# Solutions Manual for 

Statistical Inference, Second Edition

"When I hear you give your reasons," I remarked, "the thing always appears to me to be so ridiculously simple that I could easily do it myself, though at each successive instance of your reasoning I am baffled until you explain your process."

## Dr. Watson to Sherlock Holmes

A Scandal in Bohemia

### 0.1 Description

This solutions manual contains solutions for all odd numbered problems plus a large number of solutions for even numbered problems. Of the 624 exercises in Statistical Inference, Second Edition, this manual gives solutions for $484(78 \%)$ of them. There is an obtuse pattern as to which solutions were included in this manual. We assembled all of the solutions that we had from the first edition, and filled in so that all odd-numbered problems were done. In the passage from the first to the second edition, problems were shuffled with no attention paid to numbering (hence no attention paid to minimize the new effort), but rather we tried to put the problems in logical order.

A major change from the first edition is the use of the computer, both symbolically through Mathematica ${ }^{t m}$ and numerically using $R$. Some solutions are given as code in either of these languages. Mathematica ${ }^{t m}$ can be purchased from Wolfram Research, and $R$ is a free download from http://www.r-project.org/.

Here is a detailed listing of the solutions included.

| Chapter | Number of Exercises | Number of Solutions | Missing |
| :---: | :---: | :---: | :---: |
| 1 | 55 | 51 | $26,30,36,42$ |
| 2 | 40 | 37 | $34,38,40$ |
| 3 | 50 | 42 | $4,6,10,20,30,32,34,36$ |
| 4 | 65 | 52 | $8,14,22,28,36,40$ |
|  |  |  | $48,50,52,56,58,60,62$ |
| 5 | 69 | 46 | $2,4,12,14,26,28$ |
|  |  |  | all even problems from $36-68$ |
| 6 | 43 | 35 | $8,16,26,28,34,36,38,42$ |
| 7 | 66 | 52 | $4,14,16,28,30,32,34$, |
|  | 58 | 51 | $36,42,54,58,60,62,64$ |
| 8 | 58 | 41 | $2,8,10,46,48,52,56,58$ |
| 9 | 48 |  | $32,38,40,42,24,26,50,54,50$ |
|  | 41 | 26 | all even problems except 4 and 32 |
| 10 | 31 | 35 | $4,20,22,24,26,40$ |
| 11 |  | 16 | all even problems |
| 12 |  |  |  |

### 0.2 Acknowledgement

Many people contributed to the assembly of this solutions manual. We again thank all of those who contributed solutions to the first edition - many problems have carried over into the second edition. Moreover, throughout the years a number of people have been in constant touch with us, contributing to both the presentations and solutions. We apologize in advance for those we forget to mention, and we especially thank Jay Beder, Yong Sung Joo, Michael Perlman, Rob Strawderman, and Tom Wehrly. Thank you all for your help.

And, as we said the first time around, although we have benefited greatly from the assistance and
comments of others in the assembly of this manual, we are responsible for its ultimate correctness. To this end, we have tried our best but, as a wise man once said, "You pays your money and you takes your chances."

## Chapter 1

## Probability Theory

"If any little problem comes your way, I shall be happy, if I can, to give you a hint or two as to its solution."

Sherlock Holmes
The Adventure of the Three Students
1.1 a. Each sample point describes the result of the toss (H or T ) for each of the four tosses. So, for example THTT denotes T on 1 st, H on $2 \mathrm{nd}, \mathrm{T}$ on 3 rd and T on 4 th. There are $2^{4}=16$ such sample points.
b. The number of damaged leaves is a nonnegative integer. So we might use $S=\{0,1,2, \ldots\}$.
c. We might observe fractions of an hour. So we might use $S=\{t: t \geq 0\}$, that is, the half infinite interval $[0, \infty)$.
d. Suppose we weigh the rats in ounces. The weight must be greater than zero so we might use $S=(0, \infty)$. If we know no 10 -day-old rat weighs more than 100 oz., we could use $S=(0,100]$.
e. If $n$ is the number of items in the shipment, then $S=\{0 / n, 1 / n, \ldots, 1\}$.
1.2 For each of these equalities, you must show containment in both directions.
a. $x \in A \backslash B \Leftrightarrow x \in A$ and $x \notin B \Leftrightarrow x \in A$ and $x \notin A \cap B \Leftrightarrow x \in A \backslash(A \cap B)$. Also, $x \in A$ and $x \notin B \Leftrightarrow x \in A$ and $x \in B^{c} \Leftrightarrow x \in A \cap B^{c}$.
b. Suppose $x \in B$. Then either $x \in A$ or $x \in A^{c}$. If $x \in A$, then $x \in B \cap A$, and, hence $x \in(B \cap A) \cup\left(B \cap A^{c}\right)$. Thus $B \subset(B \cap A) \cup\left(B \cap A^{c}\right)$. Now suppose $x \in(B \cap A) \cup\left(B \cap A^{c}\right)$. Then either $x \in(B \cap A)$ or $x \in\left(B \cap A^{c}\right)$. If $x \in(B \cap A)$, then $x \in B$. If $x \in\left(B \cap A^{c}\right)$, then $x \in B$. Thus $(B \cap A) \cup\left(B \cap A^{c}\right) \subset B$. Since the containment goes both ways, we have $B=(B \cap A) \cup\left(B \cap A^{c}\right)$. (Note, a more straightforward argument for this part simply uses the Distributive Law to state that $\left.(B \cap A) \cup\left(B \cap A^{c}\right)=B \cap\left(A \cup A^{c}\right)=B \cap S=B.\right)$
c. Similar to part a).
d. From part b).
$A \cup B=A \cup\left[(B \cap A) \cup\left(B \cap A^{c}\right)\right]=A \cup(B \cap A) \cup A \cup\left(B \cap A^{c}\right)=A \cup\left[A \cup\left(B \cap A^{c}\right)\right]=$ $A \cup\left(B \cap A^{c}\right)$.
1.3 a. $x \in A \cup B \Leftrightarrow x \in A$ or $x \in B \Leftrightarrow x \in B \cup A$
$x \in A \cap B \Leftrightarrow x \in A$ and $x \in B \Leftrightarrow x \in B \cap A$.
b. $x \in A \cup(B \cup C) \Leftrightarrow x \in A$ or $x \in B \cup C \Leftrightarrow x \in A \cup B$ or $x \in C \Leftrightarrow x \in(A \cup B) \cup C$.
(It can similarly be shown that $A \cup(B \cup C)=(A \cup C) \cup B$.)
$x \in A \cap(B \cap C) \Leftrightarrow x \in A$ and $x \in B$ and $x \in C \Leftrightarrow x \in(A \cap B) \cap C$.
c. $x \in(A \cup B)^{c} \Leftrightarrow x \notin A$ or $x \notin B \Leftrightarrow x \in A^{c}$ and $x \in B^{c} \Leftrightarrow x \in A^{c} \cap B^{c}$ $x \in(A \cap B)^{c} \Leftrightarrow x \notin A \cap B \Leftrightarrow x \notin A$ and $x \notin B \Leftrightarrow x \in A^{c}$ or $x \in B^{c} \Leftrightarrow x \in A^{c} \cup B^{c}$.
1.4 a. " $A$ or $B$ or both" is $A \cup B$. From Theorem 1.2.9b we have $P(A \cup B)=P(A)+P(B)-P(A \cap B)$.
b. " $A$ or $B$ but not both" is $\left(A \cap B^{c}\right) \cup\left(B \cap A^{c}\right)$. Thus we have

