. If one's partner is doing well in the labor market, he or she has a comparative advantage and there are fewer incentives for the other spouse to be successful as well. Note that economic theory, quite implicitly, assumes that the comparative advantage in the labor market is more important than the comparative advantage in domestic work. Another way to look at the negative spouse effect comes from the (traditional) additional worker hypothesis, that wives have an incentive to work when their husbands are not able to earn a living. This hypothesis may have special value in periods when one salary is not enough to cope with the costs of living.

Social capital theory argues that partners have positive effects on each other's careers. It is obvious that the partner is an important part of someone's network. If one's partner has a resourceful network and if he or she has access to these resources, this network is an important source of information about labor market opportunities. The idea that resources available through the social capital of one's partner facilitate one's own career goes against the mechanism of specialization. A caveat here is that the close relationship between partners might mean that the social capital of one's partner is not much different to one's own social capital. Partners have a strong tie, and thus it may be that the expected positive effect is not large.

A third mechanism has to do with norms about female labor market participation. Since

the more highly educated have less traditional norms about the sex specific division of labor, it will especially be wives of highly educated husbands who will participate in the labor market. It is clear that this would produce a positive partner effect. On the other hand, if a couple has modern, egalitarian values about the division of labor, it may be that the husbands of highly educated wives are more willing to share in home work and refrain from pursuing only their own career. This would lead to a negative partner effect.

Research has shown that, indeed, a husband's income has a negative effect on his wife's participation in the labor market, but that his level of education has a positive effect on his wife's working hours (Bernasco et al. 1998; Blossfeld & Drobnič 2001), and it has been established that the job levels of partners are associated. Effects of wives on husbands are much less clear, partly because they have not been investigated much, probably because the variation in husbands' participation in the labor market is limited.

Although hypotheses on partner effects have been developed to explain the association between the labor market careers of partners, they can be used in a wide variety of other sociological domains, among them the sociology of religion, social aspects of health (e.g., eating and drinking habits, smoking), leisure time behavior, and consumption patterns.

stratification, politics and

David Brady

One can divide this area into how stratification shapes politics and how politics affects stratification. Since at least Marx, of course, scholars have highlighted the reciprocal relationship between these two as well. Stratification in this context has meant a system of class inequality, the processes of class attainment, mobility, and disadvantage, and has involved class identities, mobilization, and structuration (how classes become real and manifest in the experiences, actions, and cultures of class members). Stratification and politics increasingly involves racial and gender stratification as well. Politics, in this sense, involves the collective and individual behavior in regards to the state, public authorities, and powerholders. Politics covers the ground from micro level political ideology to the macro level welfare state. As Wright explains, stratification and politics integrate the micro level interactions of locations, practices, and consciousness and the macro level interactions of structure, struggle, and formation. For our purposes, the focus here is on class voting, class ideology, power resources theory, and the political sources of economic inequality.

Class voting has been one of the most studied areas within political sociology. Early research simply sought to show that the working class was more likely to vote for leftist parties within the advanced capitalist democracies. Indeed, this was the case in the first several decades after World War II, though always less so in countries like the US. Working class voters were motivated by interest since leftist parties supported welfare state expansion and redistribution. In the last few decades, critical scholars began to document a declining tendency for the working class, albeit crudely defined, to vote leftist. Based on such claims, Clark and Lipset answered affirmatively the question, "Are social

classes dying?" Sassoon contends that major reasons for the purported decline include the fragmentation of leftist politics into environmental, gender and racial identity, and social justice movements, and the rising material security and comfort of the working class.

In the past 10–15 years, interest in class voting has revitalized because of methodological and theoretical innovations that led to scrutiny over the decline of class voting. Hout, Brooks, and Manza demonstrated it is essential to use a more sophisticated class schema and measure of class voting than the traditional blue collar versus white collar Alford index. With the Erikson Goldthorpe schema and a measure of the variation in the probability of voting Democrat across the classes (Kappa), they showed that class voting had been stable in the US since 1952. More recently, Manza and Brooks showed that within this stability there have been marked shifts such that the manual working class has become a swing voter, professionals vote predominantly Democrat, while the self employed and managers vote overwhelmingly Republican. A lively debate has continued over whether class voting is in decline in advanced capitalist democracies and in former state socialist societies. The evidence has been mixed, though it is reasonable to conclude that class remains important to how people vote. Despite this renewed evidence for class voting, one emerging challenge is that regardless of whether class voting is stable or not, race and religion may have far more influence on how people vote, at least in the US.

Research on how stratification shapes ideology has remained vibrant for decades. In the 1970s and 1980s, it was common for scholars to use attitude data to examine the patterning of "stratification beliefs" across classes, occupations, and socioeconomic status. Across advanced capitalist democracies, Wright shows that the working class holds much more anti capitalism views, followed by the middle class, while the bourgeois hold pro capitalism views. Interestingly, cross national differences exist in polarization and ideological coalitions. Others show that class, race, and gender shape one's ideology on diverse topics like beliefs about schooling and attainment, job attitudes, poverty and inequality, the welfare state, religiosity, and general moral cosmologies like whether the

world is a just place. These ideologies are a dimension of structuration and a source of class formation, and research in this area has broadened our understanding of why or why not people act politically and mobilize. This research has complicated the assumption that phenomena like class voting are simply a matter of interest (economic or otherwise). Some of the advances in this area have involved the study of how race, gender, and class intersect to shape attitudes. For example, scholars have examined variation in stratification ideologies across ethnic groups and of wives in relation to their husbands and their own class position.

One of the most influential threads in this area is power resources theory. Developed by Korpi, Huber and Stephens, and others, this theory holds that in capitalist societies, the affluent always have greater power than the working class. Since capitalists control the means of production, capitalism distributes greater resources to the elite. Within a democracy, however, the working class can collectively bond together and mobilize politically (e.g., through strikes or voting) to pressure the state to redistribute resources. Thus, the working class's power resources can manifest in labor unions, leftist or social democratic political parties, and even egalitarian ideology. When these power resources mobilize, the welfare state is expanded to ensure that the working class is protected from the insecurity of unemployment, old age, and sickness and the profits of capitalism are redistributed. When an encompassing welfare state is institutionalized, the middle class can become a constituency of beneficiaries that also support the welfare state.

Work influenced by power resources theory has elaborated how politics shape inequality. This work has countered the normal explanation of economic inequality, which focused on the Kuznets curve, economic performance, demographics, and labor markets. Many scholars have shown that advanced capitalist democracies with strong labor unions and powerful social democratic parties have lower poverty and greater social equality. As Brady explained, this is because those power resources channel through the welfare state – causing a more generous welfare state, which then causes reduced poverty. In the labor market, institutions like corporatism (collective labor market organization to

ensure management-labor cooperation, long term planning, and centralized bargaining) and high unionization compress the earnings distribution and raise worker pay. Most recently, scholars have shown that stratification can be driven by the ascent of market fundamentalist, neoliberal ideology and rightist political parties. Rightist parties have ushered in a program of monetarism, privatization, and free markets and have at least sought to dismantle welfare states, labor unions, and social democracy. The rise of rightist parties in Thatcher's Britain and Reagan's US has probably contributed to the Great U Turn of increased inequality since the 1970s. Certainly, the free market ideology of rightist political parties has become quite powerful in the contemporary era after Keynes and state socialism.

Several questions warrant attention for future research. Can power resources mobilize when traditional working class organizations appear to be in decline (and if so, how)? After decades of steady decline, unions seem almost irrelevant in much of the US. As a result, it becomes difficult to envision working class mobilization when class consciousness, structuration and formation, and egalitarianism seem to have been trumped by individualism and political mobilization over cultural, religious, and gender issues. Some recent persuasive research contends that racism and racial divisions are an extremely powerful force undermining public support for the welfare state and working class formation. Though class voting may or may not have declined, it is hard to argue that the working class votes collectively in its economic interest. Because of developments like these, it is harder to sustain an orthodox power resources theory. Potentially, power resources and research on the politics of inequality can benefit from cross fertilization with the aforementioned research on stratification beliefs and ideology. Another interesting question could examine how elites, the upper middle class, and corporate power have cultivated an intellectual establishment for market fundamentalist, free market, and neoliberal opinion makers and public intellectuals. Maybe class politics has not declined per se, but in this era, it might be more about the reassertion of capitalist ideological hegemony in the public sphere. A third question could involve a greater appreciation for the

intersection of race/ethnicity/nationality, gender, and class in the politics of stratification. In many of the egalitarian social democracies and even the mid twentieth century US higher unionization was facilitated by the exclusion of ethnic minorities and the cohesion of relatively homogeneous groups of male workers. In this era of increased immigration, greater ethnic diversity, and the presence of ethnic minorities and women in the workplace and political arena, stratification politics will have to reconstitute itself in order to remain relevant. How and if that can occur is unclear. Finally, unfortunately, the study of stratification and politics, like so much of sociology, continues to neglect many of the world's regions and peoples. Certainly, this field has disproportionately concentrated on the advanced capitalist democracies, and especially the US. Africa, Latin America, and Asia (outside the former Soviet Union and China) definitely deserve greater scholarly attention. Even applying the traditional debates and theories to these regions would be a rare contribution.

stratification, race/ethnicity and

Frank van Tubergen

An important research field in the stratification literature is concerned with inequalities along the ascribed characteristics of race and ethnicity. The term race connotes biological differences among people (skin color, facial features) that are transmitted from generation to generation. As such, these biological differences are seen as permanent characteristics of people. However, the notion of race does not make much sense as a biological concept, because the physical characteristics that make people distinctive are trivial. Even though biological differences are superficial, they are important sociologically. For if people believe that others are biologically distinctive, they tend to respond to them as being different. Furthermore, skin color is transmitted from generation to generation by assortative marriage, a prime sociological phenomenon.

Race is considered a social construct and in that sense incorporated in the more general notion of ethnicity. An ethnic group is a sub population of individuals who are labeled by the majority and by the members of a group itself as being of a particular ethnicity. The term ethnicity refers to the (perceived) historical experiences of a group as well as its unique organizational, behavioral, and/or cultural characteristics. Thus, ethnic groups can be distinguished by their country of origin, religion, family practices, language, beliefs, and values. The more visible the characteristics marking ethnicity, the more likely it is that those in an ethnic category will be treated differently.

Ethnic inequality is documented in different ways. Important aspects of inequality include education (school dropout, educational attainment), the labor market (unemployment, occupational status, income), wealth, housing

quality, and health. These issues are examined at the national level, telling us something about the distribution within a population, and at the individual level, informing us about mobility. Questions on mobility include examinations of the life course of people (i.e., intragenerational) and studies comparing parents and their children (i.e., intergenerational).

The literature on ethnic stratification is divided into three different research lines. The first is concerned with the position of *indigenous populations* that were annexed through military operations and colonization, such as the American Indians in North and South America, Aborigines in Australia, and Maori in New Zealand. The second focuses on ethnic groups that are the offspring of *slaves* or *involuntary migrants*, such as African Americans in America. The third is concerned with the economic position of *voluntary migrants* and their offspring, such as the Italians who moved to the US at the turn of the twentieth century.

Research on indigenous populations has focused on native Indians in the US. The levels of education attained by Native Americans are below those attained by white Americans. Native Americans are under represented in white collar occupations and over represented in service occupations. For example, in 1990 almost 42 percent of Native Americans were employed in white collar occupations compared with 61 percent of white Americans. Native Americans tend to have lower quality housing and lower incomes than whites. Over the last decade the incomes of Native Americans have risen somewhat.

A considerable amount of research on the position of involuntary migrants has focused on the economic position of African Americans in the US. The general assessment is that inequalities between whites and blacks are declining, but still persist long after slavery was abolished. For instance, in 1960, 20 percent of blacks attained a high school degree, compared to 43 percent among whites. In 2000, the figures were 79 percent and 88 percent, respectively. In 1960, 55 percent of blacks were living in poverty; in 2000 this was 23 percent. The black family median income as a percentage of white median income increased from 0.54 in 1950 to 0.68 in 2000.

Research on voluntary migrants has focused on the economic mobility within and between

immigrant generations. Chiswick (1978) argued and indeed found that after a certain time, immigrants of the first generation catch up economically with natives in the US. Borjas (1987), however, showed that the assimilation effect was largely due to lowering quality of (un)observed human capital in immigration cohorts. The intragenerational mobility of immigrants still attracts ample research, and the issue of assimilation remains highly debated. Evidence of economic mobility is more convincing with respect to intergenerational comparisons.

Several studies have compared the economic standing of voluntary migrants, involuntary migrants, and indigenous populations simultaneously. One classical study is by Van den Berghe (1967). He found that hierarchies of ethnic stratification are quite similar in Brazil, Mexico, South Africa, and the US. In all countries, those at the top of the ethnic hierarchy are of European ancestry. These are the offspring of voluntary migrants from Portugal (Brazil), Spain (Mexico), Great Britain and the Netherlands (South Africa), and Great Britain (US). At the bottom of the hierarchy are blacks, who either formed the indigenous population (South Africa) or who were imported as slaves (Brazil, Mexico, US). In the countries of North and South America, native Indians fall in between these two groups. A more contemporary study that compares African Americans and white immigrants can be found in Lieberman (1980).

Different explanations of ethnic inequality have been proposed. Some theories have been applied exclusively to one of the three research fields (voluntary migrants, involuntary migrants, indigenous populations), whereas other ideas have been applied to two or all of them.

The idea of assimilation was proposed by Park and Burgess (1969), worked out later by Warner and Srole (1945) and Gordon (1964), and more recently by Alba and Nee (2003). Although the idea has many variants, the core assumption is that over time ethnic groups will gradually integrate into mainstream society. Thus, it was expected that both within and across generations immigrants and ethnic groups will experience upward mobility to the point that their economic position equals that of the native majority.

Chiswick (1978) provided a human capital explanation for the assimilation idea. The

human capital theory states that people's life chances depend on their human capital, and that people are aware of this relationship and rationally invest in their own human capital. Chiswick argued that immigrants have a weaker economic position at arrival than natives because immigrants have less human capital: they have less command of the host language, fewer occupational experiences, and less knowledge of the host labor market. Because immigrants invest in post school training, gradually learn the host language, and acquire knowledge of the host labor market, they improve their position over time. And because the offspring of immigrants obtain their schooling in the host country and have perfect language skills, their position will outperform that of their parents. In this way, the human capital theory explains why ethnic groups will gradually reach economic parity with natives.

One empirical challenge for the assimilation theory and the human capital interpretation is the observation that economic incorporation differs between groups. Why do some immigrant groups rapidly integrate economically, whereas other ethnic groups, such as African Americans, remain economically at a disadvantage? Borjas (1987) and other researchers have tried to explain these issues with an extended human capital framework, incorporating notions of selective migration and the influence of (unobserved) skills, talents, and motivation. Alternatively, researchers have proposed a number of other theories to explain differences between ethnic groups. These are notions of inheritance, cultural values, discrimination, spatial mismatch, and ethnic capital.

One of the oldest explanations of ethnic group differences is the idea that groups have different biological endowments, which are genetically transmitted from generation to generation. Such biological explanations flourished in the US during the late nineteenth and early twentieth centuries, providing "scientific" evidence of the biological inferiority of non Anglo Saxon groups and justifying their subordinate status. The evidence is typically drawn from studies that compare intelligence test performances of ethnic groups and the native population. One recent example is Herrnstein and Murray's *The Bell Curve* (1994), in which they claim that African Americans and Latinos are less

intelligent than whites and for that reason have a lower economic standing. As with other studies that are informed by notions of inheritance, their study was heavily criticized by psychologists and sociologists on theoretical, methodological, and empirical grounds. For instance, contrary to the statement of Herrnstein and Murray that the race–intelligence link is stable over time, researchers showed that intelligence test scores of blacks and numerous ethnic groups improved dramatically over the course of the twentieth century. Overall, most researchers nowadays conclude that inheritance is unable to explain ethnic stratification.

Another, more sociological explanation of group differences in ethnic stratification is concerned with cultural values. Echoing the Weberian notion of the Protestant work ethic, Sowell argues in *Markets and Minorities* (1981) that Asians are model minorities at school and in the labor market because of their cultural traits of effort, thrift, dependability, and foresight. By contrast, the disadvantaged socioeconomic positions of African Americans, Latino Americans, and American Indians today are portrayed as a consequence of their cultural characteristics, which are perceived to be incompatible with a modern industrial society. The cultural approach of Sowell was criticized by several researchers, most notably Steinberg in *The Ethnic Myth* (2001).

Another cultural explanation of ethnic group differences is the hypothesis of “oppositional culture,” which argues that black youth develop an oppositional identity relative to whites because they focus on their parents’ past experiences of discrimination. As a consequence, blacks distrust the dominant society and develop distinct cultural norms in which they reject schooling as a route to socioeconomic mobility.

Many researchers use notions of discrimination to explain group differences in ethnic stratification. Two different types of ethnic discrimination (i.e., the unequal treatment of minority groups) are outlined: attitudinal and institutional. Attitudinal discrimination refers to discriminatory practices influenced by prejudice. Research shows that prejudice, and, in turn, discrimination, tends to increase when ethnic groups are perceived as threatening to the majority population in terms of cultural, economic, or political resources. Ethnic groups

that are numerically large and that are distinct culturally are especially vulnerable to discrimination. This led to theories about ethnic competition and split labor markets. Another important theory is that of statistical discrimination.

Institutional discrimination refers to rules, policies, practices, and laws that discriminate against ethnic groups. This type of discrimination is used to explain the economic difficulties that African slaves and their offspring experienced in the US. For instance, through the first half of the twentieth century, they were formally excluded from acquiring or inheriting property, marrying whites, voting, testifying against whites in court, and attending higher quality schools. Contemporary evidence on institutional discrimination is provided by Massey and Denton (1993).

Researchers have argued that group differences in ethnic inequality can be explained by the residential concentration of ethnic groups and regional variations in economic opportunities. One influential idea states that the economic opportunities of blacks are hampered because they live in inner cities. In *The Declining Significance of Race* (1981) and *The Truly Disadvantaged* (1987), Wilson maintained that the economic position of the black inner city poor has deteriorated because of structural economic changes, including change from goods producing to service producing industries, increased industrial technology, and the flight of industries from central cities. The process of deindustrialization has created an economic mismatch between the available jobs and the qualifications of inner city residents, predominantly blacks. As a result, the economic position of the African American urban poor is diminishing.

Another argument stresses the role of social or “ethnic” capital, that is the resources that are available to a person through their relations with others. A highly debated issue in this respect is whether “ethnic enclaves,” in which ethnic capital is shared, promote the economic incorporation of ethnic groups. Authors have argued that more sizable and geographically concentrated ethnic groups develop an independent, mono ethnic labor market in which their members can obtain positions otherwise held by the native majority. In ethnic economies the returns to human capital are expected to be higher than outside the ethnic economy.

Various research designs have been used to study ethnic stratification. The classical design is the case study, in which a single ethnic group in a single receiving context is examined. Because this design provides little information on contextual effects, comparative macro designs have also been developed. One such popular framework is the "comparative origin" method, which compares multiple ethnic groups in a single location, yielding important insights into ethnic group differences. Similarly, researchers have paid attention to the role of the receiving context by comparing a single ethnic group across multiple destinations, such as cities or nations ("comparative destination" design). More recently, these macro approaches have been combined into a "double comparative" design, which studies multiple origin groups in multiple destinations simultaneously. This design provides a better understanding of ethnic origin, the receiving context, and the specific interaction between origin and destination ("ethnic community").

Another methodological development in the literature is to rely on dynamic designs. Initially, researchers compared the position of ethnic groups at a single point in time (e.g., by relying on a single cross sectional survey). By pooling cross sectional surveys that are apart in time, researchers were able to disentangle assimilation effects from cohort effects ("synthetic cohort design"). Dynamic designs have been improved further by the appearance of panel surveys on immigrants.

In general, three different measures of ethnicity are used: country of origin, nationality, and ethnic self identification or subjective ancestry. Country of origin and nationality are often used to study *voluntary* migrants. A drawback of using nationality as a measure of ethnicity is that voluntary migrants who are successful in the labor market are more likely to naturalize, leading studies on nonnaturalized migrants to underestimate their economic performance. For that reason, researchers generally prefer the country of origin of the respondent, the parents, and the grandparents.

Research on *involuntary* migrants and *indigenous* populations generally relies on ethnic self identification and subjective ancestry. These measures are problematic for several reasons. First, like nationality, ethnic self identification

is partly an outcome of people's economic position, leading the more successful people not to identify with their lower status ethnic background. Second, ethnic and racial boundaries and self identified characterizations change over time. For instance, previously "non white" ethnic groups such as Irish and Italians became "white," often by deliberately distinguishing themselves from blacks. Third, subjective measures of ethnicity assume a single identification, whereas, through intermarriage, a considerable proportion of the population has multiple identifications.

In many countries, general population surveys or specific immigration surveys contain questions on country of origin or nationality, providing a wealth of data for studies on *voluntary* migrants. Large scale surveys rarely contain subjective measures of ethnicity, leading to fewer data sources available for the study of *involuntary* migrants and *indigenous* populations. An exception is the census of the US. As an alternative, several researchers have conducted small scale or qualitative studies to examine these populations.

Researchers nowadays agree that ethnicity plays a role in people's life chances, that ethnic groups gradually improve their economic standing across generations, and that the process of assimilation can be interpreted in terms of human capital accumulation. At the same time, it is found that assimilation rates of ethnic groups vary. Initially, researchers have relied on theories of biological traits and cultural dispositions to explain such group differences, but they have been largely replaced by extensions of the human capital theory, ideas on discrimination, the concept of ethnic capital, and spatial differences in economic opportunities. In recent work, researchers have combined the theories explaining group differences with micro level approaches explaining individual assimilation.

Methodologically, as more large scale data become available, researchers increasingly prefer to use comparative research methods rather than the case study. Much of the classical and contemporary work on ethnic stratification has been done in the US, but research in other countries is rapidly growing. This opens the possibility of comparing patterns of ethnic stratification cross nationally, possibly also including ethnic groups in developing countries.

Another important direction of future research is the development and application of dynamic research designs to study ethnic mobility.

stratification systems: openness

Wout Ultee

All societies are stratified, but some more so than others. Perhaps the most visible variable feature of a society's stratification system is the difference in the standard of living of its

inhabitants at a particular point in time. Nowadays, most advanced industrial societies regularly publish statistics on yearly household income, such as the share of all incomes going to the top 20 and bottom 20 percent of all households. Statistics on the causes of income differences are published on a regular basis too, such as figures on inequalities in household wealth, the relation between wealth and income, and the returns to education in terms of income.

For sociologists, these measures fail to capture an important aspect of a society's stratification system: the degree to which it is open or closed. If households are made up of dual earner couples and the two partners have different incomes, this equalizes the income shares of quintile groups. To the extent that such marriages occur, a stratification system may be said to be open. But what if the individual income shares of quintiles do not change over time? Stability at the societal level does not imply that incomes of individuals remain the same: there may have been an exchange of persons between quintiles. That is why individual or household mobility, along a criterion like income, is also an important aspect of societal openness for sociologists.

Of the classical sociologists, Max Weber most clearly conceived of societal stratification as a process comprising less advanced and more advanced stages of closure. In a society consisting of strata that can be ranked according to some principle from higher to lower, those within a stratum may combine so as to limit the number of newly entering persons, in tacit or explicit cooperation with state authorities and employers. This happened in some countries during the second half of the twentieth century with respect to occupations such as general practice and printing. Medieval guilds also limited the number of new entries and strengthened exclusion by granting sons the right to succeed their fathers. A stratification system is even more closed if the members of two different societal strata do not intermarry. In Europe, the marriage of a member of the nobility with someone from another estate was at least a *mésalliance*. Weber pointed out that the Southern states of the United States forbade marriages between whites and blacks by law around 1900. The sanction against marriages between members of different classes went further in Hindu

India: according to Weber, in the India of his day a child born of a marriage between two castes belonged to a caste lower than either of the castes involved in the marriage. Compared with medieval estates, religion and magic discouraged mixed marriages. It may be added that Nazi Germany went even further: after forbidding marriages between Aryans and Jews, it sought to discourage friendly association between Aryans and Jews by refusing Jews entry to public meeting places like restaurants and cinemas. In the end, Nazi Germany destroyed Jews in specially built gas chambers. Weber referred to the phenomenon of who marries whom as *connubium*, and that of who befriends and shares meals with whom as *convivium* and commensality.

Turning to contemporary sociologists, Lenski (1966) distinguished stratification systems by the number of dimensions along which a society's members may be ranked from more to less advantaged in life chances and endowment in resources (complexity). As the position of a person on the various dimensions need not be the same, inconsistency is another aspect of a society's stratification system. The range of variation along one dimension Lenski called *span*, and movement along one dimension he labeled *mobility*. Lenski hardly focused on *connubium* and *convivium*.

Several recent studies attest that in advanced industrial societies with higher income inequalities, mobility is less widespread on average. This was established by Erikson and Goldthorpe (1992) for a dozen advanced industrial societies by way of odds ratios for the relation between father's and son's social class. It has been held that the United States has high income inequality and high mobility, but recent figures seem to indicate that for this country father and son earnings mobility, as computed over a period of several decades, is less widespread than in Sweden and Finland, two countries with limited income inequality. Lipset and Bendix (1959) took father-son mobility and assortative marriage according to broad occupational groupings as interchangeable indices of societal openness. Ultee and Luijkx (1990) established, with figures for 23 advanced industrial societies from around 1970, that greater father-son mobility across the manual/non manual divide goes hand in hand with more educationally mixed marriages.

stratification: technology and ideology

Nazneen Kane

Several theories of social stratification have emerged from the discipline of sociology. The ultimate focus of this body of knowledge has quite clearly been the production of a comprehensive understanding of inequality within and across human societies over time and place. Yet, few theories have constructed adequate working models of stratification that satisfy geographical and historical particularities.

Gerhard Lenski's ecological evolutionary theory of social stratification, however, has quite adequately addressed the research question and has come closest to attaining the goal. His theory was, for the first time ever in the discipline, able to provide a causal explanation of *how* things came to be (Huber 2004). Indeed, Lenski's ecological evolutionary theory attempts to comprehensively explain the ultimate and proximate causes of societal differences. Although Lenski addressed many realms of societal difference, the focus here is specifically on the relationship

between subsistence technology, ideology, and social stratification.

SUBSISTENCE TECHNOLOGY → IDEOLOGY

The theory argues that subsistence technology, “The technology that is used by the members of a society to obtain the basic necessities of life” (Lenski & Nolan 2004: 366), is the key factor in making possible (but not determining) societal differences, including the level of stratification within and across societies. Within societies, ideology, defined as “cultural information used to interpret human experience and order societal life,” is then developed in attempts to understand the existing material conditions (p. 363). The main premise of the theory is that societal differences “begin in the realm of technology and extend into almost every other sphere of life” (Lenski 1966: 144). Because the level and form of technology vary across societies, so too does ideology. In short, changes in stratification levels are dependent upon shifts in subsistence technology (Lenski & Nolan 2004). For example, the shift from the wooden digging stick of simple horticultural societies to the metal hoe of advanced horticultural societies also allowed for an increase in economic inequality. Ideologies may then also shift and are often used by elites to legitimate unequal distributions of power and wealth. For example, US slavery was often legitimated by racist ideologies of black inferiority. Thus, the nature and formation of class stratification and other trends in social inequality are all shaped primarily by subsistence technology.

TYPES OF HUMAN SOCIETIES

Hunting and gathering society (average population size: 40; approximate date of first appearance: 100,000 BCE). The subsistence technology of hunting and gathering societies is described as that which can be derived from nature. Wood, bones, and stone are used as tools for survival. Hunting and gathering societies have little or no economic surplus because of their nomadic character and limited subsistence technology. Sharing is the norm and resources are readily available in nature. These societies

consequently experience relative equality in terms of distribution of goods and services.

Inequality in hunting gathering societies varies but is generally limited to “functional inequality” (Lenski 1966: 105). That is, the elderly, those attributed with possessing super natural powers, and those with exceptional hunting capabilities are often afforded greater prestige. In general, however, there is very minimal inequality in power, wealth, and privilege and those prestige inequalities that do exist are mainly individually based. The accompanying ideology is often animism, the religious belief that spirits inhabit everything in nature, and is used to explain this prestige inequality. The dominant belief is that those individuals imputed with prestige are more in tune with the rituals of the spirits and are blessed as they please these spirits (Lenski & Nolan 2004: 98). In sum, due to the limited subsistence technology, hunting gathering societies are relatively equal with little prestige inequality, and ideology has little effect on societal change.

Simple horticultural society (average population size: 1,500; approximate date of first appearance: 8000 BCE). In the gardening economy of simple horticultural societies, the digging stick is the basic subsistence tool. Because land and tools are readily available to any member of society who is willing to put forth the effort, there are no significant inequalities in material possessions. There are, however, both more and varied possessions as compared to hunting gathering societies. This increase in possessions is due to the fixed character of simple horticultural societies. The digging stick allows for gardening, which in turn decreases reliance upon hunting and stabilizes communities in terms of movement. It is this increased permanence of settlement that is associated with ideology emphasizing the importance of kinship and the increasing incidence of ancestor worship and religious rituals.

Simple horticultural societies demonstrate the population/surplus dialectic. That is, permanency of settlement allows for food surplus, making possible a population increase. In turn, population increase also allows greater productivity. Fixed communities can accumulate more possessions, and a larger population allows for some members of society to specialize in production of goods such as tools, clothes, pottery,

and baskets as “leisure” time becomes more prevalent. This leisure is said to allow for ceremonial activities, warfare, and political organization. Social inequalities become more pronounced as society becomes increasingly hierarchical with political subordinates, slavery, wealth inequality (often in the form of wives), and prestige inequality. Forms of prestige are broadened to encompass not only hunting and spiritual recognition, but also political and military prowess.

Advanced horticultural society (average population size: 5,250; approximate date of first appearance: 4000 BCE). In advanced horticultural societies, “inequality is carried to a level far beyond anything ever observed in technologically less developed societies” (Lenski 1966: 154). Indeed, it is in advanced horticultural societies that substantial differences in social inequality emerge. Lenski attributes this to the shift in subsistence technology, from the digging stick to the metal hoe. Metallurgy is the distinguishing technological difference between simple and advanced horticultural societies.

The metal hoe allowed for increased efficiency and permanency of settlements as it could reach nutrients previously unreachable by the digging stick. Consequently, soil was not exhausted as quickly and plots of land could be utilized for longer periods of time. This allowed for greater food production, an increase in population, greater specialization, and a more complex political organization.

The increased complexity and growth of the government led to state building. Those linked most closely to the king tended to make up the small warrior nobility who became increasingly distinguishable from the mass of commoners. The primary determinant of status in advanced horticultural society is the relationship of an individual or group to the king. Metal weapons allowed for successful militaries that not only subjected and controlled the common population, but also allowed for empire building and the subjection of more distant communities. Those privileged in the state hierarchy tended to live in walled urban centers and controlled the redistribution of resources. Redistribution was not equal and often led to severe exploitation of those working the land.

Wealth, privilege, and status are directly tied to this distribution of goods and services.

Extreme exploitation of the king’s subjects, a numerous class of slaves with no legal rights, human sacrifice, and the exchange of women are all prevalent in these types of human societies. Lenski and Nolan (2004) argue that it is in these types of societies that ideology begins to play a major role in societal development. Traditional beliefs in the cult of the warrior often led to increased warfare, and hence further shifts in societal development.

Agrarian society (average population size: 100,000; approximate date of first appearance: 3000 BCE). Horticultural societies often evolved into agrarian societies. In this fourth type of human society, the distinguishable subsistence tool was the plow and the harnessing of animate energy. With this major technological shift, cultivated fields replaced gardens, population size greatly expanded, and food production increased (Lenski 1966). “The net effect of all these innovations was the substantial enlargement of the economic surplus. Under agrarian conditions of life, far less of the total product of man’s labor was required to keep him alive and productive, and hence more was available for other purposes” (Lenski 1966: 193).

“Other purposes” often meant a greater division of labor and developments in arts, crafts, and particularly in military technology and war, i.e., the strengthening of the state. The simultaneous growth of economic surplus and government meant elites were controlling that surplus. This interdependency of economics and politics allowed significant forms of stratification to emerge (Lenski & Nolan 2004).

A greater division between the governing, landowning, urban literate class and the illiterate rural mass was salient. In many of these societies, peasants were required to give all produced surplus over to elites, exacerbating class inequality to unprecedented levels. Military forces were often used to extract taxes and goods and to control the peasant population. This economic and political control was often justified through appeals to religion. Religion, in fact, becomes a major site of ideological control. Universal faiths such as Buddhism, Christianity, and Islam emerged, and while it was during this era that church and state began to separate, elites remained closely tied to clergy, often giving them land grants, tax exemptions, and generous financial support. Clergy defended elites,

justifying their privilege through appeals to divinity and lineage (Lenski & Nolan 2004). Ideology was in this way a tightly controlled outcome that was continually reconstructed to legitimate the status quo. In sum, following the subsistence pattern, as stratification in agrarian societies increased in complexity and inequality, so too did ideology transform.

Industrial society (average population size: 17 million+; approximate date of first appearance: 1800 CE). Industrial society is marked by the technological shift from human and animate energy to machine technology. Industrialization is revolutionary in that the trend toward increasing inequality reverses itself. While the “range of possibilities for inequality” has increased and the stratification system has become more complex, the standard of living for the average person simultaneously increases (Lenski & Nolan 2004: 257). Lenski argues that these changes led to greater specialization, occupational stratification, greater organizational complexity, growth of government, and a rise in market economies. Indeed, specialization meant an increase in societal interdependence, and hence the rise of a moneyed capitalist economy. From these changes come a series of short and long term societal changes. For example, within industrial societies, opportunities for participation in political decision making have broadened, income inequality has been reduced, and “the overall level of inequality in industrial societies is considerably less than that in agrarian societies of the past, or in most nonindustrial societies in the world today” (Lenski & Nolan 2004: 271). However, Lenski also argues that inequality between the rich and poor nations of the world is increasing, as the wealthy consume considerably more of the world’s wealth and resources.

Because of the vast increase in economic surplus and consequential socioeconomic transformations, ideologies seemingly shift to make sense of these changes. New secular ideologies such as democracy and capitalism replaced the traditional beliefs of many (Lenski & Nolan 2004). Such ideologies defended free market policies and the interests of wealthy business enterprises. Economic surplus increased, however, unlike the previous trend of increasing economic inequality, and wealth and income were no longer as unequally distributed,

according to Lenski. From this idea came an important line of work concerning the relationship between stratification systems and democracy (Hewitt 1977).

In sum, Lenski’s theory of human societies explains not only what society *is*, but *how* and *why* it came to be. Subsistence technology is, for Lenski, the ultimate cause of societal difference. The type of technology used to ensure survival is a necessary precondition for the significant increase in the size and complexity of society. Subsistence technology, then, is not necessarily a determinant of societies, but rather limits what is possible and is the main explanation for great intersocietal (dis)advantage.

Although Lenski does recognize societal variation, his ecological evolutionary theory provides a general and extensive theory of human societies. From it has emerged a small but significant body of work such as that produced by Joan Huber and Rae Blumberg, both of whom have extended the theory to better understand sex and gender stratification. That an entire issue of *Sociological Theory* (Vol. 22, June 2004) was devoted to Lenski’s life, career, and social thought is evidence of this. Lenski’s theory of social stratification is not without criticism and much future work remains to be done. Further, Lenski’s work sits awkwardly next to sociological theories of *post* industrial society and postmodernity, a societal type not theorized by Lenski. However, as Patrick Nolan says of Lenski’s theory, “a good theory should provoke more questions than it answers” (2004: 336).

stratification in transition economies

Péter Róbert

Although one could argue that all economies are in transition, permanently, from one state to another, this entry will focus on former socialist societies, which have undergone a post communist transition both in a political and a socioeconomic sense. Accordingly, economies that experienced a transition to democracy but not to a market economy (e.g., countries in South America) are not considered. Thus, this entry provides information on developments in social stratification in societies as a consequence of political and economic changes since the collapse of socialism at the end of the 1980s.

The sociological context is a change in mechanism, which creates social inequalities and generates stratification in socialist planned economies and in capitalist market economies. Former socialist societies represent good test cases for studying these different mechanisms because the same nations with their historical and sociological characteristics can be observed before and after the transformation, in a situation dominated earlier by socialist *redistribution* and later by the capitalist *market*. With respect to these two mechanisms, the basic assumption is that inequalities under socialism are generated by the redistribution and reduced by the market, while inequalities in market economies are produced by the market and decreased by state intervention (Manchin & Szélenyi 1987; Szélenyi & Kostello 1996).

A more elaborated and detailed set of hypotheses referring to different elements of this transformation process has been developed by Nee (1989) as market transition theory (MTT). One of its assumptions is the *market power thesis* and it expects that the power of the former communist cadres or party members will be replaced by the new power based on market ability. The persistence or feebleness of the advantageous position in the former redistribution system is one of the key issues in stratification of transitional economies. This research question focuses on the elite in these societies and formulates two alternative hypotheses. The first, in accordance with MTT, predicts an elite circulation by assuming that the new elite of transforming societies will replace the former (communist) elite. The second hypothesis expects less circulation but more reproduction and predicts that the former cadres will be able to convert their political capital into economic capital (Hankiss 1990; Staniszkis 1991; Szélenyi & Szélenyi 1995). A further elaboration of this latter hypothesis adds that only those members of the nomenklatura who have cultural capital and good educational credentials can successfully move from political positions into economic ones.

Another element of MTT is called the *market incentive thesis* and it expects that educational investments will obtain higher financial returns. One of the main features of socialist stratification used to be the low returns to human capital investment (i.e., professionals like engineers, teachers, and doctors were not paid much better than the manual, skilled labor force). Nevertheless, the level and field of education strongly determined occupational chances in these societies, in line with how the planned economy worked under socialism: when leaving the school system, young people could find a job that suited their studies and labor market mobility was restricted even later during further careers.

Another element of MTT focuses on the role of the emerging private sector. The *market opportunity thesis* assumes that individual ambitions, aspirations, and habitus were hindered under socialism when people were employed in big state owned, inefficient firms, but individual capabilities will lead to higher social status and more salaries when working in the

private sector for private companies or as an entrepreneur in one's own business. With respect to the new entrepreneurship under post communism, Szélenyi (1988) formulated the interrupted embourgeoisement theory. This hypothesis predicted that the offspring of previously bourgeoisie families with appropriate habitus, ambition, and some material capital, who were forced to stay in the "parking lot" under decades of communism, would get into a private market position during the transition process.

MTT expects a kind of *meritocratic* change, which restructures the stratification system of the transition economies. Former merits connected to political trustfulness are replaced by other personal credits like education, ambition, and hard work and these merits will basically determine individuals' status attainment. During this process the stratification of transition economies gets closer to the stratification of advanced market economies. This does not mean, however, that former socialist countries transform simply into capitalist states. Their past and historical roots and experiences influence the transition process in every element of the emerging markets in these countries (Stark 1992).

Two major structural shifts strongly influenced the stratification in transition economies. First, in consequence of privatization, employment in the public sector has shrunk and became restricted to such sectors as health, education, and governance, while employment in the private sector has increased. Privatization techniques varied in the different countries, but a *decrease* in the size of firms and an *increase* in their number is a common feature. The big state owned companies could not be privatized in one step; they were split into smaller units and smaller private enterprises have been established. At the same time, the old economic structure dominated by heavy and light industry went through a crisis; post industrialization obtained a push, with new private companies in the service sector, finance, trade, social services, personal services, etc. Second, transition economies, which were characterized by full employment, experienced a huge drop in economic performance and employment in the first half of the 1990s. The new private owners rationalized companies' economic activities and

dismissed part of the labor force. A class system of cadres and workers turned into a dichotomy of *winners and losers*.

With respect to the winners, post socialism brought new political and economic prospects for a definite group of people. The political elite expanded as the multiparty system replaced the one party system; the new democratic parties opened up new political positions as well. Privatization increased available managerial positions, since the big state owned firms turned to several smaller companies, generating special upward mobility paths – a step forward for those who had occupied lower positions. Characterizing this process, some talked about the "revolution of deputies" (Kolosi 2002), others about the rise of managerial capitalism (Eyal et al. 1998). In any case, occupants of the new political and economic elite positions did not come from the "bottom" of society; they had been in good positions either in the redistributive hierarchy or in the quasi market of the socialist second economy. Thus, empirical evidence does not fully support either the elite circulation or the elite reproduction hypothesis based on former party position, and the interrupted embourgeoisement theory cannot be confirmed either. However, human capital, cultural capital combined with social capital (useful network relationships), helped to maintain advantages in the transition economies, as analysis of privatization reveals (Stark & Bruszt 1998).

As for the losers, their largest group consisted of employees of former big industrial state firms who were not well educated, had restricted skills, and were too old to learn something new and to adapt to the changes. After being dismissed, if they were not able to find a new job, the unemployed went frequently to disabled pension or to old age pension. The hope that the emerging private service sector could provide jobs for everybody who had been dismissed from state industry turned out to be an illusion. Though women could find a job more easily in the service sector, in most transition economies they are over represented among the unemployed. Early pension programs were an escape for the older representatives of the former political and economic elite without appropriate human and cultural capital. However, unlike manual workers, these former cadres received a

specific high allowance when they had to leave their advantageous positions. The level of unemployment is still substantial in several transition economies, but it is not the main reason why the official employment rate is lower in most of these countries. The black economy is also widespread and it employs a sizable fraction of the labor force. Since young school dropouts have difficulty finding a legal job, both unemployment and black employment persist.

Education also takes a leading part in generating stratification in transitional economies. As expected by the market incentive theory, human capital investments have higher returns and tertiary diploma holders especially are better paid. Although transition economies experienced great educational expansion, the tertiary level of schooling pays well, especially if the diploma is obtained in some developing field and if one is employed in the private sector. Nevertheless, the level of schooling of the labor force is still lower in transition economies than in OECD countries. Even with higher income returns in comparison to the socialist era, salaries in transition economies are significantly lower than in developed market economies, while consumer prices are not that much lower. With the lower purchasing power of wages, differences in salaries play a greater role in generating stratification. Income differences used to be low under socialism and increased considerably during the transition. Income differences are still not extremely high, but living on a low income means greater poverty in an absolute sense. Low education is the strongest factor in decreasing the chances of finding a job and increasing the likelihood of becoming unemployed and consequently living in poor conditions.

The occupational distribution of the labor force indicates similar tendencies to those in developed market economies: the proportion of agricultural laborers decreases, employment in the service sector and the percentage of the "service class" (managers and professionals) increases (Domanski 2000). A typical feature of the structural changes was the rapid increase in the numbers of self employed. Entrepreneurship is a mixed category in transition economies; the distinction between winners and losers is relevant here, too. For some, the market opportunity thesis holds because some people benefited from the transformation: they had the

opportunity to follow their ambitions, motives, and habitus for becoming private entrepreneurs and now they earn more and live in better conditions. Others, however, were simply forced into self employment because nobody wanted to employ them, as the employee–unemployed–self employed sequence indicates in some research on occupational careers.