$$
\begin{array}{rlr}
P\left(\left(A \cap B^{c}\right) \cup\left(B \cap A^{c}\right)\right) & =P\left(A \cap B^{c}\right)+P\left(B \cap A^{c}\right) & \text { (disjoint union) } \\
& =[P(A)-P(A \cap B)]+[P(B)-P(A \cap B)] \quad \text { (Theorem1.2.9a) } \\
& =P(A)+P(B)-2 P(A \cap B) . & \tag{Theorem1.2.9a}
\end{array}
$$

c. "At least one of $A$ or $B$ " is $A \cup B$. So we get the same answer as in a).
d. "At most one of $A$ or $B$ " is $(A \cap B)^{c}$, and $P\left((A \cap B)^{c}\right)=1-P(A \cap B)$.
1.5 a. $A \cap B \cap C=\{$ a U.S. birth results in identical twins that are female $\}$
b. $P(A \cap B \cap C)=\frac{1}{90} \times \frac{1}{3} \times \frac{1}{2}$
1.6

$$
\begin{gathered}
p_{0}=(1-u)(1-w), \quad p_{1}=u(1-w)+w(1-u), \quad p_{2}=u w \\
p_{0}=p_{2} \quad \Rightarrow \quad u+w=1 \\
p_{1}=p_{2} \quad \Rightarrow \quad u w=1 / 3
\end{gathered}
$$

These two equations imply $u(1-u)=1 / 3$, which has no solution in the real numbers. Thus, the probability assignment is not legitimate.
1.7 a.

$$
P(\text { scoring } i \text { points })= \begin{cases}1-\frac{\pi r^{2}}{A} & \text { if } i=0 \\ \frac{\pi r^{2}}{A}\left[\frac{(6-i)^{2}-(5-i)^{2}}{5^{2}}\right] & \text { if } i=1, \ldots, 5\end{cases}
$$

b.

$$
\begin{aligned}
P(\text { scoring } i \text { points } \mid \text { board is hit }) & =\frac{P(\text { scoring } i \text { points } \cap \text { board is hit })}{P(\text { board is hit })} \\
P(\text { board is hit }) & =\frac{\pi r^{2}}{A} \\
P(\text { scoring } i \text { points } \cap \text { board is hit }) & =\frac{\pi r^{2}}{A}\left[\frac{(6-i)^{2}-(5-i)^{2}}{5^{2}}\right] \quad i=1, \ldots, 5 .
\end{aligned}
$$

Therefore,

$$
P(\text { scoring } i \text { points } \mid \text { board is hit })=\frac{(6-i)^{2}-(5-i)^{2}}{5^{2}} \quad i=1, \ldots, 5
$$

which is exactly the probability distribution of Example 1.2.7.
1.8 a. $P$ (scoring exactly $i$ points $)=P($ inside circle $i)-P($ inside circle $i+1)$. Circle $i$ has radius $(6-i) r / 5$, so

$$
P(s \text { scoring exactly } i \text { points })=\frac{\pi(6-i)^{2} r^{2}}{5^{2} \pi r^{2}}-\frac{\pi((6-(i+1)))^{2} r^{2}}{5^{2} \pi r^{2}}=\frac{(6-i)^{2}-(5-i)^{2}}{5^{2}} .
$$

b. Expanding the squares in part a) we find $P$ (scoring exactly $i$ points) $=\frac{11-2 i}{25}$, which is decreasing in $i$.
c. Let $P(i)=\frac{11-2 i}{25}$. Since $i \leq 5, P(i) \geq 0$ for all $i$. $P(S)=P$ (hitting the dartboard) $=1$ by definition. Lastly, $P(i \cup j)=$ area of $i$ ring + area of $j$ ring $=P(i)+P(j)$.
1.9 a. Suppose $x \in\left(\cup_{\alpha} A_{\alpha}\right)^{c}$, by the definition of complement $x \notin \cup_{\alpha} A_{\alpha}$, that is $x \notin A_{\alpha}$ for all $\alpha \in \Gamma$. Therefore $x \in A_{\alpha}^{c}$ for all $\alpha \in \Gamma$. Thus $x \in \cap_{\alpha} A_{\alpha}^{c}$ and, by the definition of intersection $x \in A_{\alpha}^{c}$ for all $\alpha \in \Gamma$. By the definition of complement $x \notin A_{\alpha}$ for all $\alpha \in \Gamma$. Therefore $x \notin \cup_{\alpha} A_{\alpha}$. Thus $x \in\left(\cup_{\alpha} A_{\alpha}\right)^{c}$.
b. Suppose $x \in\left(\cap_{\alpha} A_{\alpha}\right)^{c}$, by the definition of complement $x \notin\left(\cap_{\alpha} A_{\alpha}\right)$. Therefore $x \notin A_{\alpha}$ for some $\alpha \in \Gamma$. Therefore $x \in A_{\alpha}^{c}$ for some $\alpha \in \Gamma$. Thus $x \in \cup_{\alpha} A_{\alpha}^{c}$ and, by the definition of union, $x \in A_{\alpha}^{c}$ for some $\alpha \in \Gamma$. Therefore $x \notin A_{\alpha}$ for some $\alpha \in \Gamma$. Therefore $x \notin \cap_{\alpha} A_{\alpha}$. Thus $x \in\left(\cap_{\alpha} A_{\alpha}\right)^{c}$.
1.10 For $A_{1}, \ldots, A_{n}$

$$
\text { (i) } \quad\left(\bigcup_{i=1}^{n} A_{i}\right)^{c}=\bigcap_{i=1}^{n} A_{i}^{c} \quad \text { (ii) }\left(\bigcap_{i=1}^{n} A_{i}\right)^{c}=\bigcup_{i=1}^{n} A_{i}^{c}
$$