A further characteristic of the stratification in transition economies is increasing flexibility. Atypical forms of labor force participation emerged, such as self employment, part time work, and employment with fixed term contracts. This caused growing uncertainty, further increased by the collapse of the safety net and the decline of the state in compensating social inequalities.

stratified reproduction

Amy Agigian

Stratified reproduction is a term originally coined by Shellee Colen in her classic 1986 study of West Indian nannies and their (female) employers in New York City, which found inequalities of race, class, gender, culture, and legal status played out on a social field that was both domestic and transnational. Colen elaborated the term in her later work to describe situations in which women perform physical and social reproductive labor structured by economic, political, and social forces and differentiated unequally across hierarchies of class, race, ethnicity, gender, and place in a global economy (Colen 1995). Many feminist social scientists since the 1980s have adopted stratified reproduction as a theoretical framework within which to examine a variety of issues relevant to the intersections of reproduction and stratification.

The term stratified reproduction implicitly acknowledges both the sexual politics and the political economy of reproduction. In this way it derives from, and elaborates on, second wave feminist concerns with removing childbearing (biological reproduction) and domestic labor (social reproduction) from the realm of the “natural” and placing them squarely under critical, social scientific analysis. Researchers of stratified reproduction continue the feminist project, demystifying still relatively unexamined gender relations and gender inequalities, particularly those related to procreation and

carework. Prior to second wave feminism, social and biological reproduction – pregnancy, childbearing, childcare, housework – was undertheorized within sociology and seen largely as private and “natural,” as opposed to political and socially constructed (Laslett & Brenner 1989). Scholars of stratified reproduction examine the ways that reproduction is stratified within and across cultures, with particular attention to the transnational organization of reproduction. For example, Ehrenreich and Hochschild examine global flows of nannies, maids, and sex workers, while Inhorn (2002) analyzes the gendered and cultural impact of “western” reproductive technologies in Egypt. Since reproduction is so inextricably entwined with women’s bodies, the political reverberations of the study of stratified reproduction are immediate and often radical. As with other analyses of sexual politics, injustices in people’s intimate and private lives become apparent. Similarly, the stains of both colonialism and eugenics on current global hierarchies of embodiment become unavoidable.

As a social scientific framework, stratified reproduction has enabled scholars across fields including sociology, history, political science, and especially anthropology to examine power relations and inequalities in the realm of reproduction. Inherent in this framework is the understanding that certain kinds of reproduction are privileged, encouraged, and supported, while others are stigmatized, discouraged, and oppressed. As Ginsburg and Rapp (1995: 314) note, “Throughout history, state power has depended directly and indirectly on defining normative families and controlling populations.” In this understanding, reproduction is shaped by struggles among and within powerful institutional forces such as the state, global capitalism, religion, and gender hierarchies. Reproduction can be, and is, stratified along multiple axes of social status and exclusion. Relevant inequalities include gender, race, class, nation, sexual orientation, age, health and disability status, and legal status. Such social inequalities are played out dramatically in differential access to and use of reproductive technologies such as fetal screening, prenatal care, donor sperm and eggs, and a choice of skilled birth attendant, as well as in reproductive sites such as surrogacy and genetic counseling.

Stratified reproduction can also be seen in the policy realm when some forms of reproduction are encouraged and resourced while others are stigmatized and discouraged. Some children are considered highly worthy of being born, and considerable resources are used to enable their births (e.g., through in vitro fertilization made available to affluent, predominantly white heterosexual couples), while others are strongly discouraged (e.g., through welfare policies that impose "family caps" limiting the subsistence income of poor mothers who have children). Some women are seen as reproductive threats to society and "reproductive sinners" by virtue of their race, class, and/or other characteristics. For instance, Chavez (2004) analyzes popular discourses about the presumably dangerous sexuality and procreation of Latina women in the United States. Roberts (1997) documents the brutal impact of US welfare laws that punish poor, African American women for having children. Conversely, other women are seen as potential "reproductive saviors" of the state, ethnic group, religion, and/or normative family. Kahn's (2000) study of the use and regulation of reproductive technologies in Israel, for example, finds that a strong pronatalist ethic outweighs concerns regarding the potential social disruption occasioned by the new forms of assisted reproduction. Another group that is encouraged to procreate, though in a very different way, is Ivy League educated, white, blond, tall, "healthy" young women, who are paid tens of thousands of dollars to sell their eggs on the global market. While these incentives and disincentives to procreate may appear to be unrelated phenomena, the theoretical framework of stratified reproduction promotes articulation of the important links among them.

The lens of stratified reproduction overlaps and differs in significant ways from other sociological approaches to the study of reproduction. For example, while it may use demography to understand trends in transnational caregiving, stratified reproduction emphasizes the political and cultural forces shaping migratory caregiving, the care deficits left behind in regions vacated by third world caregivers when they depart for first world households, and the ways that paid caregiving reinscribes patriarchal power in high earning, heterosexual, two career households. Similarly, studies of stratified

reproduction in alternative insemination demonstrate how racial, class, homophobic, and phenotypic hierarchies are inscribed in the practices of sperm banking and sperm selection.

Research regarding stratified reproduction tends to favor qualitative methodologies. In depth, on the ground studies of particular sites of stratified reproduction are the bases for the development of theoretical frameworks as well as for claims about the importance of reproduction to all social theory. *Conceiving the New World Order* (1995), edited by feminist anthropologists Faye D. Ginsburg and Rayna Rapp, was a pivotal book in articulating the significance of stratified reproduction as a framework for the burgeoning work of feminist social scientists on reproduction. The second section of the book, "Stratified Reproduction," suggests something of the concept's scope. In addition to Colen's work there are chapters on lesbian motherhood (Lewin); the politics of race, class, and gender in female headed households (Mullings); and early childbearing (Ward).

The use of the theoretical framework of stratified reproduction appears to be well on its way to becoming mainstreamed in the sociological study of areas including procreation, transnational carework, and reproductive technology.

stress and health

Jeffrey E. Hall

Stress is an emotional psychophysiological state that occurs in a situational context when an individual is confronted with cues that elicit fear or anxiety responses. Medical sociologists are interested in stress because the situations that cause it are often social and increase a person's risk of disease by taxing or exceeding his or her adaptive capacities (Wheaton 1994). Admittedly, the word stress has other connotations, but this view captures the essential facets of an extensive body of research that has been expanding for almost a century.

THE STRESS PROCESS

Although various stress process models exist, they generally involve (1) a stimulus problem, (2) a processing state where information regarding the stimulus is organized, and

(3) some form of response. The first stage of the stress process involves the presence of stimulus problems or "stressors" consisting of environmental, social, and internal demands that challenge adaptive abilities and call for behavioral adjustments (Holmes & Rahe 1967). The content of stressors varies greatly depending upon individual and group circumstances. For example, adaptive abilities may be significantly challenged by (1) the loss of a job or the death of a loved one; (2) minor but regular annoyances, such as traffic problems and inconsiderate neighbors; (3) enduring exposures to urban problems, such as crowding, environmental pollution, and high rates of crime and unemployment; or (4) disruptive experiences, such as unemployment, war, and acts of terrorism. Such categories of problems are, respectively, labeled life events, daily hassles, chronic strains, and traumas (Pearlin 1989; Thoits 1995). These categories have emerged out of research identifying and measuring stressful stimuli.

Once a stressor is encountered, information regarding the stimuli is evaluated in preparation for the selection or elicitation of a response. Specifically, the threat potential of stressors is assessed and determined based upon the meanings given to these occurrences within specific social contexts (Lazarus & Folkman 1984). This segment of the stress process is termed primary appraisal; the results of activities here vary according to stressor features such as the intensity and controllability of the stimulus and individual traits like personality dispositions.

Logically, appraisal activities also include actions of a secondary nature, hence the use of the term secondary appraisal. Entry into this phase of appraisal is initiated after it is determined that some form of response is needed. Possible responses may include the generation of (1) coping or (2) stress responses. Coping responses are actions that "help individuals maintain psychosocial adaptation during stressful periods; [they] encompass cognitive and behavioral efforts to reduce or eliminate stressful conditions and associated emotional distress" (Holahan et al. 1996). During secondary appraisal, coping repertoires (the possible strategies for dealing with problems) are evaluated first to determine the feasibility of eliminating stressors or reducing their aversive impacts.

If an appropriate coping response is available and perceived as a potentially effective means of dealing with a stressor, then the negative affects of the stressor may be neutralized. If, however, it is determined that a suitable response is not within one's coping repertoire or is available but ineffective, then a stress response is generated.

Stress responses include (1) physiological and biochemical responses, such as the arousal of the sympathetic nervous system and changes in corticosteroid steroid levels (Selye 1936); (2) physical health problems such as cardiovascular disease, hypertension, and ulcers (e.g., Aneshensel & Gore 1991); and (3) reactions involving the onset and course of forms of psychological distress. Initially, stress responses were studied separately with primary attention given to specifying the breadth and depth of stressor impacts upon specific outcomes. Later efforts (e.g., Thoits 1995), however, focused on interconnected and multifaceted stress situations. This effort entails explorations of junctures among physical and psychological health, and attempts to define the implications of stress induced changes in one domain for functioning in the other. In summary, the stress process links our bodies to the environment by way of our minds and their psychosocial filters. Encountered stimuli become threatening and thus "stressful" if they are appraised as such relative to specific cultural and individual meanings and cannot be adequately responded to using available coping responses.

PERIPHERAL ELEMENTS OF THE STRESS PROCESS: VULNERABILITY FACTORS AND MODERATORS

While the conception presented in the previous section is useful, it is limited in that it only depicts the basic framework of the stress process. The history of stress research also identifies other influential variables. Two classes of these variables are particularly important: vulnerability factors and mediators.

Vulnerability Factors

Early stress research depicted the stress process beginning with the emergence of a potentially

stressful stimulus. In contrast, subsequent research has acknowledged the need to model the effects of statuses and dispositions that may increase (1) the probabilities that stressors will be encountered or (2) the likelihood that problems will be experienced in the face of stress. Such statuses and dispositions are considered vulnerability factors (Turner & Avison 1989).

Demographic statuses such as age, race, gender, education level, and marital status have been classified as vulnerability factors because they "determine the stressors to which people are exposed, the mediators they are able to mobilize, and the manner in [and the extent to] which they experience stress" (Pearlin 1989: 241). These statuses are indicators of social location that convey contextual information about the circumstances in which specific stressors are more likely to be generated, contended with, and felt. They also reflect differences in the initial positioning of certain groups relative to society's goals (e.g., sound health and financial success) and in relation to the approved networks and pathways for reaching and retaining them (e.g., quality medical care and stable, lucrative employment). Lastly, they influence the form of the stress response that is called forth when attempts to eliminate stressors are ineffective.

Personality dispositions such as the consistent exhibition of Type A behavioral patterns (TABP) and perfectionist behavior are other factors that may render individuals more susceptible to the adverse effects of stressors. The increased vulnerability associated with the possession of the Type A personality may be attributable to its interference with the "natural" course of secondary appraisal. It inspires the selection of inadequate coping responses that subsequently compromise efforts to diffuse the effects of stressors (Vingerhoets & Flohr 1984). The perfectionist personality type increases stressor vulnerability in quite a different manner. It increases the frequency of encounters with stressors and amplifies their negative psychological effects by changing minor issues into major problems and by increasing the likelihood that failures will be interpreted as signs of personal deficiency (Hewitt & Flett 1993). Social statuses and personality dispositions can affect each stage of the stress process.

Mediators

An extension of the stress process model focuses on the role of constructs that govern the effects of stressors on outcomes and function as barriers to the adverse effects of exigencies. These constructs are called mediators (Pearlin 1989). This entry has already presented one mediator (coping) in its description of options for response that are selected during secondary appraisal. Other constructs that may act as mediators include personal resources and social resources. Coping responses, personal resources, and social resources may improve or protect well being by reducing the effects of existing stressors and by discouraging the occurrence of secondary stressors.

Coping Responses

Coping responses are elicited or enacted in order to manage specific situational demands (Lazarus & Folkman 1984; Pearlin & Schooler 1978). These responses are intended to regulate or alter stressor effects. The first set of responses is known as "emotion focused" coping, while the second is "problem focused" coping. Emotion focused coping includes behaviors such as venting, positive reframing, religion, acceptance, and the use of emotional support. In contrast, use of instrumental support, active coping, and planning are actions exemplifying problem focused coping.

A third set of coping responses that may be elicited in response to stressors entail actions that deny the threat posed by potential stressors. Such responses are labeled as either avoidant or disengagement coping styles (Carver & Scheier 1993). Avoidant coping typically involves the initiation of activities or the occupation of mental states that prevent or delay direct confrontations with stressors and their implications for well being. Such responses include self distraction, substance use, behavioral disengagement, and the excessive use of humor. Problem focused, emotion focused, and avoidant coping responses are elicited based upon the personal and cultural meanings assigned to specific stressors. Coping involves interaction between environmental, personality, and health factors.

Psychological Resources

Psychological resources are personality characteristics that people draw on to help them withstand the threats posed by events and objects in their environment. These resources function as internal "barriers," reducing the impact of stressors on the self and decreasing the levels of distress experienced. Two forms of commonly studied psychological resources are self esteem and mastery.

Self esteem refers to the positiveness of one's attitude toward oneself. High self esteem has been shown to significantly reduce psychological symptoms and to moderate the emotional consequences of stressors (Thoits 1995; Turner & Roszell 1994). Mastery refers to "the extent to which one regards one's life chances as being under one's own control in contrast to being fatalistically ruled" (Pearlin & Schooler 1978: 5). Studies suggest that individuals with higher levels of mastery are less vulnerable to the impacts of stressors, less likely to experience psychological disruptions, and more likely to have better mental and physical health compared to individuals with low mastery levels (Mirowsky & Ross 1990). High levels of mastery and self esteem may inspire self appraisals that reduce the level of threat assigned to stressors. In addition, they may elevate confidence in one's ability to control these stimuli. In addition, high levels of mastery may promote greater accuracy in the selection of ways of responding to stressful stimuli, while high self esteem levels may make it less likely that encountered problems will give rise to self evaluations that might engender emotional distress.

Self efficacy, resiliency, and optimism are other psychological resources that may serve as mediators. Although these constructs have received less attention than either self esteem or mastery, they may have a role in the stress process.

Social Resources

Social resources constitute the final class of mediators considered in the stress literature. These resources consist of various forms of social support: functions performed by others

to aid individuals in dealing with stressors (Thoits 1995). Forms of social support used to explain variations in stress responses include: (1) emotional support, which is the expression of positive affect, emphatic understanding, and the encouragement of expressions of feelings; (2) informational support, the offering of advice, information, guidance, or feedback; (3) instrumental support, which is the provision of material aid or behavioral assistance; and (4) expressive support, which involves the expression of love and affection.

Although studies by House and Kahn (1985) indicate that these forms of support are highly correlated, scrutiny of each is warranted since specific forms of support may be more or less effective in counteracting particular stressors (Cohen & McKay 1984). For instance, emotional and expressive support may be required during bereavement, while informational and instrumental support may be vital when confronting the physical limitations accompanying an injury such as an ankle fracture. Furthermore, it is noted that each form may also contribute uniquely and interactively to the acquisition of particular stress outcomes (Rook & Underwood 2000). Emotional and expressive supports directly address basic needs for love and esteem, whereas instrumental and informational supports assist in the performance of problematic activities and provide function promoting regulation. Combinations of emotional, expressive, instrumental, and informational may help to stabilize and strengthen interactions with internal and external environments.

Attention has been given to the perceptual elements of social support and their roles in the stress process. Work in this area illustrates the health related significance of perceptions concerning resource availability apart from the actual receipt of resources. Specifically, whether or not one receives support has been shown to be less important for health and adjustment than one's beliefs about resource availability. The belief that support is available diffuses stressor impacts by way of the secondary stage of appraisal; it increases the likelihood of concluding that one has "enough" or the "right" coping responses and social resources to deal with specific circumstances. The extent to which stressor effects are mediated by resources depends on ideas about what is supportive, as well as actual

resource levels. Stress related experiences reflect the social dispositions possessed and cognitive postures assumed when stimuli are defined as threatening.

THE STRESS PROCESS AND HEALTH: SYNOPSIS AND SYNTHESIS

Generally, the term stress is used to describe feelings experienced when a person is confronted by disruptions, demands, or challenges. Yet among stress researchers this term is linked to a process that takes shape far before the arousal of any feelings. In this latter context stress has internal and external origins, includes occurrences requiring adjustments acutely, daily, and chronically, and is expressed both emotionally and physiologically. Moreover, the process is seen as affected by factors that increase or decrease exposures to potentially noxious stimuli.

This entry provides an overview of the stress process and health as one of many domains impacted by stressors and mediators. It is limited in that some ideas about the stress process were not covered (e.g., the array of stress model variants depicting relations among vulnerability factors, stressors, mediators, and health; the role of social capital and social networks in the stress process). Information concerning developments in these areas can be obtained by consulting works by Ensel and Lin (1991) among numerous others.

stress and migration

Judith T. Shurval

Migration within and between different countries is an ongoing, worldwide phenomenon which is likely to continue well into the twenty first century and involve over 130 million persons. It is caused by population pressures, environmental deterioration, poverty, wars, persecution, and human rights abuses. Migration is a response to the flow of capital, technology, and cultural innovations in an inter active process across the globe. It links countries by flows and counter flows of people in sets of networks which are both interdependent and independent of each other. Countries of origin and destination are determined by historical ties based on earlier colonization, political influence, trade, investment, or cultural ties – as well as the present economic, social, and political contexts.

Migrants are extremely diversified. They include a wide variety of people and the various categories of migrants may shift over time from one type to another. The most prominent categories include permanent settlers, temporary and seasonal workers, refugees and asylum seekers, legal and illegal immigrants, diaspora migrants who return to their former homeland, persons who come for purposes of family reunion, skilled and unskilled persons of varying social class backgrounds, persons of urban and rural origins, wage earners and entrepreneurs, and many varieties of ethnic groups.

Extensive illegal immigration characterizes many of the receiving societies and poses a major threat to the authority and power of the state, since it represents a loss of control in the flow of people and goods over borders. Efforts to

control illegals have included penalties on employers who provide them with jobs, as well as limitations on such benefits as welfare payments, tax and housing assistance, family support, student loans, and medical care.

Illegal migrants take the least desired jobs on the market, make their living in the "informal" sector, and satisfy employers' demand for cheap labor. Because of their willingness to accept lower wages, illegals pose a job threat to the local population. Illegals are subject to increased stress in some countries because of their ineligibility for health and welfare benefits, education for their children, and fear of deportation. In many parts of the world there is a concern that immigrants import Islamic fundamentalism and terror as well as increasing crime rates. Humanitarian concerns have been compromised for security considerations by imposing tighter controls on the entry of illegal immigrants.

Stress occurs when an individual confronts a salient situation in which their usual modes of behavior are inadequate and the consequences of not adapting are sufficiently disturbing to result in a disruption in homeostasis. Situations are not objectively stressful, but are constructed as such by individuals in relation to their own social and cultural norms. If one is unable to mobilize personal or social resources to cope with the situation in such a manner as to restore homeostasis, energy will be bound up dealing with the perceived disturbance.

The availability and usability of coping mechanisms constitute the link that determines whether a situation will in fact result in stress for the individual. Indeed, there is considerable evidence for the stress mediating and stress buffering roles of coping resources. Such coping resources are of two types: individual (e.g., personal skills, personality traits, intelligence, knowledge) and social (e.g., formal institutions, informal groups, social norms and values). In the context of migration, earlier, familiar coping mechanisms may lose their efficacy in the transition from one cultural setting to another. Furthermore, stress experienced in the country of origin may be "imported" into the destination and even be exacerbated by the newer stresses of the migration process.

Stress may be viewed as both a cause and a consequence of migration. On the causative level, stress in any given location may act as a

motivator of migration, when people believe that they can reduce stress and improve their overall situation by migrating to a different setting. In order to serve as an effective motivator, two conditions are required: (1) a level of stress which is perceived as sufficiently powerful and salient to justify uprooting oneself and one's family from a familiar setting; and (2) knowledge about the destination and a belief that conditions there will provide less stress and a more satisfactory setting.

The relationship between migration and stress is best conceptualized in terms of an integrated, macro micro framework. On the macro level, the changing nature of state responses to the presence of immigrant communities needs to be considered against a background of shifting notions of nationhood and transnational processes. Processes of globalization which induce the circulation of capital, commodities, people, and cultural practices, reconfigure spaces and identities, and change earlier notions of attachment and citizenship. While people from less developed parts of the world try to move to the economically developed regions, there is anxiety in migrant receiving countries about job loss and changes to national culture which promote state policies to restrict, control, and select international migrants.

On the micro level it is necessary to consider issues of individual and collective identity, life chances, and how immigrants perceive themselves and their social reality. Social networks are micro structures which play a core role in migration processes by their role in providing assistance at the destination in job location, financial support, practical information, and a base for the migration of additional persons. The ongoing nature of the process is seen in the fact that the larger the number of people who migrate, the thicker the social networks at the destinations and the consequent amount of available help; this tends to decrease the costs and risks of migration for others from the same origin. Widespread policies of "family reunification" reinforce these networks.

The processes of change which are inherent in migration undermine the sense of the self with respect to the individual's place in the social order. One of the major sources of stress for immigrants is the loss of numerous self identities that were embedded in their former

communities, jobs, skills, language, and culture. These represent a serious loss in human capital. Racism, prejudice, and xenophobia exacerbate the difficulties encountered in the reconstruction of identity. Role theorists have suggested that when a person has multiple identities, they are better able to cope with the loss of a specific role because viable alternative identities are available and can be given increased weight in defining one's self.

Migration has stimulated the rise of transnational communities which challenge conventional identities, notions of belonging, rights, and responsibilities. Studies of diaspora migration have highlighted the multiple ethnic identities that are maintained by immigrants – as ties to former homelands are retained through cheap travel and electronic modes of communication. These patterns have challenged older notions of the nation state and patterns of exclusive loyalty and identity.

On the structural level, migrants are not dispersed at random in a social system, but tend to be located in specific occupational and geographical niches, often in marginal locations. These patterns reflect informal or formal barriers imposed by the host society, as well as immigrants' choices. Since migration is frequently a response to job openings in the host society, the types of jobs available vary widely, from unskilled laborers to skilled technicians or professionals. Limited options for housing and exclusionary mechanisms often force migrants into slum neighborhoods and substandard housing. Thus, the structural location of the migrant in the social system exposes them to different stressors, including health risks.

Occupational and geographic concentration contributes to the visibility of migrants, and this affects both the migrant group itself and other populations in the society. Insofar as the migrants are concerned, a common structural location carries implications for self identification, solidarity, and feelings of commonality. A sense of cohesion may result, promoting group identification and social support, but may also exacerbate stress by encouraging or reinforcing collective perceptions of exploitation and deprivation.

Ethnic enclaves composed of immigrants and their offspring have attained growing

legitimacy as demands for cultural assimilation have been found to be incompatible with democratic values of tolerance and equality. Ethnic pluralism has become normative in many societies. One result has been the long term persistence and viability of ethnic communities and neighborhoods in which traditional cultural patterns are retained and reinforced over several generations. These have strengthened ethnic cohesion as well as ties with former homelands which encourage the development of cross national communities. But when such enclaves are perceived as ghettos which serve as a barrier to mobility and achievement, the resulting sense of deprivation is often expressed in hostility or violence focused on other accessible target groups, which include immigrants stemming from different cultural backgrounds or veteran groups in the host society who are perceived as legitimate targets. Indeed, violence as a mode of attaining goals may be part of the normative cultural baggage of some groups of immigrants in a multi ethnic society.

There is a dynamic quality to structurally determined stressors. During the early period in the host society, migrants often accept low status or deprivation as inevitable; however, there is generally a strong underlying expectation of change for the better. When the host society's culture includes such values as equality, achievement, and social mobility these expectations are reinforced. If improvement is perceived as slow or absent, such lack of change serves as a stressor. Stress is felt by subgroups in such a value context, as they feel they are not succeeding or are not attaining as much as relevant others. Migrants are especially vulnerable to such feelings when they have been in the host society for increasing lengths of time and especially in the second and third generation. Under such conditions, it may be said that the stress induced by migration is multi generational and its effects can be long term, as they spread to other segments of the population.

Attitudes of groups in the host society toward migrants range from acceptance and tolerance to hostility or overt aggression. In any case, the visibility of the migrants makes possible a clearer focus on them by the host population or by subgroups in it. Expressions of prejudice, intolerance, aggression, or xenophobia

may serve as stressors, especially when the more successful migrants are perceived as competing with, or advantaged relative to, veteran members of the society.

Another structural dimension on which migrants are not randomly distributed is the power and influence hierarchy in the host society. At the time of entry, migrants tend to be low on these factors. For migrants who enjoyed and utilized power before their move, its absence may serve as a stressor in the new society. However, when large numbers of immigrants from one country of origin arrive, they may themselves constitute a political power in the host country. Their interests may dictate that they lobby for the admission of groups from specific countries of origin, for limitations in the numbers of immigrants, or for their own special interests.

Absence of power may express itself on the simplest level by lack of citizenship. For a period of time the migrant may be unable to vote, hold office, acquire property, or qualify for certain jobs. Once formal citizenship has been acquired, migrants may still encounter barriers in the economic and political spheres, where positions of power are occupied by veterans who have little interest in relinquishing such influence to newcomers. In open, democratic societies, political organization of migrant groups may provide channels to acquire power and influence within such groups and through them eventually enter into the broader political context.

On the informal level, migration often results in a shift in the balance of power within families and other informal social contexts. Thus, persons who traditionally have wielded power in the family (e.g., grandparents or fathers) may find themselves stripped of their accustomed roles as a result of different patterns of family life in the new society. Unless alternative rewards are found for the demoted traditional leaders, they are likely to experience stress.

The above processes are intensified by globalized media messages which serve to inflate expectations and intensify trends toward increased democratization. Immigrants often expect rapid improvement in their economic and social status in the host society, immediate rewards, and a voice in decision making. When these are slow in coming, the ensuing frustration may lead to violence.

stress, stress theories

Gerald F. Lackey

What differentiates the study of stress in sociology from similar work in fields like biology or medicine is the attention given by sociologists to the social distribution of mental health and well being. Sociological inquiry focuses on how the causes of stress, the resources for coping with stress, and the outcomes of stress vary across subgroups in the population. As distinct from a psychological or biological approach, the sociological study of stress focuses on how the social condition can determine a number of different stress outcomes. A significant step forward in this endeavor was made by Pearlin et al. (1981) when they formalized a sociological theory of the stress process.

There are three fundamental concepts that form the core of the stress process: stressors, moderators/mediators, and stress outcomes. Stressors can be external, environmental, or social factors, or internal, biological, or psychological factors that challenge an individual to adapt or change. They can be discrete events such as the destruction of one's home by a tornado or chronic problems such as a degenerative neurological illness like Alzheimer's disease. Related, moderators are the social or personal resources that attenuate the effects of

stressors or change the situations that are producing the stressors. In addition to this buffering effect, research also shows that certain resources can have mediating effects on stress outcomes. The three types of moderators/mediators are coping strategies, personal resources, and social support. Lastly, stress outcomes are the psychological, emotional, or physiological conditions resulting from exposure to stressors, after accounting for the the moderators/mediators.

In a simplified model of the stress process, people's position in the social structure exposes them to stressors, which in turn leads to stress outcomes. Moderators and mediators primarily have effects between the stressors and the outcomes, and the social structure and the stressors. This simplified model hides the reciprocal relationships and agentic processes that exist in practice between stressors and moderators, outcomes and stressors, and also individually among stressors, moderators, and outcomes. Nonetheless it accurately represents the underlying connections among the key stress theory concepts (Pearlin 1999).

There are two broad categories of stressors: event stressors and chronic stressors. Event stressors include any sudden and generally unexpected phenomena that result in a stress outcome. Initial work measured the effect of an event stressor by the amount of change it required of an individual (i.e., the larger the magnitude, the more negative the outcome), but subsequent work has shown this to be a poor measure when taken on its own. In defining the effect of an event it is important to take into account whether or not the event was anticipated (e.g., retirement), whether it represents a closure of another stressor (e.g., divorce after a long period of litigation), or even whether the individual deliberately sought the event as a problem solving strategy to other stressors (e.g., getting fired from a miserable job). Thus, research shows that seemingly negative life events may actually decrease the likelihood of having a negative stress outcome when considered in context of a person's other life course trajectory. In fact, current work embeds an understanding of life events (both positive and negative) within the life course framework of transitions, trajectories, and pathways.

Chronic stressors comprise a wide variety of stressors, including status strains, role strains,

ambient strains, and quotidian strains. As their name suggests, status strains are stressors that arise out of a person's position in the social structure (e.g., living in abject poverty). Furthermore, the holding of a status that is stigmatized or devalued by society (e.g., a particular race, gender, sexuality, or religion) can also be a status strain. Role strains focus on the stressors that arise from conflicts or demands within an individual's role set and they provide stress theory's key link between macro level influences and individual outcomes. Initial research focused only on the negative effect of having many roles, arguing that they create competing demands on the individual, thus acting as stressors. Yet subsequent research has shown that under certain conditions having many roles can benefit the individual by providing more fungible resources that carry over from one role to another. Ambient strains focus on the stressors that come from an individual's proximal environment, most often measured as their neighborhood. Here the focus is on threats of crime or violence, or on access to resources like schools, hospitals, fire departments, and other public services. Quotidian or daily strains are perceived to produce the lowest intensity stressors and arise out of the daily hassles of things like waiting in traffic, fighting for a spot on the subway, or cooking. Research suggests that the effect of these strains may stem more from the fact that they are repeated daily than from the individual stressors themselves.

It is important not just to know the types of stressors an individual faces, but also the timing and interrelationship of these stressors. Stressors rarely occur in isolation from one another. Often, some primary stressor leads to several secondary stressors, a process known as stress proliferation. When the sequence of stressors is considered in conjunction with a person's multiple roles, the concept of a carry over effect is introduced, whereby stressors in one role domain or life stage may have impacts in other domains or stages. For example, facing multiple stressors in childhood may have consequences for adult mental health. Similarly, facing stressors at home may have consequences for anxiety levels at work. The study of sequencing is an increasingly important one in the sociological study of stress, as it can better account for the dynamic link between individuals and society as

well as illuminate the long term consequences of stressors that are often obscured by cross sectional or short term studies.

Related to the sequencing of stressors is the sequencing of life events, a concept that is a core component of life course theory. Stress researchers and life course researchers have been combining efforts to investigate how the sequencing of life events and transitions leads to both positive and negative outcomes. Two competing arguments exist as to why the timing of life events produces stressors. One argument is that there are societal norms for when certain transitions should be made relative to others and that when individuals deviate from these paths the society produces stressors. For example, in some societies it is a violation of social norms to have children outside of wedlock, thus if a woman violates this norm it may increase her likelihood of experiencing stressors. The other argument puts less emphasis on the violation of societal norms and more on the belief that certain sequences generate practical, objective obstacles, which in turn create stressors. For example, having a child outside of marriage normally necessitates being both a full time parent and a full time mother, something which may or may not generate stressors depending on other factors. In the end, this union of methods, theories, and concepts between life course theorists and stress theorists holds promise for understanding the role of the stress process over a much longer time horizon.

The second major component to the stress model is the role of moderators/mediators like coping strategies, personal resources, and social support. Coping strategies are the changes people make to their behavioral or psychological state in response to the stressors they encounter. Coping strategies may be focused on changing the situation that is causing the stressors (e.g., finding a new job after being fired), on preventing a stressor from occurring (e.g., marriage counseling to prevent divorce), on reinterpreting the stressors in a different light (e.g., looking at increased job responsibility as an opportunity instead of a burden), or on managing the stress outcomes (e.g., including meditation in one's daily routine). In order to make use of these coping strategies individuals need coping resources which can be either personal or social.

Personal resources include a sense of self mastery or control over one's life and environment, as well as one's self esteem. More of the research on personal resources has focused on self mastery and less of it on self esteem, but both have been shown to directly reduce the severity and prevalence of stress outcomes as both mediators and moderators. More work, however, still needs to be done to understand the interaction effect these personal resources have with social support and coping strategies, as well as their potential to condition the types of social support and coping strategies one receives.

Social support has been the most widely studied resource and continues to show strong, significant direct and buffering effects on stress outcomes. Social support comes chiefly in the forms of instrumental assistance, informational assistance, and emotional assistance from other people. Three major conclusions can be drawn from the literature on social support: (1) being a member of a closely knit group has direct positive mental health benefits, but does not act as a moderator on stress outcomes; (2) perceived emotional support (whether real or not) has both direct and buffering effects on the severity and significance of negative life events for stress outcomes; (3) having an intimate relationship that encourages confiding in one another has the largest effect on attenuating stress outcomes.

The biggest shortcoming with the work on social support is with how the concept is measured. Progress has been made in treating social support as a type of social network with defined measures of range, density, composition, and availability, but this is not standardized. Furthermore, it is largely measured only from the perspective of the individual under observation without acknowledging that these are reciprocal, social relationships. Along similar lines, future work on social support needs to consider the reciprocal relationship between support and stressors, as having too many stressors or too long a duration of stressors may lead to a weakening of one's social support network.

The final step in the stress process model is the stress outcome, which can be any health or mental health illness. Most often sociologists study generalized depression, anxiety, or drug/alcohol abuse, but there is a push to study the comorbidity of multiple health and mental

health outcomes. Aneshensel et al. (1991) were the first to note the importance of studying multiple outcomes in a single study. In their words, "single outcome studies . . . are clearly inadequate for identifying the impact of social factors on overall psychological well being across subgroups of the population." This conclusion is made all the more important given that one of the primary contributions of the sociological study of stress is its focus on the social distributions of mental health and well being. Much more work is needed on this part of the stress model, but it promises to make an important contribution to researchers in fields outside of sociology.

stress and work

Johannes Siegrist

While stress is a popular concept in everyday life that describes a feeling of pressure resulting from overload, it is also a scientific term of growing importance. In a scientific perspective, stress differs from the everyday notion in at least two important ways. First, stress defines a reaction to a challenge (stressor) from the external world or from within the organism that interrupts or threatens the usual behavior and normal functioning of a person and that requires specific efforts to meet the challenge. These efforts are termed coping. It is important to note that major stressors that are experienced in everyday life emerge from the social rather than the physical environment. Examples of such social stressors are interpersonal power, role obligations, competition between organizations, groups, or individuals, and social deprivation or inequality. Therefore, stress is an important sociological topic.

A second difference between everyday and scientific notions of stress concerns the distinction of several dimensions of a person's response to a stressor. In scientific terms, four dimensions of the stress response are distinguished: the cognitive, the affective or emotional, the physiological, and the behavioral response. At the cognitive level, a challenge is appraised according to its degree of threat or harm. This appraisal is paralleled by negative or positive affective responses. Most importantly, the experience of threat goes along with intense negative emotions of anger, irritation, or anxiety. At the physiological level, stress reactions elicit arousal of the organism through activation of the autonomic nervous system and the so called stress hormones. Through this activation the person is prepared to adapt their behavior in terms of fight or flight. If the challenge is met by

successful coping efforts, positive emotions of self esteem and self efficacy are experienced, and the organism recovers quickly. However, if an overwhelming challenge results in a defeat or in a chronic unresolved struggle, strong negative emotions and sustained autonomic activation are evoked that "get under the skin." In the long run they trigger bodily dysfunction and disease, such as cardiovascular disease, metabolic or gastrointestinal diseases, or affective disorders (Weiner 1992).

Work and employment belong to those core social circumstances that produce recurrent stress responses in exposed people. Therefore, the scientific inquiry into associations of stressful working conditions with health is considered a prominent topic of medical sociology. This subdiscipline of general sociology is in a unique position to bridge the social sciences with the biomedical sciences by combining sociological, psychological, and physiological information in epidemiological study designs. When analyzing associations of work related stress with health one has to keep in mind that the nature of work has changed considerably over the past several decades in economically advanced societies. Industrial mass production no longer dominates the labor market. This is due in part to technological progress and to a growing number of jobs available in the service sector. Many jobs are confined to information processing, controlling, and coordination. Sedentary rather than physically strenuous work is becoming more and more dominant. New management techniques may be introduced, and economic constraints can produce work pressure, greater rationalization of tasks, and reduction in personnel. These changes go along with changes in the structure of the labor market. More employees are likely to work on temporary or fixed term contracts, or in flexible job arrangements. Overemployment in some segments of the workforce is paralleled by underemployment, job instability, or structural unemployment in other segments. Overall, a substantial part of the economically active population is confined to insecure jobs, to premature retirement, or job loss.

Why is work so important for human well being, and how does work contribute to the burden of stress and its adverse effects on health? In all advanced societies work and occupation in adult life are accorded primacy for the

following reasons. First, having a job is a principal prerequisite for continuous income and thus for independence from traditional support systems (family, community welfare, etc.). Increasingly, level of income determines a wide range of life chances. Second, training for a job and achievement of occupational status are among the most important goals of socialization. It is through education, job training, and status acquisition that personal growth and development are realized, that a core social identity outside the family is acquired, and that goal directed activity in human life is shaped. Third, occupation defines an important criterion of social stratification. Amount of esteem in inter personal life largely depends on type of job and level of occupational achievement. Fourth, occupational settings produce the most persuasive continuous demands during one's lifetime, and they absorb the largest amount of active time in adult life, thus providing a source of recurrent negative or positive emotions. It is for these reasons that stress research in organizations where paid work takes place is of particular relevance.

There is now growing awareness among all parties of the labor market that stress at work produces considerable costs, most importantly a high level of absenteeism, reduced productivity, compensation claims, health insurance, and direct medical expenses. Permanent disability and loss of productive life years due to premature death add to this burden. At the same time, scientific evidence on associations between stress at work and health is growing rapidly. This research differs from traditional biomedical occupational health research by the fact that social stressors cannot be identified by direct physical or chemical measurements. Rather, theoretical models are needed that aim at identifying the "toxic" components of stressful work within the complexities and diversities of occupational settings. Ideally, such a sociological model has rather general explanatory power and can be applied to a wide range of different working conditions. With its focus on the social reality of work it may identify specific occupational risk groups and thus explain the burden of work related illness above and beyond individual susceptibility.

During the past 30 years, several sociological models of work stress have been developed

and tested. The "person-environment-fit" approach was probably the first one of these models (Caplan et al. 1980; Cooper 1998; Dunham 2000). More recently, two such concepts received special attention in health related research: the "demand control" and the "effort reward imbalance" models (Karasek & Theorell 1990; Siegrist & Marmot 2004).

The demand control model is based upon the premise that stress at work occurs when there is high psychological work demand in combination with a low degree of task control. Low control at work is defined in terms of low level of decision latitude (authority over decisions) and a low level of skill utilization. Job task profiles characterized by high demand and low control are assumed to evoke recurrent stress responses among those exposed. Conversely, demanding jobs that offer a high level of decision latitude and skill utilization promote personal growth and thus may be beneficial to health. More recently, the two dimensional demand control model was modified to include a third dimension, social support at work. If social support at work is available, it may act as an interpersonal coping resource to buffer the adverse effects of stress on health. On the other hand, high demand/low control conditions at work were shown to produce highest levels of stress reactions among those who work in social isolation or who suffer from inadequate social support.

The effort reward imbalance model is concerned with contractual fairness at work. It assumes that effort at work is spent as part of a contract based on the norm of social reciprocity where rewards are provided in terms of money, esteem, and career opportunities, including job security. Work contracts often fail to be fully specified and to provide a symmetric exchange between requested efforts and given rewards. In particular, this is the case when there are few or no alternative employment opportunities for the employees. Additional conditions of non equivalent exchange were identified by the model, including a personal pattern of coping with work demands ("overcommitment"). Non symmetric work contracts are expected to be frequent in a global economy characterized by job insecurity, forced occupational mobility, short term contracts, and increased wage competition. The model of effort reward imbalance

claims that lack of reciprocity between the costs and gains (i.e., high cost/low gain condition) elicits recurrent stress reactions due to obvious violation of a basic norm of social exchange, reciprocity. In the long run, the negative emotions that parallel these stress reactions result in increased risks of ill health and disease. These two models of stress at work complement each other. They offer opportunities for combining information on work stress and health, as conditions of low control and low reward often occur simultaneously in the same work environments.

Evidence of reduced health due to exposure to the social stressors that are defined by the two models is growing rapidly. Overall, prospective epidemiological investigations found a twofold elevated risk of a number of physical and mental disorders among employees working under high demand/low control or high effort/low reward conditions. Elevated risks were documented for coronary heart disease and cardiovascular mortality, for depression, for type II diabetes, and for alcohol dependence. Although some of the prospective findings seem to be restricted to men, they are not confined to a specific occupational group. Rather, work stress is found to affect the health of employees in industrial as well as in service and administrative occupations and professions. Currently available prospective evidence is supplemented by a large body of data derived from cross sectional investigations, case control studies, and experimental findings testing the two work stress models. For instance, higher rates of sickness absence, musculoskeletal disorders, health adverse behaviors (e.g., smoking), and biomedical cardiovascular risk factors (high blood pressure, elevated blood lipids, and fibrinogen) were observed in association with high demand/low control or effort/reward imbalance (Schnall et al. 2000). Finally, in search of psychological mechanisms linking exposure to social stressors with illness susceptibility, elevated levels of stress hormones, reduced competence of the body's immune system, and reduced heart rate variability were documented.

These findings of health related sociological research have policy implications, given the fact that up to one third of a country's workforce may be exposed to conditions of work related stress that were identified by the two models.

Moreover, a risk factor that doubles the incidence of frequent disorders, such as cardiovascular disease, depression, or musculo skeletal disorders, calls for increased preventive efforts. Health promoting improvements of quality of work require specific measures of organizational and personnel development that can be derived from the theoretical models. Concerning the demand control model they include job redesign in terms of increased autonomy, skill discretion, job enlargement, and enhanced participation. Provision of compensatory wage systems and models of gain sharing, strengthening of non monetary gratifications (e.g., through leadership training), and ways of improving promotional opportunities and job security are measures derived from the effort reward imbalance model. Clearly, the power of economic life and the constraints of globalization limit the options and range of worksite health promotion measures. Such measures need to be supplemented by more comprehensive interorganizational and governmental activities that aim at reducing the gap between scientific evidence and policy development. Research on work stress and health illustrates the promising contribution sociology can make to this end.

stressful life events

William R. Avison

Stressful life events are discrete social experiences or life changes that require individual adjustment or manifest themselves in emotional arousal or physical reactions. The defining characteristic of life events as stressors is that they are observable life changes that have relatively clear onsets and endings. This quality of discreteness distinguishes stressful life events from chronic stressors that typically have more insidious onsets and whose conclusions are less easily demarcated. Chronic stressors tend also to have longer time courses than life events.