Proof of $(i)$ : If $x \in\left(\cup A_{i}\right)^{c}$, then $x \notin \cup A_{i}$. That implies $x \notin A_{i}$ for any $i$, so $x \in A_{i}^{c}$ for every $i$ and $x \in \cap A_{i}$.
Proof of (ii): If $x \in\left(\cap A_{i}\right)^{c}$, then $x \notin \cap A_{i}$. That implies $x \in A_{i}^{c}$ for some $i$, so $x \in \cup A_{i}^{c}$.
1.11 We must verify each of the three properties in Definition 1.2.1.
a. (1) The empty set $\emptyset \in\{\emptyset, S\}$. Thus $\emptyset \in \mathcal{B}$. (2) $\emptyset^{c}=S \in \mathcal{B}$ and $S^{c}=\emptyset \in \mathcal{B}$. (3) $\emptyset \cup S=S \in \mathcal{B}$.
b. (1) The empty set $\emptyset$ is a subset of any set, in particular, $\emptyset \subset S$. Thus $\emptyset \in \mathcal{B}$. (2) If $A \in \mathcal{B}$, then $A \subset S$. By the definition of complementation, $A^{c}$ is also a subset of $S$, and, hence, $A^{c} \in \mathcal{B}$. (3) If $A_{1}, A_{2}, \ldots \in \mathcal{B}$, then, for each $i, A_{i} \subset S$. By the definition of union, $\cup A_{i} \subset S$. Hence, $\cup A_{i} \in \mathcal{B}$.
c. Let $\mathcal{B}_{1}$ and $\mathcal{B}_{2}$ be the two sigma algebras. (1) $\emptyset \in \mathcal{B}_{1}$ and $\emptyset \in \mathcal{B}_{2}$ since $\mathcal{B}_{1}$ and $\mathcal{B}_{2}$ are sigma algebras. Thus $\emptyset \in \mathcal{B}_{1} \cap \mathcal{B}_{2}$. (2) If $A \in \mathcal{B}_{1} \cap \mathcal{B}_{2}$, then $A \in \mathcal{B}_{1}$ and $A \in \mathcal{B}_{2}$. Since $\mathcal{B}_{1}$ and $\mathcal{B}_{2}$ are both sigma algebra $A^{c} \in \mathcal{B}_{1}$ and $A^{c} \in \mathcal{B}_{2}$. Therefore $A^{c} \in \mathcal{B}_{1} \cap \mathcal{B}_{2}$. (3) If $A_{1}, A_{2}, \ldots \in \mathcal{B}_{1} \cap \mathcal{B}_{2}$, then $A_{1}, A_{2}, \ldots \in \mathcal{B}_{1}$ and $A_{1}, A_{2}, \ldots \in \mathcal{B}_{2}$. Therefore, since $\mathcal{B}_{1}$ and $\mathcal{B}_{2}$ are both sigma algebra, $\cup_{i=1}^{\infty} A_{i} \in \mathcal{B}_{1}$ and $\cup_{i=1}^{\infty} A_{i} \in \mathcal{B}_{2}$. Thus $\cup_{i=1}^{\infty} A_{i} \in \mathcal{B}_{1} \cap \mathcal{B}_{2}$.
1.12 First write

$$
\begin{aligned}
P\left(\bigcup_{i=1}^{\infty} A_{i}\right) & =P\left(\bigcup_{i=1}^{n} A_{i} \cup \bigcup_{i=n+1}^{\infty} A_{i}\right) \\
& =P\left(\bigcup_{i=1}^{n} A_{i}\right)+P\left(\bigcup_{i=n+1}^{\infty} A_{i}\right) \quad\left(A_{i} \mathrm{~s}\right. \text { are disjoint) } \\
& =\sum_{i=1}^{n} P\left(A_{i}\right)+P\left(\bigcup_{i=n+1}^{\infty} A_{i}\right) \quad \text { (finite additivity) }
\end{aligned}
$$

Now define $B_{k}=\bigcup_{i=k}^{\infty} A_{i}$. Note that $B_{k+1} \subset B_{k}$ and $B_{k} \rightarrow \phi$ as $k \rightarrow \infty$. (Otherwise the sum of the probabilities would be infinite.) Thus

$$
P\left(\bigcup_{i=1}^{\infty} A_{i}\right)=\lim _{n \rightarrow \infty} P\left(\bigcup_{i=1}^{\infty} A_{i}\right)=\lim _{n \rightarrow \infty}\left[\sum_{i=1}^{n} P\left(A_{i}\right)+P\left(B_{n+1}\right)\right]=\sum_{i=1}^{\infty} P\left(A_{i}\right)
$$

1.13 If $A$ and $B$ are disjoint, $P(A \cup B)=P(A)+P(B)=\frac{1}{3}+\frac{3}{4}=\frac{13}{12}$, which is impossible. More generally, if $A$ and $B$ are disjoint, then $A \subset B^{c}$ and $P(A) \leq P\left(B^{c}\right)$. But here $P(A)>P\left(B^{c}\right)$, so $A$ and $B$ cannot be disjoint.
1.14 If $S=\left\{s_{1}, \ldots, s_{n}\right\}$, then any subset of $S$ can be constructed by either including or excluding $s_{i}$, for each $i$. Thus there are $2^{n}$ possible choices.
1.15 Proof by induction. The proof for $k=2$ is given after Theorem 1.2.14. Assume true for $k$, that is, the entire job can be done in $n_{1} \times n_{2} \times \cdots \times n_{k}$ ways. For $k+1$, the $k+1$ th task can be done in $n_{k+1}$ ways, and for each one of these ways we can complete the job by performing
the remaining $k$ tasks. Thus for each of the $n_{k+1}$ we have $n_{1} \times n_{2} \times \cdots \times n_{k}$ ways of completing the job by the induction hypothesis. Thus, the number of ways we can do the job is $\underbrace{\left(1 \times\left(n_{1} \times n_{2} \times \cdots \times n_{k}\right)\right)+\cdots+\left(1 \times\left(n_{1} \times n_{2} \times \cdots \times n_{k}\right)\right)}_{n_{k+1} \text { terms }}=n_{1} \times n_{2} \times \cdots \times n_{k} \times n_{k+1}$.
1.16 a) $26^{3}$. b) $26^{3}+26^{2}$. c) $26^{4}+26^{3}+26^{2}$.
1.17 There are $\binom{n}{2}=n(n-1) / 2$ pieces on which the two numbers do not match. (Choose 2 out of $n$ numbers without replacement.) There are $n$ pieces on which the two numbers match. So the total number of different pieces is $n+n(n-1) / 2=n(n+1) / 2$.
1.18 The probability is $\frac{\binom{n}{2} n!}{n^{n}}=\frac{(n-1)(n-1)!}{2 n^{n-2}}$. There are many ways to obtain this. Here is one. The denominator is $n^{n}$ because this is the number of ways to place $n$ balls in $n$ cells. The numerator is the number of ways of placing the balls such that exactly one cell is empty. There are $n$ ways to specify the empty cell. There are $n-1$ ways of choosing the cell with two balls. There are $\binom{n}{2}$ ways of picking the 2 balls to go into this cell. And there are $(n-2)$ ! ways of placing the remaining $n-2$ balls into the $n-2$ cells, one ball in each cell. The product of these is the numerator $n(n-1)\binom{n}{2}(n-2)!=\binom{n}{2} n!$.
1.19 a. $\binom{6}{4}=15$.
b. Think of the $n$ variables as $n$ bins. Differentiating with respect to one of the variables is equivalent to putting a ball in the bin. Thus there are $r$ unlabeled balls to be placed in $n$ unlabeled bins, and there are $\binom{n+r-1}{r}$ ways to do this.
1.20 A sample point specifies on which day ( 1 through 7 ) each of the 12 calls happens. Thus there are $7^{12}$ equally likely sample points. There are several different ways that the calls might be assigned so that there is at least one call each day. There might be 6 calls one day and 1 call each of the other days. Denote this by 6111111 . The number of sample points with this pattern is $7\binom{12}{6} 6$ !. There are 7 ways to specify the day with 6 calls. There are $\binom{12}{6}$ to specify which of the 12 calls are on this day. And there are 6 ! ways of assigning the remaining 6 calls to the remaining 6 days. We will now count another pattern. There might be 4 calls on one day, 2 calls on each of two days, and 1 call on each of the remaining four days. Denote this by 4221111. The number of sample points with this pattern is $7\binom{12}{4}\binom{6}{2}\binom{8}{2}\binom{6}{2} 4$ !. ( 7 ways to pick day with 4 calls, $\binom{12}{4}$ to pick the calls for that day, $\binom{6}{2}$ to pick two days with two calls, $\binom{8}{2}$ ways to pick two calls for lowered numbered day, $\binom{6}{2}$ ways to pick the two calls for higher numbered day, 4 ! ways to order remaining 4 calls.) Here is a list of all the possibilities and the counts of the sample points for each one.