Interest in the relationship between stressful life events and health can be traced to Hans Selye's biological research which concluded that events that constitute a threat to the organism produce a series of responses, some of which are adaptive and others of which are maladaptive. Wheaton (1994) argued that an engineering model of stress may be more useful conceptually to social science researchers because it conceives of stress as an external force or pressure that exceeds the capacity to adjust. Both formulations distinguish between relatively discrete or eventful stressors and more continuous, ongoing challenges or threats.

The early work of Thomas Holmes and Robert Rahe in developing a life events checklist (the Social Readjustment Rating Scale) stimulated much of the subsequent research on stressful life events and their consequences for mental health and illness. Their inventory of life events generated a substantial body of subsequent research that took two distinctive directions. Dohrenwend and Dohrenwend (1974) led the way in further developing and refining life events inventories to address contextual effects and the problem of intra event variability. Their

approach retained the life events checklist method but elaborated this approach with additional probes and editing procedures that addressed problems of measurement. Their work focused on the importance of stressful life events as mediators of the relationship between social status and mental health problems. George Brown's approach (Brown & Harris 1989) has been to focus on the psychological meaning of life events by conducting in depth interviews that focus on the strong emotions that life events produce. Although these two approaches differ substantially in method and emphasis, both have stimulated a wealth of research that documents the association between the experience of stressful life events and a wide range of mental health outcomes.

Despite the early excitement among researchers that the experience of stressful life events might constitute an important determinant of mental health problems, several researchers observed that the magnitude of the association between stressful life events and mental health outcomes was relatively small. This observation generated a vast body of research that attempted to explain how the theoretically compelling association between stressful life events and mental health could be so modest empirically. A number of important conclusions have emerged from this research.

There is substantial evidence of variability in stressful life events both in terms of the events themselves and the social contexts in which they occur. A number of researchers have addressed the issue of intra event variability by incorporating probe questions in checklists in order to better specify the nature of stressors. From a sociological perspective, a more important development has been the recognition that stressful life events occur in different social contexts. Brown's work has been important in understanding how individuals' life experiences around the occurrence of stressful life events condition their meaning and emotional impact. Other researchers have documented how biographical histories influence the experience of events and how community contexts modify the impact of stressors on mental health. Still others have demonstrated how certain circumstances lead to stress proliferation and how some stressors amplify the effects of other life events on symptoms of mental illness.

In the 1980s there was substantial interest in the possibility that the modest association of stressful life events with symptoms of mental illness might be due to the differential vulnerability, responsiveness, or susceptibility of more disadvantaged social groups to stressors. The sources of this differential vulnerability were hypothesized to be group differences in social resources such as social support, in more personal resources such as mastery or coping capacity, or in other susceptibilities including biophysiological differences. Over time, sociologists have largely concluded that there is little evidence for the hypothesis of differential vulnerability. When exposure to stressors is measured comprehensively and when a wide array of mental health outcomes are considered, social group differences in vulnerability appear to be less important in accounting for variation in mental health outcomes than are differences in exposure to stressors.

These findings have had important implications for a broader conceptualization of the domain of stress. Wheaton (1994) has argued for a much more elaborate stress universe that supplements standard life events checklists with measures of chronic stressors, traumatic experiences in childhood and adolescence, and daily hassles. Subsequent research suggests that consideration of a much broader array of stressors reveals a much more robust association between stressors and mental health than can be observed for stressful life events alone. Moreover, research shows that reliance only on measures of stressful life events may underestimate social group variations in exposure to stress.

Perhaps the most important contribution that sociologists have made to the study of stressful life events and mental health is to document how individuals' positions in the social structure of society profoundly affect their experience of social stressors that ultimately manifest themselves in symptoms of mental illness. Pearlin (1989) clearly articulated this in outlining his vision of the sociological study of stress. Since then, many sociologists have documented how variations in social status and role occupancy are associated with differential exposure to stressful experience.

Another noteworthy development in the sociological study of stress is the incorporation

of the life course perspective. Sociologists have increasingly argued for the importance of considering the impact of stressful life experiences on mental health over the life course. The theoretical rationale for this has been specified by Pearlin and Skaff (1996) and George (1999).

The challenge for future sociological research on stressful life events is to integrate concepts and ideas from the broader sociological discipline so that we can better specify the interplay among social structure, stress, and health. In this way, the importance of stress in social life will be better understood.

strong objectivity

Nancy A. Naples

The notion of strong objectivity was first articulated by feminist philosopher Sandra Harding. Strong objectivity builds on the insights of feminist standpoint theory, which argues for the importance of starting from the experiences of those who have been traditionally left out of the production of knowledge. By starting inquiry from the lived experiences of women and others who have been traditionally outside of the institutions in which knowledge about social life is generated and classified, more objective and more relevant knowledge can be produced. In fact, Harding (1986) and Hartsock (1983) argue that knowledge produced from the point of view of subordinated groups may offer stronger objectivity due to the increased motivation for them to understand the views or perspectives of those in positions of power.

A scholar who approaches the research process from the point of view of strong objectivity is interested in producing knowledge for use as well as for revealing the relations of power that are hidden in traditional knowledge production processes. Strong objectivity acknowledges that the production of power is a political process and that greater attention paid to the context and social location of knowledge producers will contribute to a more ethical and transparent result. In fact, Harding (1991) argues, an approach to research and knowledge production that does not acknowledge the role that power and social location play in the knowledge production process must be understood as offering only a weak form of objectivity.

Another aspect of traditional approaches to science and knowledge production that contributes to a weak form of objectivity is found in the move to greater and greater generalization.

As a result, material reality is replaced with abstractions that bear little resemblance to the phenomenon originally under examination. Smith (1987), another scholar who has contributed to the development of standpoint theory, explains that the traditional androcentric approach to sociology that privileges a white, middle class, and heterosexual point of view produces results that are both alienating and colonizing (see Stanley 1990). Harding (1998) has been especially concerned with the role of colonization in marginalizing the situated knowledges of the targets of colonization. Western science has developed through the exploitation and silencing of colonial subjects. In this way, much useful knowledge has been lost or rendered suspect (see Sachs 1996). Strong objectivity involves acknowledging the political, social, and historical aspects of all knowledge (Longino 1993). The strongest approach to knowledge production is one that takes into account the most diverse set of experiences.

Reflexivity is another practice that contributes to strong objectivity. Harding argues for a self-reflexive approach to theorizing in order to foreground how relations of power may be shaping the production of knowledge in different contexts (also see Naples 2003). The point of view of all those involved in the knowledge production process must be acknowledged and taken into account in order to produce strong objectivity. In this way, knowledge production should involve a collective process, rather than the individualistic, top-down, and distanced approach that typifies the traditional scientific method. For Harding (1991), strong objectivity involves analysis of the relationship between both the subject and object of inquiry. This approach contrasts with traditional scientific method that either denies this relationship or seeks to achieve control over it. However, as Harding and other standpoint theorists point out, an approach to research that produces a more objective approach acknowledges the partial and situated nature of all knowledge production (also see Hartsock 1983; Haraway 1988; Collins 1990).

Postmodern critics of this approach point out that the goal of producing a strong objectivity replicates the limitations of traditional scientific methods, namely, privileging one or more accounts as most "accurate" or true (Hekman

1992). Postmodern theorists argue that all social positions are fluid. Such fluidity makes it impossible to identify individual knowers who can represent any particular social group. Furthermore, they insist, the search for truth, even one that is partial, is fraught with marginalizing other accounts. However, those who adopt the stance of strong objectivity argue that it can avoid the "arrogant aspirations of modernist epistemology" (Longino 1993: 212).

Strong Program

Lena Eriksson

The Strong Program is a programmatic statement that calls upon social scientists to examine the social content and underpinnings of scientific knowledge. It played an important part in the wider development of the field of sociology of scientific knowledge. The Strong Program originated from the so called Edinburgh school in the mid 1970s and was most famously set out by David Bloor in his 1976 book, *Knowledge and Social Imagery*. Bloor was part of a group of sociologists and historians based in the University of Edinburgh who proposed that social scientists should treat and analyze scientific knowledge claims as they would any other type of knowledge claims: as knowledge constructed and located in a specific societal framework. The Strong Program was inspired by Wittgenstein's argument about rules, which states that to apply a rule, or a taxonomy, or a term, a judgment of similarity or difference is needed. The Edinburgh group introduced the concept of *finitism* to argue for why the content of scientific knowledge could not, and should not, be exempt from sociological analysis. No two cases or events are ever "the same," or "not the same," without a human decision about similarity or difference.

Scientific knowledge claims had hitherto been excluded from sociological analysis – it was considered to be a unique type of knowledge derived by special means. The way in which scientists arrived at their conclusions, via systematic empirical study, granted such knowledge a special status. Scientific knowledge was seen as the simple result of our observations of nature; inextricably linked to that nature by force of the scientific method. Thus, while one could conduct interesting sociological analysis of

the circumstances that surround scientific knowledge production, such as Robert Merton's famous studies of scientific institutions, the actual *content* of scientific knowledge was seen as exempt from any social influences. The Strong Program challenged this assumption and instead argued that no distinction should be made between natural knowledge and other types of knowledge. Thus, all knowledge claims should be treated as material for sociological investigation and explanation.

The most well known part of the Strong Program is the four tenets of causality, impartiality, symmetry, and reflexivity. The tenet of causal ity is concerned with the conditions that will enable or give rise to a certain belief or state of knowledge. Just as we look for causality in nature, we should systematically examine the causes and conditions that bring about our knowledge about the natural world. One example of such causal conditions could be wider political structures. Many analysts working within the framework of the Strong Program during the 1970s and 1980s invoked external interests of particular groups to explain internal states of knowledge. One pivotal study by his torian Steven Shapin correlated the rise of phre nology in Edinburgh during the 1820s with the interests of a burgeoning middle class whose status and legitimacy were boosted by the idea of biological heritage over that of inherited privilege. Such scientific theories were resisted by an upper class, mainly represented by the Royal Society, whose power and legitimacy depended on the idea that ability and fitness to rule were class dependent.

The tenet of impartiality states that the analyst should examine all beliefs on an equal basis, regardless of whether they are held to be true or false, rational or irrational. This requirement overlaps with the third tenet, that of symmetry. The tenet of symmetry is the most well known feature of the Strong Program and is perhaps also its lasting legacy in the field of science studies today. Symmetry means that all knowledge claims should be explained in the same way and with the same methods, e.g., in terms of their social causes and by means of detailed empirical investigation. This should be done regardless of their societal status as "true" or "false." Beliefs held to be irrational thus warrant

the same level of attention by the sociologist as rational beliefs would. Furthermore, they should be treated and explained by reference to their social causes and conditions, without reference to "nature." Our beliefs about nature are the objects of sociological investigation, and the argument would thus become circular if those beliefs were explained by reference to themselves.

Bloor uses the metaphor of a train crash – it is when things go wrong that we tend to look for "the human factor." Perfectly functioning train services are, of course, as "social" as the ones that go wrong, but we never launch investigations into why trains do not crash. We exempt seemingly unproblematic events from sociological investigation. Social science analysis that explains knowledge or beliefs thought to be false or irrational with reference to its social production, but leaves claims held to be true and rational as in no need of sociological attention, is referred to as a "sociology of error."

Finally, the tenet of reflexivity means that the same types and patterns of explanations should and must be applicable to sociology itself. Sociology does not think of itself as standing apart from other types of knowledge production, and is therefore as viable a material for sociological investigation as any other type of knowledge claim.

The Strong Program has been criticized for containing an inherent asymmetry, as scientific knowledge is explained by reference to social interests, but the social interests themselves are taken as "real" and stable entities. Another weak point is the so called "problem of imputation" – how do you first identify, for example, a class interest and then show that this is directly linked to a given aspect of scientific belief?

Even though few people today would identify themselves as followers of the Strong Program, its legacy in the wider field of science studies is well recognized and the tenet of symmetry still holds sway, both as a methodological principle and as a theoretical position.

structural equation modeling

Xitao Fan

Structural equation modeling (SEM) has witnessed an exponential growth in its application in social and behavioral science research in the last two decades. Because of its versatility, SEM has been heralded as a unified model that joins methods from econometrics, psychometrics, sociometrics, and multivariate statistics (Bentler 1994). Many statistical techniques can be considered as special cases of SEM, including regression analysis, canonical correlation analysis, confirmatory factor analysis, and path analysis (Bentler 1992; Fan 1996; Jöreskog & Sörbom 2001).

Several aspects of SEM distinguish it from other multivariate procedures (e.g., multivariate analysis of variance, exploratory factor analysis). Unlike other multivariate techniques, SEM takes a *confirmatory* rather than an exploratory approach. The pattern of relations among variables is specified a priori based on theoretical expectations. This characteristic of SEM lends itself especially well to testing theoretical models.

Many researchers in social sciences are familiar with the traditional path analysis for modeling causal relationships. The major weaknesses of path analysis are (1) all variables are assumed to have been measured *without* error;

(2) there is a lack of statistical mechanisms for testing the model–data fit. The assumption that variables are measured without error is obviously unrealistic, because measurement error is the norm in social sciences. Path analysis only describes “causal” relationships among observed variables, and it is not capable of dealing with latent constructs represented by multiple observed indicators. The lack of model–data fit test also imposes a major limitation on the use of path analysis.

Confirmatory factor analysis (CFA) is a submodel (measurement model) of SEM. In measurement practice, a subscale may consist of multiple items (or item composites) as its observed indicators, and an instrument may consist of multiple subscales. Substantively, the subscales often represent different constructs (or latent variables), and these subscales, or latent variables, are often correlated to some degree. Because CFA as a submodel of SEM describes the relationships between measured indicators and latent constructs, and those among the latent constructs themselves, it is particularly useful for construct validation in instrument development.

The distinction among path analysis, CFA, and SEM can be characterized as follows: path analysis examines the “causal links” among observed variables; confirmatory factor analysis examines “causal links” from constructs (factors, latent variables) to their respective observed indicators; and structural equation modeling examines the “causal links” among the latent constructs and those from the latent constructs to their respective indicators. In SEM analysis, a variable is either exogenous or endogenous. An exogenous variable (observed or latent) “gives” effect to other variable(s) in the model, but itself does not “receive” effect from any variable in the model. An endogenous variable “receives” effect from other variable(s) in the model, and it may also “give” effect to other variable(s) in the model. Statistically, the variation in an endogenous variable is assumed to be accounted for by the model (i.e., by other variables in the model), while the variation in an exogenous variable is assumed to be accounted for by something outside of the model. A hypothetical structural equation model is graphically represented in Figure 1.

Figure 1 A hypothetical SEM model.

The prerequisite for conducting SEM analysis is to construct a model (e.g., Fig. 1) that represents the theoretical expectations about the data structure (i.e., relationships among the variables). The parameter value of each coefficient in the model will either be specified (i.e., equal to a specific value, including zero) or estimated from sample data. Once the model (including all its path coefficients) is specified, the sample data are used to test the fit of the model–data fit. First, the unspecified parameters are estimated based on an estimation method (e.g., maximum likelihood estimation, generalized least squares). Then the parameter estimates, both those specified by the researcher and those estimated from sample data, are used to reproduce the *model implied covariance matrix*. The model implied covariance matrix is compared against the original sample covariance matrix to see how much difference there is between the two matrices. The difference between the two covariance matrices is quantified as the “minimal fit function,” and this fit function is translated to a χ^2 (chi squared) statistic for testing model–data fit. A small difference between the two matrices suggests that the model fits the data well, while a large difference leads to the rejection of the model for its poor fit to the sample data.

Unlike most statistical tests (e.g., t test, regression), in SEM analysis model degrees of freedom (df) are based not on sample size but on the difference between the number of unique elements in the sample covariance matrix and the number of parameters to be estimated in the model. For k variables, the

number of unique elements in the covariance matrix is $k(k+1)/2$, and $df = k(k+1)/2 - (\# \text{ estimated parameters})$.

Although testing model–data fit in SEM appears conceptually straightforward, in practice considerable uncertainty and subjectivity often arise. Statistically, the test for model–data fit is the χ^2 test, with the null hypothesis being that the model fits the data. Rejection of the null hypothesis indicates that our theoretical model is not statistically consistent with the sample data. Unlike most hypothesis testing situations, in SEM we usually want to see that the null hypothesis is not rejected. However, statistical significance is heavily influenced by sample size, and SEM is a large sample technique (Boomsma 1987; Bentler 1998; Jöreskog & Sörbom 2001). Because large sample size results in high statistical power, it is not surprising that, when sample size is large, the χ^2 test may declare a model as having poor fit, even though the model implied covariance matrix differs minimally from the sample covariance matrix, and the model makes strong substantive sense.

The dissatisfaction with the χ^2 test led to the mushrooming of many goodness of fit indices for assessing model–data fit. These fit indices are generally descriptive, in contrast to the inferential nature of the χ^2 test. However, there is a lack of consensus regarding which one(s) to use for decision making. To get a sense of this variety of indices, one can take a look at the types of fit indices provided by a typical SEM software package (e.g., LISREL, AMOS, SAS/CALIS).

For most social science researchers without sophisticated quantitative training, it is difficult to have a good understanding of all the differences/nuances among the fit indices. However, it is generally advised that information from three sources should be considered in considering model–data fit: (1) χ^2 test; (2) some fit indices (e.g., TLI, RMSEA, SRMR, CFI); (3) the fitted covariance matrix residuals (the difference between the sample and the model implied covariance matrices). As discussed by many (e.g., Jöreskog & Sörbom 2001), relying solely on one index (especially the χ^2 test) may cloud one's judgment. Although there have been some interesting developments in this area (Hu & Bentler 1998, 1999) in specifying cutoff criteria of fit indices in model–data fit assessment, the issues are still far from being settled (Marsh et al. 2004).

Appropriate application of SEM depends partially on whether some basic assumptions have been met. In SEM application, it is assumed that the variables involved have a multivariate normal distribution. This assumption is relevant because, under typical SEM estimation procedures (maximum likelihood, generalized least squares), the χ^2 test and the standard error estimation in SEM are sensitive to departure from multivariate normality. If this assumption is not met, "the statistical basis of the method is lost and standard errors and chi square tests have little meaning" (Bentler 1982: 421). When there is evidence that the data depart considerably from multivariate normality, one of several approaches can be taken. First, we may use estimation methods that do not require multivariate normality (e.g., asymptotic distribution free, or ADF). Alternatively, a test statistic corrected for the effect of data non normality can be used (e.g., the Satorra Bentler scaled χ^2 test), and standard errors corrected for the effect of data non normality can also be obtained. More recently, the bootstrap method has also been advocated as an empirical approach for dealing with the data non normality issue in SEM application (e.g., Byrne 2001).

Statistically, the data covariance matrix should be used for SEM analysis. Statistical theories for the estimation methods (e.g., maximum likelihood, generalized least squares) were developed for covariance matrices

(i.e., unstandardized variables), but not for correlation matrices (i.e., standardized variables). As discussed in SEM literature (e.g., Cudeck 1989; Loehlin 1998; Jöreskog & Sörbom 2001), using correlation matrix in SEM analysis may be problematic in several aspects, such as unintentional alteration of the model being tested due to scale changes caused by converting covariance matrix to correlation matrix, possible incorrect χ^2 test and other fit indices, and possible incorrect standard errors for parameter estimates. In practice, the correlation matrix is sometimes substituted for the covariance matrix to circumvent the interpretation problem caused by different measurement scales of the observed variables (Loehlin 1998). This strategy may be deemed acceptable in some practical situations, but it should not be considered as the norm. It would be preferable for the covariance matrix to be analyzed whenever possible. The interpretational difficulty caused by different measurement scales can be compensated by producing a standardized solution, an available option in all SEM software packages.

In SEM application, the model fitted to the data represents a researcher's theoretical expectation about the data structure, and it is typically desirable that the model is not statistically rejected. The power to reject the model, however, increases with the sample size. Statistical theory underlying SEM is such that, for the χ^2 test to be valid, it is assumed that the sample size is sufficiently large. Although there is no rule of thumb about what sample size is sufficiently large, sample size of a couple of hundred (e.g., Boomsma 1987) is usually considered as the minimum, and should be considered in light of the complexity of the model (Floyd & Widaman 1995). The requirement for a sufficiently large sample in SEM application creates a dilemma: large sample size increases the power of the test, and as a result small discrepancies between the model and data tend to lead to the rejection of the model.

In SEM application, the model–data fit may be found to be inadequate, and it may be tempting to modify the model to achieve better model–data fit. SEM computer programs also routinely provide "modification indices" that pinpoint possible model change(s) that lead to better model–data fit. Before revising the theoretical

model, it is important to understand the consequences of such post hoc model modification. First, a distinct advantage of SEM is its confirmatory approach. Post hoc model modification may transform the confirmatory approach of SEM into an exploratory analysis. Statistically, it is always possible to obtain better model-data fit by continuously modifying our model, with or without the guidance of substantive theory (Cliff 1983). Second, sample data always contain some idiosyncrasies due to sampling error. In fitting a model to sample data, what we want to obtain is a model that will fit future similar data well, not just to obtain good fit for this particular sample. As Loehlin (1998: 195) discussed, researchers want "genuine improvement in measurement or theory, not just a procedure for decreasing chi square." If modifications are not based on theoretical considerations, it is very likely that the model revision will capitalize on sample data idiosyncrasies, and the model fit improvement cannot hold for different sample data.

This concern naturally leads to model validation. In research practice, if model modifications are made based on either statistical or substantive considerations, it is imperative that cross validation be carried out with independent sample data to make sure that the improved model fit is not just the result of sample data idiosyncrasies. Ideally, the cross validation should be carried out in a new sample. In practice, if the original sample is reasonably large, the model validation issue can be readily accommodated by randomly splitting the original sample into two independent data sets: one used for fitting the initial model and making necessary modifications, and the other used for testing the revised model.

A variety of statistical software packages are available for implementing SEM analysis, such as LISREL, EQS, AMOS, Mplus, SAS/CALIS, SYSTAT, and Mx. These programs typically offer considerable flexibility in conducting SEM analysis, and a researcher's choice of a particular program is usually based on personal preference.

structural functional theory

Jeffrey W. Lucas

Structural functional theory holds that society is best understood as a complex system with various interdependent parts that work together to increase stability. For most of the twentieth century the structural functional perspective (also called functionalism) was the dominant sociological approach in the US and Western Europe. Although the label structural functional theory has subsumed multiple perspectives, there are a few basic elements that generally hold for all functionalist approaches in sociology: social systems are composed of interconnected parts; the parts of a system can be understood in terms of how each contributes to meeting the needs of the whole; and social systems tend to remain in equilibrium, with change in one part of the system leading to (generally adverse) changes in other parts of the system.

HISTORICAL DEVELOPMENT

An irony in the development of structural functional theory as a perspective that essentially came to define the discipline of sociology is that the theory in large part arose out of a nineteenth century effort to link the emerging field of sociology with other more established disciplines. Comte, the social theorist first to use the term sociology, attempted to gain legitimacy for his emerging field by linking it with the biological sciences. Comte's social theory largely grew out of his vision of a good or correct society. In his view, society had in many ways broken down as a result of influences including the French Revolution, and he sought ways to restore order to society. As an outgrowth of these interests, Comte initiated a focus on how various aspects of society contribute to the functioning of the whole. In this vein, and in an attempt to link sociology with the more established field of biology, Comte likened society to a biological organism. He theorized that society is an ordered system of

interdependent parts, but in a sense greater than the sum of those parts, requiring that it be studied as a whole.

With this approach, a reasonable concern becomes how each part of the system contributes to the functioning of the whole. Spencer argued that in order to determine the function of a social institution or arrangement one must determine the need that it meets for society as a whole. Toward this end, he developed the concepts of *structure* and *function* that lie at the core of structural functional theory. To Spencer, understanding society consists of understanding the functions that various structures serve for society as a whole.

Another theorist closely associated with structural functional theory is Durkheim. While rejecting many of the positions of Comte and Spencer, Durkheim retained the primary elements of their functional approaches. Durkheim's sociology focused on the interrelationships among the parts of society and their contributions to the functioning of the whole. For example, Durkheim (1965) discussed the function of religion in society: "Before all, it is a system of ideas with which the individuals represent to themselves the society of which they are members, and the obscure and intimate relations which they have with it. This is its primary function." Durkheim also built on the functionalism of Comte and Spencer in his distinction between causal analysis and functional analysis. Causal analysis, to Durkheim, consists of studying why a structure or social form exists. Functional analysis, in contrast, assesses the functions that a structure performs for society as a whole. Durkheim argued that a sociological analysis of any structure is incomplete without each of these elements.

Talcott Parsons was perhaps most instrumental in promulgating structural functional theory in the twentieth century (Parsons 1937). He constructed a theory of social action which argued that individual action is rooted in the norms of society and constrained by its values. In this way, individuals carry out actions that benefit the whole of society. Drawing on Spencer's work, Parsons also asserted that all societies must meet certain needs in order to survive. His AGIL scheme (Parsons 1951) proposed that all societies must fulfill an *adaptive* function, a

goal attainment function, an *integrative* function, and latent pattern maintenance (*latency*).

Following Parsons, Robert K. Merton laid out a working strategy for how to “do” structural functional theory in distinguishing between manifest (or intended) functions and latent (or unintended) functions, noting that the same acts can be both functional and dysfunctional for the social whole. Merton (1968) proposed that sociologists can examine the functional and dysfunctional elements of any structure, determine the “net balance” between the two, and conclude whether or not the structure is functional for society as a whole.

CENTRAL ELEMENTS

Although structural functional theory has taken various forms, there are a few basic elements that are central to the perspective. First, the theory leads to a focus on the functions of various structures. By “functions,” theorists in the perspective generally mean consequences that benefit society as a whole, contribute to its operation, or increase its stability. “Structure,” in its broadest sense, can mean anything that exists independent of individual actors. Social arrangements such as stratification systems therefore are social structures, as are social institutions such as marriage. Structural functional theorists tend to examine social structures in terms of the functions they serve for society. Davis and Moore (1945), for example, developed a functional theory of stratification in which they argued that a stratification system is a functional necessity, with positions in society that are more functionally important garnering higher rewards.

A second basic element of structural functional theory is rooted in the organic analogies of Comte and Spencer. The theory treats society as an integrated whole with a series of interconnected parts. Further, the theory holds that the various parts contribute to the functioning of the whole. Durkheim, for example, proposed that when all of the parts of the social whole are fulfilling their necessary functions, then society is in a “normal” state. When individual parts are not fulfilling their functions, Durkheim argued, society is in a “pathological” state.

Third, structural functional theorists assume that society rests on the consensus of its members, and that there is widespread agreement on what is good and just for society. Davis and Moore’s theory of stratification, for instance, rests on an assumption that members of society generally agree on which social positions are most important for society.

CRITICISMS

In the middle of the twentieth century, structural functional theory became the dominant sociological perspective in the US and Western Europe. In the 1960s, however, criticisms of the theory began to mount. These criticisms took a variety of forms, but two were perhaps most common: the theory deemphasizes social conflict and it does not adequately address social change.

According to critics, structural functional theory overemphasizes social cohesion while ignoring social conflict. By treating society as an interconnected whole, structural functional theory emphasizes integration among the various parts of society. With this approach, critics hold that the theory disregards social conflict. Moreover, because of its focus on social consensus and integration, any attention the theory does pay to conflict tends to treat it as disruptive.

Critics also contend that structural functional theory is ill equipped to deal with social change. Another consequence of viewing society as a system of interconnected parts is that any changes are seen as having the consequence of disrupting the entire system. To early thinkers in the functionalist perspective, change was a major threat. Herbert Spencer, for example, held that any change made with the objective of benefiting society will have unforeseen negative impacts. While more contemporary theorists in the structural functional paradigm have not been as hostile to social change as was Spencer, the theory still has difficulty in dealing with change. This has led to a criticism of the perspective as being conservative in nature.

A third criticism that can be leveled against structural functional theory stems from its assumption that the parts of society function together to support the whole, while at the same

time it seeks to determine the functions of various social structures. In traditional structural functional theory, then, any institution that exists in society must be functional for the whole. For example, Davis and Moore treated stratification as a functional necessity in society. However, because all known societies have contained some level of stratification, it is impossible to find independent evidence for the functional benefits of a stratification system. That is, we cannot know what functions a stratification system serves that would not be served in its absence or that might be served by alternative structures.

Largely as a result of criticisms lodged against it, structural functional theory has seen a decline in sociology since the 1960s. There are, however, contemporary approaches that draw significantly on the roots of the perspective.

CONTEMPORARY FUNCTIONALISM

Perhaps the best known contemporary variant of structural functionalism is the neofunctionalism of Alexander and colleagues (Alexander 1998; Alexander & Colomy 1990). Neofunctionalism is largely a reconstruction of Parsons's body of work, avoiding many of the pitfalls of earlier structural functional theorists. It accomplishes this in part by not taking social integration as a given, by giving greater weight to social action, and by specifying the role that the perspective should play in the production of knowledge.

Early functionalists, most notably Parsons, took integration of a social system as a given. This thought lay at the root of many of the criticisms brought against structural functional theory. The assumption of social integration led to the perspective's conservative character, its deemphasis of conflict, and its difficulty in dealing with social change. With neofunctionalism, Alexander argues that integration of functional parts should not be considered a fact, but instead should be treated as a social possibility. Although Alexander has distanced himself from the functionalist perspective since his writings in the late 1990s, the neofunctionalist approach he developed with his colleagues remains an important contemporary contribution to structural functional theory.

By treating society as a number of structural elements unified into an integrated whole, structural functional theory has tended to view individuals as constrained by the social system. Further, in his theory of action, Parsons accorded little room to human agency. Neofunctionalism sought to address this shortcoming of structural functionalism. Drawing from symbolic interactionism, ethnomethodology, and exchange theory, Alexander's neofunctionalism offered a theory of action that gives equal weight to social order and to the actions of individuals.

Alexander also argues for a distinction between sociological discourse and sociological explanation. Sociological discourse, in Alexander's distinction, is more speculative and general, while sociological explanation is geared toward empirical evidence and the determination of causal relationships. To Alexander, functionalist approaches should be seen as discourse; that is, not as formal theories but rather as general pictures of social systems and their parts in a descriptive rather than explanatory sense. In this regard, neofunctionalism, and structural functional theory in general, should be seen less as theories with testable propositions and more as orienting strategies comprised of broad assumptions about how society operates.

Another contemporary link to the historical roots of structural functional theory lies in the growing trend in sociology to take human evolution as a framework for social theory. Evolutionary theory, particularly the assumption that organisms retain characteristics that help them to adapt to (or function in) their environments, is an inherently functional perspective. While those carrying out research on the evolution of human characteristics and social structures are not likely to consider themselves structural functional theorists, they share some basic assumptions with the roots of the perspective. In fact, it was an early structural functional theorist, Herbert Spencer, who first popularized the term "survival of the fittest." Although structural functional theory has seen a decline over the past four decades, theoretical perspectives seldom die, but rather become reinvented in new iterations. In this way, structural functional thinking continues to be expressed in contemporary formulations.

structural strains, successive transition of

Koichi Hasegawa

The successive transition of structural strains refers to the mechanism and social process of the following vicious cycle: a policy or a countermeasure aimed at solving one problem gives birth to another serious problem, and the solution of that problem results in the creation of yet another more serious one and finally reaches a dead end. The first step in the wrong direction leads into deep woods that are impossible to escape. In research into the social impacts of the Tohoku and Joetsu bullet train line construction project, Funabashi (1988) invented this concept and described this vicious cycle. The concept of structural strain, defined as deprivation caused by a structural factor neither personal nor accidental, came from Smelser's

(1963) concept. This perspective reveals how the response to one risk factor can result in the creation of new risks, and that subsequent attempts to address the new risks produce yet further risks, until, finally, no remedy can be found. The concept explains rapid environmental degradation and other social problems.

One example is the mechanism by which huge budget deficits grow rapidly:

slowing down of the economy → *increasing public investment* → *budget deficits* → *raising tax* → *recession* → *revenue deficits* → *reducing public investment* → *heavy recession* → *increasing revenue deficits*

Another example is the social process leading to the concentration of nuclear facilities in Rokkasho Village in the northern part of Japan (see Funabashi et al. 1998):

failure of building settlements and cultivating farmland → *failure of the proposed Mutsu Steelworks project* → *failure of cultivating beetroots* → *setbacks in developing new rice fields* → *the Mutsu Ogawara Industrial Park fiasco* → *the introduction of nuclear fuel processing facilities* → *the accumulation of radioactive waste* → *the further concentration of nuclear facilities in the area*

We can also observe the workings of this vicious cycle in typical cases of establishing nuclear power stations:

depopulation of the area → *electric utility company proposes to establish a nuclear power station* → *community confrontations over the issue* → *construction and start of operations at the new nuclear power station* → *sharp drop in labor demand with completion of construction works* → *population decrease* → *local government develops a dependency on revenue from the nuclear power station* → *local government invites an additional nuclear power plant* → *construction works and start of operations* → *increase in the amount of radioactive waste generated* → *storage of this waste in the area* → *construction of storage facilities to accommodate spent fuel*

The latter two cases clearly illustrate the vicious cycle that compounds environmental degradation: the establishment of a single nuclear facility or plant often results in an ever-expanding number of risky nuclear facilities.

The center or "upstream" area of a society has a lot of alternatives to escape from the vicious cycle. But for peripheral or "downstream" areas

where lower class or minority people are living it is more difficult to escape. For example, the experience of development projects in the global South resulting in steeper economic decline exemplifies this successive transition of structural strains.

structuralism

Mark A. Schneider

Structuralism is a catchall term for a set of explanatory approaches or paradigms in the social sciences that emphasize the causal force of the relations among elements in a system or of emergent properties of their patterning. The character of the elements themselves (beyond what conditions their relations) is viewed as arbitrary and of no explanatory bearing. Various structural approaches have at times been popular in linguistics, psychology, anthropology, and sociology. In the latter two fields, distinct forms developed that can both be traced back to Émile

Durkheim, while sociology has also produced strains of structuralism influenced by Georg Simmel. Arising from Durkheim and Simmel as well has been the programmatic contention that in structuralism alone will be found a basis for distinguishing sociology from other disciplines.

Anthropological structuralism achieved celebrity in the third quarter of the twentieth century through the writings of Claude Lévi-Strauss. He argued that structural factors pattern our cultural expressions so as to make them resonate with us beneath awareness. His explanatory strategy first involved reducing expressive objects (e.g., artwork or mythological stories) to *contrastive structures* in which some elements were opposed to others. These structures were then argued to be similar in form to (or otherwise influenced by) an abstract picture of the social structure in which they were produced. The formal correspondence produced a resonance that explained why particular expressive objects were enjoyed and repetitively consumed. Methodologically, Lévi-Strauss followed Prague School linguists who saw meaning as conveyed structurally by contrasts among sound elements, as well as Ferdinand de Saussure's suggestion that meaning arose from relations among essentially arbitrary linguistic elements. Substantively, Lévi-Strauss followed Durkheim's suggestion in *The Elementary Forms of the Religious Life* and in *Primitive Classification* (written with Marcel Mauss) that certain cognitive constructs have the same form as elements of social life.

For example, in *Tristes Tropiques* Lévi-Strauss reduced the face paintings of the Caduveo of Brazil to a pattern that is diagonally sectioned, defining two dimensions of contrast such as we see in playing cards. The two dimensions played symmetry off against asymmetry to achieve a striking effect unique to the Caduveo among surrounding tribes. To explain this, Lévi-Strauss argued that the Caduveo faced a particular social structural problem that their neighbors had solved. A system of castes which exchanged marriage partners within themselves exerted disintegrative pressures on Caduveo society, pressures reduced in surrounding tribes by marriage rules that forced exchanges across caste lines. This produced a social symmetry that balanced the hierarchic asymmetry of castes

and thus held these tribes together. The Caduveo were too snobbish to marry across caste lines, argued Lévi Strauss, but they produced the same balance of symmetry and asymmetry in their face paintings, which he interpreted as a cultural solution to a social structural problem. In this analysis, both the cultural product and the social structure were reduced to contrastive relations between symmetric and asymmetric features, with social factors influencing cultural phenomena.

In Lévi Strauss's later work on Amerindian myths (*Mythologiques*), the influence of social structure dropped out and myth was analyzed as an elaborate self organizing system reflecting fundamental structuring habits of the human mind. The stories that myths told, which often seemed surreal, were viewed as less important to listeners than the harmonies that derived from logical relations among properties of the creatures, artifacts, or incidents that the myths included. It was these harmonies that caused myths to please people, and thus to be told over and over even when they lacked intelligible narrative structure. Lévi Strauss argued that "savage minds" employed different principles in constructing myths from those we use in stories – ones that were entirely novel and heretofore unimagined. In his decoding of myths, the reduction to contrastive structures was retained, but the explanation of their pattern took a path similar to the generative grammar being formulated in linguistics by Noam Chomsky, looking to features of the human brain rather than social structure.

This revolutionary work soon came under attack. It was seen as too systematic and scientific by some scholars in the humanities (e.g., Derrida 1978; for an overview, see Culler 1975), whose critiques were instrumental in launching poststructuralism and postmodernism as intellectual currents. At the same time, some anthropologists and sociologists (e.g., Harris 1968; Schneider 1993) criticized it as a form of self validating idealism that depended upon dubious interpretive methods and unlikely cognitive mechanisms. It never propagated as a method.

In sociology, structuralism has had a longer, more varied, and less meteoric career. One strand of structural analysis follows Durkheim and Mauss in viewing *expressive culture* (which differs from *instrumental culture* – such as our

tools – in being relatively free of practical constraints) as determined by social structure. Another carries forward Simmel's view of social structure as having formal properties that condition behaviors well beyond the domain of expressive culture. They join in viewing social structure as the source of what Durkheim called *social facts*, that is, causal currents that generally operate outside the awareness of social actors.

The attempt to uncover structural determinants of expressive culture has been handicapped by disagreement among sociologists and anthropologists over the precise meaning of social structure. Without consensus over the important dimensions along which social structure varies, not to speak of measures thereof, scholarship has been eclectic and has not given rise to organized research traditions. Two examples must suffice.

In *The Birth of the Gods*, sociologist Guy Swanson argued that the structure of relations among organized groups in society determined how the spiritual world was conceptualized. His approach modified Durkheim's argument in *Elementary Forms* to make it more amenable to testing. Using anthropological sources for a sample of world societies, Swanson showed, for instance, that the concept of a "high god" directing lesser spiritual agents occurred with frequency only in societies with a significant number of hierarchically organized "sovereign groups," each having jurisdiction over an array of human affairs. Societies with lesser numbers of such groups believed either in unorganized spiritual forces or in multiple, competing divinities. Thus the structure of sociopolitical organization was shown to determine relative monotheism within the cultural domain.

Anthropologist Mary Douglas looked to different aspects of social structure in explaining why some cultures or subcultures enjoy rituals while others find them hollow. Drawing on comparative case studies, Douglas hypothesized that impermeably bounded groups divided among many ranked statuses favored ritual, whereas more permeable groups with few ranked statuses viewed ritual as empty, opting for individually crafted or spontaneous ceremonies that were seen as more authentic. Thus important aspects of cultural style were argued to be determined by variation in social structure.

If this Durkheimian strand of structuralism has devoted itself largely to explaining variation in expressive culture, the Simmelian strand has taken a more systematic approach to defining and mapping social structure, and used the result to explain a wider range of social behavior. The main objective is to show how well defined properties of social structures (or occupancy of particular positions within them) constrain behavior. The structures range from small scale friendship or work groups, mapped sociometrically, to entire societies, viewed in terms of specific structural properties.

Network theories, for instance, use features of social structure such as the comparative intimacy of social relationships, the proportion of weak to strong ties among individuals, and the relative frequency of bridging ties among groups, to explain an array of social phenomena ranging from the capacity of communities to mobilize politically to the comparative catholicity of cultural tastes. An interesting feature of network theories has been their suggestion that occupants of positions that are connected to other positions in similar ways should behave similarly (Burt 1982). The explanatory power of the principle of structural equivalence is only now being explored.

A somewhat different approach was taken by Blau (1977), who viewed the skeleton of social structure as composed of the different dimensions along which people are differentiated from one another. Among these might be wealth, education, gender, religious confession, political party, and so on. Societies vary in the number of dimensions involved in drawing distinctions (their heterogeneity) and the tendency of dimensions to be ranked (their inequality). They also vary in the degree to which positions allow for interaction with diverse others (the relative intersection of dimensions) and the degree to which ranking on one dimension predicts ranking on others (relative consolidation of dimensions). Blau explores many features of social life that are dependent upon these variables, as well as on the proportions of the population distributed into differentiated groups and rates of mobility among them. For instance, greater intersection of dimensions seems to decrease the likelihood of intergroup conflict.

Bridging this approach and the one derived from Durkheim, DiMaggio (1987) argues that

the tendency of societies to view expressive culture as divided among distinct genres is determined by such structural features as social heterogeneity, the prevalence of weak ties, and the relative complexity of role structure in a society. DiMaggio also notes that the relative consolidation of status dimensions within the society determines its tendency to see genres as ranked and their mixing as a species of cultural pollution. Less consolidation leads to less stratification of genres and consequently less concern with their mixing. DiMaggio's theory draws upon symbolic interaction as well as Durkheimian and Simmelian strands of structuralism, and connects with structuralist arguments that were central to Goffman's sociology of culture.

Programmatic structuralism advances the claims of Durkheim and Simmel that the integrity of sociology as a scientific discipline depends upon establishing a realm of causation distinct from those explored by psychology or economics. Among contemporary sociologists, this position has been most forcefully argued and illustrated by Black (1976, 2000). Neither Durkheim nor Simmel, he argues, had the strength of their convictions, since both consistently relied on individual psychologistic explanations despite their evident concern with sociology's disciplinary integrity. All classical and most modern sociology, suggests Black, is psychological, teleological, and individualistic. Its focus is on understanding people rather than understanding social life, with the consequence that it is not really sociological. To finally become sociological, sociologists must replace their interest in people with an interest in social life and how it can be explained structurally.

Black's structural theory attempts to explain the behavior of law as a property of social life. Law, taken to be governmental social control, can be viewed as a quantitative variable. For instance, social life is more regulated by law as the average social distance among individuals increases. Law's "direction" influences its quantity as well. More law flows downward from higher ranking positions in social structures than flows upward, and more flows outward from positions more densely connected to those less densely connected. The greater the vertical and horizontal distance between two positions, the greater the proportion of downward and outward law in comparison with

inward and upward. In practice this means that lower ranking and more peripheral litigants succeed in court less frequently against higher ranking and more central litigants, with the imbalance directly proportional to their positional distance. Like DiMaggio, Black shows how these structural effects play out in a wide range of human interaction, connecting his structural analysis to what Goffman called the interaction order.