| 6111111 | $7\left({ }^{12}\right) 6!=$ | 4,656,960 |
| :---: | :---: | :---: |
| 5211111 | $7\left({ }^{12}\right) 6\binom{7}{2} 5!=$ | 83,825,280 |
| 4221111 | $7\binom{5}{4}\binom{6}{2}\binom{8}{2}\binom{6}{2} 4!=$ | 523,908,000 |
| 4311111 | $7\binom{12}{4} 6\binom{8}{3} 5!=$ | 139,708,800 |
| 3321111 | $\binom{7}{2}\binom{12}{3}\binom{9}{3} 5\binom{6}{2} 4!=$ | 698,544,000 |
| 3222111 | $7\binom{12}{3}\binom{6}{3}\binom{9}{3}\binom{7}{2}\binom{5}{2} 3!=$ | 1,397,088,000 |
| 2222211 | $\binom{7}{5}\binom{12}{2}\binom{10}{2}\binom{8}{2}\binom{6}{2}\binom{4}{2} 2!=$ | 314,344,800 |

The probability is the total number of sample points divided by $7^{12}$, which is $\frac{3,162,075,840}{7^{12}} \approx$ .2285 .
1.21 The probability is $\frac{\binom{n}{2 r} 2^{2 r}}{\binom{2 n}{2 r}}$. There are $\binom{2 n}{2 r}$ ways of choosing $2 r$ shoes from a total of $2 n$ shoes. Thus there are $\binom{2 n}{2 r}$ equally likely sample points. The numerator is the number of sample points for which there will be no matching pair. There are $\binom{n}{2 r}$ ways of choosing $2 r$ different shoes
styles. There are two ways of choosing within a given shoe style (left shoe or right shoe), which gives $2^{2 r}$ ways of arranging each one of the $\binom{n}{2 r}$ arrays. The product of this is the numerator $\binom{n}{2 r} 2^{2 r}$.
1.22
a) $\frac{\binom{31}{15}\binom{29}{15}\binom{31}{15}\binom{30}{15} \cdots\binom{31}{15}}{\binom{380}{180}}$
b) $\frac{\frac{336335}{366} \ldots 316}{\binom{366}{30}}$.
1.23

$$
\begin{aligned}
P(\text { same number of heads }) & =\sum_{x=0}^{n} P\left(1^{s t} \operatorname{tosses} x, 2^{n d} \operatorname{tosses} x\right) \\
& =\sum_{x=0}^{n}\left[\binom{n}{x}\left(\frac{1}{2}\right)^{x}\left(\frac{1}{2}\right)^{n-x}\right]^{2}=\left(\frac{1}{4}\right)^{n} \sum_{x=0}^{n}\binom{n}{x}^{2}
\end{aligned}
$$

1.24 a.

$$
\begin{aligned}
P(A \text { wins }) & =\sum_{i=1}^{\infty} P\left(A \text { wins on } i^{t h} \text { toss }\right) \\
& =\frac{1}{2}+\left(\frac{1}{2}\right)^{2} \frac{1}{2}+\left(\frac{1}{2}\right)^{4}\left(\frac{1}{2}\right)+\cdots=\sum_{i=0}^{\infty}\left(\frac{1}{2}\right)^{2 i+1}=2 / 3
\end{aligned}
$$

b. $P(A$ wins $)=p+(1-p)^{2} p+(1-p)^{4} p+\cdots=\sum_{i=0}^{\infty} p(1-p)^{2 i}=\frac{p}{1-(1-p)^{2}}$.
c. $\frac{d}{d p}\left(\frac{p}{1-(1-p)^{2}}\right)=\frac{p^{2}}{\left[1-(1-p)^{2}\right]^{2}}>0$. Thus the probability is increasing in $p$, and the minimum is at zero. Using L'Hôpital's rule we find $\lim _{p \rightarrow 0} \frac{p}{1-(1-p)^{2}}=1 / 2$.
1.25 Enumerating the sample space gives $S^{\prime}=\{(B, B),(B, G),(G, B),(G, G)\}$, with each outcome equally likely. Thus $P$ (at least one boy $)=3 / 4$ and $P($ both are boys $)=1 / 4$, therefore

$$
P(\text { both are boys } \mid \text { at least one boy })=1 / 3
$$

An ambiguity may arise if order is not acknowledged, the space is $S^{\prime}=\{(B, B),(B, G),(G, G)\}$, with each outcome equally likely.
1.27 a. For $n$ odd the proof is straightforward. There are an even number of terms in the sum $(0,1, \cdots, n)$, and $\binom{n}{k}$ and $\binom{n}{n-k}$, which are equal, have opposite signs. Thus, all pairs cancel and the sum is zero. If $n$ is even, use the following identity, which is the basis of Pascal's triangle: For $k>0,\binom{n}{k}=\binom{n-1}{k}+\binom{n-1}{k-1}$. Then, for $n$ even

$$
\begin{aligned}
\sum_{k=0}^{n}(-1)^{k}\binom{n}{k} & =\binom{n}{0}+\sum_{k=1}^{n-1}(-1)^{k}\binom{n}{k}+\binom{n}{n} \\
& =\binom{n}{0}+\binom{n}{n}+\sum_{k=1}^{n-1}(-1)^{k}\left[\binom{n-1}{k}+\binom{n-1}{k-1}\right] \\
& =\binom{n}{0}+\binom{n}{n}-\binom{n-1}{0}-\binom{n-1}{n-1}=0
\end{aligned}
$$

b. Use the fact that for $k>0, k\binom{n}{k}=n\binom{n-1}{k-1}$ to write

$$
\sum_{k=1}^{n} k\binom{n}{k}=n \sum_{k=1}^{n}\binom{n-1}{k-1}=n \sum_{j=0}^{n-1}\binom{n-1}{j}=n 2^{n-1}
$$

c. $\sum_{k=1}^{n}(-1)^{k+1} k\binom{n}{k}=\sum_{k=1}^{n}(-1)^{k+1}\binom{n-1}{k-1}=n \sum_{j=0}^{n-1}(-1)^{j}\binom{n-1}{j}=0$ from part a).
1.28 The average of the two integrals is

$$
\begin{aligned}
{[(n \log n-n)+((n+1) \log (n+1)-n)] / 2 } & =[n \log n+(n+1) \log (n+1)] / 2-n \\
& \approx(n+1 / 2) \log n-n .
\end{aligned}
$$