The above examples illustrate again the lack of agreement among sociologists over how to define social structure. Were consensus reached, problems of measurement would still plague structuralist theorizing, since many of its propositions will be hard to test unless and until metrics are established that allow comparisons across the important dimensions of social structure. Put somewhat differently, a successful structuralism must be able to assign to particular positions an absolute location at the intersection of multiple dimensions of social structure, rather than, as is most often the case today, assigning a relative location along only one dimension. Until this methodological problem can be solved, structuralist theorizing is apt to remain suggestive rather than establishing the core of a purified sociology.

A much more detailed and somewhat broader view of structuralism is available in Turner (1998), who includes an array of sociologists who have made anatomizing social structure and analyzing the processes by which it is reproduced over time the subject of scrutiny.

structuration theory

Rob Stones

Structuration theory is a term used by the British sociologist Anthony Giddens in a series of publications in the 1970s and early 1980s as he attempted to define a distinctive approach to the study of social relations. Giddens wanted the term to both embrace and go beyond the more static notion of social “structure.” He wanted the praxis and dynamic qualities of agency also to be included within the term. Thus, both structure and agency are captured within the philosophy of structuration. Many commentators soon noted the striking similarity between Giddens’s structuration theory and the work of Pierre Bourdieu in France. Bourdieu also wanted to go beyond the reification and objectivism of approaches that emphasized the pressures of the social milieu to the exclusion of individual and collective action. By creating a synthesis of the best from different traditions, Giddens was able to fashion a path between the deterministic tendencies of Marxism and Positivism, on the one hand, and the overly voluntaristic, free floating approaches of interpretive sociologies such as ethnomethodology and symbolic interactionism, on the other. Bourdieu, working within the French post war intellectual scene, devised a path between the overly

objectivist and dehumanizing tendencies of structuralism and Marxism, and the idealistic and subjectivist tendencies of existentialism, which put far too high a premium on the role of an individual's will power.

Structuration theory includes the weight of structures within its compass, the material, social, and personal inheritances from the past that set the limits to what can be done by people in the present. It also includes the sense that this structural inheritance provides the enabling conditions that are drawn on by individual or collective actors in pursuing their projects. However, it goes beyond these insights in emphasizing the dynamic and recurring processes by which these structures are "worked upon" by actors who draw from them, and who then either reproduce the structures or change them through the very process of acting. The reproduction or the changes can either be intended or unintended outcomes of the agent's practices.

Thus, we have a "duality of structure" whereby agents draw on structures to produce actions that then change or maintain structures. More than this, however, in structuration theory the structures themselves must be conceptualized in terms of praxis. The very existence of social structures themselves relies on their continuing to be "put to work" by the agents within them. A concrete institutional structure such as a library only continues to exist in a meaningful form as long as people continue to run it and use it as a library. This, in turn, requires that these people share a phenomenological understanding of what a library is and of how to "do" things such as cataloging, searching, lending, borrowing, reserving, and so on. The latter emphasis on phenomenology and the sociological traditions it has spawned, including a prominent place for ethnomethodology, is central to Giddens's version of structuration theory. Social actors possess stocks of mutual knowledge that exist within a wider worldview, and it is necessary to hermeneutically interpret and understand these actors' worldviews or "frames of meaning" in order to be truly able to grasp what they do and why they do it. An agent would not be able to act in the world without some "knowledgeability" of her circumstances, and this is always knowledge

embedded within a view of the world containing all sorts of formative cultural, social, and religious influences.

The way in which structuration incorporates phenomenology into its approach means that it also conceptualizes a "duality of structure and agency" whereby the social structures "out there" beyond the agent in focus enter "in here" into her body and mind in terms of knowledgeability and dispositions. For Giddens, the structures out there that mold or influence the body and perceptions in here can be analytically divided into three different dimensions. Thus, one can look at any one or all of the structures of power, norms, or meaning and significance in terms of how they provide enabling or constraining conditions for action. Bourdieu gave a particular emphasis to how the cultural discourses and forms of life out there necessarily mold, influence, and implicate the bodily, perceptual, and appreciative dispositions of agents, capturing this in his celebrated concept of *habitus*.

The status and significance of this intertwining of structure and agency is one among a series of conceptual issues germane to the structuration project that have been given greater clarity and analytical precision through subsequent debates. Structuration has by now developed beyond its founders as a vibrant, lively tradition in its own right, strengthened and emboldened by critique, counter critique, diverse empirical applications, and synthesis (Stones 2005). The work of Chris Bryant and David Jary, drawing together and critically dissecting a legion of theoretical contributions and empirical studies, has played a particularly important role in the formation of structuration's status as an internally evolving tradition.

Beyond this there have been a number of key moments in the conceptual elaboration of structuration, all of them much more concerned with empirical application than the early philosophically oriented work of Giddens. Margaret Archer, while supporting the structure-action-structure-action sequencing promoted by structuration theory, famously criticized the way that structuration's emphasis on structures entering into the agent unhelpfully confused the clear boundaries between the agent and her structural context. Archer felt that this undermined our

ability to have a clear sense of objective constraints, limits, and possibilities. She argues that we need to maintain a clear “dualism” between structure and agency. Subsequent criticism of Archer accepted that it is important to be able to conceptualize dualism, but argued that this was not incompatible with also needing to conceptualize the duality of structure and agency. Indeed, Nicos Mouzelis works, in effect, with dualism, the duality of structure, and the duality of structure and agency. On this basis he has developed a series of conceptual categories that allow one to distinguish between a subtle variety of structure–agency relationships. These allow one, for example, to distinguish between (1) the degrees of power that different agents possess to affect aspects of the world out there; and (2) to investigate whether particular agents have more or less ability to achieve a critical and/or strategic distance from the inherited cultural and normative milieu. Further issues concerning differences between knowledge of the immediate conjuncture and the more general and transposable dispositions captured by *habitus*; the conceptualization of the relational meso level of position practices within which individual practices are enacted (Cohen 1989); the methodology of empirical applications; and the relationship of structuration theory to more traditional macro conceptions of structure, have all been the subject of recent developments in structuration.

structure and agency

Rob Stones

The concepts of structure and agency are central to sociological theory. Structures are typically seen as the more fixed and enduring aspects of the social landscape. As used by Durkheim and others working within a similar tradition, *structure* is a metaphor that denotes qualities of society that are akin to the skeleton of a body in the field of anatomy, or to the frame of a building in architecture. Durkheim's work was heavily influenced by his desire to establish a sphere of study for sociology that was distinct from both biology and psychology. To this end he insisted that there are structured ways of acting, thinking, and feeling that are general throughout a society and that act as external constraints over its members. This was to emphasize the role of society in the process of causation, as opposed to individual or group agency. Some writers taking issue with this position went to the other extreme. Weber, for example, emphasized the role of individuals and rejected the idea that terms such as “society” or “group” could refer to any reality other than that of individuals and their actions.

For writers seeking to include both structure and agency in their analytic frameworks, the Durkheimian emphasis on structures is maintained. Now, however, agency is conceived as the more processual, active, dimension of society – analogous to the physiology of an organism or to the activities conducted within the spaces of a building. Agency is the ability of individuals or groups, such as class movements,

governments, or economic corporate bodies, to “make things happen” within given structural constraints and opportunities. There is a close parallel between this conception and Marx’s dictum that people make history, but not in circumstances of their own choosing. This “middle way” approach to structure and agency is the dominant conception in contemporary sociological theory. Now debates are less in terms of structure *versus* agency and more about specific emphases and the precise ways in which these two major aspects of social life affect each other or are combined. Key questions within this approach have concerned the extent to which structures constrain or determine the actions of agents, and the extent to which agents act independently of social structures.

Although mutually entwined, structure and agency can still be conceptualized independently. Much of the agency/structure debate revolves around just how independent of each other they are or can be. Lopez and Scott (2000) argued that there are two primary ways of conceptualizing structure, both deriving from Durkheim. The first is the *relational* notion of structure, referring to networks of social relations that tie people together into groups and social systems. These networks of interdependencies, characterized by mutual reliance within divisions of labor, are typically clustered into specialized sectors of social relations such as kinship, religion, the economy, the state, and so on. Durkheim referred to these as *collective relationships*. Georg Simmel similarly emphasized relationships, conceiving of society as a dynamic complex of social forms and interactions. These may involve smaller or larger numbers of people or specific types of association that structure the way that agents behave in one another’s presence. Norbert Elias’s *figurational sociology* likewise emphasized the webs and networks of relationships within which individual agents must act. Pierre Bourdieu consistently argued against a view of social life that analyzed social entities without placing them in the context of the relations that produced and sustain them, and which provide the fields in which the actions of such entities produce their consequences. Recent work on social and policy networks has also taken a relational viewpoint, looking at such things as the frequency, direction, duration, and quantity of in house and

external relationships between individual and corporate agents.

The second notion of structure, the *institutional*, refers to the beliefs, values, symbols, ideas, and expectations that make up the mutual knowledge of members of a society and that allow them to communicate with each other. Durkheim (1984) referred to this dimension of structure as a society’s *collective representations*. The structural functionalist tradition associated with the work of Talcott Parsons, Robert Merton, and others, captured this aspect of structure under the rubric of “social institutions.” Other writers emphasized cultural patterns. Parsons’s focus was on the rules and normative expectations into which agents were socialized as children, and on their adaptation to the various roles and positions they occupied as adults. This emphasis on rules and norms held in individual minds within institutions can be seen to continue in various ways in diverse strands of current writing, including the neo functionalism of Jeffrey Alexander, new institutionalists such as Powell and DiMaggio, and in the work of Pierre Bourdieu and Anthony Giddens.

Both approaches to structure are compatible with another metaphor routinely associated with structure: *pattern*. The notion of a pattern is often included in the very definition of structure. For example, social structure may be seen as “a system of patterned relationships of actors in their capacity as playing roles relative to one another” (Parsons 1945). Such patterns can be produced by agents acting in accordance with normative expectations, as in the institutional version of structure, or in accordance with the requirements of mutual interdependence, as in the relational view of structure.

Both notions exist side by side in many theoretical traditions. Marxism, for example, emphasizes the importance of one’s position with respect to the relations and forces of production, and also the significance of ideology or cultural hegemony in the perpetuation of class oppression – themes emerging from the Frankfurt School and from Gramsci and the neo Gramscians. Nicos Poulantzas’s later work also explicitly stressed a relational approach to political strategy. The two notions of structure, relational and institutional, are clearly not mutually exclusive. The precise way in which

the two notions should be combined is, however, a much more complex question.

Contemporary theorists increasingly have confronted the uneasy relationship between these accounts of structure and the concept of *agency*. Alan Dawe's account of "Theories of Social Action" noted a theoretical tension between social order – associated with the enduring qualities of structure – and creative, potentially disruptive, social action. To account for the reproduction of relatively stable social circumstances, major theorists such as Parsons ultimately allowed their concern with agency and action to be subsumed by the normative rules, sanctions, and regulations associated with the institutional approach to structure. Structures mold, constrain, and determine the actions of agents. This *substantive* privileging of structure over agency is often associated with structuralist writers such as Claude Lévi Strauss, Roland Barthes, and Louis Althusser, who tended to treat agents as the mere "bearers" of structures, and with Michel Foucault, whose emphasis on the overwhelming force and imposition of discursive regimes (institutional structure) and multiple power relations (relational structure) led him to pronounce the death of the subject or agent.

Agency theorists have asserted that structural approaches fail to recognize how agents are involved in the production of structured patterns or of social change. From the founding texts of sociology through the 1960s, a variety of ways of establishing and conceptualizing the autonomy of agency have been offered. Two overlapping traditions have dominated. One – the tradition of pragmatism and symbolic interactionism – includes Mead, Blumer, and Goffman (although, intriguingly, Goffman also borrowed heavily from Durkheim). The other includes Weber, Schütz, Berger and Luckmann, and Garfinkel in the neo Kantian and phenomenological traditions. Their common emphasis is on the internal makeup of agents and action. They assumed from the start that agents and their actions were not subjugated to structures, and thus set out to explore their key characteristics. Weber, for example, distinguished between four different types of social action: *instrumentally rational* action geared towards "the attainment of the actor's own rationally pursued and calculated ends"; *value rational*

action, which is pursued for reasons of personally held value irrespective of the prospects for success of that action; *affectual action*, determined by the actor's emotional states and orientations; and *traditional action*, "determined by ingrained habituation" (Weber 1968: 24–5). Mead and Blumer emphasized the reflection, reflexivity, and creativity inherent in the very process of interaction itself, and in the making of selves. Schütz, and also Berger and Luckmann, drew attention to the storehouse of preconceptions, typifications, of objects and practices – the latter as "recipe knowledge" – that we draw upon in appropriate circumstances. Garfinkel highlighted the array of competencies, skills, and moral commitments that are intrinsic to agents' routine accomplishments. Goffman, like Garfinkel, emphasized the chronic role played by tacit knowledge in the production of social practices. His insightful cameos prefigured the work of writers such as Bourdieu and Giddens in drawing attention to the ways in which such agential knowledge was permeated by structured social norms. All three writers stress the powerful sense individual agents have that others expect them to behave in manners appropriate to the immediate social context.

Bourdieu, Giddens, and Jürgen Habermas are major contemporary theorists who have each attempted to synthesize the two notions of structure and the two traditions of agency outlined above. The syntheses are facilitated by philosophical insights that help to both reveal and refine previous oversimplifications of core concepts. Each combines structure and agency in a more nuanced and inclusive manner than their predecessors. Each emphasizes not only structures external to agents, and the stocks of knowledge possessed by agents, but also the *social* origins and grounding of agents' knowledgeability. The key mediating concepts are *habitus* for Bourdieu, *practical consciousness* for Giddens, and the phenomenological *lifeworld* for Habermas. Social structures are seen as having entered into agents. These traces of structures within agents are drawn from both the relational and the institutional. Giddens's notion of "virtual" structures within agents, for example, draws on the institutional in stressing normative and signifiatory structures, whereas the relational seems to be emphasized more with respect to structures of domination or power. Each of

these authors also emphasizes the agent's phenomenological frame of meaning and the attendant role played by the agent's situational "horizon of relevance" in affecting how she draws upon stocks of knowledge.

A final way that contemporary theorists acknowledge the separate treatment of structures and agents is *methodological*. Here structures are not thought to subsume agents. Rather, agents are treated as important components of the very makeup of structures (thus complicating and moderating the analogies made with skeletons or the walls of a building), and as having much to contribute to the reproduction or transformation of structures and to the unfolding of events. It is just that the theorist may want to focus temporarily on the conceptualization, mapping, and analysis of specific characteristics of social structures (e.g., on norms, rules, regulations, and on the nature of networked and patterned relations and interdependencies) without attending to the specific characteristics and contribution of agents.

Recent contributions to the development of structure and agency have been made by Nicos Mouzelis, who has elucidated the range and variety of types of interconnection between structure and agency, and Mustafa Emirbayer and Anne Mische, and also Margaret Archer, on different dimensions of relations between temporality, structure, and agency. All have called for more links between the conceptual apparatus of structure and agency and the empirical, *in situ* level. This will necessarily require that greater attention be paid to methodological issues than hitherto. An accompanying call to further refine the concepts themselves has been prompted by a related desire to increase their practical utility.

student movements

Christopher Rootes

Although students have been prominent among the actors in many revolutions and revolutionary movements, as well as other forms of contentious politics, student movements – social movements comprised wholly or mainly of students, especially university or college students – are a distinctively modern phenomenon. Their emergence is predicated upon the existence in a society of a critical mass of students.

Student movements have emerged in all manner of modern and modernizing societies, often as agents of change, sometimes in reaction against change, but usually as challengers of regimes perceived to lack legitimacy or moral authority. They have appeared in authoritarian states in Europe, Asia, Africa, and Latin America, as well as in the liberal democratic states of the industrialized world.

Student movements have an important place in the development of social movement theory. In the US, it was dissatisfaction with the psychosocial and reductionist explanations of student protest (see, e.g., Feuer 1969) that stimulated explanations that took social

movements seriously as forms of political action. In Europe, theories of “post industrial” society and “new social movements” were developed by Touraine (1971) and others as explanations of the student protest that confronted orthodox Marxist theories.

Sociological interest in student movements was excited principally by the eruption during the 1960s of student protest in the US and in many states in Europe and the Pacific. Protests against the US’s prosecution of the war in Vietnam were central to the student movements of the 1960s, but they also had other and deeper causes.

In the US, the student movement emerged in the early 1960s out of the campaign for civil rights for African Americans in the South as well as the socialist Student League for Industrial Democracy, which became Students for a Democratic Society (SDS) in 1960. It came to prominence with the student revolt, in the name of freedom of speech, at the University of California, Berkeley, in 1964, the Berkeley events inspiring new scholarly interest in student movements as well as student mobilizations on other campuses across the US and beyond. The US student movement, fueled by increasing opposition to the Vietnam War, spread nationwide before reaching a crescendo in the spring of 1970. In Western Europe, student movements developed in most countries and, most spectacularly, brought normal life to a halt in much of France in May 1968 when students appeared to put revolution back on the political agenda of liberal democratic states. However, student movements also challenged regimes and/or contested government policies in Australia, Asia, and communist ruled Eastern Europe.

Student movements emerged in the advanced industrialized societies toward the end of a period of doubling, even trebling, of enrollments in higher education. As a result, students were everywhere unprecedentedly numerous, both relatively and absolutely. The expansion of higher education had various sources. One was demographic pressure – the swelling, consequent upon the post war “baby boom,” of the age cohorts from which most students were drawn. But everywhere the main pressures for expansion were political – from governments influenced by human capital theorists to invest in more highly qualified workforces in the hope

of improving economic competitiveness, and from newly affluent parents concerned to ensure the career prospects of their offspring. As socio-technical change sketched in the outlines of the “knowledge economy” and began to transform occupational structures, so demand for and the supply of higher education grew dramatically. At the same time, increasing affluence made it possible for unprecedentedly large numbers of young people to enjoy a moratorium upon adult obligation. Youth as a distinct stage of life was born, and the university was its ideal locus.

The numbers of students expanded just at the time that demographic and socioeconomic changes combined to enhance the status and visibility of youth. The entry of this generation produced strains within universities which, in many countries, were elitist and traditionalist. Inadequate facilities, unreformed curricula, and antiquated rules generated conflicts between students who considered themselves adults and authorities who regarded themselves as acting in loco parentis. These local conflicts with university authorities were, however, symptomatic of wider strains in society.

Yet these were not simply the self interested complaints of the materially deprived. Everywhere, students were drawn disproportionately from the relatively privileged strata of societies. Actual or anticipated graduate unemployment, sometimes proffered as an explanation of the rise of student radicalism, played little or no part. This was before the peak of the long post war economic boom and, even in Italy, where the mismatch between output and labor market was legendary, the peak years of the student revolt coincided with historic lows in the frequency of graduate unemployment. If there were grievances about employment prospects, they were less about the lack of jobs than about demands for “jobs worth doing.”

Social, demographic, and educational changes provided the actors for student movements, and local difficulties that raised civil libertarian issues often generated the first sparks, but it was events in the wider political arena that accounted for the spread of protest and cross and intranational variation in its incidence. Students’ local grievances generally highlighted political rigidities at state level as university authorities found themselves powerless to respond in ways that might defuse protest, as

in France where university rectors had no power even to modify dormitory regulations. However, the general political condition that stimulated the development of student movements was an effective vacuum of political opposition to government policies within the mainstream political arena.

In the US, where only a few legislators voiced opposition to the Vietnam War, the draft compelled students to think seriously about the issues, and student opposition expanded to fill the space available. In Western Europe, the sclerotic politics of states frozen by the communist/anti communist divide were similarly conducive. In West Germany, the absence of opposition was almost literal, as student socialists had been expelled from the Social Democratic Party and a "grand coalition" government of Social and Christian Democrats overwhelmingly dominated the parliament. The vacuum of opposition was often reproduced at local levels. In Europe, the student movements of the 1960s usually began not at campuses such as the Sorbonne, Heidelberg, Munich, or Rome where the institutionalized left was strong, but at those, such as Nanterre, Berlin, Frankfurt, Trento, and Turin, where the left was weak or absent. The most propitious condition for the development of the utopian student movements that so captured the imagination of observers was their political and social isolation (Statera 1975: 119).

The subsequent development of student movements was the product of interaction between the movements, their environments, and their internal social and political dynamics. Mass media coverage generalized student movements, but raised the stakes and contributed to internal dynamics that were divisive and ultimately destructive (Gitlin 1981). Media attention amplified recruitment but, once the movement had peaked, a "reverse bandwagon" effect exaggerated its decline. By focusing upon the outspoken and the outrageous, media coverage created "leaders" without authority or political acumen, encouraged spectacular and provocative actions, and amplified the incidence of violence. This deepened the movement's political isolation and encouraged political adventurism, with the result that in several countries, including Italy, Germany, and the US, small minorities of student activists drifted

into terrorism. More generally, frustrated by the limitations of their student constituencies, they rediscovered Marxism and embarked upon mostly fruitless missions to revolutionize the proletariat. Secular processes may have dictated the inevitable demobilization of student movements, but the turn to sectarian theorizing and Leninist organization everywhere hastened the process, antithetical as they were to the civil libertarian and moral protests that had inspired student mobilization in the first place (Rootes 1980).

Although encounters with apparently unjust authority were crucial to the mobilization of student movements, it was crucial to their survival that official repression should remain moderate and unsystematic. Nowhere in the West did the level of repression of student protest reach the levels usual in Eastern Europe, Asia, or Latin America. Student movements were thus able to develop in the free spaces of liberal democracies aided by the intermittent stimuli of erratic police action. On those few occasions where repression was extreme – as with the 1970 shooting of four students at Kent State University – the immediate reaction was indignant protest, but the longer term effect was demoralizing and demobilizing. Generally, however, the repression of student movements was mild compared with that of striking workers. State responses were more generally reformist than simply repressive.

In most countries student movements simply declined, but in the US and France they collapsed suddenly. In the US, the invasion of Cambodia demonstrated the impotence of the movement, and the shootings at Kent State raised the stakes. Most students returned to their books, but the most radicalized minority, as the Weather Underground, resorted to clandestine political violence. In France, the student movement was overwhelmed by the political crisis it unleashed, and outmaneuvered by General de Gaulle's appeal to the electorate. Thus disconcerted, the libertarians in the movement were no match for the Marxist sects who, emboldened by the crisis, sought to hegemonize a chimerical worker–student alliance. The student movement's rediscovery of the proletariat occurred almost everywhere and guaranteed the extinction of student movements as activists' mobilizing efforts were directed off campus.

Only in Germany was the student movement so completely isolated from the working class that, in forming an extra parliamentary opposition, it looked to broader sections of society, thereby intimating the coalition of forces that eventually coalesced into the Greens.

By 1971, student movements had burned themselves out almost everywhere. The turn to Marxism meant that, in the rare cases where issues stimulated renewed protests by students, they did not generally produce student movements. In 1976, the longest and most wide spread student strike in French history paralyzed the universities, but it found little wider resonance, both because the political context had changed and because the prominence of leftist groups determined to portray the protests as anti capitalist obscured the elements of cultural critique that had made the 1968 revolt so iconic. Because most protesting students rejected leadership of any kind, the presence of the sectarian left was less an aid to more effective mobilization than an obstacle to it, and the collapse of the protests left no significant legacy.

The direct impact of the 1960s student movements upon political structure was extremely limited. Their one nearly universal legacy – the extension of the franchise to 18 year olds – has made little impact. Nowhere in the West did student movements succeed in overthrowing elected governments. Even in France, the demise of de Gaulle in 1969 was less a delayed result of the student revolt than of his own political miscalculation. Nor did student protests influence elections in the ways they hoped. The election that ended the French student revolt produced a decisive shift to the right. If student protest persuaded Lyndon Johnson not to seek reelection, the outcome was the election not of a liberal anti war candidate but of Richard Nixon. Student movements' impacts upon policy were probably more positive. Student protest certainly raised the salience of the Vietnam War and probably hastened US withdrawal. But the greatest impacts were in higher education where both curricula and governance underwent reform.

The wider political impacts of student movements were diffuse. Graduates of the "generation of '68" contributed to the radicalization of Labour parties in Britain and Australia, and the secularization of communist parties in Italy

and Spain, but their most important legacies were in the other social movements they inspired, the women's and personal liberation movements chief among them. "Movement entrepreneurs" who learned their skills in the student movement moved on to organize workers and the poor as well as to the environmental and anti nuclear movements that emerged in the 1970s. By these means, student movements contributed to the legitimization of protest and the "participatory revolution" in liberal democracies whose effects continue, especially in Western Europe.

In and since the 1980s, observers, especially in the US, have claimed to detect in various campus based campaigns – from disinvestment in South Africa under the apartheid regime to that against sweatshop labor in developing countries – the makings of a new student movement comparable to that of the late 1960s. But although students have indeed been among the early activists in such campaigns and in the anti globalization/global justice movement, none has developed as a fully fledged student movement. The principal reason is that, in all these cases, either students rapidly found allies in other, more powerful social or political actors, or the movements that developed quickly mobilized much broader cross sections of society.

What is extraordinary about western student movements is not that they so quickly disappeared but that anybody should have expected them to endure. The conditions of student life and the rapid turnover of student generations scarcely favor a politics of the long haul. The student movements of the 1960s arose out of an extraordinary conjunction of demography and social change, sustained rises in living standards, the expansion of higher education in response to technological change and changes in occupational structures, and an effective vacuum of political opposition. It is possible that some of these conditions will recur; it is improbable that they will again occur in such conjunction. The 1960s now appear as a transitional stage in the development of industrialized societies in two respects. First, they marked the point at which youth emerged as a distinct stage of life and was accorded the liberties and rights of adulthood. Second, the 1960s was the crucial decade in the transformation of the university from an elite institution at one remove from society into a site

of mass education increasingly integrated with the demands of the market for highly skilled labor.

The transformation of higher education amounts in many places to its dilution. Not only are studies increasingly vocational, but students themselves are less likely to be 18 year olds straight from school. Students are increasingly obliged to work at least part time, and policies favoring late entry and recurrent education have encouraged universities to enroll greater numbers of older students. The status of "student" has, in consequence, become less determinate as students are increasingly integrated into the social and economic mainstream. Cultural and moral concerns have not disappeared from student politics, but they have, with the proliferation of the "new" social movements, become more widespread in non student politics. Distinctively student politics have, as a result, come more closely to resemble the politics of other sectional interest groups.

If student movements have all but disappeared from the liberal democratic states of the advanced industrialized societies, they have continued intermittently to play important roles in authoritarian states. In the 1970s, student movements played critical roles in the democratization of Franco's Spain and of Greece during years of military dictatorship, in Spain because the universities enjoyed a degree of political immunity and so provided space for political discussion and organization not enjoyed by other groups in society, and in Greece because students dared to challenge an increasingly unpopular regime. In Hungary, Poland, and Czechoslovakia, student movements repeatedly challenged communist regimes from the 1950s to the 1980s. Sometimes their protests were bloodily repressed – as in Hungary in 1956 – but student movements kept alive democratic aspirations and so contributed to the eventual collapse of those regimes.

The role of student movements in the democratization of Asian societies is even clearer. In Thailand, South Korea, Taiwan, and Indonesia, despite often savage repression, student movements provoked political crises in authoritarian regimes that ultimately issued in the expansion of civil liberties and democratic rights. Student protests against more closed and systematically repressive regimes have, however, had less

fortunate results. The student movement in Burma/Myanmar has been aggressively repressed, but perhaps the best known example, both for the hopes it raised and the brutal way in which they were dashed, was the Chinese movement that focused upon Beijing's Tiananmen Square in 1989.

What these and the many other instances of student movements in authoritarian states have in common is that it was generally students who first challenged oppressive regimes in the name of universalist principles of liberty, morality, and democracy. The critical conditions for the emergence and development of student movements are a suitably moralistic political grievance, an absence of effective opposition within the polity from other, more powerful political actors, and a lack of powerful allies. Chief among the conditions of their success, however, is their ability to attract allies either from reformists within governing elites or from other sections of society, and upon the vigor of the state's repressive response. Students, who are relatively unconstrained by the obligations of adult life, may be the least inhibited partisans of anti authoritarianism, but they are seldom able by themselves to achieve their objectives.

The development of student movements in modernizing societies under authoritarian regimes is common, but their development in fully democratic states in economically advanced societies is wholly exceptional.

subculture

David Muggleton

A subculture in general terms is a group with certain cultural features that enable it to be distinguished from other groups and the wider society from which it has emerged. But before it is possible to attempt a more precise clarification of the concept of subculture, it is necessary to examine the wider and related term “culture.” The definition of culture that underpins the analysis of subculture is that which derives from the discipline of anthropology, and is concerned with the study of “a whole way of life” of a group or society. This widely encompassing and democratic definition does, however, raise the issue of what aspects of groups or societies are, or are not, “cultural.” Sociologists have always regarded both religious and secular systems of values and beliefs to be cultural, along with those “styles of life” that arise from patterned modes of consumption. More recently, the discipline of cultural studies has reserved the term culture for those “signifying practices” – including cinema, fashion and design, cuisine, popular recreations, advertising, music, and so forth – through which people communicate their tastes and give expressive form to their emergent identities.

This does raise the issue of the level of generality or specificity at which culture is shared. In an age of global communications, certain cultural forms clearly cross national boundaries; yet it is also possible to identify distinctive national cultures. Within nations, cultural patterns are also cross cut by region, religious affiliation, and other social characteristics such as class, gender, age, ethnicity, and sexuality. It might therefore be appreciated why early definitions of subculture proposed the term to refer to a unified subset or division of the wider, national culture, one that had an integrative function for the individual member. Other initial attempts at conceptualization preferred to employ the designations subworld, population segment, or scene. But while precise agreement has never been reached over what constitutes subcultures, they can fundamentally be regarded as social groups whose specific, shared culture, lifestyle, or identity is distinctive enough to mark them off as different in some significant way from their “parent culture” (the immediate cultural milieu from which they arise). They can be organized around many kinds of shared interests and activities, including drug taking, fashion and music, or sport. Any particular social class, age span, gender, or ethnicity could conceivably dominate membership, although sociological studies of subcultures have often focused on those composed of white, male, working class youths.

In a pluralistic and highly differentiated society, cultural identifications do not all wield the same influence or share equal status; rather, they are unevenly ranked in terms of power, so it is broadly possible to identify cultural clusters that stand in mutual relationships of domination and subordination. While subcultures can emerge from relatively powerful parent cultures, such that they can be considered enclaves within the dominant culture, ultra radical groups of this kind whose values and activities are too sharply opposed to those of the dominant culture, and/or that are perceived to have developed a potentially revolutionary political self awareness, tend to be conceptualized as “contra cultures” or more often “countercultures.” On the other hand, the term subculture is rarely used to denote sets of practices that are too conservative, reactionary, or reflective of the dominant culture. The assumption is that

subcultures are inherently oppositional in that they are necessarily predicated on some form of disorder, delinquency, or deviance. Further more, they are also held to be “subterranean,” their underground status and lack of formal barriers to membership contrasting sharply with the bureaucratic entry requirements of “official” organizations and legitimately sanctioned groups. The concept of subculture has therefore more typically been applied to those groups, arising from a subordinated parent class culture, whose position vis à vis the dominant culture is less clearly articulated or overtly politicized than those of the countercultures.

Various forms of social inquiry into a range of subcultural groups had taken place long before the concept itself had begun to gain currency in academic circles from the late 1940s onwards; but the pioneering, institutional research in this respect was that conducted by members of the sociology department at the University of Chicago in the period between the two world wars. The Chicago School, as they were collectively known, were concerned with the ecology of the urban environment and specifically the high incidence of crime and delinquency occurring in “zones of transition” – areas of rapidly shifting population and social disorganization in which normative controls had been weakened. By treating the city as a “social laboratory,” the resulting case studies of juvenile gangs, hobos, and taxi dance hall habitués were characterized by the symbolic interactionist principle of examining the world from the point of view of those being studied.

The Chicago School’s legacy of commitment to qualitative interviews and ethnographic practice can be discerned in American studies of deviant and delinquent subcultures undertaken throughout the 1950s and 1960s. It also surfaced during this time in a slightly different strain of American sociological research into subcultures, one influenced by anomie theory, which suggests that certain groups, having internalized dominant success goals, find it impossible to realize their aspirations due to their structural position in society. A situation of anomie or “normlessness” results in which legitimate means are abandoned and alternative, “illegitimate” ones proposed. Lower working class youth, for example, having suffered educational

failure, blocked opportunities, and “status frustration,” invert respectable middle class values, placing emphasis instead upon delinquent activities that are prized from the perspective of their own peer group. In this sense, the delinquent subculture can be said to arise as one collective “problem solving” device. This paradigm was to dominate US subcultural theory throughout this period, albeit with various attempts at modification (including an analysis of the differential opportunities for illegitimate as well as legitimate means for success). It was also to become influential in Britain during the 1960s and 1970s, but took on slightly different emphases, being allied first with interactionism, then Marxism.

Of the various approaches apparent in British subcultural research during the first two post war decades, two are particularly worthy of note. The first involved ecological explorations of delinquent, deviant, or impoverished urban communities and of the groups that formed within these neighborhoods. Unlike American studies that emphasized social disorganization or anomie theory as explanations for the formation of subcultures, the British context more usually stressed differential socialization – an adherence to alternative, subterranean working class values and disassociation from middle class notions of respectability. The second approach focused more specifically on schools and how streaming and banding (the allocation of pupils to school classes on the basis of perceived academic ability) aided the creation of pro and anti school pupil subcultures that respectively revered or rejected the educational ethos of academic achievement. The role of the teacher in ascribing either a positive or negative label to the pupil (such as “hardworking” or “troublemaker”) and the response of the pupil in rejecting or, alternatively, accepting and internalizing the label, could also be seen as a factor in the formation of these school based subcultures; as, indeed, could be the home background of students and their socialization into the parental social class culture, as well as their involvement in commercialized youth leisure activities.

By the late 1960s and early 1970s, youth subcultures based around highly visible styles of dress became an explicit focus of academic

attention in Britain. Initial explorations were concerned with how social reactions to deviance could escalate the problem through the generation of “moral panics” – a form of collective righteous indignation involving calls for greater law enforcement measures and tougher penalties for offenders. This involved an analysis of how the media, along with the agencies of social control such as the police and judiciary, labeled, stereotyped, exaggerated and, in so doing, amplified the very forms of delinquent behavior they sought to contain. Even so, the problem solving approach was still relied on for structural explanations of the *origins* of the initial deviance and thus of the subcultures themselves. Throughout the 1970s the interactionist dimension of this body of work was displaced by a neo Marxist mode of theorizing that saw these and other style based subcultures, such as teddy boys, skinheads, and punks, as attempts by working class youth to resist “hegemony” – the process by which middle class (or bourgeois) culture attempts to define and circumscribe on its own terms the experience of subordinate classes. But again, in a manner echoing the American delinquency theory of the 1950s, each successive subculture was seen as an attempt at a solution to a historically specific “problem” faced by its working class parent culture.

It is important to recognize two very different methodological strands within this general theoretical approach, associated with the Centre for Contemporary Cultural Studies (CCCS) at the University of Birmingham, UK. The first harked back to the classic ethnographic tradition of Chicago School sociology with its use of qualitative interviews and participant observation. The second more innovatively borrowed from French theory the principles of structuralism and semiotic analysis, which enabled all cultural practices to be read like a language. In this way, the styles of the subcultures were “decoded,” like texts, for their hidden meanings, without recourse to the subjective motives of the subcultural members themselves. Some of the CCCS work was also notable for its consideration of how British “race relations” and black style subcultures, such as rude boys and Rastafarians, impacted upon the formation of white, indigenous British youth

subcultures. But much of the output by its male academics was silent on issues of gender divisions: the too close identification with male dominated groups and the masculine elements of style had rendered “invisible” the presence of girls in subcultures. To date, the few extensive, systematic explorations that have been conducted on females in male dominated subcultures have confirmed the tentative assumptions made by early feminist critiques of the CCCS – that females use subcultures as a means of negotiating and resisting aspects of conventional femininity.

Although the work of the CCCS has proved highly influential in many other English speaking countries, its position as the dominant paradigm in subcultural studies has been slowly undermined since the early 1990s by intense criticism from a new generation of academics who, eschewing textual analysis and once more embracing ethnography, have attempted to engage with the rapidly changing cultural conditions of contemporary youth. These developments have been further stimulated by the emergence of the “Acid house,” rave, or techno party event from the late 1980s onwards. Because this new youth movement could not be easily accounted for by existing youth subcultural theory, academic attempts to come to terms with its prominence have helped advance the field of study. It is perhaps now accurate to say that we are in a situation where no one theoretical perspective dominates, although two of the major contenders for supremacy are those influenced by the work of Pierre Bourdieu and Michael Maffesoli, respectively.

The concept of “subcultural capital” has been developed on the basis of Bourdieu’s “cultural capital” to explain the hierarchies of taste operating within both clubbing crowds and subcultures. It refers to that form of “hip” status accrued by having esoteric knowledge regarding what is currently “in or out” on that scene, and is a means by which members of such groups display their “authenticity” – the legitimacy of their underground tastes in comparison to what is perceived to be the mass tastelessness of commercialized, “mainstream” culture. Maffesoli’s concept of the “tribus” has, in the guise of “neo tribe,” also been applied to subcultures and dance crowds because of its

connotations of transitory membership, eclectic tastes, and multiple allegiances – all markers of the “postmodern,” and which are said to characterize contemporary youth movements.

Indeed, the widespread use of such concepts as “clubculture,” “neo tribe” or, in some cases, “lifestyle” has led to a questioning not only of the relevance of existing theory but the very term subculture itself. It would seem, however, that despite the polemical pronouncement that we are now “post ” or “after ” subculture, future work will not necessarily dispense with the concept of subculture, but is likely to emphasize the characteristics of flux, fluidity, and hybridization that these groups do, and perhaps to some extent always have, displayed.

subcultures, deviant

T. J. Berard

Subcultures come in an incredible diversity of forms, associated with street gangs, organized crime families, prison inmates, drug addicts, football hooligans, surfers, religious cults, hippie communes, and punk rockers. On a grander societal scale, subcultures include working class and underclass subcultures, racial/ethnic subcultures, immigrant subcultures, regional subcultures, and youth subcultures. Although not all subcultures are deviant, the term subculture is often used to refer to the values and attitudes of deviant groups, and especially deviant groups of juveniles. Therefore, the study of deviant subcultures has traditionally been associated with the sociology of deviance and crime, criminology, and youth social work. But the study of deviant subcultures has expanded well beyond its traditional disciplinary boundaries.

DEFINING CHARACTERISTICS

The term *subculture* is similar to culture in that both refer to a shared collection of traits, including beliefs, values, interests, language, behaviors, and a collective identity. The terms subculture and culture can alternately refer to the *group(s)* or *populations* of persons characterized by distinctive traits. The distinction between subculture and culture deals primarily with the relative size of different cultural groups sharing the same territory. Distinctive cultural groups become “sub” cultures by contrast to the conventional or mainstream values of a larger cultural group which serves as the cultural standard, due to its numerical majority and often greater status and power. Because the members of a subculture are characterized by cultural difference in relation to a larger, dominant, or mass culture, these differences are often evaluated as *deviant*, meaning that they violate conventional standards or fall short of conventional expectations. Some subcultures actually oppose or resist dominant culture, and these subcultures can be called *counter* cultures.

ALBERT COHEN'S DELINQUENT BOYS

The sociology of deviant subcultures was first delineated in Albert Cohen's *Delinquent Boys: The Culture of the Gang* (1955). Cohen combined "cultural transmission" theories of delinquency with a "psychogenic" account at the level of individual psychology. Cohen attempted to explain the prevalence and persistence of urban delinquency in terms of neighborhood subcultures which recruit successive youth groups as subcultural "carriers." Recruitment depends on the provision of subcultural "answers" to problems of adjustment experienced by members of each subsequent cohort of working class boys, each facing similar risks of status frustration in the face of middle class norms, especially in school.

Cohen's arguments reference earlier scholarship on delinquency and gangs from the Chicago School of sociology. Clifford Shaw and Henry McKay's *Juvenile Delinquency and Urban Areas* (1942) had revealed higher rates of delinquency in Chicago's working class immigrant and minority neighborhoods. Cohen attributed the "cultural transmission" theory of delinquency to Shaw and McKay, and to Edwin Sutherland's later theory of differential association. Cohen also drew on Shaw and McKay and subsequent scholarship on the social disorganization or differential social organization of urban working class communities as causes of delinquency. Frederick Thrasher's study *The Gang* (1927) was related to the structural and ecological theory of social disorganization, although Thrasher was also instrumental in drawing attention to the *group* nature of much delinquency, and for pioneering observational research on gangs. Cohen also attributes to Shaw and McKay the theory of "culture conflict," best known from Thorsten Sellin's *Culture Conflict and Crime* (1938), in which Sellin analyzes crime partly in terms of the existence of different normative groups in society, resulting in a conflict of "conduct norms" or "cultural codes." Cohen acknowledges Shaw and McKay yet again with respect to the "illicit means" theory, which he secondarily attributes to Robert Merton. Merton was responsible for disseminating this theory under the name of anomie or strain theory, which explains economic street

crime as an illicit or innovative means of satisfying American cultural norms of materialism and economic success.

One of Cohen's more distinctive contributions was to emphasize that new cultural forms emerge and are perpetuated through social *interaction* in youth peer groups, as youths *collectively* "solve" shared problems of social adjustment through delinquency. Cohen's subcultures thus provide a microsociological bridge between class and neighborhood location and delinquency. Previous usage had often referred to the subcultures of abstract population segments such as classes and races, rather than genuine groups, but in Cohen's hands, the term became more concrete.

SUBSEQUENT STUDIES AND THEORIES OF DEVIANT SUBCULTURES

The institutionalization of deviant subcultures as a topic within the sociology of crime and deviance was cemented when Cohen's *Delinquent Boys* (1955) was followed by Cloward and Ohlin's *Delinquency and Opportunity* (1960). Despite some differences, the two books were similarly theoretical in nature, and both saw deviant subcultures and delinquency as responses to problems of "adjustment" caused by structural issues of class inequality. A third influential author during this period was Miller (1958), who described lower class culture in terms of a number of "focal concerns," including trouble, toughness, excitement, and autonomy. Cloward and Ohlin, and especially Miller, disagreed with Cohen's thesis that working class boys experienced status anxiety over failure to live up to middle class norms, but all agreed that the culture of delinquents should be understood against the background of class structure, with subcultures serving as links between class location and delinquency.