Let $d_{n}=\log n!-[(n+1 / 2) \log n-n]$, and we want to show that $\lim _{n \rightarrow \infty} m d_{n}=c$, a constant. This would complete the problem, since the desired limit is the exponential of this one. This is accomplished in an indirect way, by working with differences, which avoids dealing with the factorial. Note that

$$
d_{n}-d_{n+1}=\left(n+\frac{1}{2}\right) \log \left(1+\frac{1}{n}\right)-1
$$

Differentiation will show that $\left(\left(n+\frac{1}{2}\right)\right) \log \left(\left(1+\frac{1}{n}\right)\right)$ is increasing in $n$, and has minimum value $(3 / 2) \log 2=1.04$ at $n=1$. Thus $d_{n}-d_{n+1}>0$. Next recall the Taylor expansion of $\log (1+x)=x-x^{2} / 2+x^{3} / 3-x^{4} / 4+\cdots$. The first three terms provide an upper bound on $\log (1+x)$, as the remaining adjacent pairs are negative. Hence

$$
0<d_{n} d_{n+1}<\left(n+\frac{1}{2}\right)\left(\frac{1}{n} \frac{1}{2 n^{2}}+\frac{1}{3 n^{3}}\right)-1=\frac{1}{12 n^{2}}+\frac{1}{6 n^{3}} .
$$

It therefore follows, by the comparison test, that the series $\sum_{1}^{\infty} d_{n}-d_{n+1}$ converges. Moreover, the partial sums must approach a limit. Hence, since the sum telescopes,

$$
\lim _{N \rightarrow \infty} \sum_{1}^{N} d_{n}-d_{n+1}=\lim _{N \rightarrow \infty} d_{1}-d_{N+1}=c
$$

Thus $\lim _{n \rightarrow \infty} d_{n}=d_{1}-c$, a constant.

|  | Unordered | Ordered |
| :--- | :--- | :--- |
|  | ano | $\{4,4,12,12\}$ |
|  |  | $(4,4,12,12),(4,12,12,4),(4,12,4,12)$ |
|  | $(12,4,12,4),(12,4,4,12),(12,12,4,4)$ |  |

Unordered Ordered
$(2,9,9,12),(2,9,12,9),(2,12,9,9),(9,2,9,12)$
$\{2,9,9,12\} \quad(9,2,12,9),(9,9,2,12),(9,9,12,2),(9,12,2,9)$

$$
(9,12,9,2),(12,2,9,9),(12,9,2,9),(12,9,9,2)
$$

b. Same as (a).
c. There are $6^{6}$ ordered samples with replacement from $\{1,2,7,8,14,20\}$. The number of ordered samples that would result in $\{2,7,7,8,14,14\}$ is $\frac{6!}{2!2!1!1!}=180$ (See Example 1.2.20). Thus the probability is $\frac{180}{6^{6}}$.
d. If the $k$ objects were distinguishable then there would be $k$ ! possible ordered arrangements. Since we have $k_{1}, \ldots, k_{m}$ different groups of indistinguishable objects, once the positions of the objects are fixed in the ordered arrangement permutations within objects of the same group won't change the ordered arrangement. There are $k_{1}!k_{2}!\cdots k_{m}$ ! of such permutations for each ordered component. Thus there would be $\frac{k!}{k_{1}!k_{2}!\cdots k_{m}!}$ different ordered components.
e. Think of the $m$ distinct numbers as $m$ bins. Selecting a sample of size $k$, with replacement, is the same as putting $k$ balls in the $m$ bins. This is $\binom{k+m-1}{k}$, which is the number of distinct bootstrap samples. Note that, to create all of the bootstrap samples, we do not need to know what the original sample was. We only need to know the sample size and the distinct values.
1.31 a. The number of ordered samples drawn with replacement from the set $\left\{x_{1}, \ldots, x_{n}\right\}$ is $n^{n}$. The number of ordered samples that make up the unordered sample $\left\{x_{1}, \ldots, x_{n}\right\}$ is $n!$. Therefore the outcome with average $\frac{x_{1}+x_{2}+\cdots+x_{n}}{n}$ that is obtained by the unordered sample $\left\{x_{1}, \ldots, x_{n}\right\}$
has probability $\frac{n!}{n^{n}}$. Any other unordered outcome from $\left\{x_{1}, \ldots, x_{n}\right\}$, distinct from the unordered sample $\left\{x_{1}, \ldots, x_{n}\right\}$, will contain $m$ different numbers repeated $k_{1}, \ldots, k_{m}$ times where $k_{1}+k_{2}+\cdots+k_{m}=n$ with at least one of the $k_{i}$ 's satisfying $2 \leq k_{i} \leq n$. The probability of obtaining the corresponding average of such outcome is

$$
\frac{n!}{k_{1}!k_{2}!\cdots k_{m}!n^{n}}<\frac{n!}{n^{n}}, \text { since } k_{1}!k_{2}!\cdots k_{m}!>1
$$

Therefore the outcome with average $\frac{x_{1}+x_{2}+\cdots+x_{n}}{n}$ is the most likely.
b. Stirling's approximation is that, as $n \rightarrow \infty, n!\approx \sqrt{2 \pi} n^{n+(1 / 2)} e^{-n}$, and thus

$$
\left(\frac{n!}{n^{n}}\right) /\left(\frac{\sqrt{2 n \pi}}{e^{n}}\right)=\frac{n!e^{n}}{n^{n} \sqrt{2 n \pi}}=\frac{\sqrt{2 \pi} n^{n+(1 / 2)} e^{-n} e^{n}}{n^{n} \sqrt{2 n \pi}}=1 .
$$

c. Since we are drawing with replacement from the set $\left\{x_{1}, \ldots, x_{n}\right\}$, the probability of choosing any $x_{i}$ is $\frac{1}{n}$. Therefore the probability of obtaining an ordered sample of size $n$ without $x_{i}$ is $\left(1-\frac{1}{n}\right)^{n}$. To prove that $\lim _{n \rightarrow \infty}\left(1-\frac{1}{n}\right)^{n}=e^{-1}$, calculate the limit of the log. That is

$$
\lim _{n \rightarrow \infty} n \log \left(1-\frac{1}{n}\right)=\lim _{n \rightarrow \infty} \frac{\log \left(1-\frac{1}{n}\right)}{1 / n}
$$

L'Hôpital's rule shows that the limit is -1 , establishing the result. See also Lemma 2.3.14.
1.32 This is most easily seen by doing each possibility. Let $P(i)=$ probability that the candidate hired on the $i$ th trial is best. Then

$$
P(1)=\frac{1}{N}, \quad P(2)=\frac{1}{N-1}, \quad \cdots \quad, P(i)=\frac{1}{N-i+1}, \quad \cdots \quad, P(N)=1 .
$$