One of the most searching criticisms of the theory of deviant subcultures came with the work of David Matza. Matza's *Delinquency and Drift* (1964) criticized existing positivist theories of deviant subcultures for emphasizing determinism and constraint at the expense of

the will or agency of subcultural members. He also argued that the norms of delinquents could not be sharply differentiated from conventional norms. Two related suggestions were that delinquents employ conventional moral techniques for neutralizing norms or excusing violations, and that delinquent culture and conventional culture overlap in a "subterranean" fashion. Jock Young later pursued Matza's subterranean analysis with great effect in his book *The Drug takers* (1972). Young suggests that values of hedonism and disdain for work, for example, are subterranean values throughout society, and that drug takers accentuate these values rather than create them as unique features of a deviant subculture.

In the 1970s, subcultural theories of deviance took on new forms in Britain, largely associated with Birmingham University's Centre for Contemporary Cultural Studies. Stuart Hall and Tony Jefferson's collection *Resistance Through Rituals* (1975) signaled the arrival of the British on the scene. The influence of 1960s labeling theory was evident in that British theorists and ethnographers skipped the foundational American concerns with the reform or control of juvenile delinquents. Instead, British scholarship reflected a neo Marxist project of class analysis sympathetic to the symbolic resistance ostensibly represented by working class youth subcultures. Paul Willis's *Learning to Labour* (1977), which documents a group of working class youths leaving school and accommodating themselves to their place in the labor market, became one of the most celebrated ethnographies of deviant subcultures. Another landmark British contribution was Dick Hebdige's *Sub culture: The Meaning of Style* (1979), a semiotic analysis of the aesthetics adopted by musical subcultures such as punk rockers. Both Willis and Hebdige suggested, in different manners, that youth subcultures signify ideological resistance to the hegemonic and oppressive nature of post war capitalist society. The British tradition was distinct in many respects, but generally shared with American studies an underlying tendency to treat culture as secondary to structural and economic conditions, and to treat subcultural responses to structural inequality as ultimately ineffective, if not outright dysfunctional.

POLITICS AND MORALITY

The theoretical contributions of the early Chicago School partly reflected a liberal, reformist position on urban social problems, evident in their arguments that delinquency and crime were to be explained by the social disorganization of communities rather than in terms of individual pathology or racial proclivities. In the 1940s and 1950s, Cohen, and Cloward and Ohlin, raised more critical questions about unequal opportunities in American society, but stopped far short of radical critiques of the American class structure. Such early criminological theory also displayed an underlying correctional morality.

Ethnographic work remains perhaps the least evaluative and least political of traditions in the study of deviant subcultures, although ethnographers often cooperate with social service institutions, and portray their subjects with more sympathy than condemnation. Many British contributors identified unabashedly with the neo Marxist theoretical tradition, but this in the post war period when neo Marxism entailed cultural critique rather than revolutionary politics. British work suggests that the problem is not so much delinquent youth groups as class inequality, unemployment, disruptive urban planning, and the like. In the US the "culture of poverty" argument has been used at times to hold the poor responsible for their poverty. The sociology of deviant subcultures has therefore always been associated with discourse on social problems, whether deviant subcultures serve as targets for reform, as targets for crime control, or as indicators of larger problems rooted in class relations, race relations, and urbanization.

It is important to recognize, however, that the term deviant subculture does not necessarily reflect a sociologist's judgment that particular groups are deviant. While the term can reflect such judgments, it can also be used by sociologists in a purely descriptive, non judgmental sense, in reference to the common evaluation of a subculture in the wider cultural environment, which the sociologist merely observes to be the conventional evaluation. Howard Becker's *Outsiders* (1963) served as an

influential introduction to non judgmental studies of deviance and deviant subcultures.

METHODOLOGICAL ORIENTATIONS AND ISSUES

Methodologically, the study of deviant subcultures is complicated by the coexistence of two largely distinct traditions of research. Many positivist, quantitative studies starting in the 1960s have tested formal theories of delinquency, but these theories often address subcultures only tangentially, and many are not specifically *cultural* explanations of deviance. In such studies, subcultures might figure as a potential explanation for deviance, rather than as phenomena in their own right. Qualitative studies often describe real subcultural groups, who really deviate from middle class norms and criminal codes. Qualitative researchers are often not concerned with formal theory testing, for formal theory construction, or even causal explanation. Studies of deviant subcultures have often been of the latter, qualitative variety, employing observational and interview methods, which offer accounts of identity, behavior, and commitment as these are related to a way of life and system of meanings.

One of the more reflective methodological discussions is provided by Ned Polsky, a later member of the Chicago School, in his book *Hustlers, Beats, and Others* (1998). Polsky advocates studying criminals in their natural environment, and raises several objections to research trends in the sociology of crime and criminology. Polsky argues that good ethnographic research on criminals requires a disinterested stance on questions of morality and law, and finds fault with those who approach their studies with a social control or social work orientation. He charges that these trends have worsened recently because opportunities for jobs and grants are increasingly weighted towards the practical concerns of criminal justice administration. He objects to the common practices of studying criminals in "anti crime settings" such as prisons and half way houses, and criticizes the over reliance on the recollective testimony of such caught criminals. He criticizes what he

suggests are scientific prejudices and bureaucratic fetishes leading to the dismissal of unstructured field observations in favor of more structured research methods. The more structured methods, he charges, erect screens between researcher and subjects and prevent the observation of subjects in their ordinary life situations.

While all of these are serious and important issues, Polsky risks being overly dismissive. Many noteworthy studies have been informed by the labeling/social reaction theory, which studies deviance as a function of social labeling, thus opening up new topics for research. Stan Cohen in his *Folk Devils and Moral Panics* (1972) noted the role of media in constructing a moral panic about youth subcultures, which led ironically to increased affiliations with such subcultures. Similar observations have been made about the gang eradication efforts of social workers and police. Meehan (2000) suggests that gang activities are in an interesting sense constructed by police dispatchers and gang units for bureaucratic and political reasons. Solid work has also been done in correctional settings. John Irwin explored inmate subculture in *The Felon* (1970), and D. L. Wieder's *Language and Social Reality* (1973) analyzes the "convict code" in a half way house, prefiguring contemporary interest in the relevance of language for displaying subcultural norms.

A more recent discussion is provided by Katz and Jackson Jacobs (2004) in a survey of gang research. Although the research surveyed includes noteworthy quantitative and positivist studies, Katz and Jackson Jacobs note several shortcomings of quantitative data. Data from official sources, victim surveys, and self report surveys are all problematic in different ways. Gang identities can go unremarked and unrecorded, can be recorded erroneously or inconsistently, or can be recorded in insufficient detail. Katz and Jackson Jacobs argue that the field of gang studies "is structured on a quiet agreement not to press the causal question" (p. 93). They suggest that causal explanations may be tautological, and they ask whether gang membership causes violence, or vice versa. More broadly, these authors note that gangs are often treated as an index of the background social conditions

which happen to preoccupy each given theorist, resulting in a failure to document the realities of gang life.

Although many quantitative studies have had minimal impact on subsequent theory and research, the entire project of explaining deviance in terms of subcultures is premised on statistics suggesting different rates of deviance in different segments of the population or in different neighborhoods. Such data cannot demonstrate that deviance is caused by subcultures, but they can be suggestive. The *lack* of statistical differences across groups or neighborhoods can throw subcultural theories into question, also. For this reason, self report studies indicating that middle class youth might engage in delinquent behavior at similar rates as poorer youth have added an interesting debate to the study of delinquency, as have studies suggesting that lower class youth have similar rates of delinquency regardless of membership in delinquent peer groups. The theoretical relevance of quantitative analysis is also limited in part by the theories in question, which have frequently been criticized for being difficult to test or for being tautological. Such issues may ultimately reflect divergent traditions of inquiry. Theories of deviant subcultures have rarely been designed to satisfy the requirements of formal theory, although they have often implied a researchable causal relationship amid largely interpretive accounts of deviant subcultures.

FUTURE DIRECTIONS

By the 1980s the sociology of deviant subcultures had established a core literature, around which much discussion still revolves. This has led to an under appreciation of historical developments, including the increasingly economic and violent character of street gangs in the US, blamed largely on the drug trade, and the further commercialization of youth subcultures, especially with respect to music and fashion. Academic developments have had greater influence on deviant subcultures scholarship. Sarah Thornton expanded subculture theories by incorporating Pierre Bourdieu's sociology into her *Club Cultures* (1996). The interpretive and linguistic turn in the social sciences has brought new attention to the identities and

commitments of subcultural members as understood by the members themselves. Sue Widdicombe and Robin Wooffitt's *Language of Youth Subcultures* (1995) is exemplary in this vein.

Although the first generations of theory and research on deviant subcultures tended to focus on the delinquent behavior of young urban males, the literature has expanded considerably to address a wide range of deviant behavior, in a great variety of settings, and among girls as well as boys, adults as well as juveniles. The expansion of the subject area has occurred hand in hand with the proliferation of relevant theories and perspectives. Within criminology and the sociology of crime and deviance, relevant work is addressed to social learning and differential association theories, social disorganization and social control theories, labeling theory, class conflict and cultural conflict theories, and several others. Many relevant publications appear outside the sociology of crime and deviance, including in youth studies, cultural studies, urban studies, minority studies, and many other fields. Studies of cults, organized crime, hate groups, and other deviant subcultures are often pursued as independent topics, in what are now largely separate literatures. The sociology of youth culture, in particular, has broadened the discussion of subculture towards cultural rather than criminal deviance, for example emphasizing alternative music and dress rather than vandalism and street fights. Michael Brake's *Comparative Youth Culture* (1985) traces as well as represents this trend. Much of the existing momentum in the study of subcultures is now addressed to youth culture, and is associated with the field of cultural studies as well as sociology. Importantly, the early tendency to resort to subcultures primarily as an explanation for the apparently irrational behavior of urban youth, in the context of a structuralist emphasis on class relations, has been counterbalanced to some degree. In recent studies, cultural analysis sometimes appears as an alternative to structural analysis, meaning that subcultural identity, commitment, values, and styles are not always understood as determined and dysfunctional.

The relationship between deviance and cultural groups and cultural differentiation continues to be a rewarding topic of study, and has informed and even generated theoretical

and empirical work across a growing variety of disciplines and subdisciplines.

subjectivity

Vivienne Boon

In sociology, subjectivity is often positioned as the opposite of objectivity, with objectivity being the ideal to which all empirical sociology should aspire. When Auguste Comte coined the phrase sociology, he had in mind the objective study of human behavior according to rational principles. A pertinent example of objective sociological analysis is that of Émile Durkheim, who argued that sociologists should analyze the internal (and impersonal) causes of social phenomena through the observation of concrete facts. Another notable example is, of course, the scholarship of Karl Marx, who also believed in a form of social scientism that went beyond

the surface of social life through the analysis of concrete social facts. Durkheim distinguished this analysis from philosophical introspection and generalizations that would be unduly affected by subjective influences such as beliefs and values (Giddens 1993; Crow 2005).

Objective sociology has been criticized by those who believe that the observation of social phenomena cannot and should not be separated from our subjective perspective, since doing so entails a form of distortion and even repression. Here, introspection and philosophical reflection play an important role and social analysis proceeds through the chief methods of "imagination, psychological insight and historical interpretation" (Mayer 1934: 341).

However, subjectivity is more than the mere opposite of objective social research. For it is an intrinsically modern concept that is bound up with ideas of the self as an acting agent. Through secularizing and modernizing processes, it was no longer a universal order that predetermined individual actions but, rather, it was within the thinking subject herself that reason and freedom were to be found. It was as a result of modernization processes that a preoccupation with the flourishing of the authentic individual self emerged (Berman 1970).

In the Enlightenment writings of Immanuel Kant, the transcendental subject stood at the center of all possible knowledge and reason. It was in the unified subject that sensibility and understanding collided, giving rise to the universal (Kant 1968). This idea of the unified subject was already contested by Georg Wilhelm Friedrich Hegel, who argued that the subject was not in and of itself but, rather, became aware of its subjectivity through its relation to surrounding objects and subjects.

Yet, it was with Friedrich Nietzsche that the subject disintegrated and became celebrated as an aesthetic endeavor. For Nietzsche intended to "inculcate a greater degree of personal agency, and the taking of responsibility for one's actions in the process of self creation" (Hall 2004: 70). Nietzsche is hence often regarded as the forefather of postmodern and poststructuralist thought, which claims that there is no grand knowledge (Lyotard 1984) and no centered (or unified) subject (Lacan 1977; Foucault 1984).

According to Michel Foucault, our subjectivities are formed through our subjection to

various discourses that position a subject within a web of knowledge–power relations. Whilst these discourses of power are oppressive, they also provide a site of resistance in that we can continuously reinvent our subjectivities (Foucault 1984: 41–2). It is for this reason that Foucault endeavored to engage in a genealogical critique that consists of a “historical investigation into the events that have led us to constitute ourselves and to recognize ourselves as subjects of what we are doing, thinking, saying” (1984: 46). Thus whilst we are subject to various historical discursive processes, we are also agents acting and interfering in these historical processes.

Appeals to active subjective agents have been made in light of identity and subcultural politics. For example, within identity politics, it is argued that women’s voices provide alternative voices (through their female subjectivity) within a political realm that is dominated by a male hegemonic order. Similarly, subcultural styles such as punk have also been heralded as the creation of new subjectivities (Hebdige 1979).

We should be careful, however, not to conflate the notions of identity and subjectivity, even though they are rather difficult to distinguish since they are intrinsically related. It is difficult to think of one’s identity without regarding one’s subjectivity, just as it is hard to perceive of one’s subjectivity without a sense of I, or identity. Yet, as Heidrun Friese notes, identity thinking in the social sciences has often been motivated by the desire for unity of the subject, and has proceeded through the construction of narratives and the process of naming that synthesized the manifold (Friese 2002: 26). Reflection on subjectivity is slightly different from identity thinking in that it is more specifically focused on the consciousness of being, on the medium of one’s own mind in the perception of things, and on the awareness of one’s subjective feelings. Thus reflection on subjectivity is more related to the idea of consciousness and stands at the intersection of “two lines of philosophical inquiry: epistemology (the study of how we know what we know) and ontology (the study of the nature of being or existence)” (Hall 2004: 4).

suburbs

Judith J. Friedman

Social scientists in the US usually identify a city’s suburbs as the municipalities (plus any “urban” unincorporated areas) that are located outside the political boundaries of that city, but are adjacent to the city or to its other suburbs. A city’s suburbs form a band around the city that has (1) lower population density overall than the city, yet (2) predominantly urban land

uses. Unless the city is located near another city, its suburbs end where farmland or open space predominates. The term suburb refers either to the entire band of suburbs around a city or to particular places within a suburban band. The term suburban also can refer to a way of life identified with suburbs.

The definition of suburb and the characteristics of suburbs differ around the world, in part because of differences in local government structure. In many countries, suburbs are relatively new neighborhoods within a city or within a metropolitan area served by one government. This entry focuses on suburbs in the US, where municipalities, including those considered suburbs, have substantial political and fiscal autonomy. In 2000, half the US population lived in suburbs of metropolitan areas (Hobbs & Stoops 2002).

Early US cities absorbed more people and more activities by (1) using land more intensively, and (2) expanding on the edge, as developers converted farmland to an urban use. Cities routinely annexed the newly urban land. In the nineteenth century, railroads permitted a new kind of small town: a primarily residential town linked by rail to a city. These towns were called suburbs. As the city expanded toward a commuter suburb, well-to-do residents frequently resisted annexation. State laws in Eastern states soon facilitated this method of retaining local political control by making incorporation relatively easy, and annexation difficult.

The US population shifted from small towns and farms to large towns and cities during the nineteenth century, and additional types of suburbs formed. Before 1900, street car lines facilitated lines of urban land use that extended outside city limits. Factory owners built modern factories on the city's outskirts, creating industrial suburbs. Cities annexed some of this newly urban land, but residents of other new places incorporated. New urban land uses eventually surrounded older towns, cities, and commuter suburbs. Despite the resulting diversity among a city's suburbs, the term suburb retained a connotation of new, residential, and middle class.

Factories built during World War II brought more jobs to former farmland around cities, and both residential and commercial construction boomed after the war. Farmland near a city provided ideal locations for large developments,

especially when near a highway. Diverse federal and state policies subsidized new schools, hospitals, sewer lines, and other infrastructure, but did little to repair and upgrade existing infrastructure. Federal housing policies combined with banking and real estate practices also tended to put cities at a disadvantage. Some cities, especially cities in the West, continued to annex new development. If a city did not annex growing areas, its suburban band expanded in land area, employment, and population. If the city itself failed to attract new residents and businesses, its property tax revenue declined, putting it at further disadvantage.

As cities stopped routine annexation, social scientists and administrators needed a straightforward definition for this urban land outside city limits, a definition that would facilitate both data collection and comparisons among places and across time. The US Bureau of the Census based such definitions on political boundaries – municipal or county. Standard Metropolitan Statistical Areas (SMSAs) contain a large city and its “ring” – the rest of the county that contains the central city land plus any adjacent counties economically tied to the city. An SMSA can include substantial rural areas. In 1910 the Census identified 25 metropolitan districts – cities plus adjacent “urban” minor civil divisions (Gardner 1999) – but published little information about the “fringe” of each district. In 1950 the Bureau defined 35 urbanized areas, units again based on minor civil divisions. A city's fringe could include incorporated places (residential suburbs, industrial suburbs, older towns and villages) plus unincorporated land that had a population density of 1,000 per square mile or more or was surrounded by other land within the fringe. Since land area and the population size of a city's fringe depended in part on past annexation, large fringe areas were more typical of cities in the Northeast than of cities in the West or South.

In Census reports and in academic research using Census data, a city's fringe (and its ring) became its suburbs. Individual incorporated places within the fringe or ring also are called suburbs. Demographers such as Schnore (1965) emphasized the diversity of these incorporated places, and suggested categories. Schnore reserved “suburb” for primarily residential

municipalities; suburban residents still largely commuted to city jobs. Schnore called municipalities that provided substantial employment, and hence had some independence from the city, "satellites."

Even in 1950, distinctions between city and suburb were not always obvious, particularly in highly urban areas. Jersey City, NJ could be a central city or a satellite, but was it a satellite of Newark or of New York City? Similarly, was Newark a city with suburbs, or a part of New York City's suburbs? With each subsequent Census, this situation has become more common and more complex.

Further changes in land use, particularly the growth of jobs in suburbs, have generated a new kind of commute and a new term: exurb. Exurbs are small towns or unincorporated areas with sizable new housing developments. Located outside the suburban fringe, an exurb houses many people who work in suburbs.

The suburbs (and exurbs) of any US city tend to be different from each other, yet internally homogeneous. Employment is no longer a key distinction. Municipal zoning practices, economic development policies, and other local policies mean that a suburb can appear residential, yet have substantial commercial, office, and even industrial activity. Suburbs now concentrate such activities in malls or in "parks" located near highway interchanges, effectively out of sight as corporate landscaping blends into the residential landscape.

The critical difference among US suburbs today involves ability to finance municipal services. US municipalities, counties, and school districts depend heavily upon property tax revenue, and per capita property tax revenue varies substantially. Federal and state funds have not equalized local revenue (and services). A suburb with wealthy residents plus substantial non residential development can provide services more easily than a primarily residential community with low income residents. Over time, these differences have produced substantial "stratification of place" among each city's suburbs. As this suggests, there is wide variation in median family income as well. Suburbs are not necessarily middle class.

The processes creating the decline of annexation, suburban stratification of place, and substantial population and housing homogeneity

within each suburban municipality involve more than municipal finance. Long held beliefs about proper land use planning, use of local land use planning (rather than metropolitan area planning), and the importance of home ownership as a financial investment make substantial contributions. The initial characteristics of each suburb also have lasting impact. Older industrial suburbs, for example, tend to follow a different track than older suburbs that began as upper middle class residential areas.

Housing stock can be especially important, as it varies with the period in which a suburban municipality experienced rapid growth (Friedman 1994). Suburbs that grew rapidly before World War II include satellites with substantial multi family housing and other housing built for the working class. Other older residential suburbs can have large homes that have retained, even gained, value. Places that grew rapidly just after World War II are likely to include former defense plants and post war housing tracts that initially had small houses on small lots. In this period, many municipalities, anticipating future growth, zoned for large lot single family homes. In part for this reason, average house size increased rather steadily after 1948. Single family homes built in 1955 averaged 1,270 square feet. The mean for new single family homes increased to 1,500 in 1970, 2,080 in 1990, and 2,330 in 2003 (HUD and US Bureau of the Census 2004). Suburbs also vary in the extent they have added condominium and townhouse developments, a possible source of "moderate" cost (but not necessarily "affordable") housing.

The total suburban population of the US is becoming less "white" as others settle in suburbs. By 2000, over half (58 percent) of the Asian population, half (49 percent) of the Hispanic population, but only 39 percent of the black population lived in suburbs (defined as the rings of SMSAs) (Logan 2001). Koreans and Asian Indians are especially suburban, in part because immigrants are settling directly in suburbs. In the entire country, 75 percent of the 2000 suburban population was non Hispanic white. The remaining 25 percent included 11 percent classified Hispanic, 8 percent black, and 4 percent Asian (US Census).

The suburban history of blacks is complex. US suburbs have always housed and employed

African Americans (Wiess 2004). Before World War II, high status suburbs typically had neighborhoods that housed African American servants and other local workers. In the South, African Americans typically lived on the outskirts of the city. In the North, freed slaves founded villages and towns that are now within a city's fringe. The vast majority of the housing developments that went up outside (and also inside) city limits before, perhaps, 1970 were, however, entirely white. Homogeneity in residential neighborhoods was "best practice." Realtors and sociologists alike argued that neighborhoods homogeneous in income, race, ethnicity, and other characteristics were more likely to retain property value over time. Further, housing discrimination was legal until the late 1960s. Since then, the percentage of blacks living in suburbs has slowly increased. Informal practices continue, however, to limit housing integration.

suicide

Steven Stack

Suicide is among the top ten leading causes of death. Over 30,000 Americans take their own lives each year: about 85 per day. Further, there are an estimated 250,000–600,000 suicide attempts each year. There are at least 5 million living Americans who have attempted suicide in the past. While Americans fear being murdered more than dying by their own hand, the suicide rate is currently double the murder rate.

The dominant mode of analysis of suicide has stressed Durkheim's (1966) concept of social integration – bonds between the individual and society. Subordination of the individual to society is thought to provide meaning and prevent selfishness or "egoism." Groups lacking in ties to society, such as widowers, the divorced, atheists, the unemployed, and non church members, are at higher than average risk of suicide.

According to Durkheim, the greater the number of religious beliefs and practices shared with co religionists, the lower the suicide rate of a group. Historically, Catholics were more integrated (e.g., meatless Fridays, confession, weekly church attendance) than Protestants, and had lower suicide rates. In modern times, Islam is a religion with a high level of integration (e.g., prayer is expected multiple times a day). Research finds that the higher the proportion of Muslims in a nation, the lower the nation's suicide rate.

Marriage and parenting are seen as providing a set of responsibilities, such as obligations to a spouse (e.g., giving and receiving emotional support) and children, that act as protections against excessive self involvement or egoism. A review of 132 studies found strong support for

this thesis in 77.9 percent of their findings. For example, in Austria, the suicide rate of divorced persons is 128.6/100,000. This rate is 4.22 times higher than the suicide rate among married persons (30.5/100,000). Divorce rates are the best predictor of suicide rates in the 50 American states for all census years (e.g., 1940, 1950, 1960, 1970).

CHANGES OVER TIME IN THE TOPIC AND ITS TREATMENT

Religion and Suicide

Two new theories have linked religion to suicide. First, Stack's theory of religious commitment and suicide argues that belief in a few life saving principles (as opposed to the many that Durkheim posited) may be enough to prevent suicide. For example, belief in a blissful afterlife for those who persevere may protect against risk factors such as poverty, divorce, and death of loved ones. Second, Pescosolido's religious networks perspective argues that friends from church (co religionists) may provide emotional and material support for other wise suicidal individuals. It may not be religious beliefs per se that save lives, but the social support networks in churches that prevent suicides. Most of the empirical work on these new, perhaps complementary, perspectives has supported the respective theories. For example, in an analysis of 261 Canadian census divisions, a 10 percent increase in the proportion with no religious affiliation (a sign of both low religious commitment and religious networking potential) is associated with a 3.2 percent increase in the suicide rate.

Economic Strain and Suicide

Durkheim argued that poverty was a school of social constraint. The poor were toughened by impoverishment and could handle life's adversities better than the more affluent. However, in the last 50 years, most research on social class and suicide risk has found that lower status persons have higher, not lower, suicide rates. For example, data for the US indicate that laborers have a suicide rate of 94.4 suicides per 100,000, eight times the national suicide

rate. The high suicide rate of lower class persons is partly a consequence of their high rates of severe mental troubles, alcoholism, and family disruption.

Unemployment can influence suicide by affecting suicide risk factors such as lowering household income, self esteem, work centered social networks, and increasing depression levels. For example, in London, the unemployed had a suicide rate of 73.4/100,000, five times that for the general population (14.1/100,000). In Austria the suicide rate for the unemployed was 98.3/100,000, a figure nearly four times that for the general population (25.0/100,000).

Alcohol and Suicide

Durkheim rejected alcohol abuse as a contributing factor to suicide, although his own data, if carefully analyzed, showed a significant association. Nevertheless, alcohol can increase suicide risk through such means as emotional disinhibition, which enhances impulsive behavior including suicide, pharmacological effects, and depression. To the extent that a culture provides positive definitions of alcohol use, it may indirectly promote suicidal behavior. Sociological research over the past three decades has often illustrated an association. For example, at the level of individuals, in a panel study of 40,000 men over four decades, the lifetime prevalence of suicide by age 60 was 4.76 percent for alcohol abusers compared to 0.63 percent for non abusers.

CURRENT EMPHASES IN RESEARCH AND THEORY

Media and Suicide

Durkheim, on the basis of scant data, viewed media based stories, such as those in newspapers, on suicide as largely irrelevant to explaining suicide rates. However, since 1967 many of the 106 studies on this issue have found copycat effects. From news and other coverage of suicide, depressed people may learn that there are troubled individuals who commit suicide in response to life's problems. For example, the publication of *Final Exit*, a guide recommending

suicide through asphyxiation for the terminally ill, was associated with an increase of 313 percent in suicide by this method in New York City. This was for the year that the book was published. A copy of *Final Exit* was found at the scene of 27 percent of these suicides.

From the standpoint of social learning theory, widely publicized suicides are most likely to trigger copycat suicide if the model is a celebrity, someone that many people identify with, a well known and admired person. In particular, studies of the widely publicized suicides of entertainment or political celebrities are 14 times more likely to find a copycat effect than studies of ordinary suicides. When famous movie stars commit suicide, there are, on average, 217 additional suicides during the month of news coverage of their suicide.

Gender Suicide Ratio

After a century of converging, the suicide rates of men and women are diverging. For example, while the suicide rate of women was half that of men 50 years ago, it is currently only a quarter that of men in the US. Stack developed a cultural theory of a curvilinear relationship in the gender suicide ratio. First, female rates of suicide would rise along with increases in labor force participation. The cultural definition of women's place as being in the home would promote a certain amount of strain and guilt for many working women, increasing their risk of suicide and closing the gender gap. However, after a critical mass of women was in the labor force, culture defined the working mother in more positive terms. Supportive social institutions such as day care centers emerged, and women's percentage share of better jobs in the professions increased. Women could take more advantage of the benefits of work, such as adult companionship, careers, and higher household income, and their suicide rate declined. However, the gains for women in such areas as medicine, law, and the professorate represent corresponding losses in occupational mobility for men. Male suicide rates have increased proportionately, thus widening the gender suicide gap. Pampel has successfully applied Stack's curvilinear theory to a sample of other industrial nations.

Sexual Orientation and Suicide

Given significant homophobic tendencies in the cultural systems of western developed societies, one might anticipate that persons with homosexual orientations would have a higher incidence of suicidal behavior. It is often argued that the recognition of one's homosexuality is often associated with anxiety, depression, confusion, and other suicidogenic conditions. The families of many gay youth may multiply the risk of suicidal behavior through the rejection of the gay child. While there are few well designed research studies on sexual orientation and suicide, two patterns are found in the existing research evidence. First, homosexuals have higher rates of suicide attempts than heterosexuals. For community samples, the prevalence of having attempted suicide among gay males ranges from 20–35 percent and is about twice that of heterosexual males. Among disturbed samples (e.g., runaway youth) the prevalence rate of attempted suicide sometimes exceeds 50 percent. The prevalence of suicide attempts is higher among lesbians, but the gap between lesbian and heterosexual women is smaller than that for men. Second, while completed suicide and sexual orientation is an understudied area, there is no evidence that homosexuals have a higher rate of completed suicide than heterosexuals. Further, the stress and other factors underlying the suicides of gay and heterosexual persons were more similar than different and include relationship difficulties with lovers. However, gay suicides are more apt than heterosexual suicides to use hanging as a method and to have been diagnosed schizophrenic.

QUALITY OF SUICIDE DATA

Data on suicide tend to underreport the phenomenon. Some authorities seek to conceal suicide as a cause of death. The best estimates of underreporting place the suicide undercount as being somewhere between 3 percent and 18 percent. For example, suicide is undercounted by 2.8 percent for males and 5.6 percent for females. These error rates are not large relative to undercounts for crime rates. For example, crime underreporting in federal crime statistics amounts to 67 percent of all index crimes,

including 49 percent of the rapes and 50 percent of the burglaries.

Analyses of data for 404 American county groups support the validity of suicide data. Indicators of misreporting in the official statistics have little discernible effect on the relationships between major sociological variables (e.g., divorce rates, religion) and suicide rates. The errors in suicide reporting are not considered large enough to preclude meaningful sociological analyses.

FUTURE DIRECTIONS

The vast majority of sociological studies on suicide deal with suicide as a phenomenon isolated from other forms of deviant behavior. However, recent research finds that suicidal persons, those who are basically depressed and out of touch with the value of life, are involved in a broad range of deviant behaviors. For example, analyses of national data found that suicidal youth are more likely than others to engage in each of the following deviant behaviors: crack cocaine use (9.25 times more likely), marijuana use (3.25 times more likely), binge drinking (2.69 times more likely), heavy smoking (3.17 times more likely), unsafe sex (2.65 times more likely), getting someone pregnant/getting pregnant (4.63 times more likely), carrying a gun (4.73 times more likely), aggravated assaults (6.56 times more likely), and threatened with a weapon (5.23 times more likely). Research on crime and deviant behavior could benefit by viewing deviance, in part, as an expression of suicidality.

Of course, in future research there is the issue of the direction of causality. Does suicidal behavior cause deviance, or does deviance cause suicidality? Perhaps a common factor x may account for many types of deviant behavior, including suicidal behavior. The common factor may be, as Durkheim argued, lack of adequate subordination of the individual to society: low social integration. Factor x may also include a psychological state such as depression, which has been associated with a wide variety of deviant behaviors, especially suicide.

Sumner, William Graham (1840–1910)

Bernd Weiler

William G. Sumner, born in Paterson, New Jersey, is commonly regarded as one of the most influential American social scientists in the late nineteenth and early twentieth centuries. In his stories of sociology he is often portrayed or – as some would argue – misportrayed as a conservative apologist for “tooth and claw” capitalism and as the great Social Darwinist antipode to his progressive and reform oriented contemporary and fellow countryman L. F. Ward.

After graduating from Yale in 1863, Sumner, the son of an immigrant mechanic and pious Protestant from Lancashire, attended

the universities of Geneva, Goettingen, and Oxford to study languages, history, and theology and to prepare himself for the ministry. In 1866 he returned to Yale as a classics tutor and, shortly afterwards, joined the Protestant Episcopal clergy. In 1872 he was appointed to the newly founded chair of political and social sciences at Yale, a post he held until his retirement in 1909. In the 1870s Sumner also served as a politician for the Republicans. Disillusioned, he left politics after a few years and became a liberal Mugwump. In 1908, two years before his death, Sumner succeeded L. F. Ward as the second president of the American Sociological Society.

Among the main intellectual influences on Sumner's work were classical economic theory, especially Malthus's population theory, the positivistic approach to the study of history (e.g., Buckle), Darwinian evolutionism, Spencerian sociology, and, later in his career, the emerging comparative researches in ethnography and cultural history (e.g., Lippert), as well as the contributions of the "Austrian Struggle School." Like many theorists of his age who converted from religion to social science, Sumner replaced the belief in a divine providential design with a naturalistic conception of the lawfulness of the social world.

Sumner's writings span a broad spectrum of subjects and genres. Apart from extended treatises on American economic history and political biographies, Sumner, in the first part of his career, gained fame as a public intellectual who vigorously supported laissez faire economics and adhered to a Social Darwinist philosophy. In numerous articles he polemicized against bimetalism, protective tariffs, trade unionism, socialism, governmental paternalism, amateurish "meddling" in social affairs, and utopianism. Far from simply glorifying the status quo and contrary to the prevailing optimism of his time, however, Sumner remained skeptical about societal progress, warned against the danger that plutocrats might undermine the independence of political life, and argued forcefully against the emerging American imperialism.

In the second part of his career, following a breakdown in health in 1890 and accompanying his increasing disillusionment with American society, Sumner turned his attention from current social, political, and economic affairs to the

cross cultural study of the importance of tradition for human conduct. The major works resulting from this research, in the course of which Sumner and his collaborators collected and indexed a massive amount of data from cultural history and ethnography, are the loosely structured treatise *Folkways* (1906) and the voluminous, similarly unsystematic, posthumously published *The Science of Society* (1927). At the core of Sumner's late theoretical work, which was not free from contradictions, lie his identification of four universal needs (hunger, love, vanity, fear), his argument that societies had developed different means or "folkways" to satisfy those needs, his claim of the priority of the group over the individual, his analysis of the antagonistic relationship between "we groups" vs. "others groups," his inquiry into the universal nature of "ethnocentrism," and his emphasis on the mighty and unconscious influence that "folkways" exerted over all people, whether "savage" or "civilized." The main thrust of Sumner's late work, however, may be seen in the enormous collection of empirical data. Though Sumner and his disciple Keller neglected the use of statistical methods, were unable to synthesize their data in a satisfactory manner, and were unable to lay the foundations for a comparative science of society, they anticipated and influenced the much more comprehensive and systematic *Human Relations Area Files* that are intimately linked to the name of G. P. Murdock, another Yale scholar.

Sunbelt

Vern Baxter and David Johnson

The Sunbelt is a contested construct adopted by scholars in the late 1970s from journalistic accounts of industrial relocation and shifts in population and political power to the Southern and Western regions of the US after World War II. The Sunbelt is defined by juxtaposing rapid economic growth and the rise of conservative politics in the South and West, with economic collapse and political liberalism in the Northeast and Midwest (Frostbelt). Sunbelt boundaries are ambiguous, depending on whether attention is directed to relocation of old industry, location of new industry, or political realignment. Sale's (1975) early designation of the Sunbelt as that area below the 37th parallel (northern border of North Carolina through lower third of California) was largely confirmed by Rice and Bernard's (1983) survey of business and public perceptions of the region, but other scholars believe the Sunbelt represents a sloppy form of regionalization that combines disparate patterns of growth and prosperity found in the South and West.

While scholars quarrel about geographic boundaries, most agree the Sunbelt represents economic growth and conservative politics in a new urban environment. Spurred by federal investment in military and space programs, the expansion of Sunbelt defense, aerospace, electronics, agribusiness, oil and gas, and tourist industries places the region at the center of

the new economy. Industrial restructuring and flexible production methods favor Sunbelt cities as locations of new industry and for relocation of northern manufacturing plants. Sunbelt cities generally offer lower labor costs, non union workforces, and less stringent environmental and zoning regulations than found in the north. Larger cities like Los Angeles, Houston, and Atlanta now challenge the prominence of New York and Chicago, while medium size Sunbelt cities like Charlotte and Albuquerque are peers to Cincinnati and Providence. Automobile transportation facilitates urban sprawl in Sunbelt cities where annexation and city-county mergers favor private investment and unfettered, if uneven, economic growth. Internal migration to the South and West and extensive immigration from Asia and Latin America increased population and political representation of increasingly Republican Sunbelt states that spearheaded realignment of national politics.

Convergence and uneven development theories provide the broadest explanations of Sunbelt economic growth. Convergence theory emphasizes long term equilibrium in national market economies. Earlier industrial growth, higher incomes, and lower unemployment in Northern industrial cities was eventually offset by lower wages and factor costs in the Sunbelt. Regional convergence occurred as investors took advantage of lower costs and backlogs of unapplied technologies in industry and agriculture. Rostow (1977) argues that the global economic upswing after 1972 favored the Sunbelt with higher food and energy prices and expansion of electronics and petrochemical investment, while demand stagnated for products like textiles, shoes, steel, and autos produced up north. Ecological theories highlight a filtering process whereby firms move from higher to lower wage regions and take advantage of new infrastructure in the Sunbelt. Both convergence and ecological theories emphasize private rather than public sector impetus for Sunbelt economic growth. The superior business climate that attracts investment to the South and West is enhanced by lower taxes, weak regulation, and local coalitions committed to privately organized growth.

Theorists of uneven development argue that capitalist economies grow in a spatially concentrated and uneven fashion that creates divergent development patterns that engender

dependence of one set of cities on another. Watkins and Perry (1977) argue that economic investment is not dispersed throughout the country by some equilibrating mechanism, but that historic conditions change so old centers of growth (Northern steel, autos, rubber) lose momentum and new ones (Sunbelt defense, electronics, oil) emerge. The Sunbelt has not prospered because low wage manufacturing moved South, but because new high wage, high tech industries located in the South and West. Contrary to convergence theory, uneven development theorists emphasize the role of government in the rise of the Sunbelt. They argue that inequities in federal spending broke earlier barriers to Southern industrial development. New Deal era federal spending on highways and infrastructure and Cold War federal spending on defense technology and military bases are critical determinants of Sunbelt growth.

The political importance of the Sunbelt is widely debated. Controversy initially centered on whether the emergent Republican majority in most Sunbelt states would fragment the national polity and undermine the liberal consensus that supported the welfare state. Debate extended to whether regional shifts were occurring in the composition and politics of the ruling class. One view is that political ascendance of the New Right evidences a shift from dominance by moderate Eastern "Yankee" to ultraconservative Southwestern "Cowboy" capitalists. The "Yankee Cowboy" thesis is that rapid post World War II economic growth in the Sunbelt created new elites who made money speculating in oil, defense, and real estate. These "Cowboy" elites oppose government intervention in the economy and advocate an expansionist foreign policy, states' rights, weak unions, and individualistic morality. Opponents insist that the 1970s corporate profit squeeze and political reactions to Civil Rights and environmental protection legislation catalyzed a convergence of elite politics on a New Right consensus. Empirical research finds little consistent evidence of a split between "Cowboy" and "Yankee" elites. Salt (1989) finds that Sunbelt capital was more supportive than Northeastern capital of conservative candidates in national elections held between 1978 and 1986, while Midwestern capital was more supportive of the New Right

than either Sunbelt or Northeastern capital. Refutation of the Sunbelt "Cowboy" thesis comes from Cohen (1977), who finds that Sunbelt economic growth remains dependent on Northern and Midwestern banks, accounting, and law firms and that no real shift has occurred in corporate control with the rise of the Sunbelt.

Debates about local politics in Sunbelt cities concern the extent to which governance of Southern cities by white business and civic elites has given way to suburban growth coalitions committed to fiscal conservatism, annexation, and private initiative and urban minority ruling coalitions committed to wealth redistribution. While business oriented urban and suburban growth coalitions still dominate most Sunbelt cities, black or immigrant minority mayors and minority based coalitions have risen to power in places like Birmingham, San Antonio, New Orleans, Atlanta, and Miami.

Scholarly interest in the Sunbelt has waned, largely because of difficulties characterizing regional patterns of economic development and political change. Economic growth stagnated in the South and West in the 1980s and whatever growth did occur was uneven and unequally distributed between urban and rural areas and across racial and ethnic groups. It is also difficult to characterize urban politics across the Sunbelt and differentiate them from the politics of Northern cities. For example, traditional ruling coalitions in New Orleans, Nashville, and Memphis look a lot like the party machines that dominated urban politics in the North; and battles over governmental reform in the South resemble similar battles fought in the North.

The Sunbelt remains ambiguous. Perhaps the South and West are too disparate for any regional synthesis to gain explanatory traction. Old distinctions also remain salient between urban and rural and between urban and suburban, and this confounds efforts to highlight regional differences in economic development, culture, and politics. During the 1990s the idea of globalization largely supplanted regional and even national level analysis of industrial restructuring and decentralization. However, suburban and leisure tourism scholars still find the Sunbelt a useful construct to understand migration and cultural differences in the US, and recent patterns of Hispanic immigration have reinforced the salience of the Sunbelt (Goldfield

2003). To conclude, the Sunbelt construct served as a bridge in the analysis of shifts in the global division of labor and national politics between the eras of post war industrial prosperity and liberal politics and the current era of globalization and conservative realignment of national politics in the post industrial economy.

supermarkets

Kim Humphrey

Defined in commercial terms a supermarket is a predominantly self service retail shop selling a range of foodstuffs and household goods. These products are displayed mostly on open shelves, selected by the shopper and placed in a basket

or trolley, and purchased by way of moving through a check out or past a cash register. The supermarket is differentiated from other food stores in terms of the range of foods available within it (which usually includes manufactured and packaged products, fruit and vegetables, and refrigerated produce) and the area of selling space. Supermarkets are generally larger than similar environments such as corner shops or convenience stores, but smaller than other types of large, self service establishments such as hypermarkets.

Initially, then, the supermarket can be understood as an economic institution, and one which is dominant (or at least highly significant) as a vehicle of everyday retail food distribution within nations as diverse as the United States, Britain, Australia, Germany, France, Japan, and China. This increasing dominance of the supermarket as a retail form is matched in many countries with a high concentration of commercial ownership, such that a small number of retail companies or “chains” own and operate a large number of supermarkets dispersed throughout a region or nation and sporting the same logo, store design, and product profile.

Yet the supermarket is also much more than an economic phenomenon. It is a part of everyday life within many industrialized countries – so much so, that the above definition can seem a little ludicrous, as if to make the very ordinary and already known somehow strange and technical. It is this everydayness, and the position of the supermarket within a much broader field of consumption, that has recently begun to interest those working in the social sciences and humanities. Beyond the economic, the supermarket is a *social space*, in the sense in which it is a terrain of interaction; a *cultural field*, in the sense in which it marks out particular ways of symbolizing and emotionally valuing consumer goods; and a *terrain of politics*, in the sense in which it is embedded within a set of labor practices, global production frameworks, and environmental consequences. Supermarkets, then, may be mundane and ordinary, but they are not simple or unimportant places because of this. On the contrary, supermarkets are central to the nature and levels of consumption within the contemporary highly industrialized world.