1.33 Using Bayes rule

$$
P(M \mid C B)=\frac{P(C B \mid M) P(M)}{P(C B \mid M) P(M)+P(C B \mid F) P(F)}=\frac{.05 \times \frac{1}{2}}{.05 \times \frac{1}{2}+.0025 \times \frac{1}{2}}=.9524 .
$$

1.34 a.

$$
\begin{aligned}
& P(\text { Brown Hair }) \\
& \quad=P(\text { Brown Hair } \mid \text { Litter 1) } P(\text { Litter } 1)+P(\text { Brown Hair } \mid \text { Litter } 2) P(\text { Litter 2) } \\
& \quad=\left(\frac{2}{3}\right)\left(\frac{1}{2}\right)+\left(\frac{3}{5}\right)\left(\frac{1}{2}\right)=\frac{19}{30} .
\end{aligned}
$$

b. Use Bayes Theorem

$$
P(\text { Litter } 1 \mid \text { Brown Hair })=\frac{P(B H \mid L 1) P(L 1)}{P(B H \mid L 1) P(L 1)+P(B H \mid L 2) P(L 2}=\frac{\left(\frac{2}{3}\right)\left(\frac{1}{2}\right)}{\frac{19}{30}}=\frac{10}{19} .
$$

1.35 Clearly $P(\cdot \mid B) \geq 0$, and $P(S \mid B)=1$. If $A_{1}, A_{2}, \ldots$ are disjoint, then

$$
\begin{aligned}
P\left(\bigcup_{i=1}^{\infty} A_{i} \mid B\right) & =\frac{P\left(\bigcup_{i=1}^{\infty} A_{i} \cap B\right)}{P(B)}=\frac{P\left(\bigcup_{i=1}^{\infty}\left(A_{i} \cap B\right)\right)}{P(B)} \\
& =\frac{\sum_{i=1}^{\infty} P\left(A_{i} \cap B\right)}{P(B)}=\sum_{i=1}^{\infty} P\left(A_{i} \mid B\right) .
\end{aligned}
$$

1.37 a. Using the same events $\mathrm{A}, \mathrm{B}, \mathrm{C}$ and $\mathcal{W}$ as in Example 1.3.4, we have

$$
\begin{aligned}
P(\mathcal{W}) & =P(\mathcal{W} \mid A) P(A)+P(\mathcal{W} \mid B) P(B)+P(\mathcal{W} \mid C) P(C) \\
& =\gamma\left(\frac{1}{3}\right)+0\left(\frac{1}{3}\right)+1\left(\frac{1}{3}\right)=\frac{\gamma+1}{3} .
\end{aligned}
$$

Thus, $P(A \mid \mathcal{W})=\frac{P(A \cap \mathcal{W})}{P(\mathcal{W})}=\frac{\gamma / 3}{(\gamma+1) / 3}=\frac{\gamma}{\gamma+1}$ where,

$$
\begin{cases}\frac{\gamma}{\gamma+1}=\frac{1}{3} & \text { if } \gamma=\frac{1}{2} \\ \frac{\gamma}{\gamma+1}<\frac{1}{3} & \text { if } \gamma<\frac{1}{2} \\ \frac{\gamma}{\gamma+1}>\frac{1}{3} & \text { if } \gamma>\frac{1}{2} .\end{cases}
$$

b. By Exercise $1.35, P(\cdot \mid \mathcal{W})$ is a probability function. $A, B$ and $C$ are a partition. So

$$
P(A \mid \mathcal{W})+P(B \mid \mathcal{W})+P(C \mid \mathcal{W})=1
$$

But, $P(B \mid \mathcal{W})=0$. Thus, $P(A \mid \mathcal{W})+P(C \mid \mathcal{W})=1$. Since $P(A \mid \mathcal{W})=1 / 3, P(C \mid \mathcal{W})=2 / 3$. (This could be calculated directly, as in Example 1.3.4.) So if $A$ can swap fates with $C$, his chance of survival becomes $2 / 3$.
1.38 a. $P(A)=P(A \cap B)+P\left(A \cap B^{c}\right)$ from Theorem 1.2.11a. But $\left(A \cap B^{c}\right) \subset B^{c}$ and $P\left(B^{c}\right)=$ $1-P(B)=0$. So $P\left(A \cap B^{c}\right)=0$, and $P(A)=P(A \cap B)$. Thus,

$$
P(A \mid B)=\frac{P(A \cap B)}{P(B)}=\frac{P(A)}{1}=P(A)
$$

b. $A \subset B$ implies $A \cap B=A$. Thus,

$$
P(B \mid A)=\frac{P(A \cap B)}{P(A)}=\frac{P(A)}{P(A)}=1
$$

And also,

$$
P(A \mid B)=\frac{P(A \cap B)}{P(B)}=\frac{P(A)}{P(B)}
$$

c. If $A$ and $B$ are mutually exclusive, then $P(A \cup B)=P(A)+P(B)$ and $A \cap(A \cup B)=A$. Thus,

$$
P(A \mid A \cup B)=\frac{P(A \cap(A \cup B))}{P(A \cup B)}=\frac{P(A)}{P(A)+P(B)}
$$

d. $P(A \cap B \cap C)=P(A \cap(B \cap C))=P(A \mid B \cap C) P(B \cap C)=P(A \mid B \cap C) P(B \mid C) P(C)$.
1.39 a. Suppose $A$ and $B$ are mutually exclusive. Then $A \cap B=\emptyset$ and $P(A \cap B)=0$. If $A$ and $B$ are independent, then $0=P(A \cap B)=P(A) P(B)$. But this cannot be since $P(A)>0$ and $P(B)>0$. Thus $A$ and $B$ cannot be independent.
b. If $A$ and $B$ are independent and both have positive probability, then

$$
0<P(A) P(B)=P(A \cap B)
$$

This implies $A \cap B \neq \emptyset$, that is, $A$ and $B$ are not mutually exclusive.
1.40 a. $P\left(A^{c} \cap B\right)=P\left(A^{c} \mid B\right) P(B)=[1-P(A \mid B)] P(B)=[1-P(A)] P(B)=P\left(A^{c}\right) P(B)$, where the third equality follows from the independence of $A$ and $B$.
b. $P\left(A^{c} \cap B^{c}\right)=P\left(A^{c}\right)-P\left(A^{c} \cap B\right)=P\left(A^{c}\right)-P\left(A^{c}\right) P(B)=P\left(A^{c}\right) P\left(B^{c}\right)$.
1.41 a.

$$
\begin{aligned}
& P(\text { dash sent | dash rec) } \\
& \quad=\frac{P(\text { dash rec } \mid \text { dash sent }) P(\text { dash sent })}{P(\text { dash rec } \mid \text { dash sent }) P(\text { dash sent })+P(\text { dash rec } \mid \text { dot sent }) P(\text { dot sent })} \\
& \quad=\frac{(2 / 3)(4 / 7)}{(2 / 3)(4 / 7)+(1 / 4)(3 / 7)}=32 / 41
\end{aligned}
$$

b. By a similar calculation as the one in (a) $P($ dot sent $\mid$ dot rec $)=27 / 434$. Then we have $P($ dash sent $\mid$ dot rec $)=\frac{16}{43}$. Given that dot-dot was received, the distribution of the four possibilities of what was sent are

| Event | Probability |
| :--- | :--- |
| dash-dash | $(16 / 43)^{2}$ |
| dash-dot | $(16 / 43)(27 / 43)$ |
| dot-dash | $(27 / 43)(16 / 43)$ |
| dot-dot | $(27 / 43)^{2}$ |

1.43 a. For Boole's Inequality,

$$
P\left(\cup_{i=1}^{n}\right) \leq \sum_{i=1}^{n} P\left(A_{i}\right)-P_{2}+P_{3}+\cdots \pm P_{n} \leq \sum_{i=1}^{n} P\left(A_{i}\right)
$$

since $P_{i} \geq P_{j}$ if $i \leq j$ and therefore the terms $-P_{2 k}+P_{2 k+1} \leq 0$ for $k=1, \ldots, \frac{n-1}{2}$ when $n$ is odd. When $n$ is even the last term to consider is $-P_{n} \leq 0$. For Bonferroni's Inequality apply the inclusion-exclusion identity to the $A_{i}^{c}$, and use the argument leading to (1.2.10).
b. We illustrate the proof that the $P_{i}$ are increasing by showing that $P_{2} \geq P_{3}$. The other arguments are similar. Write

$$
\begin{aligned}
P_{2}=\sum_{1 \leq i<j \leq n} P\left(A_{i} \cap A_{j}\right) & =\sum_{i=1}^{n-1} \sum_{j=i+1}^{n} P\left(A_{i} \cap A_{j}\right) \\
& =\sum_{i=1}^{n-1} \sum_{j=i+1}^{n}\left[\sum_{k=1}^{n} P\left(A_{i} \cap A_{j} \cap A_{k}\right)+P\left(A_{i} \cap A_{j} \cap\left(\cup_{k} A_{k}\right)^{c}\right)\right]
\end{aligned}
$$

Now to get to $P_{3}$ we drop terms from this last expression. That is

$$
\begin{aligned}
& \sum_{i=1}^{n-1} \sum_{j=i+1}^{n}\left[\sum_{k=1}^{n} P\left(A_{i} \cap A_{j} \cap A_{k}\right)+P\left(A_{i} \cap A_{j} \cap\left(\cup_{k} A_{k}\right)^{c}\right)\right] \\
& \quad \geq \sum_{i=1}^{n-1} \sum_{j=i+1}^{n}\left[\sum_{k=1}^{n} P\left(A_{i} \cap A_{j} \cap A_{k}\right)\right] \\
& \quad \geq \sum_{i=1}^{n-2} \sum_{j=i+1}^{n-1} \sum_{k=j+1}^{n} P\left(A_{i} \cap A_{j} \cap A_{k}\right)=\sum_{1 \leq i<j<k \leq n} P\left(A_{i} \cap A_{j} \cap A_{k}\right)=P_{3} .
\end{aligned}
$$

The sequence of bounds is improving because the bounds $P_{1}, P_{1}-P_{2}+P_{3}, P_{1}-P_{2}+P_{3}-P_{4}+$ $P_{5}, \ldots$, are getting smaller since $P_{i} \geq P_{j}$ if $i \leq j$ and therefore the terms $-P_{2 k}+P_{2 k+1} \leq 0$. The lower bounds $P_{1}-P_{2}, P_{1}-P_{2}+P_{3}-P_{4}, P_{1}-P_{2}+P_{3}-P_{4}+P_{5}-P_{6}, \ldots$, are getting bigger since $P_{i} \geq P_{j}$ if $i \leq j$ and therefore the terms $P_{2 k+1}-P_{2 k} \geq 0$.
c. If all of the $A_{i}$ are equal, all of the probabilities in the inclusion-exclusion identity are the same. Thus

$$
P_{1}=n P(A), \quad P_{2}=\binom{n}{2} P(A), \quad \cdots \quad, P_{j}=\binom{n}{j} P(A)
$$

and the sequence of upper bounds on $P\left(\cup_{i} A_{i}\right)=P(A)$ becomes

$$
P_{1}=n P(A), \quad P_{1}-P_{2}+P_{3}=\left[n-\binom{n}{2}+\binom{n}{3}\right] P(A), \ldots
$$

which eventually sum to one, so the last bound is exact. For the lower bounds we get

$$
P_{1}-P_{2}=\left[n-\binom{n}{2}\right] P(A), \quad P_{1}-P_{2}+P_{3}-P_{4}=\left[n-\binom{n}{2}+\binom{n}{3}-\binom{n}{4}\right] P(A), \ldots
$$

which start out negative, then become positive, with the last one equaling $P(A)$ (see Schwager 1984 for details).
1.44 $P$ (at least 10 correct|guessing $)=\sum_{k=10}^{20}\binom{20}{k}\left(\frac{1}{4}\right)^{k}\left(\frac{3}{4}\right)^{n-k}=.01386$.
$1.45 \mathcal{X}$ is finite. Therefore $\mathcal{B}$ is the set of all subsets of $\mathcal{X}$. We must verify each of the three properties in Definition 1.2.4. (1) If $A \in \mathcal{B}$ then $P_{X}(A)=P\left(\cup_{x_{i} \in A}\left\{s_{j} \in S: X\left(s_{j}\right)=x_{i}\right\}\right) \geq 0$ since $P$ is a probability function. (2) $P_{X}(\mathcal{X})=P\left(\cup_{i=1}^{m}\left\{s_{j} \in S: X\left(s_{j}\right)=x_{i}\right\}\right)=P(S)=1$. (3) If $A_{1}, A_{2}, \ldots \in \mathcal{B}$ and pairwise disjoint then

$$
\begin{aligned}
P_{X}\left(\cup_{k=1}^{\infty} A_{k}\right) & =P\left(\bigcup_{k=1}^{\infty}\left\{\cup_{x_{i} \in A_{k}}\left\{s_{j} \in S: X\left(s_{j}\right)=x_{i}\right\}\right\}\right) \\
& =\sum_{k=1}^{\infty} P\left(\cup_{x_{i} \in A_{k}}\left\{s_{j} \in S: X\left(s_{j}\right)=x_{i}\right\}\right)=\sum_{k=1}^{\infty} P_{X}\left(A_{k}\right)
\end{aligned}
$$

where the second inequality follows from the fact the $P$ is a probability function.
1.46 This is similar to Exercise 1.20. There are $7^{7}$ equally likely sample points. The possible values of $X_{3}$ are 0,1 and 2. Only the pattern 331 ( 3 balls in one cell, 3 balls in another cell and 1 ball in a third cell) yields $X_{3}=2$. The number of sample points with this pattern is $\binom{7}{2}\binom{7}{3}\binom{4}{3} 5=14,700$. So $P\left(X_{3}=2\right)=14,700 / 7^{7} \approx .0178$. There are 4 patterns that yield $X_{3}=1$. The number of sample points that give each of these patterns is given below.