Historians and cultural analysts have recently turned their attention to the rise of

supermarketing, drawing on and reformulating histories of retailing, shopping, and individual companies. An indisputably "American" phenomenon, the supermarket is seen to have appeared in the 1930s, particularly in New York where there was originally an emphasis on large warehouse type stores selling a plethora of goods at cheap prices. These stores were integrally dependent on changes in food manufacturing and packaging, on the suburbanization of cities, and on the rise of the automobile as a form of transport. They were also modeled on much earlier retail experimentation in North America, Europe, and elsewhere with the practices of cash and carry and self service. By the 1950s the supermarket was fast becoming the dominant form of retail food distribution in the United States and, as a retail form, it was emerging in Britain, Australasia, Canada, France, Germany, and in other western nations. This pace of development continued, such that by the mid 1960s the supermarket could claim status as a global phenomenon, having spread beyond the West into Southeast Asia, parts of Africa, and elsewhere. In the process, the supermarket had become a preeminent symbol of capitalist modernity, connected with images of choice, convenience, abundance, and everyday luxury. Its internationalization spurred also further retail experimentation, with the development in France of the hypermarket during the early 1960s.

Within a number of countries this consolidation of the supermarket resulted in significant restructuring of the economics of retailing and the social practices of shopping. With the rise of the supermarket the number of retail shops, particularly grocery stores, dramatically decreased within many countries, while the size of retail grocery outlets, in terms of area of selling space, grew significantly. Older forms of retailing, along with the independent shopkeeper, were thus eclipsed by the rise of supermarket chains which, in turn, consolidated the economic dominance of key manufacturers of foods and household goods and fostered highly commercialized forms of agricultural production. Socially, the supermarket also quickly transformed everyday consumption, shifting the responsibility for the selection and transport of goods purchased onto the shopper, and thus increasing the domestic workload of many

women who have always constituted the majority of supermarket shoppers. Equally, the goods available within the supermarket gradually contributed to population wide transformations in dietary intake. Moreover, the supermarket as a social space reframed the experience of shopping, placing people within an environment which blurred class distinctions, partially challenged the highly gendered nature of everyday provisioning, and positioned people as autonomous within an ideological framework of consumer choice.

These and other consumption practices and frameworks mark the contemporary supermarket as well. Yet it is only comparatively recently that scholars have turned their attention to the supermarket and taken it seriously as a subject of social and cultural analysis. This recent work has been productive in terms of exploring the very particular place of the supermarket within the broader historical development of consumption cultures. Analysts have thus explored the supermarket in terms of the rise of mass marketing, transformations in technologies of manufacturing and packaging, the development of post World War II cultures of capitalist abundance, and shifts in the nature of domestic work. Further, scholars have explored the connections between everyday supermarket shopping and the concepts of self identity, cultural fragmentation, and rituals of provisioning under conditions of modernity and beyond.

It might also be said, however, that the future direction of such analysis is undergoing timely challenge. The recent study of consumption, and of the supermarket along with it, has arguably been dominated by explorations of the cultural significance and social dynamics of shopping in terms that have been too narrowly focused on questions of identity, meaning, and postmodernity. This has tended to eclipse an analysis of other aspects of supermarket retailing: its placement within global systems of provision, its connection with the logic of global capitalist expansion, and its embeddedness within systems of overconsumption leading to significant individual, social, and environmental costs. It is perhaps to these more avowedly critical explorations of the supermarket, and life within and *beyond* it, that commentators might now turn.

supply chains

Chris Lonsdale

The term supply chain is actually a metaphor for a complex series of interactions between a set of organizations responsible for delivering a product or service to an ultimate customer. Indeed, this series of interactions has more recently been referred to as a network (Hakansson and Snehota 1990; Harland 1996). A supply chain starts with a set of raw materials and ends with the delivery of a finished product or service to the ultimate customer(s). Figure 1 provides a simplified representation of a supply chain.

The term gained prominence within the management field because of the realization that an organization's prospects are dependent not only on its interactions with its immediate customers, competitors, and suppliers, but also on those that take place elsewhere in the chain or network. This can be explained using the hypothetical supply chain in Figure 1. First, organization A can be affected by the actions of organization B, despite having no direct commercial relationship with it. For example, organization B might be ineffective at providing demand information to organizations D and E. If that then affects the ability of those two organizations to interact effectively with

organization A, then this will have an adverse effect on organization A. Given that the problem is poor demand information, the effect could be related to organization A's efforts to plan its capacity.

Alternatively, organization A can be affected by the actions of organization C, again despite having no direct commercial relationship with it. For example, organization C may refuse to adhere to an agreement with organization F, one of organization A's own suppliers. If organization C's actions affect the ability of organization F to supply organization A, then organization A may well suffer adverse effects, perhaps to its production schedule. More dramatically, the same principle means that all of the participants in the supply chain are dependent on the actions of organization G.

While this realization was initially made in the manufacturing context, it is also entirely applicable to both the service and public sector contexts. For example, work has been undertaken on supply chain optimization in the health care sector, the advertising sector and, of course, the defense sector, where considerations of supply chain efficiency have long been a key concern of armed forces. Work in the construction and information systems industries has also shown that the concept of the supply chain can be applied to a project as well as process environment.

The contribution that the concept of the supply chain has made to the study of management and organizations, therefore, has been to broaden the focus of business management from dyadic and direct interactions to the wider terrain of the supply network. It has highlighted the broader range of interdependencies which organizations need to cope with in order to fulfill their objectives (Gadde et al. 2003).

Supply chains and their management have been studied by academics from a vast range of disciplines. For example, contributions have come from the areas of operations management, purchasing and supply, information technology, institutional economics, strategic management, organizational behavior, law, and marketing. However, it is possible to provide some kind of organizing schema. This schema is based upon the view that the supply chain subject area consists of three broad dimensions: structures, relationships, and operations.

Figure 1 A simplified representation of a supply chain.

The study of supply chain structures has focused on a number of issues, some of which have long been of interest to economists. These include assessments of vertical integration, or its recently fashionable opposite, the virtual organization (Chesbrough & Teece 1996). Related to this has been the study of outsourcing and make buy decisions. Finally, there has also been interest in the positioning decisions made by organizations within supply chains. Different stages of supply chains offer different levels of profitability and organizations have often shifted their position accordingly (Gadiesh & Gilbert 1998). The literature that has supported this dimension of the study of supply chains has included resource based theory, institutional economics, and marketing theory.

A second dimension to the study of supply chains has concerned relationships. On the one hand, this has concerned the internal relationships that impact upon organizational buying behavior (Ronchetto et al. 1989). On the other, it has concerned inter organizational relationships, with contributors again utilizing resource based theory, institutional economics, and marketing theory, but also accessing information economics, behavioral economics, game theory, and law. Relationships with other customers, suppliers, and competitors have been

described in the supply chain literature as a key organizational resource. For example, Gadde et al. (2003) comment: "Firms operate in the context of interconnected relationships, forming networks ... these relationships affect the nature and the outcome of the firm's actions and are their potential sources of efficiency and effectiveness."

If we look at the relationships organizations have with their suppliers, for example, we can begin to understand why Gadde et al. might hold this view. Take IBM. According to recent company statistics, 73 percent of IBM's revenue generated by sales of manufactured goods was accounted for by supply inputs (Urioste 2000). There are two consequences to this. First, the quality of IBM products is heavily dependent upon the performance of suppliers. Second, the ability of IBM to control its costs is heavily dependent on its ability to manage its relationships with suppliers effectively.

Much of the study into relationships within supply chains has investigated the perceived need for organizations to match relationship forms with transactional circumstances. Again using the example of supply side relationships, it has been shown in the literature that organizations face transactional circumstances that differ in terms of magnitude, complexity,

uncertainty, power relations, asset specificity, and likely duration. As a result, most academics studying supply side relationships have advised managers that they need to adopt a contingent approach to relationship management (Williamson 1985; Cox et al. 2000; Gadde & Hakansson 2001). Similar ways of thinking have been employed in relation to the study of customer relationships.

The third dimension of the supply chain literature concerns operational management. Over the past 20 years, a great deal of attention has been paid to the perceived need for production operations to be integrated or synchronized along the whole of the supply chain. There are sound reasons for this. As has been pointed out, it is literally the case that a supply chain is only as strong as its weakest link. Supply chains that have a mixture of effective and ineffective participants have a tendency to develop "islands of excellence." This can either lead to high levels of inventory in the chain if the offending party is a customer, or production delays if it is a supplier. This logic has led to the operations management discipline broadening its focus from the individual organization to the overall supply chain.

Much work has been undertaken, therefore, on how organizations might integrate their operations. In particular, traditional operational methods such as batch production have been challenged by methods based on just in time (JIT) or "pull" systems. Indeed, JIT production, with all of the organizational and information technology integration that it entails, has been put forward by its proponents as a superior approach to supply chain management rather than an alternative (Womack et al. 1990), although as we shall see below this is questioned by many.

There are, therefore, three broad dimensions or domains to the study of supply chains. They each contribute to making the subject area extremely diverse. This is not to say, however, that all academics include all three in their work. For example, the tendency in the US is for supply chain academics to focus on operational issues, whereas in Europe the focus is more (although by no means exclusively) on structure and relationships (Giannakis & Croom 2004).

The debates in the supply chain literature echo those of the management literature in

general. Perhaps the most significant debate in the literature concerns the issue of supply chain integration. There is a divide in the supply chain literature between those that are optimistic about the achievement of supply chain integration and those that believe that supply chains or networks will always be messy and the deliverer of highly imperfect outcomes. In considering this debate, it is hard to overstate the impact that the models of integrated supply chain management have had over the past 15 to 20 years. The best known is the lean supply model. The model encompasses two of the three dimensions of the subject area outlined above: operations and relationships. In terms of operations, the lean supply model provides techniques aimed at integrating the supply chain. In terms of relationships, the lean supply model takes a view on the type of relationships required to support the operational techniques.

The lean supply model was originally developed on the basis of comprehensive research into the Japanese automotive industry – particularly Toyota – although over the past 10 years the model has been applied and modified in a range of other industrial contexts. The research highlighted that the Japanese automotive assemblers had a totally different approach to managing the supply chain from their western counterparts. While the supply chains of the western assemblers were conflictual and anarchic, those of the Japanese assemblers were apparently more consensual and orderly, with a network of collaborative relationships referred to as a *keiretsu*.

From these observations of Toyota (and many of its Japanese competitors), a number of academics proceeded to develop the lean supply model. This was then widely disseminated during the 1990s (Womack et al. 1990; Lamming 1993; Hines 1994). There are four key operational principles to the lean supply model. First, there is the insistence that value is specified from a customer perspective. Such a specification requires the abandonment of sectional interests within the supply chain, whether they be at a firm or intrafirm level. Second, it is stated that supply chain participants should then consider how that proposition can be delivered in the most efficient manner possible. The starting point of this task is process mapping.

The aim of process mapping is to (1) identify the total process that currently exists and (2) locate the problems within that process. Once the problems have been located, remedial action can be taken. This remedial action has as its target the reduction of waste. Lean supply identifies seven types of waste: overproduction, unnecessary waiting, excessive transportation, inappropriate processing, unnecessary inventory, unnecessary motions, and defects. In the mapping process, all current supply chain activities are divided into three categories: value adding, non value adding but necessary, and non value adding. The aim of lean supply is to minimize the second category and eradicate the third category.

Third, and key to the reduction of waste, is the just in time (JIT) principle. JIT is a method of production where a supply chain process only operates when a customer indicates its demand. JIT or "pull" systems are said to benefit the firm by contributing to the reduction of inventory within the chain, reductions in number of defects, a reduction in the requirement for storage space, and an increase in the ability of managers to identify problems early. Finally, the fourth principle of lean supply is that of continuous improvement. Lean supply strongly adheres to the principle of continuous improvement and takes the view that the task of pushing out the productivity frontier is never complete.

These operational principles are then supported within the lean supply model by the development of close, collaborative buyer-supplier relationships. Such relationships include high levels of product/process information exchange (e.g., proprietary or cost information), extensive operational linkages (e.g., aligned information systems), cooperative norms (e.g., a code of conduct), and transaction specific investments (Cannon & Perrault 1999).

The lean supply model has been very successfully disseminated throughout the world. One of the early texts outlining the model, *The Machine that Changed the World*, by Womack, Jones, and Roos (1990), has sold over half a million copies. This success has not, however, stopped many supply chain academics from criticizing it. In particular, claims that lean supply is a universally applicable model of supply chain "best practice" have been widely contested. In a critique that echoes the realist critiques of many

other management models, Cooney (2002) argues that the "value creation" in the lean supply model is not just dependent on just in time flow, but is also contingent on general business conditions (economic cycles), the differing nature of buyer-supplier relationships in a supply chain, and the structure of social and political institutions in different national contexts. These are all factors that, according to Cooney, the lean supply model simply dismisses.

With respect to the nature of buyer-supplier relationships, one of the factors that is said to cast doubt on the universality of the lean model is the existence of buyer-supplier power relations (Ramsay 1996; Ford 1997; Cox et al. 2000; Cooney 2002). The lean supply model requires the development and maintenance of long term, collaborative relationships throughout the supply chain. However, according to the lean supply model's critics this is not always going to be possible because the nature of buyer-supplier power relations will not permit it.

Ford et al. (1998) seek to make this point by referring back to the original exemplar upon which the lean supply model was based – the Japanese automotive industry. They comment: "It seems that many of the Japanese subcontractors have been more or less forced into relationships involving extensive coordination by a customer because of the considerable power of those customers ... It is likely to be very difficult for a small customer to involve large suppliers in these efforts [collaborative relationships] except on the most favorable terms" (p. 147). Cooney (2002) argues that because of the variable nature of buyer-supplier power relations, other, more traditional methods of managing supply chains (e.g., batch systems of operational production and arm's length relationships) may well have to be adopted on many occasions.

The general consensus of the critics of the lean supply model is that the management of supply chains cannot be modeled on any set template of "best practice." Rather, their management is about "identifying the scope for action, within existing and potential relationships, and about operating effectively with others within the internal and external constraints that limit that scope" (Gadde et al. 2003: 357). The view is taken that organizations

will need to develop many different approaches to operations management, adopt many different customer and supplier relationship types (arm's length and collaborative, equal and unequal), and understand that the organization will influence and be influenced by such relationships. It will also need to remain flexible in the face of changing supply chain circumstances and understand that change is likely to be incremental rather than the result of strategic planning.

This philosophical divide over the management of supply chains is underpinned by methodological differences. The academics researching the implementation of lean supply and other similar supply chain integration models, such as agile supply (Christopher 2000), are mainly positivists undertaking quantitative research into operational techniques. Those providing the critique are mainly, although not by any means exclusively, critical realists undertaking qualitative research into intra organizational and inter organizational relationships and processes. Not surprisingly, many of those that fall into the former camp are those with an operations management background, whereas those in the latter have emerged from the disciplines of marketing, organization theory, political economy, and institutional/behavioral economics.

Consideration of the future direction of research into supply chains and their management brings to mind three comments. First, it is possible that the idea of a contingent approach to the management of supply chains will become more prominent in the coming years. Such an approach is widely accepted among industrial marketing academics (especially those in the influential Industrial Marketing and Purchasing Group) and is slowly gaining more prominence among purchasing and operations management academics.

Second, supply chain academics from all disciplinary backgrounds will have to continue to monitor the impact of the Internet on supply chain management. The Internet based software that facilitates supply chain relationships and real time auctions will continue to have an impact on the structural features, relationships, and operational practices within supply chains and has the potential to challenge many closely held assumptions.

Third, it seems that the high level assumption of the supply chain fraternity – that individuals and organizations need to be seen as operating within a wider network of interdependencies – is likely to become more and more influential within other management disciplines. The network concept can already be seen in the strategy literature (Dyer & Singh 1998) and the human resource management literature (Harris 2002), for example, and this trend only seems likely to continue.

surveillance

David Lyon

Most of us take for granted today that our personal data are required for many purposes and that our images, scans, and traces are used by organizations. When we identify ourselves we usually need evidence to back up our claim: an ID card, a PIN, a drivers' license, or a passport. We are not surprised to see video surveillance cameras in the street or the shopping mall and we are aware that our transactions, phone calls, and emails are logged and processed. Personal data are extremely valuable to many agencies today, from marketers to insurance companies to the police.

Not all ordinary citizens, workers, travelers, or consumers realize, however, the scale or significance of surveillance today. Personal data

businesses are worth billions of dollars, and government departments and law enforcement agencies mount massive computer and telecommunications systems to support their processing of such data. Surveillance in these circumstances cannot but involve questions of power and the distribution of rights and responsibilities. While ostensibly personal questions about privacy may well be raised, public issues also demand attention – of how our choices and life chances are affected by surveillance and how trust and accountability can be enhanced.

Surveillance is as old as human history, but over the past few decades it has risen rapidly to a position of central importance – and controversy – in sociology. The reasons for this are complex, but relatively clear. The use of new technologies in surveillance and their promotion and adoption by a wide range of agencies have created a situation in which surveillance capacities are unprecedented and their effects widespread. Surveillance is also politically disputed. At the same time, sociological tools for understanding and analyzing surveillance have been developed, especially since the groundbreaking work of Foucault. This has also generated debate regarding already existing theory and the possibilities of new theories that question how far Foucault's work really addresses the key issues in surveillance today.

Surveillance may be defined as the focused and systematic attention to personal details for the purposes of influence, management, or control (which is similar to the definition in one of the earliest sociological treatments of surveillance, Rule 1974). Not all "watching" is focused and systematic, but "watching over," as in the French verb *surveiller*, is likely to be so. The watching may be literal, as in daycare assistants "watching over" children, or street intersection cameras "watching out" for speeders who cross the line on a red light, but it may also be metaphorical. Our activities may be "seen" in our telephone records or our credit card purchases. But the watching is always purposeful – in these examples, to care for children or to catch out careless drivers. Marketers may wish to influence consumers, employers to manage their workers, or prison guards to control their inmates.

Before considering some contemporary situations, however, it is worth noting the long

history of surveillance. Ancient civilizations such as the Chinese or the Roman used censuses, for example, to keep track of citizens for taxation or conscription purposes. And overseers of work projects have always checked on their labor forces to ensure that the project is done correctly and on time. The use of clocks, from the thirteenth century, aided this endeavor. The making of maps was also a means of locating, in general terms, where people were. So both direct supervision (another English word meaning “watching over”) and record keeping are antique practices of coordination and control.

The coming of modernity made many such practices routine and systematic. Indeed, modernity is in part defined by such routinization and systematization. Bureaucratic methods of organizations, within a hierarchy governed by rules, in which communication passes only through certain prescribed channels, and files are kept – on persons as well as transactions and events – were examined classically by Weber (see Dandeker 1990). But Marx also observed astutely that within capitalist organizations there are additional incentives to maintain control, and that, for example, placing workers together under one roof in early factories enabled monitoring and supervision more readily to take place. Such analyses were pursued in the twentieth century, for example in the much debated work of Braverman on *Labor and Monopoly Capital* (1974).

Another dimension of surveillance, emphasized by Foucault, was modernity’s shift away from forceful, coercive, and sometimes brutal methods of social control. In their place, argued Foucault, were “technologies of power” that induced self discipline through surveillance. For Foucault (1979), the Panopticon, Jeremy Bentham’s late eighteenth century semi circular prison design with a central watchtower, was the archetype of modern surveillance power. Prisoners would be constantly observed, and, being in back lit cells, would be continuously visible. At the same time, the inspector in the tower would be obscured from view by slatted blinds, so that prisoners could never be sure that anyone was actually there. But they would develop self discipline and act appropriately, just in case they were being watched.

The big change on which Foucault made no comment was the use of computers in surveillance. While the earliest surveillance involved direct watching and supervision, plus some basic record keeping, and modern surveillance adopted rational methods of bureaucratic governance, a key development in the later twentieth century was computerization. James Rule researched this in relation to items such as credit card and social security systems, and Gary T. Marx (1985) established some crucial new dimensions of surveillance based on new technologies. He argued that it transcends barriers of darkness and distance and that data storage means it transcends time. New surveillance tends to be capital – not labor – intensive, introduces categorical suspicion, and tries to prevent violations. It is decentralized, hard to discern, is both more intensive and extensive. He warned about the potential for new soft forms of secret manipulation and control.

Of course, social changes relating to computers depend in turn on the perceived needs for and benefits of certain kinds of surveillance. The new technologies do have “effects,” but they are also subject to social, economic, and political forces that give them their chance in the first place. Thus some effects are intended – government departments wish to reduce costs, including fraud, and thus install systems to detect violators, for instance – but some are unintended. Notoriously, systems set up to increase production or distribution efficiency in manufacturing may also have surveillance side effects in allowing workers to be monitored more closely. Similarly, retail surveillance to prevent shoplifting may be expanded to check on staff.

The technologies that facilitate deeper surveillance have appeared at a snowballing pace, each adding another dimension while maintaining previous capabilities. In the later 1980s searchable databases extended surveillance capacities (Lessig 1999) and in the 1990s networked multimedia provided increased opportunities for integration between previously separate databases. Those opportunities were also earnestly sought, for example by policing networks, keen to trace offenders in cross border activities such as drug smuggling, or corporations desiring to target more precisely their most profitable consumers (Gandy 1993).

A further boost to integrative ambitions came following the “terrorist” attacks of 9/11, when law enforcement bodies ratcheted up their efforts not only to get different departments cooperating more intelligently with each other, but also to obtain personal data from whatever source – including commercial, educational, and medical – that might provide them (Lyon 2003).

It is important to understand, however, that no surveillance system can work fully without the cooperation, witting or unwitting, of its subjects. In many cases ordinary people trigger surveillance practices in the mundane routines of everyday life. When cards are swiped, web sites accessed, or when phone numbers or postal codes are given to store clerks, data are extracted. Those data reveal when transactions were made and for how much, and today, cell phones and other locational devices may also indicate where we are geographically. And if ordinary people are involved in enabling surveillance, they may as readily question or block surveillance as simply comply with it. People sometimes withhold information, or alter it slightly, in order to evade the gaze. In particular cases, outcry may be strident, such as when otherwise law abiding citizens of Athens spray painted surveillance camera lenses before the 2004 Olympics.

The diagram of the Panopticon provides a useful way of organizing theoretical approaches to surveillance (Wood 2003). It has stimulated an ongoing debate about the best ways to understand and explain what is going on within and under the “gaze.” A number of writers (e.g., Poster 1996) proposed that electronic technologies enable the perfection of Bentham’s ideas. Software architectures can achieve more completely what the bricks and mortar of the original plan were meant to do – to create control through uncertainty. But others object that the Panopticon’s genius cannot be generalized to other situations. It may be present for cases such as welfare recipients, but in other contexts other models must be sought. In this critique, the panoptic paradigm is relevant but limited.

Those who doubt the extent of the Panopticon’s usefulness for theory may themselves fall into one or another group. The “pre panoptics” are those who insist that the works of say, Marx, Weber, or Machiavelli yield plenty of clues about how surveillance works and why

it is expanding and intensifying. Its meanings may be found in the inner workings of capitalism, in bureaucratic management, or in geopolitical control. The “post panoptics,” on the other hand, would now include theorists such as Gilles Deleuze, Michael Hardt and Antonio Negri, or Giorgio Agamben, who work from other guiding models. Deleuze’s notion of “societies of control” suggests how surveillance simply closes or opens opportunities for action. Hardt and Negri’s “empire” claims that surveillance is vital to new global regimes of imperial power. And Agamben proposes that Foucault never worked out “how sovereign power produces biopolitical bodies” and why exclusion is today a more powerful surveillance effect than inclusion in the Panopticon.

Needless to say, issues of theory provoke questions of methods. How do we know what kinds of surveillance are in place, and what their effects are, given the high degree of secrecy in some corporations and government departments? And how can researchers avoid being seen merely as critics of surveillance with the consequence that access to sites and spokespersons may be blocked by those who argue that the surveillance is necessary or desirable? One could say, of course, that these issues have always produced problems for academic investigation, and that the task of independent researchers is still to find out as much as possible by whatever means are legal and ethical. No doubt critics of surveillance studies would say that the enterprise is hypocritical – have not social scientists always been in the business of surveillance themselves? Such methodological questions do present difficult conundrums, but these can also be placed in context by recalling some key points from the above discussion.

Surveillance is moving steadily closer to the center of social order and governance in technologically advanced societies. New technologies are implicated in this as they facilitate and even “drive” some developments, but those technologies are also themselves shaped by social, economic, and political factors. In the early twenty first century this is seen clearly in the surveillance responses to security threats in the “war against terror.” Much surveillance accompanies current thrusts towards efficiency and safety in the modern world and thus its effects may never be correctly viewed as only

negative. Surveillance is always ambiguous. But because questions of trust and responsibility in relation to the handling of personal data are paramount, yoking sociological work to the ethics and politics of information is vital.

survey research

Patricia Snyder

Survey research refers to systematic investigations designed to gather information from populations or samples for the purposes of

describing, comparing, or explaining phenomena. Survey research involving samples often is distinguished from census surveys, which involve the study of populations. As Kerlinger noted in *Foundations of Behavioral Research* (1986: 377): "Survey research studies large and small populations (or universes) by selecting and studying samples chosen from the populations to discover the relative incidence, distribution, and interrelations of sociological and psychological variables."

Several types of research approaches are described in the survey methodology literature. *Descriptive or status* survey research focuses on accurately characterizing information about defined units of analysis, such as individuals, social groups, geographic areas, or organizations. In descriptive research applications, surveys are used to quantify phenomena such as unemployment rates in a state, the health status of citizens of the US, or the number of certified teachers in a school district. Public opinion surveys or polls (e.g., Gallup Poll or Harris Survey) are a type of status survey designed to quantify information from defined samples about their subjective preferences, beliefs, or attitudes. *Correlational* survey research is directed toward examining interrelationships among variables. An example of correlational survey research might involve using surveys to examine familial and community factors associated with juvenile delinquency. *Explanatory* survey research typically involves hypotheses testing to explicate relationships between attribute or predictor variables and criterion variables of interest. Although explanatory survey research does not permit causal inferences, because of the lack of experimental manipulation and control, it offers important opportunities to model and test complex relationships among variables of interest using advanced statistical techniques such as multiple regression analysis, structural equation modeling, or hierarchical linear modeling.

Commonly employed survey research designs include cross sectional and longitudinal designs. In cross sectional designs, information is collected at a single point in time from a sample of respondents. Three common types of longitudinal designs include panel, trend, and cohort. Panel designs involve data collected at different points in time from the same sample. In trend designs, different samples from the same general

population are used at each measurement occasion. Cohort designs involve identifying a specific population who share a common attribute, such as infants born in the US in 2005 or those who graduated from high school in Texas in 2004. The same specific population is involved in the cohort study over time, but a new sample from this population is selected each time survey data are gathered.

Survey research involves processes common to other quantitative research approaches, including identification of the research question, selection of the study design, selection of the sample, development or selection of the survey instrument, pretesting of instruments, data collection, data coding and processing, data analysis, data interpretation, and dissemination of findings. Fowler (1993) characterized the *total survey design* approach as one focused on the complete data collection process and suggested that in survey research particular attention be paid to the quality of the sample, the quality of the measures, the quality of data collection, and the mode of data collection. Decisions made about each of these components impact the accuracy and validity of survey results. In a widely cited text, Groves (1989) details sources of imprecision and bias found in survey research that are associated with four common types of error: sampling, coverage, nonresponse, and measurement.

Sampling decisions are important in survey research, particularly when the intent is to evaluate the precision of sample estimates in relation to population characteristics. Three interrelated processes are associated with sampling decisions: defining the sample frame, determining sample size, and choosing a sampling method. The sample frame is the list of people or objects that comprise the accessible population. Survey samples are selected from the frame by specifying sample size and determining whether probability or nonprobability sampling methods will be used to select units. Probability sampling permits use of statistical tools to estimate the amount of sampling error. Random sampling error occurs due to chance variations in different samples drawn from the same population. Systematic sampling error occurs when inadequate sampling procedures are used. Coverage error is a form of systematic sampling error. An example of coverage error

would be surveying only individuals with access to computers when the variables of interest are related to having or not having computer access. Errors in sampling also can arise from poor definitions of the sampling frame and the use of small sample sizes. Fowler (1993) offers an expanded discussion of factors to consider when making sampling decisions.

Biases associated with low response rates often are problematic in survey research and represent a major source of survey error. Low response rates are particularly problematic when researchers are unable to characterize how responders differ from nonresponders. Dillman (2000) describes tailored design methods and presents strategies designed to enhance response rates.

Survey questions are designed to operationalize variables of interest. Comprehensive instrument development and validation strategies should be used to ensure that questions are well formulated and that reliable and valid data are obtained when surveys are administered across samples of respondents. Pilot testing of survey items and data gathering procedures is uniformly recommended to help reduce measurement error. Reliability and validity should be systematically evaluated each time a survey is used with a sample of respondents because these two characteristics are not static properties of measures.

Modes of survey administration involve face to face, telephone, mail, and web based formats. Use of computers in survey research is becoming commonplace, including laptops and personal data assistant (PDA) devices. Each mode has its strengths and limitations. Decisions related to the mode of administration to be used typically involve considerations of the characteristics of the sample to be surveyed, the types of questions to be asked, the response rate desired, and time and cost considerations. Entire texts are devoted to describing strategies for minimizing systematic error by standardizing interviews and telephone surveys (Fowler & Mangione 1990; Lavrakas 1993).

Survey research is one way to collect quantifiable data in a standardized way from samples or populations. As noted in this review, if not conducted with appropriate rigor, survey research is particularly susceptible to various sources of error related to sampling, measurement, and data collection processes.

Sutherland, Edwin H. (1883–1950)

Gilbert Geis

Edwin H. Sutherland is generally regarded as the father of the scientific study of criminology in the United States. In 1924 he published *Criminology*, the first systematic textbook study of crime. Sutherland advanced the principle of differential association, a social learning construct that sought to interpret criminal behavior in theoretical terms. He also coined the term

white collar crime in his 1939 presidential address to the American Sociological Society. In addition, Sutherland wrote a pioneering monograph on confidence scams, as well as highly regarded papers on the death penalty and prisons. He also published journal articles critical of sexual psychopath laws and psychiatric interpretations of illegal behavior.

Sutherland was born in Gibbon, Nebraska, and spent most of his formative years in Grand Island, Nebraska, where his father, a Baptist minister, served as president of Grand Island College. Sutherland did his undergraduate work at the college, and tied with a friend for a Rhodes scholarship that eventually was awarded to the other man. He taught Greek and short hand at the college for several years, and then enrolled in the divinity program at the University of Chicago, but soon switched to sociology, where he came under the tutelage of Charles Henderson. He later focused on political economy, working with William Hoxie, a labor historian and disciple of Thorsten Veblen, earning a joint PhD, magna cum laude, in sociology and political economy. His dissertation dealt with the work of public employment agencies in Chicago.

Sutherland's first teaching position was at William Jewell College, a Baptist school in Liberty, Missouri, where he remained for six years and published just one article, on the results of rural health surveys. His Chicago connections then served to secure him a teaching job at the University of Illinois (1925–6). The next year, he moved to the University of Minnesota (1926–9). He spent 1930 visiting prisons in England, Western Europe, and Sweden under the auspices of the Bureau of Social Hygiene. Following that, he was appointed to a research position at the University of Chicago, which ended in 1935 under uncomfortable circumstances that are still not clear. In the fall of 1935 Sutherland became the founder and chair of the sociology department at Indiana University, where he assembled a sterling faculty and attracted a cadre of to be eminent graduate students, including Donald Cressey, Albert Cohen, Lloyd Ohlin, and Karl Schuessler, as well as many others. He remained at Indiana for the next 15 years, until his death.

Sutherland's *Criminology* textbook dominated the study of the subject until the 1960s.

The book (its title altered in later editions to *Principles of Criminology* and then back again) would go through 10 editions over a span of almost 70 years, with Cressey as co author from the fifth edition until the tenth, when David Luckenbill assumed that role. The text was notable for the strikingly sophisticated analysis of empirical and ethnographic work on law breaking. Sutherland would inventory the relevant research findings and then systematically assess their credibility and shortcomings in a list that often would begin “First, . . .” and then continue through half a dozen or more precise summaries of the state of knowledge on the subject.

The book dropped from its preeminent position primarily because it was too austere and perhaps too erudite for later generations of students and, more importantly, because it analyzed criminal behavior in general in terms of social correlates, such as race and ethnicity, social class, mental competence, and immigration. Successfully competing later textbooks adopted an approach that focused substantively on forms of crime, such as homicide, sex offenses, and robbery. In addition, as criminology became the creche and the graveyard for a plethora of interpretive schemes, the Sutherland text’s single minded focus on differential association left devotees of other approaches out in the cold. Newer textbooks sought to attend to the ever expanding roster of theoretical postulates in the field of criminology.

Sutherland coined the term white collar crime, now in common popular and professional use throughout the world, and in 1949 published *White Collar Crime*, a pioneering monograph detailing and interpreting crimes committed by high status offenders in their occupational roles. He offered varying definitions of what constituted such crime and squabbling about the proper realm of its subject matter has taken up a great deal of the intellectual energy of scholars doing research on such subjects as fraud, anti trust violations, insider trading, and embezzlement. At the same time, the term white collar crime has entered into popular usage and, as with pornography, there are many persons who indicate that while they cannot define the term precisely they recognize the behavior perfectly well when they see it.

Hermann Mannheim, an eminent English criminologist, was among many of Sutherland’s colleagues who were greatly impressed with *White Collar Crime*. Mannheim wrote that if there were a Nobel Prize for preeminent criminological contributions, then Sutherland assuredly would have earned it for that monograph. On the other hand, critics, especially criminal law scholars, persistently have faulted *White Collar Crime* for what they regard as its muck raking slant and its failure to attend to legal doctrines which differentiate criminal behavior from civil violations and administrative wrongdoing.

White Collar Crime had its roots in the populist, anti business mood prominent in Nebraska politics during Sutherland’s time in the state. It also reflects Sutherland’s strong moral values, values that were epitomized in an interview he gave when he taught summer school at the University of Washington in 1942, not long after America’s entrance into World War II. He had the courage to tell a reporter for the student newspaper that the evacuation of the Japanese from the west coast and their forced internment in “resettlement camps” had “resulted more from race prejudice than from military necessity.”

Sutherland’s theory of differential association consists of nine postulates that maintain that crime is a behavior learned from association with others who transmit attitudes, teach tactics, and offer rationalizations that put persons on the path to illegal behavior. The postulates themselves are an uneven conglomerate, some of them core concepts, others rather in the nature of asides. It is arguable that criminal behavior is learned only in primary groups, that is, from family and friends, as Sutherland’s theory maintains. A considerable literature now concludes that secondary learning sources, such as television and song lyrics, can lead to violent law breaking. Sutherland’s formulation also rather gratuitously indicates that crime is *not* the result of imitation, a position enunciated at the time by Gabriel Tarde, a French sociologist, who maintained that what humans did was a product of what they saw being done. Sutherland makes the important point that criminal behavior is not an expression of general needs and values, since noncriminal behavior results from these same

conditions. Two people may need money; one will commit a robbery, the other will get a second job pumping gas.

Differential association today is generally regarded as overly simple and absolutely untestable as Sutherland formulated it: how, for instance, can the ratio of experiences favorable to crime and those pushing in the other direction, a key element in the theory, be measured? How can the theory explain why persons who seemingly are exposed to similar experiences respond very differently to these stimuli? The theory also has been faulted for its total neglect of biological and genetic contributions to criminal and to law abiding behavior. For Sutherland, human behavior is the product solely of those things that we encounter and absorb after birth.

Interestingly, the most pointed critique of the theory was by Sutherland himself in an unpublished essay written in 1944 and circulated among his colleagues. It carried the whimsical title, “The Swan Song of Differential Association.” Sutherland noted that he had not given adequate attention to “opportunity” as a necessary correlate of illegal behavior, nor had he sufficiently calibrated the intensity of particular needs in terms of the role they play in triggering criminal acts. He concluded that the sufficiency of differential association as an explanation of criminal acts was “questionable.” Nonetheless, the theory continued to dominate the field for several more decades.

Sutherland was not a prolific writer, but what he published tended to be carefully crafted. As three of his close colleagues note: “Sutherland’s writing is distinguished by unusual clarity, simplicity, and unpretentiousness. He seldom wasted words, and he seldom repeated himself in different papers.” His was a serious, humorless style, though the man himself was an iconic figure to most of the graduate students with whom he worked. Albert Cohen, in a tribute to Sutherland as a mentor, observed: “It was not only that we felt that Sutherland was at the frontier; we felt we were at the frontier.” For all the tenacity of Sutherland’s own views, Cohen added, he “was never overbearing, never didactic, never arrogant. He invariably treated the students with respect, never humiliated them, always made them feel we were partners in a quest.”

In addition to his monograph on white collar crime, a subject that he came to late in his career, Sutherland used material furnished by Chic Conwell, a skilled con artist, to write *The Professional Thief*, and, with Harvey Locke (one of his very few collaborations) he wrote a monograph about homeless men in Chicago during the Depression. Critics regard the former book as marked by a kind of hero worship, and insist that Conwell conned Sutherland into accepting a tale that was at best only a partial truth; that Sutherland either was in the dark or chose to ignore Conwell’s history of drug addiction. They also argue that while Sutherland was appalled by corporate predators, he romanticized a smooth talker such as Conwell, who boasted that he was an outlaw, and proclaimed that only the greed of his victims allowed him to exploit them.

Sutherland’s articles critiquing sexual psychopath laws remain relevant today when community notifications regarding released sex offenders add an extra judicial penalty to the sentence that the offenders have served. Sutherland’s writings on prisons have worn less well. Today, his view that the length of incarceration ought to be left to the professional judgment of social scientists and prison authorities – a common position when he was writing – seems unpromising and likely to be unduly punitive. Objections also are raised that such a program would punish people for what they are rather than only for what they have done. On the other hand, Sutherland’s diatribe against corporate criminals, which he sought in vain to camouflage as objective social science, resonates in our time, as major American businesses are charged with crimes involving the theft of extraordinary amounts of money and their culpable executives are handcuffed and led off to prison.

Suzuki, Eitaro (1894–1966)

Yasushi Suzuki

Eitaro Suzuki is one of the pioneers of Japanese rural and urban sociology. Graduated from Tokyo Imperial University in 1922, he taught at Gifu Agricultural High School and Seoul Imperial University. After World War II, he became a professor at Hokkaido University.

Sociology was introduced to Japan in the 1880s, but empirical research on Japanese society did not develop until the 1920s.

By then, Japan had reached an early stage of industrialization and urbanization. Sociology of the family, rural sociology, and urban sociology were launched in this historical context. Suzuki was a pioneer of rural sociology in the 1930s and turned his interest to urban sociology in the post war era.

Suzuki studied the social structure of Japanese rural villages during the 1930s, under the influence of German cultural science, American rural sociology, and Le Play's (French) School. He published his first major work, *Principles of Japanese Rural Sociology*, in 1940. His main contribution to this field was the introduction of the concept of "natural village" as a unit of sociological analysis. Operationally, he divided "social districts" into three categories, by examining the geographical overlaps of social relations and groups of villagers. The first social district is the small neighborhood, which is a subunit of the natural village. The second is the natural village itself, and the third is the "legal village." The legal village was an artificial construct by the national government after the Meiji Restoration, and typically contained several natural villages within it. The natural village, in contrast, has been a self sustaining community, typically founded three centuries or more ago, according to Suzuki.

Referring to Sorokin's concept of cumulative community, Suzuki emphasized that the natural village was not only a cumulative community, but also a community with a collective spirit that was the ultimate source of social order in the village. As a cumulative community, it comprised many social relations and groups. It was basically composed of traditional stem families, which were taken over from generation to generation by male successors. It also included other social groups, such as formal residential associations regulated by the local government, traditional mutual aid associations, religious and kinship (Japanese lineage) groups. Moreover, the natural village is a distinctive entity. It owned common forests and properties, and managed water systems collectively (Japanese agriculture typically uses water laden paddies). It had its own guardian deity and the group of shrine parishioners. They were considered to be the legitimate members of the village. In addition, the natural village held a collective consciousness that Suzuki called "the spirit of the

village.” It is this spirit that controlled traditional behaviors and attitudes of villagers.

Thus, by describing the social structure of the natural village in the 1930s, Suzuki constructed the ideal type of Japanese rural community. The natural village and its elements have become basic concepts in Japanese rural sociology. Although natural villages have disappeared in the face of rapid urbanization since the 1950s, their remnants today can still be seen, even in highly urbanized areas.

After World War II, Suzuki devoted himself to the study of urban sociology and published his second major work, *Principles of Urban Sociology*, in 1957. This book is not tightly organized, but includes many insightful concepts, a classificatory schema for social relations and groups, and detailed descriptions and analyses of urban traits. Among these, the “nodal organ” thesis, the “normal life of the normal population” thesis, and the concept of “life structure” are widely known among Japanese sociologists.

Based on his observations of various rural and urban communities in Japan, Suzuki developed his own definition of the city: the city is a community that differs from a rural one in the way that it contains nodal organs (social institutions) that connect social interactions to the national society as a whole. This definition is unique in that it has no reference to any demographic or other traits. Rather, he argued that urban traits such as population size, density, heterogeneity, strangeness, and so on are accompanied by the concentration of institutions and that the city should be defined in relation to the nodal function in the national society. The presence of nodal institutions, such as government agencies, retail and wholesale services, and the offices of various kinds of corporations and associations, makes a community a city. He argued that all the communities in the national society are organized in a hierarchical urban–rural system, in which the rural communities are positioned at the lowest level. Thus the characteristics of the nodal institutions in a given community determine its position as a city in the nationwide hierarchy of urban system.

Other Japanese urban sociologists suggested similar definitions. Fukutaro Okui (1996 [1940]), another pioneer of Japanese urban

sociology, argued that although a “city in itself” may be defined in terms of its population aggregation and regions, it is important that we study it in relation to the development of the national society as a whole. He claimed that the “essence” of the city is the locus of the central functions in a wider social economic life. Later, Takeo Yazaki (1962) also emphasized the integrative function of urban institutions. These suggestions reflect the fact that Japanese cities have been controlled by the central government and its local agencies since the Tokugawa era. Suzuki made it clear that urban and rural communities are organized within the national hierarchy, and, therefore, cities should be defined and analyzed in relation to the wider society.

In addition to the “nodal organ” thesis, Suzuki suggested a general framework for analyzing the social structure of cities. In order to clarify the urban social structure, he emphasized “the normal life of the normal population,” instead of “abnormal life” or “abnormal population.” By “abnormal,” he meant a state which is unable to reproduce itself if it continues. The “normal life” should therefore constitute the “structure” of complex urban life. The ordinary life of the ordinary urbanite entails commuting between home and the workplace. Suzuki therefore identified households and workplaces (and schools for children) as central axes of the structure. He added neighborhoods and leisure groups to them. Yet he maintained that leisure groups were merely “superficial elements of the structure, or accessories [of urban life], no matter how exaggerated or gorgeous they appear.” Although some critics argue that one could find distinctive characteristics (and problems) of urban life within the “abnormal life” and “abnormal population,” Suzuki’s intent was to emphasize that the urban social structures were not disorganized, as claimed by some of the followers of American urban sociology. While he estimated the number of abnormal populations in cities, he argued that these must be ignored in order to understand the basic urban structures.

Before introducing Suzuki’s concept of metropolitan areas, it is worth mentioning his basic concept of the community. By community, he meant “a local social unity that performs the functions of cooperation for living

and of collective defense.” This conception of community applies to both cities and villages. Both serve the defense function against enemies and disasters (floods, fires, and earthquakes). It is clear that the villagers cooperate for living. As for the city, he claimed that some basic human needs are satisfied within the community by public services and private transactions. This is the critical point, however, for his development of another scheme for analyzing the metropolitan areas: “the pre social unity existing within and beyond the city.” As a site of concentration of nodal institutions, a city interacts with other communities positioned at a lower level. Such interactions produce five types of metropolitan areas: urban living area, urban dependency area, urban users’ area, urban dominance area, and urban influential area.

The urban living area is where urbanites lead their everyday life. It constitutes adjoining areas to shop for basic life necessities. The urban dependency area encompasses residents who depend on the city for their livelihood, typified by the commuting sphere. The urban users’ area includes all residents who use urban institutions. Since such institutions are typically located in central business districts or subcenters, it constitutes the trading areas of the central city. The urban dominance area is where the institutions of the city deploy their branch offices. In theory, it differs from institution to institution, but in reality they overlap significantly. Finally, the urban influential area extends to all residents who receive information transmitted by the city. Since the mass media in Japan are concentrated in Tokyo, Suzuki suggested that Tokyo’s urban dominance area extends across Japanese society as a whole. Other urban centers are, in comparison, “like the light of a candle under the Sun.”

Each area is defined in terms of particular types of relationships between persons and institutions. Here, the spatial orders of “the normal life of the normal population” combine with “nodal institutions.” This is one dimension of Suzuki’s “life structure of the city.”

Suzuki defined “life structure” as a set of spatial and temporal orders of the community. It refers to a dynamic aspect of urban life. He argued that the routine activities of persons and institutions must follow a set of spatial and temporal orders, and thus produce cyclic pulses

of urban life. These orders are not only the effects of aggregation of individuals’ daily activities but also sometimes institutionalized as norms. The norms of workplaces, schools, and households define the time for work, rest, and sleep. Suzuki classified the temporal orders of the city in terms of the temporal units of the cycle (the examples mentioned below are selected from the original text):

- a day – rest, sleep, nutrition, and work for daily workers;
- a week – weekly schedules, leisure, and rest on Sundays;
- a month – salary system, rent payment, etc.;
- a year – new year holidays, gift giving, annual settlement of accounts;
- lifetime – karmic backlash;
- endlessness – traces of the feudal obligations among traditional families.

Among these, Suzuki focused on the settlement of accounts and the breaks and holidays for workers, illustrating how they occur through various terms of cycles. In addition, he aimed to describe the typical life cycle of the Japanese people. As he had previously developed a model of the life cycle of Japan’s traditional stem families, he expected to be able to apply it to urban Japanese. He thought he would be able to identify a distinctive life cycle common to Japanese urbanites but different from their counterparts in other countries.

Suzuki’s analytical schemas for urban social structures and the life structures are very clear, and fit the social conditions of Japan at the time. Suburbanization was limited, and there was no need to distinguish the natural city from the legal city. Basically, he established a descriptive framework for Japanese cities in the national context. Yet it is not clear how his definition of the city is related to the schema of the urban social structure. He failed to classify Japanese cities by their distinctive functions, e.g., manufacturing, shipping, political administration, commerce, and tourism, beyond their differential status in the urban hierarchical system. He also failed to explain how the urban social structures differ by size and status. In sum, he delineated the urban social structure common to Japanese cities without delineating their differences.

His theory of rural and urban communities was constrained by time and place, for it was based on Japanese materials in the 1930s to the 1950s. Although the concepts and schemas he developed need to be reviewed and redefined, Eitaro Suzuki's analysis is a distinctive heritage of Japanese sociology. He depicted the typical Japanese villages and cities of his time and their relationships to the national society as a whole. Thus his work continues to provide key concepts and insights for understanding cities and communities in relation to the national and global system.

symbolic classification

Simone Ghezzi

Symbolic classification – literally, complex arrangements of symbols into wholes – refers to the process of classifying and ordering by means of which individuals are able to make sense of the natural and social world. They do so by means of models of categorization that are culturally and socially determined. Such categories are cast in concrete images that we may call symbols, which are, by definition, polysemic and relativistic because they convey different meanings.

Durkheim and Mauss were among the first scholars to pick up the age old philosophical idea about the ways human beings conceive of time, space, causality, unity, plurality, and so on. Their ideas are elaborated in an article entitled “De quelques formes primitives de classification: contribution à l'étude des représentations collectives,” published in *L'Année sociologique* (1903) and translated in English as *Primitive Classification* (1963). The importance of this publication lies in the fact that some of the issues illustrated here were eventually discussed in greater depth in structuralist social theories that emerged several decades later; moreover, it may be regarded as an early contribution to the sociology of knowledge and to sociological epistemology. The central argument of their essay is that there exists a connection between the classification of natural phenomena and the social order. The act of classifying does not occur through the effect of a “spontaneous” attitude of the mind, based for example upon the principles of contiguity, similarity, and opposition among objects or among living beings, but originates within the organization of social life. When they state that the “individual's mind is incapable of classification,” it does not mean that the individual's mind lacks “the innate faculty of classification” – indeed, it would be difficult to conceive of a mind incapable of processing information and distinguishing objects of the environment; rather, Durkheim and Mauss insist on the social expression of human knowledge and on the social root of human thought. They oppose the idea both that categories exist before experience (built in or a priori categories) and that categories are the product of experience (empiricism).

To investigate and elaborate on this assertion, they focus in particular on Aboriginal totemic societies from Central Australia, held at that time to be the most primitive of all, and to a lesser extent on Native American tribes. These societies appeared to classify people, animals, and things according to taxonomic criteria corresponding to the specific organization of their society (moieties, clans, kin). Durkheim and Mauss seek evidence of this by considering the patterns of residence, the arrangements of marriage, and the dominant organizing principles of these societies, and relate these aspects to logical thought processes.

From a functionalist point of view, the classification of categories makes the relationship between phenomena explicable; from an evolutionary perspective, it constitutes the first foundations of scientific thinking. Durkheim and Mauss conclude that among the Australian tribes "the classification of things reproduces the classification of men" (1963 [1903]: 11). The implication is that ideas and worldviews are constructed on a model that reproduces the society from which they have emerged. This argument will be taken up again by Durkheim a few years later in *Les Formes élémentaires de la vie religieuse: le système totémique en Australie* (1912). Some have argued that to prove their point, Durkheim and Mauss omitted cases where social organization and symbolic classification do not correspond; nonetheless, their original ideas have influenced other scholars, such as Lévi Strauss and Mary Douglas.

Lévi Strauss analyzes symbolic classification at a much deeper, i.e., unconscious, level. Native categories of thought are the output of universal mental processes (e.g., binary or dual oppositions), which manifest themselves in different ways. Both the cosmologies of "primitive" societies and the scientific thought of industrial societies are founded upon the same bases – the unconscious but structured regularities of human thought. Whereas for Durkheim and Mauss the taxonomy of the classifications reflects the kind of relationships that regulate social institutions, for Lévi Strauss classifications are viewed and analyzed as cognitive models. Evidence of these two different viewpoints emerges in the theory of totemism. Durkheim explains totemic classifications of animals or plants in terms of a structural homology between the social and the symbolic sphere. A group identifies symbolically with an animal, a plant, or a natural phenomenon, one of which then becomes the symbol of the group itself. By contrast, for Lévi Strauss totems must be understood metaphorically in terms of the relationship between groups. The identification with a totem is arbitrary; what counts are the differences among animal or plant species because they are used to express differences among groups of people. In such a manner the observed world is used as a sort of template for a symbolic representation of the social world.

The British anthropologist Mary Douglas departs from the epistemology of Durkheim and Mauss's notion of symbolic classification and refines their sociology of knowledge. She avoids their evolutionary typology, i.e., the distinction between primitive and modern symbolic worlds, and insists time and again on the importance of classificatory impurities. To understand the environment, individuals introduce order out of the chaos by means of classification. Yet in this process individuals discover that a few objects, living beings, actions, or ideas appear to be anomalous – matter out of place – which may pollute the entire classificatory system. What does not fit must be dealt with ideologically to keep the anomaly under control, both in the natural and in the social world. Douglas's pollution studies demonstrate how the human body is used to symbolize certain social relations. Bodily substances, processes, and orifices play a significant role in rites and prohibitions by expressing relationships between social groups and categories (Douglas 1966, 1970). The ideas elaborated in the study of symbolic classification have recently been reexamined and employed. This is evident, for example, in studies on ethnicity which deconstruct the ethnic anomalies stressed by a hegemonic system of classification, especially in multi ethnic societies.

symbolic exchange

Michael T. Ryan

Symbolic exchange is the organizing principle, the cellular structure, of the earliest forms of society, the forms that Anthony Giddens designates as "tribal cultures." The exchanges that take place within and between clans, within and between tribes, and between chiefs and other members of the tribe are more than economic exchanges as we know them in modern societies, and their circulation integrates the members of these societies. Marcel Mauss conceptualizes these exchanges as a form of gift giving, and the gift is a "total social phenomenon." They are multidimensional: economic, moral, religious, mythological, juridical, political, aesthetic, and historical.

Mauss (Durkheim's nephew) created his concept from the work of nineteenth and early twentieth century anthropologists in Melanesia, Polynesia, and Northwest America. Like Durkheim, he also wanted to demonstrate the social basis for exchanges as a refutation of the utilitarian notion that individual interests were the foundation for the creation of market relations. There was no "natural" economy that had preceded political economy.

Further, while the tribes of the Americas, Africa, and Asia seemed so different, so "other," to Europeans, Mauss wanted to demonstrate through comparative analysis the underlying similarities as well. The complex structure of the gift made it more difficult for Europeans to see these groups as inferior primitives whose annihilation or assimilation would be of no loss to humanity.

Gift giving was obviously an economic phenomenon, although it did not involve the exchange of equivalent values as it does in market economies. In the Kwakiutl tribe the *potlatch*

ritual exchanges were competitive and required a reciprocal exchange at a later moment that was of more value than the original gift. This was how the chief, the clan, or the tribe maintained prestige and power; the chief would distribute the gifts later received to the members of his clan or tribe. The chief was the member of the tribe who shared the most. The goods exchanged were often destroyed in festivals which made the accumulation of wealth impossible.

Gift giving also involved a relation with nature and created a balanced reciprocal relation between society and nature. For example, since tribes deified natural forces in their animistic religions, a wood carver made an offering to the spirits of the forest before cutting down the tree that he would use. The domination of nature is a modern phenomenon; these tribes lived in nature.

Gift giving also included a morality of reciprocity. The members of tribes were obligated to give gifts as well as receive gifts. Failure to do either would mean a loss of status, perhaps enslavement, or possibly war if it occurred between two tribes. The norm of reciprocity bound clan to clan, men to women, and tribe to tribe, and the circulation of gifts reproduced these tribes as tribes.

Thorstein Veblen brought the analysis of symbolic exchange to the consumer practices of wealthy Americans in his *Theory of the Leisure Class*. Veblen developed his concepts of vicarious consumption and conspicuous consumption from the same sources as Mauss, from tribal cultures and agrarian societies. The leisure class originally derived its prestige from avoiding ignoble work and devoting its time to pursuits that had little practical significance: sports, indolence, war, religious activities, and government. They also derived prestige through the idleness and vicarious consumption of their wives, families, and servants. Further, as the members of the middle class took up practical positions as professionals and managers, they derived their prestige from conspicuous consumption, "keeping ahead of the Joneses." Further, the competitive logic of the rat race filtered down throughout the class structure. Although Veblen also recognized that, once his theory had become understood by the leisure class, the members of this elite could reverse course and practice asceticism. Old money has

often adopted low profiles in their lifestyles, and the arts and crafts movement with its functional aesthetic was very popular for members of the professional managerial class in the early twentieth century. Veblen also recognized that the pursuits of the leisure class often had functional qualities and were not always a pure waste of time and wealth.

Jean Baudrillard developed his analysis from a critical reading of Mauss, Galbraith, and Veblen. Symbolic exchange for Baudrillard was a way to escape the consumer society and the political economy of the sign. He demonstrated in his early writings how the code of consumption and the system of needs had completed the system of production. The use value of the commodity provided no way out of the capitalist mode of production as it had for traditional Marxists ("to each according to his needs") – it only provided an alibi to exchange value. Consumers were even more alienated in their private lives than they were at work engaging in unequal exchanges with capital and producing surplus value. They were unconscious of the process of semiosis that led through their acts of consumption of commodities with their coded differences to the reproduction of the capitalist mode of production. The only way out of this system was a return to symbolic exchange where the accumulation of wealth and power was impossible and where exchanges were reciprocal and reversible. Symbolic exchange was also likely to restore a balance between society and nature, whereas the logic of the consumer society, predicated on continuous economic growth and the ideology of economic growth, is likely to destroy the environment.

What are the analytical problems with Baudrillard's analysis of symbolic exchange? A number of critics point out that he does not clearly define the concept of code in his writings. But it seems that what he means is that every commodity has a hierarchical structure with the originals at the top that are appropriated by the elite and models of descending quality that are appropriated by the other strata. The consumption of the sign value of each commodity reproduces the code and the relations of domination between the programmers of consumption and the consumers. George Ritzer finds "commotion" in Baudrillard's appropriation

of concepts from diverse theorists: Marx, Durkheim, Mauss, structural linguistics, Lévi Strauss, Lefebvre, etc. But this is the procedure for dialectical method. The most serious problem is the criticism that he has given us a romantic possibility without identifying any actual agents or movements of social change.

symbolic interaction

Peter M. Hall

Symbolic interactionism (also known as interactionism) is a uniquely American theoretical perspective that draws its primary inspiration from pragmatism. It refers to humans' distinctive use of language to create symbols, common meanings, for thinking and communication with others. Herbert Blumer (1969) coined the term to express his "reading" of George

Herbert Mead's thought developed in the early 1900s and codified it in the elaboration of three premises: (1) humans act on the basis of the meanings which things have for them; (2) meanings arise in interaction between people; and (3) meanings are handed and modified through an interpretive process used by people in dealing with things encountered.

Another source for the perspective came from early twentieth century Chicago sociologists W. I. Thomas, Robert Park, and Everett Hughes (a contemporary of Blumer's), who examined urban settings, racial/ethnic hierarchies, work and occupational relations, and social problems. They presented views of social processes, social organization, and social change. While they shared many ideas with Blumer, they gave such ideas as social forces, constraints, and obduracy more emphasis. Students of both Blumer and Hughes (such as Howard Becker, Anselm Strauss, and Helena Lopata) fused the two lines of thought into what is labeled interactionism. Strauss (1993) brings this fusion together in a comprehensive vision for the perspective.

KEY ASSUMPTIONS AND CORE CONCEPTS

G. H. Mead noted two distinctive human qualities: handedness and language. The human hand allows feeling, taking apart, putting together, and modifying the environment. Language (with consciousness and mind) in conjunction with the hand facilitates thinking, imagining, creating, and communication with others to plan, coordinate, and assess social action. Humans are assumed to be at work, active in managing their existence. The hand serves as a metaphor for doing the work of affecting the environment and offering feedback of the results for thought. Society precedes any individual. As humans enter this world and develop they are socialized into it (i.e., learn how to use the hand and language). They are taught or come to know what objects mean and how they are used. They develop a self, make an object of their actions, and use this reflexivity to think and interact with others. From this foundation there are five key assumptions: process, emergence, agency, conditionality, and dialectics.

Process

Rather than static or equilibrium states, interactionists believe things social are always active, in process, ongoing, becoming, and changing. Society and the individual are seen as in process. Even in stability there is process because actions/activity are necessary to maintain that state. Interactionists also deconstruct and dereify totalities and structures into activities and processes.

Emergence

Emergence refers to unique combinations that create qualitatively different manifestations. For example, hydrogen plus oxygen creates water. Similarly, an aggregate of individuals together as a group is more than the sum of the parts. It has different consequences. Thus, the emergent developments of handedness and language lead to human social organization and culture. Emergence also means unpredictability and contingency. Interactionists are relative determinists, who because of vagaries (e.g., ambiguous communication, divergent interests, problematic coordination, and unforeseen obstacles) expect the unexpected, the accidental, novelty, or resistance/deviance. Interactionists remain open to possibilities and potentialities.

Agency

Agency refers to the idea that humans are not robots and have the capacity to exert some control over themselves, others, and the environment. Humans are able to construct, pursue, and achieve their intentions (within limits). Activity and social action are not predetermined but are constructed in the process of doing and therefore capable of being altered to meet whatever circumstances arise. Humans construct social worlds and transform environments.

Constructed Conditionality

Constructed conditionality embeds two processes. The world as we know it is a social construction. Humans have built societies, groups, and relationships. Humans then have

to live with the consequences of their constructions. They condition subsequent activity. Humans are born into societies with conditions to which they adapt, respond, and often change. There is an obdurate reality that humans must take into account. The conditions/reality do not necessarily determine social action, prevent agency, or mute social construction, but they cannot be ignored without consequences. The existing conditions shape but do not determine behavior.

Dialectics

There is a rejection of standard dichotomies or dualistic thinking. Western societies have long accepted dualisms such as mind/body, individual/society, and rationality/emotion. Interactionists see these in relational and processual terms. The self is said to be composed of a social aspect (me) and a personal (I) one, which are in conversation, dialogue, and interaction with each other. Thus, self and society are not opposites but implicated in each other and in process. The ideas of relationality, mediation, and dialectics are expressed here as interpenetrative phases and aspects. Interactionists responded to debates about macro/micro, structure/process, and agency/structure by transcending these dualities with alternative conceptualizations.

A set of core concepts draws upon these assumptions. Work as something to be done stands for action. Working things out implies "with others," thus interaction. Interactionists take the dyad or joint action as the basic social unit. From this form and process are built greater complexity. Dyads with relative stability have general agreements about identities, intentions, expectations, and coordination. Joint action occurs because each actor builds upon and completes the actions of the other. But interactionists assume agreements are working consensuses, subject to differences and obstacles, and then renegotiated.

Situations constitute basic contexts for action. Over time actors encounter familiar ones which they recognize and then produce the appropriate and consequent identities, actions, and outcomes. These are routine situations

characterized by habitual behavior. When actors encounter obstacles, novelty, or ambiguity the situations are problematic and require social action to define and specify the situation and its interactional requirements.

Much of social life occurs in collectivities of different sizes, forms, and complexities. Collective action, joint action by multiple actors, whether in teams, families, congregations, or social movements, requires significant planning, coordination, timing and spacing, and monitoring. Collectivities may be seen as networks which connect and implicate multiple others, but may vary on how tightly or loosely coordinated the collectivity is. Since such collectivities may not be located in a single space and may have projects that extend for long durations, the ability to maintain, coordinate, and accomplish their goals poses major problems. Interactionists have consequently paid attention to temporality, spatiality, and coordinated action.

Interactionists have questioned the strengths and stability of conventional organizational forms. They have offered conceptualizations of organizations as negotiated orders stressing the problematic, ambiguous, and contested nature of those contexts and the necessity of actors to reconstitute activity through negotiation. More generally, they have proposed a new concept, "social world," to represent collectivities organized around an activity/idea/purpose but dispersed across space and time with diffuse boundaries and membership. Using this concept, Becker (1982) demonstrated how art worlds involving production, dissemination, and consumption of art were held together in networks by conventions, resources, and context. Others have shown how multiple social worlds come together, interact, and evolve in organizations, institutions, and arenas of public issues and social problems. Social worlds represent a fluid, dynamic, and changing social formation due to problematic circumstances and consequential interaction.

Interactionists prefer the term social organization to social structure because they perceive greater fluidity, looseness, and change. They see dialectical relationships between order/disorder, stability/instability, yet at the same time they see processual ordering through constructed conditionality. There is recognition of

structuration, constraints, sedimentation, and inequality. Not all actors have equal access to cultural and material resources and hence agency is restricted. However, there are opportunities, contingencies, alternatives, and imaginations that provide dynamic possibilities. So while one can acknowledge that the inequality orders of class, gender, and race intersect, their ordering can be said to be "tentative, messy and incomplete."

SCHOOLS OF THOUGHT

Interactionism lacks a consensual, integrated, transmitted body of ideas; rather, scholars have taken what they wanted to fit their purposes at hand. Major faultlines in interactionism have been around Herbert Blumer's interpretation of Mead. On the one hand, some scholars believed Blumer minimized social structure and rejected a positivist approach to exploring relations between individuals and society. Others believed Blumer focused too much on the self, symbols, and cognitive aspects and insufficiently on behavior or forms of social interaction.

There are two forms of interactionism that stand in some contrast to conventional symbolic interaction. The first is the Iowa School, which has seen several forms. It was first developed in the 1950s under the leadership of Manford Kuhn, who believed (following his views of Mead and Cooley) that it was possible to pursue the scientific study of the self. His view of the self was more structural than the presumed fluid view of Blumer. Kuhn proposed the Twenty Statements Test as a simple, quantitative way to get data about people's ideas about their selves. Numerous studies were conducted and published using this instrument that led to ultimate understandings of how self conceptions were altered by social change and new conditions.

Later, in the 1970s, Carl Couch and his colleagues developed the "new" Iowa School with the same interest in systematic, scientific study. They took a position that more attention needed to be given to examining the social act and the problematic coordination of behavior. Their social behaviorism made the core

ontological units, not individuals, meanings or situations, but rather forms of coordinated behavior (e.g., dyad, triad, small group). For them, the basic building blocks of society were two or more people coordinating behavior with experienced, enduring consequences. They did so by studying the emergence of relationships and different forms of relationships in varying contexts. Carl Couch used these studies as the basis for *Constructing Civilization* (1984), which explored the evolution of complex forms of social coordination across expanses of space and time. It remains a foundation piece for interactionist studies of social organization.

The second form, the dramaturgical perspective, most completely developed by Goffman (1959), has been utilized by numerous interactionists, providing an extensive literature (see Brissett & Edgley 1990). It has its formal origins in the writings of Kenneth Burke on dramatism and was utilized by C. Wright Mills in his early work on motives. Gregory Stone and Robert Perinbanayagam were also instrumental in expanding the framework and integrating it with ongoing interactionist analysis. Several factors distinguish it from traditional symbolic interactionism. Like the Iowa School, dramaturgy focuses on actions and situations. It focuses on how people express themselves with others. But that interest involves more than verbal communication. The formulation includes nonverbal elements: appearance, attire, gestures, sounds, and movements. Following Goffman, dramaturgists believe accomplishing expressive actions jointly is problematic, socially emergent, and variable. Dramaturgists believe all social actors have to express themselves to interact, but they may or may not be aware of or be able to control how they do so. Thus, there are numerous possible alternatives in these interactions. The dramaturgical perspective and the language of theater continue to offer insights and methods for interactionists.

METHODOLOGY

Interactionists have used a variety of methods and techniques to develop an extensive empirical base. Use of different methods may arise from varying assumptions about interactionism

and social reality. Many practitioners operating from interpretive assumptions have conducted ethnographic fieldwork and depth interviews designed to access actors' perspectives, biographies, and experiences and to reveal detailed observations of group life. Other interactionists whose focus was on social action and social process chose various ways to conduct systematic observations of different behavioral phenomena in laboratory or public settings. Some of these studies utilized multiple observers and/or videotaping or photographing of social gatherings and interactions (e.g., experimental role playing or large protest demonstrations). A third approach has utilized questionnaires, hypothesis testing, and statistical analyses to explore connections between self, roles, relationships, and social structures. A final category of empirical study involves content analyses of documents or visual and print media to elicit thematic elements.

Because early ethnographic and qualitative research was criticized as idiosyncratic, Glaser and Strauss (1967) presented grounded theory as a systematic method of relating qualitative data and emerging theory through comprehensive fieldwork strategies, coding, conceptualization, and theory generation. The approach has been extensively elaborated, revised, expanded, and strengthened in later works by Strauss and others. A major recent advance comes from Clarke (2005), which integrates historical, visual, and narrative discourses and structural contexts with grounded theory to produce a more comprehensive basis for conducting qualitative research.

Another significant change in interactionist qualitative research emerges from making explicit the significance of the self in the conduct of the research. Since the researcher's self is the instrument of data gathering, it is imperative to show that their identities, perspectives, actions, and relationships affect and are affected by the field. Reflexivity, the dialogue between self as subject and object, is central to understanding that imperative and requires explication. The subjectivity of the researcher facilitates the research, but also becomes author of the research presentation. That makes the presentation and its form subject to analysis.

One result has been to adopt a narrative approach that is consciously explicit about a rhetorical structure with dramatic appeal.

It is common for interactionists to use multiple methods in their research in order to examine the empirical and theoretical problems with different information. Researchers often combine fieldwork and interviews with document analysis or surveys. Recent work has utilized self-administered questionnaires and interviews with participant diaries and videotaped conversations. Several interactionists have made strong arguments about combining qualitative and quantitative analysis where the latter can provide insightful and appropriate exploration of outcomes, variation, comparisons, and contexts to supplement processual and perspectival analysis. It is in keeping with the pragmatist tradition that the nature of the problem will determine what methods will most appropriately be applicable. Many require multi method approaches that provide complementary and triangulating assessments of the problem.

RECENT CONTRIBUTIONS

In the last 30 years there have been dramatic changes in interactionist scholarship. The renaissance of pragmatism has meant reexamination of early writings and attention to new topics such as temporality, physical objects, science, and society. Scholars have also examined power, organizations, institutions, dynamic social structures, and large scale social processes (Hall 1997). A particular new and important focus has been inequality, where scholars have examined processes of reproduction, emerging social stratification systems, and the intersection of class, gender, and race inequality (Schwalbe et al. 2000).

Other significant ventures have transformed the field of collective behavior and social movements, eliminating mythical notions of irrational actors and group minds, adding cultural/symbolic elements to instrumental/political social movement analysis, and expanding the scale and scope of studies to encompass expanses of time and space (McPhail & Tucker 2003).

Symbolic interactionists were among the first sociologists to include emotions as a topic of sociological study. Utilizing early work by Cooley, Shibutani, and Goffman, they showed the interplay between cognition and feeling, the definition and categorization of emotions, and the normative shaping of emotional behavior. More recently, interactionists have been attentive to neurocognitive research and its relationship to conceptions of mind, self, emotions, and action (Franks 2003). Recent developments in human genetics and biotechnologies have also renewed interest in biology by interactionists.

system theories

Tom Burns

In the most abstract sense, a system is a set of objects together with relationships among the objects. Such a definition implies that a system has properties, functions, and dynamics distinct from its constituent objects and relationships. A system theoretic approach is not unique to sociology. Many of the major system theorists have belonged to other disciplines, including mathematics, with conceptual and analytic challenges rather different from those confronting sociologists and social scientists. Within sociology there have been several system theories, differing from one another in the extent to which, for example, human agency, creativity, and entrepreneurship are assumed to play a role in system formation and reformation; conflict and struggle are taken into account; power and stratification are part and parcel of the theory; structural change and transformation – and more generally, historically developments – are taken into account and explained. What the various system theories have in common is a systematic concern with complex and varied interconnections and interdependencies of social life. Complexity has been a central concept for many working in the systems perspective. The tradition is characterized to a great extent by a burning ambition and hope to provide a unifying language and conceptual framework for all the social sciences.

MULTIPLE APPROACHES

Below, we consider three general approaches to studying social systems: functionalist and neo functionalist theories (identified particularly with Parsons); the historical, Marxian approach; and actor oriented, dynamic system theories

(e.g., those of Margaret Archer, Walter Buckley, and the European group including Thomas Baumgartner, Tom R. Burns, and Philippe DeVile). These three approaches are methodologically holistic (Gindoff & Ritzer 1994).

Functionalist Systems Theories

The theorists in this tradition explain the emergence and/or maintenance of parts, structures, institutions, norms, or cultural patterns of a social system in terms of their consequences, that is, the particular functions each realizes or satisfies. This includes, for instance, their contribution to the maintenance and reproduction over time of the larger system. The major functionalist in sociology is arguably Talcott Parsons (1951, 1966). Society in a Parsonian perspective is not just an aggregate of social structures but an actual functioning or operating system, with some varying degrees of coherence, integration, and effectiveness. Societal subsystems such as politics, law, economics, and education are interrelated and may contribute differentially to overall systemic performance, the quality and quantity of which may vary.

Parsons extended earlier functionalist explanations which had left open such questions as: Which are the necessary or requisite functions, if any, of a society or its institutions? Is the number infinite or finite? Is there a prioritizing of functions? Of particular importance is Parsons's theory of universal functions or *requisites*. He identified four universal social functions with which any society must deal in order to be sustainable:

- 1 Goal attainment (*G*): political and administrative institutions are designed to determine the ends to which a society should orient (both externally and internally): societal goals, priorities, and political and administrative effectiveness.
- 2 Adaptation or economic efficiency (*A*): institutions deal with the economy and the material environment: transforming material inputs to serve the physical needs of the population and to provide resources to maintain and establish particular institutions of the social system.

- 3 Latency (*L*): institutions of socialization and social control maintain commitment to, or at least acceptance of, basic cultural patterns, in particular the complex of cultural values, principles, and basic institutional arrangements.
- 4 Integration (*I*): institutions coordinate and manage individual agents and multiple societal structures to a greater or lesser extent as a coherent, functioning whole.

The performance and effectiveness of AGIL institutions in accomplishing relevant functions may be treated as variables, thus suggesting varying degrees of societal effectiveness and sustainability of any given system. Put otherwise, the reproduction of a system entails the maintenance of "essential variables" within certain limits (Buckley 1998).

In the late 1960s and 1970s criticisms emerged against Parsons's theory and mode of theorizing, his presumed ideology, and even against his person – his religious background, ethnic and cultural heritage, putative support of the power elite, and writing style. The critique of Parsonian systems theory was well placed in many instances, albeit often exaggerated and *ad hominem*. Fortunately, some sociologists (Jeffrey Alexander, Shmuel N. Eisenstadt, David Lockwood, Peter Munch, David Scull, and Bryan S. Turner, among others) continued to work with Parsonian concepts and issues and in a number of instances succeeded in overcoming some of the limitations of his original work. Alexander (1995), in particular, strengthened the theorizing about conflict and power as well as culture in Parsonian systems theory. Another important development related to Parsonian systems theory is Niklas Luhmann's (1995) autopoietic systems theory. While following a functionalist theory line, Luhmann was original in several respects. For instance, he eliminated human agents from his theory, eschewed materiality, developed a purely constructionist approach to systems theorizing, and, above all, stressed self reflectivity and self organization. However, the theory still neglected to incorporate or to develop major conceptualizations of central importance to the development of modern sociology and social science, such as institution, human agency, and creativity.

Historical, Political Economic Systems Theory

The Marxian approach to system theorizing clearly points us to sociologically important phenomena: the material conditions of social life, stratification and social class, conflict, the reproduction as well as transformation of capitalist systems, the conditions that affect group mobilization and political power, and the ways ideas function as ideologies. Marx's historical approach conceives of all societies as evolving in a series of stages. Each stage is characterized by a particular structure, a certain mode of production, the "superstructure" of politics, and a culture derived from and dependent on the substructure of production. Human beings generate these structures through their own actions, but not always under the conditions of their own choosing or in the ways they intend. Marx and Marxists focused their theoretical and empirical research on the emergence and transformation of capitalist systems. Because of contradictions between structures – between, for instance, the "forces of production" (such as new knowledge, techniques, and scientific developments that contribute to generating such forces) and the "relations of production" (such as the private ownership of the means of production) – the capitalist system undergoes crises, leading eventually to its transformation.

Marxist theory identifies and explains why certain modes of production or social structures give advantages to one group or class rather than another. The relative power of social classes is determined by the particular mode of production, the ownership of productive property, and the authority system required by a given technology (Collins 1988). Classes have not only different interests (ideology and modes of mental production), but also different capabilities and means of political mobilization and influence. The capitalist system is historically characterized by economic crises, conflicts, and tendencies for continuous transformation, not only of economic relations, but also of other social relationships. Nevertheless, institutions were developed in modern societies to deal with destabilizing developments such as overproduction, as well as other systemic problems of capitalism such as class struggle, multiple social dislocations, volatility, overexploitation of natural resources, environmental degradation, etc.

Marx's historically oriented systems theory and its variants have contributed to the development of a complex of structural concepts and analyses and to a conceptualization of particular forms of reproductive and transformative processes. In contrast to Parsonian and other system theories, however, it has been relatively weak in conceptualizing and taking into account human agency and in developing relevant institutional and cultural theories. Recent developments in neo Marxist theorizing (which rejects simplistic materialism) have overcome some of these deficiencies. Among other related major developments, world systems theory (Wallerstein 2004) should be mentioned. Inspired by Marxist theories, it addresses dependency among nations and imperialism, placing the evolution of capitalist systems in a global and comparative perspective. Another variant of Marxist system theory is that of Pierre Bourdieu (1977), which unifies the material and the symbolic, as well as agency and structure.

Actor Oriented, Dynamic Systems Theories

This family of theories – inspired to a great extent by Buckley – is largely non functionalist. It includes Buckley's (1967, 1998) "modern systems theory," Archer's (1995) "morphogenetic" theory, Burns's "actor system dynamics" (also ASD; Burns et al. 1985; Burns & Flam 1987), and the "sociocybernetics" of Geyer and van der Zouwen (1978). Complex, dynamic social systems are analyzed in terms of stabilizing and destabilizing mechanisms, with human agents playing strategic roles in these processes. Institutions and cultural formations of society are carried by, transmitted, and reformed through individual and collective actions and interactions. On the one hand, such structures are temporally prior and relatively autonomous with respect to social action, yet exhibit causal force. They constrain and enable people's social actions and interactions. On the other hand, individual and collective agents through their interactions generate structural reproduction, elaboration, and transformation. The approach concerns not only the identification and development of social structures, but also the specification of the social mechanisms, including *morphostatic* feedback processes that entail

stabilizing, equilibrating features, and *morpho genetic* processes of structural elaboration and transformation. In such terms, social structures help to create and recreate themselves in an ongoing developmental process in which human agents play constructive as well as destructive and transformative roles in the context of complex sociocultural arrangements. The approach entails systematic theorizing of individual as well as collective agents, institutions, and cultural formations and their part in processes of reproduction and transformation. Active agents with their distinctive characteristics, motivations, and powers interact and contribute to the reproduction and transformation of structure. They establish as well as reform such structures as institutions, socio technical systems, and physical and ecological structures, always within constraints and opportunities, and not always in ways they intend. The selective and structuring mechanisms that reproduce, modify, or transform social structures are themselves based on institutional arrangements and distributions of powers among societal agents and social populations such as classes and ethnic and religious groups.

This approach to systems theory, particularly in the work of Archer and ASD, theorizes institutions and sociocultural formations in their own right, identifying and explaining the real and variegated structures which have emerged historically and are elaborated and developed in ongoing social processes. The approach enables one to identify and analyze the complex mechanisms of stable reproduction as well as of the transformation of societal structures and the genesis of new forms. In other words, human agents constitute and reconstitute institutions and cultural forms through their interactions. Rule interpretation, formation, and development are viewed as a form of normatively guided problem solving and entrepreneurship.

ASD has drawn to a significant degree upon Marxist theory, redefining key Marxian concepts in modern sociological terms (above all, through institutional and cultural theorizing), including concepts such as class, power, domination, exploitation, conflict and struggle, and unequal exchange and accumulation, reproduction, and transformation.

CONTRIBUTIONS OF SYSTEM THEORIES

System theories have been applied to a wide spectrum of empirical cases and policy issues. Parsons and his followers, in particular, applied their systems theory to diverse empirical phenomena in sociology as well as in other disciplines: modernization, economics, politics, social order, industrialization and development, Fascism and McCarthyism, international relations, social change and evolution, complex organizations, health care, universities, religion, professions, small groups, and family as well as abstract questions such as the place of norms in maintaining social order both historically and cross nationally. Marxian theory and dynamic system theories have also been applied to a spectrum of diverse empirical and policy subjects.

Among the major contributions of the approaches outlined here is the development of conceptual and methodological tools to investigate *complex* interdependencies of social phenomena, including (1) the multi dimensionality of social action and interaction, (2) inter structural problems and dynamics, and (3) complex action structure loops such as those of reproduction and transformation. These are outlined below.

Multi Dimensionality

Action and interaction has been interpreted and conceptualized as multi dimensional, entailing the confluence of economic, social, cultural, instrumental, and moral factors. One implication of this perspective is that unidimensional action such as pursuit of profit or gain would tend to be functionally or evolutionarily disadvantageous to a society as a whole. Social integration – the realization in general of other social requisites – is sacrificed to productive efficiency in such a unidimensional perspective on action and interaction. Similarly, purely procedural rationality also proves disadvantageous because it ignores real consequences. More generally, the neofunctional and dynamic system theories as well as neo Marxist theory have fruitfully addressed multidimensional, multi level phenomena, taking into account human agency as

well as developments in institutionalism and in the sociology of culture.

Interstructural Problems, Forces of Change, and Dynamics

A common thread in system theories has been the analysis of interstructural relations and the instability to which they give rise. Multiple, incompatible structures cause performance failures and disorder. Lockwood (1964) addressed these issues in his distinction between *system integration* and *social integration*. He utilized Parsons's idea of a normative order, incorporating "factual order" or substratum as a determinant of social conflict and social instability. For Lockwood, the key factor in social transformation is system contradiction; for instance, between forces and relations of production. If present at the same time that there is social conflict and struggle between groups of societal agents or classes, then social transformation is likely. Among the major subtypes of interstructural problems are incompatibilities between structures of the social system and structures in the environment. Complex feedback loops between societal orders and their environments may generate uncontrollable instability and non sustainability (e.g., in connection with soil erosion or other resource depletion).

Reproductive and Transformative Action Structure Loops

In investigating complex interdependencies in social life, system approaches have typically worked with multiple forms of causality and complex mechanisms of system functioning, stability, and change. A major common interest – although formulated in different ways in the three approaches – relates to processes of system reproduction and non reproduction (or transformation). The conceptualization of reproduction processes contributes to the explanation of structural stability or morphostasis. Disturbance or blockage of these processes leads typically to restructuring via transformations or morphogenesis.

Social Reproductive Mechanisms

These entail particular types of action structure loops. Any given social structure consists of constraining and enabling factors for the agents involved. Under certain conditions, these lead to consequences maintaining and reproducing the structure. In a given context, one theorizes factors that may disturb reproductive loops and factors that may handle disturbances so that reproduction can be sustained. Some reproductive loops are consciously designed. That is, particular practices and institutions are constructed so as to contribute to, or set in motion, reproductive loops. Thus, we find in modern societies a spectrum of institutional arrangements designed to prevent or to regulate conflicts between diverse agents and groups. Democratic institutions, court systems, particular government agencies of regulation, and formalized negotiation systems deal with, for instance, labor capital and commercial conflicts. Along such lines, Sciulli (1992) emphasized procedural norms, collegial forms of organization, and symbolic media of interchange, which facilitate integration and effective collective action in the face of the substantial diversity in agents' beliefs and interests in a modern society. Also, modern societies have developed a number of institutions to deal with destabilizing features of capitalism and to assure its effective reproduction, albeit often in modified form.

Transformative Mechanisms

Endogenous processes such as economic or political competition among agents, and social entrepreneurs responding to incentives, may restructure and transform a system. Under some conditions, these initiatives result in self sustaining, cumulative transformative processes. As a result of an initial, possibly modest, change in institutional rules and/or rule enforcement activities, different opportunity and constraint structures are shaped, leading to shifts in patterns of action and interaction. These in turn may result in new initiatives, social mobilization, and successful efforts at extensive reform or transformation. In general, a transformative

action structure loop entails a type of circular causality with cumulative transformative effects. In some cases, the initial impetus may have been an external shock.

Power, knowledge, values, and interests are key ingredients in structural innovation and transformation. The power of agents to mobilize resources including wealth, government authority, and coercive powers to maintain or change institutional orders is well recognized in sociology. Emerging groups and movements may also mobilize sufficient power resources to challenge established elites and, under certain conditions, to bring about transformative loops such as revolutions. The interaction between established elites and challenging groups or movements is a common theme in the study of institutional and societal dynamics. Such power mobilization and conflict are fueled by actors' material and ideological interests. They are reflected in paradigms that define appropriate institutional arrangements, strategies, and policies to deal with collective problems, including problems of social order. In general, a political or economic order is historically vulnerable when reproductive loops are eroded or collapse. For instance, one or more of the conditions for rule enforcement, transmission, and self replication may be unsatisfied (Burns & Dietz 1992). Even initially successful institutionalization of a major reform or revolution can be undermined by complex processes of reproductive failure. There are numerous historical examples of what appeared to be successful institutional innovations, even revolutions with great visions of new, even utopian social orders. Many have collapsed, degenerating into substantially different social orders.

CHALLENGES AND OPPORTUNITIES

The vigorous critique of Parsons in the 1960s and 1970s extended to other system theoretic approaches such as those of Archer, Buckley, and ASD. These other theories generally were treated as "grand theorizing" and regarded as suspect when not rejected out of hand. Sociological textbooks neglected much of the diversity of system theorizing, such as the work of Buckley and his European followers. Including them would have complicated the picture

considerably. For a time, an exception was made for Marxist theory, which was viewed as non functionalist – although Collins (1988) later disproved this characterization – and more compatible with the ideological tenor of the times.

The general rejection of systems approaches since the 1960s did not stem the incorporation of systems concepts into other theoretical traditions by major American and European sociologists (e.g., James Coleman, Klaus Eder, Anthony Giddens, David Lockwood, Charles Perrow, W. Richard Scott, Arthur Stinchcombe, Piet Styrdom, and Piotr Sztompka). Consequently, much of the language and conceptualization of modern system theories has become part of everyday contemporary sociology (e.g., open and closed systems, loosely and tightly coupled systems, information and communication flows, reflexivity, self referential systems, positive and negative feedback loops, self organization and self regulation, reproduction, emergence, non linear systems, complexity). Institutionalists and organizational theorists in particular have co opted a number of system concepts without always pointing out their etiology.

The tendency of neofunctionalist, neo Marxist, and dynamic system theories to converge through contemporary institutional and cultural analysis is an important part of the ongoing revitalization of systems theorizing. One might ask, why not simply concentrate solely on developing institutional and cultural theories, and forget systems theorizing as such? But the multi dimensional conceptualization of action and interaction, the interrelatedness of diverse multiple structures, and the action structure loops of reproduction and transformation call for a more encompassing or holistic approach. The interplay of physical or material structures, sociocultural systems, and interaction orders cannot be properly conceptualized, described, and analyzed through strictly institutional and cultural theories.

Another key factor is the system approach's conceptual and methodological capacity to facilitate cooperation among social, natural, engineering, and medical sciences. Already there is increasing convergence and some cooperation between natural scientists and mathematicians, on the one hand, and social scientists on the other, in constructing models of "multi agent,

dynamic systems." A major force here is the emergence of complexity theory and the theoretical work and simulation of complex "multi agent systems," of interest to many mathematicians, computer scientists, and natural scientists as well as a growing number of social scientists.

System theories also perform an important intellectual function within sociology, and among the social sciences and humanities: they contribute a common language, conceptualization, and theoretical integration in the face of the extreme fragmentation among the social sciences as well as within sociology. The latter suffers as a result of the institutionalized concentration on mid level empirical and theoretical research (i.e., "middle range theorizing"). The challenge which Parsons and others including Buckley originally addressed remains to overcome the fragmentation of sociology and the social sciences generally, the lack of synergies, and the failure to develop a cumulative science by providing them a common language and integrative theoretical framework to mediate, accumulate, and transmit knowledge among all branches and sub branches of the social sciences and allied humanities (Sciulli & Gerstein 1985). On a practical level, there remains the venerable challenge to establish and develop a social science complex that can readily and systematically put pieces of specialized knowledge together to address major contemporary problems – perhaps a type of meta theoretical framework rather than a single overarching theory.

T

Takata, Yasuma (1883–1972)

Kazuo Seiyama

Yasuma Takata was a prominent neoclassical economist in the pre war era. He was also a tanka poet and published several collections of original poems.

He was born in Kurume, a city in Northern Kyushu, Japan, and graduated in sociology from Kyoto Imperial University. He taught at various universities, including Kyoto, Kyushu, and Osaka, mainly as an economics professor. He wrote more than 100 books, of which about half were on economics and about 30 were sociological.

Although his work was multidimensional he began his career as a sociologist and retained this focus throughout his academic life. His sociological works bridged various sociological fields, such as general theory, class theory, social change, population, social power, and others. He was principally a theoretical sociologist. The basics of his theory are principally addressed in his early (and voluminous) *Shakaigaku Genri* (Treatise on Sociology) (1919), in which he endeavored to construct a general sociological theory based on methodological individualism (using the term coined by economist J. A. Schumpeter in 1908, with whom Takata became acquainted sometime later when Schumpeter visited Japan).

A pivotal concept in the *Treatise* was the individual's "desire" as the main factor underlying various social phenomena and social evolution. He assumed that several kinds of desires are naturally given to people and determine their behavior. Important among them were the "desire for power" and "desire for gregarious

living." Desire for gregarious living was a ground for basic social formation. On the other hand, desire for power was a basis for dissociation, differentiation, and individuation.

This description might make Takata appear to be an old fashioned Spencerian sociologist with a hint of Tönnies' conceptual framework thrown in. But the originality of Takata's thinking lies in his way of constructing a large scale theoretical system beginning from those basic presumptions. Various original concepts were introduced, for example, "homogeneous association and heterogeneous association," "direct association and indirect association," and "fundamental society and derivative society." And several "laws" – such as "the law of fixed quantity of association," "the law of the loss of intermediate societies," and "the law of the decline of fundamental societies" – were formulated. After giving extensive explanations for these concepts and laws, he presented a theory of social evolution which emphasized three major trends: cultural flourishing, the expansion of liberty, and the development of individuality. This main framework of the *Treatise* was followed by *Principles of Sociology*, originally published in 1922 as a more compact version.

In one sense, his sociology may be characterized as a social theory of atomistic liberalism. First, he was entirely opposed to any collectivist or substantivist view of society, although these were so common as to be taken for granted by his contemporary social theorists, especially in Japan. His theory of the relationship between state and society anticipated in many respects the pluralist theory of state formulated by R. M. MacIver and H. J. Laski. Secondly, at the same time, he envisaged a social evolution in the process of individualization, arguing that it would lead to a new type of social integration and solidarity far preferable to the old one. This thesis was later developed in his *Sekai Shakai*

Ron (On World Society) (1947), in which he presented a theoretical future vista of a politically and socially unified global society where nation states would be extinguished, at least as independent political units. (It is astonishing that this was presented immediately after Japan's devastating defeat in World War II.) Thirdly, his optimistic view of social evolution was grounded in his conviction that fundamentally individual liberties would bring about a desirable and well ordered society, a view common to neoclassical economics.

Takata's theory of social change is known as "the third view of history" or "the population view of history." Many have interpreted it, mistakenly, as a claim that history is determined by the growth of population. Importantly, it was originally presented as a new interpretation of class theory in an anthology *Kaikyu Oyobi Dai San Shikan* (Class and the Third View of History) (1925), shortly after his *Treatise*. His class theory is well known as a theory of power; that is, what determines class formation and changes in class structure is neither an Idea (*Geist*) nor the relations of production, but social power. In opposition to Marxian class theory in which the power structure is supposedly subordinate to the economic structure, Takata thought that power is the most fundamental determinant of class structure. Hence, his "third view of history" should be understood as basically "a power view of history," meaning that it is neither the first, Hegelian idealist view, nor the second, Marxian materialist view.

He provided three main reasons why Marxian class theory – that class is formed according to people's common location in the relations of production – is wrong: (1) some landowners and capitalists form a class without engaging in any economic activity; (2) in a future classless society, there will still be a division of labor and differences in economic activities; (3) individuals engaged in the same profession may yet belong to different classes. Instead of similarities in economic activities, he insists that similarity in social power is the constitutive factor of class structure.

Although since his earliest work power had been the pivotal concept, his most extensive discussion of power was not produced until relatively late, in *Seiryoku Ron* (On Power) (1940), where his "power view of history" was

systematically presented by articulating and developing both theoretical and historical accounts of power. He considered this to be his major work. And yet, it should be stressed that his basic conceptual framework on power had already been formulated when he presented his extensive class theory (1922). This was well before the sociological power theories, such as those by Weber, von Wiese, or Russell, had appeared or become available to him, let alone the post war writings of Hunter, Dahl, and other political scientists.

One distinctive feature of his theory is seen in the definition of power, which was initially given as "the ability of governing another's will," but later revised in *On Power* as "the chance of being obeyed." Compared to Weber's "chance of accomplishing one's will," which should have been available to him at that time, the uniqueness of Takata's definition is that it refers simultaneously to both the power exerciser and the power obeyer. Hence it is a relational concept, not an action based concept. At the same time, it is still a broadly individualistic concept, in contrast to the Foucaultian and other current trends in conceptualizing power.

From the contemporary general theoretical perspective, whether power is defined individually or collectively is an extremely important issue.

In this regard, what is important for Takata's theory of power is that, while he was from the beginning the foremost individualist sociologist, there are various signs of collectivist ways of thinking about power in his writings. The definition above is the first example. We might note that the power exerciser does not explicitly appear in this definition. The term "chance," in contrast to "ability," expresses a contextual, relational, or structural property, as per Weber.

To be more precise, Takata's theory of power is double edged. For example, an important pair of concepts in his theory is "external power" and "internal power" which were borrowed, slightly modified, from Wiese. Basically, external power is that in which a certain individual or group is identified as a power holder, while internal power refers to the power of social norms like customs, laws, or morals, where no particular power holder exists, implying that internal power is collective. Takata considers internal power theoretically very important,

and argues that a new power emerges initially as internal power within a small group and then extends its scope as external power to a large part of the population. And yet, he emphasizes that we should not disregard those powers which come from a proper and independent personality. For Takata, power must ultimately be imputed to a person or a group of persons, even if effected by collective elements such as social norms, customs, or laws.

His theory of power fluctuates between methodological individualism and collectivism. In fact, when he describes concrete historical events in terms of power and related concepts, his description betrays his faith in methodological individualism. For example, he argues that the state is an organizational and official power of the first order, and inherently involves the legitimacy of power. And for the latter, Takata rightly emphasizes the importance of “propaganda,” “thought,” “ideology,” and “religion.” He even claims that the core of a new world power which is emerging is a thought, and a new ruling organization is established as a realization of this thought. As for the emergence of modern society in Europe, Takata explains that, as Christianity declines, the status of the pope and religious aristocrats who occupy the special position between God and human beings changed, that the rise of republican thought in Europe had removed several monarchs, and that the spread of egalitarian thought had raised the status of the proletariat class and realized the liberation of slaves. Astonishingly enough, this is a sort of idealist explanation of historical change. Of course, this is another example of the double edged character of Takata’s power theory.

His peculiar position as a central figure in neoclassical economic theory is closely related to this. Being a methodological individualist, he was inherently drawn to neoclassical thinking. But, interestingly, in developing his own economic theory – the power theory of economics – he diverged from the mainstream of economics. He repeatedly emphasized that power, or the relations of power, is the fundamental factor of the economy. He criticized the mainstream for neglecting power or, at best, treating it as a given in theory. He provided several reasons for the significance of power. First, the government and labor unions interfere extensively, as economic

powers, in various economic decisions. Secondly, socioeconomic inequalities or differences, such as in wage differences by sex, ethnicity, and educational background, should be conceived as effects of non economic, social power.

In spite of his laborious insistence and his reputation as a leading economist, Takata’s power theory of economics was never fully accepted by Japanese economists such as M. Morishima, who became one of the leading figures in post war Japanese economics, and nevertheless greatly admired him. In any case, it should be clear that, as an economist, Takata employed a collectivist mode of thinking that was unmistakably revealed in his sociology of power.

Takata’s double edgedness can also be seen in another important aspect: that is, nationalism and globalism. Of course, he was never a narrow minded nationalist, even during World War II, but was rather a noble and moderate nationalist who was born into a family of Shinto priests. At the same time, though, his sociological theory was entirely cosmopolitan and liberal. In *On World Society* (1947) he envisaged a future global world, politically unified, where individual liberty and equality would prevail. This was overly optimistic from the contemporary perspective.

However, this optimism and the various inner contradictions in his theory are rather charming, and not merely a fault in his sociology. In reading his work we certainly find profound inspirations and stimulations in these days when new social theories are waiting to emerge.

Taoism

Chee Kiong Tong and Cheuk Yin Lee

Taoism takes its name from the concept of Tao, or Way. In Chinese, the word “Tao” (or *dao* in *hanyu pinyin*) is made up of two components, one depicting a human head, the other a motion verb meaning to pass, go through, or walk. The earliest and most important work on Taoism is a short book of some 5,000 characters known as *Daode Jing* (*Classic of the Way and Virtue*) by the legendary Laozi (literally, Old Master, around sixth century BCE). The oldest manuscripts of the *Daode Jing*, unearthed in 1973 from an ancient tomb in Changsha, Hunan province, China, dated to about 200 BCE. Next to the Bible, it is probably one of the most translated works in the world, with close to 100 translations in English (see Lee et al. 1994).

The “Tao” is conceived as a metaphysical reality, the origin of heaven and earth, and the very beginning and end of all things. In Chapter 42 of the *Daode Jing*, it states: “The Tao gave birth to the One. The One gave birth to the Two. The Two gave birth to the Three. And the Three gave birth to the myriad creatures.” This process of creation can also be understood as a process of differentiation from unity to multiplicity.

RELIGIOUS ROOTS AND HISTORICAL DEVELOPMENT

The origin of religious Taoism is extremely complex. As an organized religion, it probably started during the Eastern Han dynasty (25–220 CE). However, religious Taoism did not occur suddenly in a historical and religious vacuum. Rather, it drew upon preexisting ancient Chinese religious ideas and practices, incorporating Chinese ideas of nature worship and ancestor worship. Divination and other religious arts of ancient Chinese religious experts or “shamans” also became part of the repertoire of the Taoist priests. In addition, religious Taoism was influenced by the teachings of ancient Taoist philosophers as well as the cult of immortality promulgated by religious teachers of the Warring States period (475–221 BCE). In this sense, religious Taoism can be seen as a synthesis of several currents of thought going back to the very beginning of Chinese history.

During the reign of Emperor Shun (126–144 CE) of the Han dynasty, Zhang Ling, native of Jiangsu province, established the first Taoist sect in Sichuan, China. He claimed to have received a revelation from the divine Laozi to establish a new Taoist order. Known as the “Celestial Master” sect, it made the Taoist philosophical classic *Daode Jing* the chief scripture of the sect, and followers were taught to venerate the Tao and to repent their sins. By means of sacred incantations, talismans, and purification rites, the Taoist master sought to restore the spiritual and physical health of the followers. The movement attracted a large following and quickly developed into a major religious force. At that time, the Han Empire was already on the brink of disintegration, and the country was plunged deep into civil war. The rise of religious Taoism can be viewed in the context of its ability to provide meaning and meet adherents’ spiritual and material needs at a time of sociopolitical and economic strife.

Religious Taoism may have been started as a popular movement, supported mainly by the rural peasants, but by the post Han period (third century CE) it began to attract the attention of the educated elites. The Taoist master Ge Hong (283–343 CE), an expert in Taoist alchemy and traditional medicine, is one of the key figures responsible for the “upward” swing

of the religion. Ge Hong envisioned a synthesis of Confucianism and Taoism, in which spiritual practice and moral cultivation form an inseparable union, combining the Taoist goal of attaining spiritual liberation and becoming an immortal with the Confucian emphasis on moral self cultivation, filial piety, benevolence, trustworthiness, and other moral virtues. In the fifth and sixth centuries CE, during the Eastern Jin (317–420) dynasty, two new major Taoist sects were formed: the Supreme Purity Sect (*Shangqing*) and the Numinous Treasure Sect (*Lingbao*). Over time, the Supreme Purity Sect became the dominant Taoist group in medieval China. As the hermitage of the sect was on the famous Taoist mountain, Mao Shan, in Jiangsu province, the Supreme Purity Sect came to be known as Mao Shan Taoism. The teachings of the Supreme Purity Sect concentrated on internal spiritual cultivation, supplemented by the study of scriptures and performing good deeds. Unlike the Celestial Master Sect, it does not emphasize the performance of rituals or the use of talismans and other religious devices. The Numinous Treasure Sect had a more outward orientation and emphasized both spiritual cultivation and rituals. It paid close attention to doing good deeds and universal salvation.

During the Southern Song dynasty, around 1167, a new Taoist sect with a strong monastic flavor – the Complete Perfection (*Quanzhen*) Sect – was founded. Its teachings prescribed a heavy dose of monastic discipline. Practitioners had to remain celibate, embrace poverty, abstain from indulgence of all kinds, including food and sleep, and refrain from injuring all forms of life. The Complete Perfection Sect was very successful and attracted a large following. In response, the other Taoist lineages gradually joined forces to form a new orthodoxy known as Right One (*Zhengyi*) Sect (see Qing 1988; Ren 1990).

Both the Complete Perfection and Right One Taoism venerate the “Three Pristine Ones” as the supreme gods of the cosmos. In terms of practice, however, the two are quite different. Complete Perfection Taoism is monastic; all priests must observe celibacy and live in seclusion. Right One Taoism is more lay oriented; its priests can marry and live among the common people. Doctrinally, Complete Perfection Taoism emphasizes quiet self cultivation, while

Right One Taoism relies mainly on the use of talismans, incantations, prayers, and the performance of rituals.

DIVINE HIERARCHY AND KEY TAOIST IDEAS

In Taoist religion, both Laozi and his follower Zhuangzi are worshipped as gods and founders of the religion. As an incarnation of Tao, Laozi is regarded as the “Supreme Venerable Lord.” The “Three Pristine Ones” and the other divinities of Taoism, including the Heavenly Gods, the Earth Gods, and the Human Gods, are all considered to have evolved from Tao. Thus, Religious Taoism is a devotional religion with a polytheistic structure. It has a highly sophisticated and hierarchically structured pantheon with countless gods and goddesses under the command of a sovereign high god and with specific stations in the divine hierarchy. The organizational principle seems to have been modeled on that of the imperial government. However, from the Taoist perspective, the earthly government reflects the structure of the heavenly kingdom.

The highest level of the Taoist pantheon is comprised of the Lordly Spirits of Anterior Heaven. It is headed by the “Three Pristine Ones” (*Sanqing*): the “Celestial Venerable of the Original Beginning” (*Yuanshi Tianzun*), the “Celestial Venerable of the Numinous Treasure” (*Lingbao Tianzun*), and the “Celestial Venerable of the Way and Virtue” (*Daode Tianzun*), also commonly known as the “Supreme Venerable Lord.” However, the “Three Pristine Ones” are perceived to be so exalted that they reign, but do not rule. Cosmic governance is delegated to a subordinate chief known as the “Great Sovereign Jade Emperor” (*Yuhuang Dadi*). The Jade Emperor, whose “birthday” is celebrated on the ninth day of the first month in the Chinese lunar calendar, is the supreme high god, the ruler of the Taoist universe. He has direct command over all deities and has absolute control over all human and divine matters. Like the imperial emperor, his counterpart on earth, the Jade Emperor is assisted by a multitude of officials and functionaries. These, in turn, are organized into a divine bureaucracy, and can be classified in terms of their rank, jurisdiction,

functions, and responsibilities, such as the God of Wealth, the Earth God, the Kitchen God, and the Door God.

Broadly speaking, Taoism can be divided into three interrelated traditions. A Taoist philosophical tradition associated with Laozi's *Daode Jing*, Zhuangzi's work, and other texts; a religious tradition with an organized doctrine, formalized cult activities, and institutional leadership; and a popular religion tradition, where there is a syncretic mix of Taoist beliefs, folk beliefs and rituals, including ancestor worship, and elements of Confucianism and Buddhism. This tradition is often referred to as a "diffused" religion, with no canonical scriptures and its rituals and religious ideas largely orally transmitted from one generation to the next.

While these are three different traditions, they are interrelated and draw from some of the key ideas of Taoism, such as the conception of *yin* and *yang*, and the five elements. For Taoists, the origin of the universe is known as the Great Beginning. The universe began as a void, from which the great breath (*Taiji*) developed. The Great Breath in turn gathered momentum, and split into two equal breaths; a light pure breath, *yang*, moves upwards and created heaven, while the opaque heavy breath, *yin*, descended and created earth (Robinet 1997: 8). Together, they constitute the cycle of life and death. The positioning of these forces is considered instrumental for social order on earth, and a disjuncture in the correct positioning will result in hazards and natural calamities (Kuah 2003: 23–4). *Yin* and *yang* form the foundation of both philosophical and religious Taoism. From these two forces, the five elements, fire, water, earth, wood, and metal, are produced. These, in turn, govern the four seasons and all aspects of human existence.

RELIGIOUS SPECIALISTS

As noted above, the concepts of *yin* and *yang* form the foundation of both philosophical and religious Taoism. The classical texts of Laozi and Zhuangzi explicate the principles of this philosophy, while the priests, mediums, and so on found in religious Taoism draw on these ideas in the performance of rituals relating to birth, marriage, death, festival cycles, and all

aspects of human life. Taoist priests, *daoshi*, are professionals who earn their living through providing a range of religious services and ritual performance. These ritual specialists, particularly in Taiwan, are called "red headed" Taoists or barefoot masters as they wear a red turban around their head and are barefoot when dressed in ceremonial ritual costumes.

Curing rituals are the most common of their services. Using divination techniques and traditional Chinese medical knowledge, they diagnose ailments. A simple cure for the illness requires the priest to write a charm, which the patient places in his or her house, or burns to drink the ashes as tea or to wash with. Complex problems may require more elaborate ritual solutions. For example, a *daoshi* may be called upon to exorcise demons that have invaded a person's dwelling or body. He performs dramatic rites, including sword dances and elaborate gestures, to chase the demons away.

In addition to the *daoshi*, there is another class of religious specialists who draw on Taoist ideas. Chinese spirit mediums, or shamans, are called *dang ki*, literally, "child diviners." Chinese spirit mediumship is based on the idea that a spiritual being, or *shen*, can temporarily possess a human body. In such a state, the *dang ki* becomes the personification of the *shen* and mediates between the human and spiritual worlds. Human beings can then consult the spirits seeking advice as well as solutions to human problems. Mediums, when possessed, enter into a state of trance. Rituals performed by spirit mediums include the sacrifice of offerings of food and joss papers, that is, paper printed in gold and silver and sometimes inscribed with prayers that are burnt, to appease the spirits.

There is a clear hierarchical distinction between the *dang ki* and the *daoshi*. *Daoshi* are regarded as the religious superiors of the shamans. To be a *daoshi* is to fill an office that is hereditary, and they are considered as the administrators of the spiritual world, a reflection of the bureaucracy that governs the earthly world. In fact, in Taoist traditions, Laozi is regarded as the first Heavenly Master and Zhang Ling (or Zhang Daoling) the universal head of the Taoist liturgical tradition. Succeeding Heavenly Masters have been representatives from this family line. The Heavenly Masters

bestow the hereditary office on the *daoshi*, who then become the priests of the regional and lay organizations. Thus, the group of *daoshi* is a confederacy of masters, not a church. The legitimacy of their mastership rests in part on the ownership of the manuscripts for liturgical use: books for reciting, rituals, collection of formularies, secret formulas, talismans and diagrams, passed down from each generation in the family (Schipper 1993: 59).

There is a clear distinction between the vernacular *fashi* and the classical *daoshi*. Besides the contrasting vestments and ceremonial garbs, the rituals performed by the two are significantly different. Vernacular rituals often contain ballads that describe a journey or the myth of the deity invoked. They also tend to give a mythological rendering of the other worlds. The classical rituals, on the other hand, do not contain such mythological aspects or journey narratives, as they are concerned with the expression of moral law and sentiment. They also constantly refer to the abstract cosmology of Taoism. Another distinct difference between the two is the use of trance techniques. Classical Taoism does not practice trance techniques that are quite commonly used by the vernacular Taoist priests. The classical Taoist rejects all forms of individual rites (as opposed to communal rites) such as healing and exorcism. Despite the apparent ritual differences between classical and vernacular Taoist priests, many of the rituals are complementary and may be performed together, as during the *jiao* festival, staged to pacify wandering ghosts, to purify the community's territory, and to reach cosmic renewal (see Liu 2003).

TAOISM AND CHINESE CULTURE

Confucianism, Taoism, and Buddhism form the three pillars of traditional Chinese culture. They provide a window to help understand the Chinese, their values, customs, and way of life. Taoism, unlike other religions that also flourished in China, is an indigenous religious tradition, shaped and formed by native religious beliefs from the start. Taoism can be said to embody a synthesis of traditional Chinese culture. As a popular religion, its teachings influenced the masses. In addition, it penetrated

Confucian traditions and added Taoist features and hues to the Confucian landscape. By blending its doctrine of immortality with Confucian ethics and political philosophy, it had a substantial impact on the educated elite as well.

Taoism also influenced the nature of moral education and self cultivation in China, with its emphasis on performing good deeds and the accumulation of religious merits. One popular belief is that to become a "celestial immortal" a person is required to perform at least 1,300 good deeds. Later, when the genre of Taoist writings known as "Ledgers of Merit and Demerit" gained currency, the moral teachings of Taoism became even more widespread. Essentially, daily actions are classified into good and bad deeds, each of which is assigned a fixed number of merit or demerit points. In this way, Taoism was able to regulate behavior and promote its vision of the good life.

External alchemy and internal alchemy, natural methods of nourishing and preserving life, represent the two foci of Taoist self cultivation. External alchemy is above all concerned with the manufacture of an "elixir" of everlasting life and involved an understanding of the nature of chemical processes and the properties of plants and minerals. Internal alchemy is concerned with nourishing and strengthening the internal vital energy that contributed to the concept of *Qi*, which plays a central role in the teachings of religious Taoism. Although external and internal alchemy may no longer be pursued in their classical form, their influence remains today. Rather than through overt missionary effort or deliberate indoctrination, Taoist practices simply merged with the common Chinese conception of physical health and spiritual well being. Other more conspicuous practices such as hanging a symbol of the "eight trigrams" in the front of a house or pasting talismans on doors to ward off evil spirits, among countless other practices, likewise reflect the pervasive presence of Taoism in Chinese culture.

Taoism was able to sink deep roots in China, not simply because of the worship of many gods and goddesses. The dimension of practice is equally important, especially in terms of various forms of religious arts. Taoism incorporated ancient astronomy, medicine, mathematics, alchemy, and other religious arts into its understanding of Tao, and further developed

various forms of divination such as astrology and geomancy. All these activities were and still are intimately related to the everyday life of the Chinese. Many practices that originated from Taoism, from the use of herbs and drugs and the art of *Qigong* (breathing exercise) to certain rituals and customs, have gradually and imperceptibly become part of the daily life of Chinese people.

CONTEMPORARY TAOISM

The classical secularization hypothesis suggests that a consequence of modernity, and for some scholars an inevitable outcome, is the decline in social significance of religion. The process implies that sectors of society are increasingly removed from the domination or religious institutions and symbols. In the main, it is argued that the process of secularization has been dependent on the rise of empiricist thinking and differentiation of roles and functions within society. The religious situation of Taoism in China, Taiwan, and Hong Kong shows that rather than secularization, there has been a revival of Taoist practices and rituals.

Revivalism in China

Despite the tenets of orthodox Marxist theory, and suppression and strict restrictions placed on religions during the communist era, religion in China is thriving, particularly after economic liberalization. Thousands of temples destroyed or damaged during the Cultural Revolution have been restored and increasing numbers of people are taking part in ritual activities. Currently, China has over 1,500 Taoist temples and more than 25,000 Taoist priests and nuns. With the rebuilding and reconsecrating of the temples, many Taoist priests found new job opportunities and returned to work. In addition, many Chinese communities began to celebrate elaborate Taoist *jiao*, communal sacrifices, as well as reviving elaborate funerary and ancestral rituals. There has been a renaissance of popular religion with the growing popularity of temple cults, local deities, and temple festivals. With the boom in economic activity, many Chinese could also afford to rebuild temples to their local god.

The resurgence in religious activities is also linked to the donations from overseas Chinese. They return in large numbers to attend religious rituals and to bury their dead, or at least hold services in their places of origin for those who have died overseas. Many have been persuaded to make large contributions to local schools, hospitals, and roads once they have been allowed to conduct the rituals (see Dean 1993; Fan 2003; Lai 2003a).

Although the state has always wanted the Taoists to conform to the Buddhist ideal of celibacy and monastic life, most of the Taoist priests or *daoshi* live a married life at home, wearing liturgical vestments when performing the rituals. Since they perform services and ceremonies in the context of the cults of various gods in local temples, they are not easily distinguishable from local temple shamans whose religious activities have been criticized as superstitious. In order to legitimize and effectively manage this group of Taoist priests, the National Daoist Association has classified the "correct" or "recognized" *daoshi* of the Zhengyi order. By law, the *daoshi* have to register with their local Taoist association and will receive a "Daoist certificate belonging to the Zhengyi sect," which is issued by the National Daoist Association (Lai 2003a: 424).

Popular religious practices have not lost their importance as China begins its modernization process. Instead, Fan argues that there has been an increase in spirituality among the population as many urban workers who have moved beyond basic struggle for survival are now faced with deeper questions of personal meaning. In his study on religion in the modern city of Shenzhen, Fan shows the trend toward a privatization of popular religion among urban Chinese. To them, religious beliefs are private concerns and the search for spiritual meaning is a personal one. Although many of these urban Chinese do not organize large communal worship events, they still uphold the traditional Chinese popular religion worldview of *mingyun*, *yuanfen*, and *feng shui* (Fan 2003: 455).

Taiwan's Religious Situation

Since the end of martial law in Taiwan, religion is thriving. Taoism, with over 4.5 million adherents,

is one of the most popular religions in Taiwan. The number of Buddhist and Taoist temples in Taiwan nearly doubled in 50 years from 3,661 in 1930 to 5,531 in 1981. According to the statistics provided by the Ministry of the Interior, by 2003 Taiwan was home to 8,604 Taoist temples that had registered with the state. In addition, there are numerous unregistered temples and household shrines (Katz 2003: 396).

Popular religion or folk religion is very wide spread. Temple cults in particular have retained their importance as sites for daily worship and community festivals, with popular deities worshipped for their ability to provide health and prosperity. Some of the popular deities include Mazu (patron goddess of the sea and fishermen) and the Royal Lords. Not only are these temple cults and festivals flourishing, they are also moving beyond their local boundaries to play a significant role on the national stage. These temples have also extended their reach into social services, and currently operate a total of 20 hospital and clinics as well as 180 schools ranging from kindergarten to university (Katz 2003).

In Taiwan, another modern, syncretic form of religion similar to those found in the folk or temple cults is currently growing in significance. The *Yi Guan Dao* (Religion of the One Unity) draws upon both traditional teachings and each of the world's major religions. *Yi Guan Dao* adherents try to identify common principles underlying Buddhism, Christianity, Islam, Judaism, and Hinduism. They ascribe to an idea of a god above all other gods called *Mingming Shangdi* (God of Clarity). *Yi Guan Dao* adherents follow many of the Confucian rituals and engage in ancestor worship. They strive to uphold the precepts of not killing, stealing, committing adultery, lying, and drinking alcohol while putting into practice the ideals of benevolence, righteousness, and universal love envisioned by Confucian teaching. As of 2001, the *Yi Guan Dao* had 887,000 believers, making it the third most popular religion in terms of number of adherents.

The Religious Situation in Hong Kong

Buddhism and Taoism, traditional Chinese religions, have a large local following with more

than 600 Chinese temples in Hong Kong. Religious practices are still very much observed today. Tablets for ancestors, Master of the Site (*dizhu*), Heaven God (*tiangong*), Kitchen God (*zaojun*), and Door God (*menguan*) are commonly found in homes where there is the practice of local religion. People regularly organize temple festivals to celebrate the birthdays of the local deities and to seek blessings. Leading deities include Buddha, *Kwan Yin*, *Guandi*, and *Luzu*. *Tian Hou*, the Queen of Heaven and Protector of Seafarers, is reputed to be worshipped by 250,000 people. During the *Tian Hou* Festival, which falls on the 23rd day of the third moon, many worshippers visit the most famous *Tian Hou* temple, at Joss House Bay on the Clear Water Bay Peninsula. The *jiao* festival is another popular event for the community. During the major *jiao* event, a large stage is constructed for the Taoist rituals and Cantonese opera. Taoist priests are hired to perform rituals that last several days. After the Taoist ritual, a Cantonese opera is performed for several days to signify the beginning of a new cosmic cycle (Liu 2003). In addition, many participate in deity festivals, birthdays, Hungry Ghost festivals, and communal *jiao* festivals. There are an estimated 500 Taoist masters of the *Zhengyi* tradition (known as *Nahm mouh* Taoist masters in Hong Kong) who are in high demand, especially for the performance of funerary rituals (Lai 2003b: 464).

In his research on Hong Kong, Lai (2003b) notes that in contrast to the *Zhengyi* Taoist tradition, which does not usually unite as a community to conduct group worship, many Hong Kong Taoists belong to sects, halls, and temples. Many of these include altars devoted to cult of *Lu Dongbin*. *Lu Dongbin* was a Taoist in the latter half of the Tang dynasty. He is an immortal and was presented as a master of internal alchemy and venerated as the patriarch of the Taoist *Quanzhen* order. He is also worshipped in the popular religious tradition as a deity famed for exorcistic and healing powers. Such *Lu Dongbin* cults were very popular in Guangdong and many Taoist altars in Hong Kong are offspring of main altars in Guangdong.

In recent years, the Taoist organizations in Hong Kong have also evolved into socially conscious, charitable organizations. Once offsprings of parent institutions in Guangdong, they have

supported the revival of Taoism in mainland China. With greater economic prosperity in Hong Kong, the Taoist organizations have raised millions of dollars to reconstruct temples in China. They have also funded universities, schools, and hospitals, established social services for old people, and set up orphanages, clinics, and study rooms for students (Lai 2003b: 466).

taste, sociology of

Jukka Gronow

The importance of taste as a sociological concept was emphatically pointed out by Pierre Bourdieu. In his sociology, probably more than any where else, taste is a central theoretical concept of analysis. By distinguishing between good and bad, tasteful and tasteless, beautiful and ugly, taste classifies and orders the natural and social world. By taste one classifies oneself and is classified by others. Understood in this way, the sociological concept of taste shares many important features with its predecessor in classical philosophical aesthetics, the power of judgment. In this capacity, taste does not just refer either to individual preferences or dispositions (the term used by Bourdieu), or to some standards used in making choices in consumption. It is an important concept in bridging the gap between an individual's choices and his or her socially shared preferences or habits. In addition, it can refer to more or less automatic responses as well as to highly reflective acts of judgment, and to behavioral responses which share both these aspects at the same time.

TASTE AND POWER OF JUDGMENT IN PHILOSOPHICAL AESTHETICS

The old saying that one should not dispute over matters of taste (*De gustibus disputandum non est*) was not originally understood to refer to the inevitably private nature of judgments of taste. Nowadays, it is often interpreted to mean that since judgments of taste are everyone's private matters, there is no use in arguing about them or presenting any reasons for one's own, presumably superior taste. The lesson to be learnt was rather the opposite. Because taste was something self evident and shared by all, it was

part of “common sense” or *sensus communis*, and it was both futile and unnecessary to argue about it. On the other hand, according to the self understanding of the representatives of this moral sense theory, taste was based on a sense of feeling about the goodness or badness of objects or forms of conduct. Therefore, it was in principle impossible to formulate any general maxims of good taste. Sole reliance on one’s sense or “instinct” of good and bad, tasteful and tasteless, precluded distinction of both beauty and goodness: “sense of beauty” and “sense of right and wrong” were inseparable. Taste was essentially both an aesthetic and a moral category. Thus, decent conduct, dress, and decorum, as well as eating habits, were all indicators of an individual’s moral and aesthetic value, or good taste.

In neoclassical economics taste is an exogenous factor. Consumer preferences are taken as given and regarded simply as something which lie behind an individual’s choices. Therefore, in economics, individual tastes and the social process of their formation are neither theoretically problematized nor empirically studied.

ANTINOMY OF TASTE

This problem inherent in the common sense of taste (i.e., taste as basically both totally private and subjective, and universally valid and objective) was formulated most poignantly by Immanuel Kant in his third critique, *The Critique of Judgment*. He called it the antinomy of taste. According to Kant, in claiming that something is beautiful we only express our own feeling or subjective taste, but at the same time presume that all others will join us in this judgment. Without this latter presumption, our statements of taste would only express our subjective feelings of sensual pleasure and their general validity would be decided solely empirically by counting how many fellow citizens join us in any particular judgment of taste. In this influential tradition of thought, genuine aesthetic judgments differ from judgments of pleasure exactly because of their claim to universal validity.

Whereas the criterion of good taste gradually disappeared from the aesthetics of fine arts during the eighteenth century, it retained its role in the aesthetics of everyday life and popular

culture, in the aesthetics of “lower” arts like gastronomy or popular music, which were often understood to be closer to sensual delights. The philosophical aesthetics in the classical European humanitarian tradition of thought which culminated in Kant’s third critique has left deep traces in later sociological thinking and conceptualization of taste. One could claim that his famous antinomy of taste is repeated in two ways in later sociological thinking about taste. First, since it is obvious that people’s tastes, in fact, differed, often drastically, from each other, the question of a common or good taste became an empirical question: taste – or good taste – was understood to be either the taste of a certain group of people, representatives of a “high society,” or in a more democratic interpretation, of the great majority of people. It became in principle an empirical question to find out to what extent people shared a common taste and to what extent different tastes existed side by side in any society or culture. This tradition of research can, with good reason, be traced back to David Hume’s writings on taste. In a sense, the rich and long history of sociological studies of lifestyles and consumer choices or preferences can be understood to originate from this question: to what extent do people, as a matter of fact, share a common taste which unites them in some respects and gives coherence to their choices in various fields of consumption, from housing to clothing, from art and music to food? It is the guiding principle in most market research to search for some standards unifying certain consumer segments and various social groups at the same time as singling them out from others.

Second, taste is an important concept in sociological theories of what constitutes the relation between an individual and his or her social existence and in answering the question of what unifies the members of any social community. In the tradition of classical sociology most prominently represented by Georg Simmel, taste was something which helped to overcome the distance or opposition between an individual and the larger social totality of which she or he was supposedly a part. Through shared taste or style, people would show their affiliation to a common social group as well as preserve their individuality. In social life, as in art, it was possible to share a style, as well as retain

one's own individuality and personality, by having a taste of one's own. A painting, for instance, can be characterized as representative of the impressionistic style in art as well as a unique masterpiece painted by the French artist Monet. By the same token, a person can be recognized both as a hip hopper and an individual called John. Of equal importance was the fact that, ideally, to have a taste in common was thought to restrain an individual's own instincts and preferences less than social norms would, not to mention the legal makeup of a society. In addition, it helped to create social order by coordinating individuals' behavior. Taste united people in taste communities which, supposedly, unlike any kind of political or economic association, allowed people to express their individuality and particularity more.

TASTE AND FASHION

To Georg Simmel, the social formation of fashion was an important phenomenon of modernity. Like Baudelaire's "modern artist" at his best, it can capture the meaning of eternity in one fleeting moment. Fashion is contingent, eternally changing and fleeting. Unlike Hamlet, fashion did not have to decide "whether to be or not to be." In fashion, something could be as well as not be, at the same time. What is now in fashion becomes out of fashion the very next moment. What is even more important, fashion offers in practice, in the everyday life of ordinary people, a sociological solution to Kant's antinomy of taste. As a simultaneous process of social imitation and distinction, it is both individual and social, on the one hand, an expression of an individual's own taste – ideally choosing simply what he or she finds pleasing – on the other, socially shared taste: in fashion, I offer my own choices or judgments of taste for all others to join in and share. The community of fashion is a veritable *sensus communis* – a community of taste – which comes into being only in order to disappear the very same moment. It is just a weak community, notwithstanding effectively creating order in a rapidly changing modern social world.

One of the most pertinent tenets in the social sciences is that taste usually "trickles down"

the social ladder, as do fashionable items. New fashions and styles, just like stylish or fashionable utensils and commodities, always first appear in the higher echelons of society, only to descend, more or less gradually, to its lower groups. The consequence of this presumption is that even though the lifestyles of social classes or status groups always differ, they all have basically the same taste. Since the lower classes or status groups emulate the lifestyles of the higher ones and would prefer to live like their social superiors if only they could, they in fact share the same taste. The process of social imitation is a process motivated by the demand and will of social ascent. The dynamics of consumption in the modern world are characterized by the social aspirations of "status seekers."

Thorstein Veblen's classic study of the conspicuous consumption of what he called the leisure class interestingly emphasized the changes taking place in a modern commercial society. Whereas, earlier, men could distinguish themselves and enjoy their fellow men's esteem because of their superior work performances, in modern societies these generally become increasingly invisible to others. The result of one's labor or one's monetary resources is usually equally invisible. Therefore, "showing off" one's wealth becomes important instead. Taste in a modern society is in the final analysis guided by the aspirations to gain social esteem by explicitly showing off one's pecuniary power. Furthermore, the degree of "uselessness" and instrumental nonfunctionality adherent to an artifact or an occupation, or the amount of idle time required to spend at it competently, seems to equal the high degree of prestige and social esteem afforded its owner/practitioner. This is why, in Veblen's opinion, fine riding horses or pet dogs, just like housewives and domestic servants, among others, serve as ideal and highly visible symbols of one's social standing.

In his classic study of the Paris fashion shows, Herbert Blumer suggested another and competing interpretation of the social mechanism of fashion and of taste formation in general. According to Blumer, taste is a result of collective selection. What Blumer witnessed in the Parisian fashion shows was the process of formation of a collective or common taste. Some how the fashion designers or representatives of

fashion trade could each year select, from among a multitude of dress designs brought to the show, just a few stylistically similar ones. It looked almost as if they had reached a consensus or an agreement by actually negotiating and arguing about the merits of their own favorites whereas, in fact, they chose them largely independently of each other. What was important to Blumer was that this collective taste did not emanate from any powerful or prestigious center, but took place among peers or colleagues. Somehow, almost as if by magic, a taste shared by all crystallized out of a multitude of individual tastes and a new seasonal fashion collectively selected.

Blumer's idea has far reaching consequences for sociological reasoning because he emphasized that such dynamic social processes like taste formation do not necessarily presume any hierarchical order of superiority. The gravitational center of taste in a modern society is its social center, the middle class, and not its peak. In this respect it reminds one of Gabriel Tarde's classic work on the laws of imitation, where he claimed that in imitating social models people just imitate themselves, or others who are just like them. Consequently, taste is not a class, but a mass phenomenon. The idea of social worlds with their own aesthetics and etiquette of conduct, developed later by symbolic interactionists, makes it possible to take into account social differentiation of taste which is not hierarchic.

Fashion, without a doubt, serves economic interests and ultimately promotes the accumulation of capital by artificially aging otherwise functional products. In clothes fashion strong economic incentives are at play. But it can reasonably be argued that what goes on in the collective selection of taste is similar to a process of aesthetic judgment. The basic criterion of fashion is that it could just as well be otherwise. As far as fashion is concerned, there cannot be any objective criteria of superiority. Therefore, it does not actually matter what, exactly, is the fashion at each point in time, or, say, what will be the fashionable color of the next season or the length of the female dress this autumn. Even if manipulation of taste takes place one can always ask who manipulates the manipulators.

DISTINCTIONS OF TASTE AND SOCIAL DIFFERENCES

One of the most pertinent questions concerning the role of taste in society has been to what extent taste is an expression of an individual's preferences alone. Are the individual's choices in consumption free and conscious choices? To what extent are they socially determined and habitual? In economic market research such choices are as a rule regarded as individual preferences. Sociologists, contrariwise, emphasize choices' social origin and their socially shared nature. Pierre Bourdieu's work *Distinction: A Social Critique of the Judgment of Taste*, published in English in 1984 (French edition, 1979), has perhaps more than any other single sociological work influenced the sociological discussion of taste during the last decades. Bourdieu's work was explicitly intended as a sociological critique of Immanuel Kant's analysis of aesthetic judgment (and, with him, of the whole tradition of philosophical aesthetics). Bourdieu aimed at revealing the true social nature of good taste, which always presents itself as objectively valid and legitimate.

To Bourdieu, taste is the basic analytical concept of sociology. Distinction is a study of social distinctions of taste and their relationship, on the one hand, to social positions and, on the other hand, to different symbolic activities and lifestyles. An individual's relative social position, and, consequently, lifestyle and taste disposition, is always determined by the specific combination of the three different types of capital: economic, cultural, and social. To an extent, these three forms of capital can be transformed into each other. In Bourdieu's study, the sum total of one's capital, as well as the interplay of these three forms of capital, explain the class differences in taste dispositions and their visible expressions, different lifestyles and, finally, consumer choices.

HIERARCHY OF TASTE

If *Distinction* had only claimed that tastes and lifestyles of various social groups will vary according to the amount and type of capital in their possession, it would not differ much from