| pattern | number of sample points |  |
| :--- | :--- | ---: |
| 34 | $7\binom{7}{3} 6$ | $=1,470$ |
| 322 | $7\binom{7}{3}\binom{6}{2}\binom{4}{2}\binom{2}{2}$ | $=22,050$ |
| 3211 | $7\left(\begin{array}{l}7 \\ 3\end{array} 6\binom{4}{2}\binom{5}{2} 2!\right.$ | $=176,400$ |
| 31111 | $7\binom{7}{3}\binom{6}{4} 4!$ | $=88,200$ |

So $P\left(X_{3}=1\right)=288,120 / 7^{7} \approx .3498$. The number of sample points that yield $X_{3}=0$ is $7^{7}-288,120-14,700=520,723$, and $P\left(X_{3}=0\right)=520,723 / 7^{7} \approx .6322$.
1.47 All of the functions are continuous, hence right-continuous. Thus we only need to check the limit, and that they are nondecreasing
a. $\lim _{x \rightarrow-\infty} \frac{1}{2}+\frac{1}{\pi} \tan ^{-1}(x)=\frac{1}{2}+\frac{1}{\pi}\left(\frac{-\pi}{2}\right)=0, \lim _{x \rightarrow \infty} \frac{1}{2}+\frac{1}{\pi} \tan ^{-1}(x)=\frac{1}{2}+\frac{1}{\pi}\left(\frac{\pi}{2}\right)=1$, and $\frac{d}{d x}\left(\frac{1}{2}+\frac{1}{\pi} \tan ^{-1}(x)\right)=\frac{1}{1+x^{2}}>0$, so $F(x)$ is increasing.
b. See Example 1.5.5.
c. $\lim _{x \rightarrow-\infty} e^{-e^{-x}}=0, \lim _{x \rightarrow \infty} e^{-e^{-x}}=1, \frac{d}{d x} e^{-e^{-x}}=e^{-x} e^{-e^{-x}}>0$.
d. $\lim _{x \rightarrow-\infty}\left(1-e^{-x}\right)=0, \lim _{x \rightarrow \infty}\left(1-e^{-x}\right)=1, \frac{d}{d x}\left(1-e^{-x}\right)=e^{-x}>0$.
e. $\lim _{y \rightarrow-\infty} \frac{1-\epsilon}{1+e^{-y}}=0, \lim _{y \rightarrow \infty} \epsilon+\frac{1-\epsilon}{1+e^{-y}}=1, \frac{d}{d x}\left(\frac{1-\epsilon}{1+e^{-y}}\right)=\frac{(1-\epsilon) e^{-y}}{\left(1+e^{-y}\right)^{2}}>0$ and $\frac{d}{d x}\left(\epsilon+\frac{1-\epsilon}{1+e^{-y}}\right)>$ $0, F_{Y}(y)$ is continuous except on $y=0$ where $\lim _{y \downarrow 0}\left(\epsilon+\frac{1-\epsilon}{1+e^{-y}}\right)=F(0)$. Thus is $F_{Y}(y)$ right continuous.
1.48 If $F(\cdot)$ is a cdf, $F(x)=P(X \leq x)$. Hence $\lim _{x \rightarrow \infty} P(X \leq x)=0$ and $\lim _{x \rightarrow-\infty} P(X \leq x)=1$. $F(x)$ is nondecreasing since the set $\{x: X \leq x\}$ is nondecreasing in x . Lastly, as $x \downarrow x_{0}$, $P(X \leq x) \rightarrow P\left(X \leq x_{0}\right)$, so $F(\cdot)$ is right-continuous. (This is merely a consequence of defining $F(x)$ with " $\leq "$.
1.49 For every $t, F_{X}(t) \leq F_{Y}(t)$. Thus we have

$$
P(X>t)=1-P(X \leq t)=1-F_{X}(t) \geq 1-F_{Y}(t)=1-P(Y \leq t)=P(Y>t)
$$

And for some $t^{*}, F_{X}\left(t^{*}\right)<F_{Y}\left(t^{*}\right)$. Then we have that

$$
P\left(X>t^{*}\right)=1-P\left(X \leq t^{*}\right)=1-F_{X}\left(t^{*}\right)>1-F_{Y}\left(t^{*}\right)=1-P\left(Y \leq t^{*}\right)=P\left(Y>t^{*}\right)
$$

1.50 Proof by induction. For $n=2$

$$
\sum_{k=1}^{2} t^{k-1}=1+t=\frac{1-t^{2}}{1-t}
$$

Assume true for $n$, this is $\sum_{k=1}^{n} t^{k-1}=\frac{1-t^{n}}{1-t}$. Then for $n+1$

$$
\sum_{k=1}^{n+1} t^{k-1}=\sum_{k=1}^{n} t^{k-1}+t^{n}=\frac{1-t^{n}}{1-t}+t^{n}=\frac{1-t^{n}+t^{n}(1-t)}{1-t}=\frac{1-t^{n+1}}{1-t}
$$

where the second inequality follows from the induction hypothesis.
1.51 This kind of random variable is called hypergeometric in Chapter 3. The probabilities are obtained by counting arguments, as follows.

$$
\begin{aligned}
& \begin{array}{ll}
x & f_{X}(x)=P(X=x) \\
\hline 0 & \binom{5}{0}\binom{25}{4} /\binom{30}{4} \quad \approx .4616
\end{array} \\
& 1 \quad\binom{5}{1}\binom{25}{3} /\binom{30}{4} \approx .4196 \\
& 2 \quad\binom{5}{2}\binom{25}{2} /\binom{30}{4} \approx .1095 \\
& 3 \quad\binom{5}{3}\binom{25}{1} /\binom{30}{4} \approx .0091 \\
& 4 \quad\binom{5}{4}\binom{25}{0} /\binom{30}{4} \quad \approx .0002
\end{aligned}
$$

The cdf is a step function with jumps at $x=0,1,2,3$ and 4 .
1.52 The function $g(\cdot)$ is clearly positive. Also,

$$
\int_{x_{0}}^{\infty} g(x) d x=\int_{x_{0}}^{\infty} \frac{f(x)}{1-F\left(x_{0}\right)} d x=\frac{1-F\left(x_{0}\right)}{1-F\left(x_{0}\right)}=1
$$

1.53 a. $\lim _{y \rightarrow-\infty} F_{Y}(y)=\lim _{y \rightarrow-\infty} 0=0$ and $\lim _{y \rightarrow \infty} F_{Y}(y)=\lim _{y \rightarrow \infty} 1-\frac{1}{y^{2}}=1$. For $y \leq 1$, $F_{Y}(y)=0$ is constant. For $y>1, \frac{d}{d y} F_{Y}(y)=2 / y^{3}>0$, so $F_{Y}$ is increasing. Thus for all $y$, $F_{Y}$ is nondecreasing. Therefore $F_{Y}$ is a cdf.
b. The pdf is $f_{Y}(y)=\frac{d}{d y} F_{Y}(y)= \begin{cases}2 / y^{3} & \text { if } y>1 \\ 0 & \text { if } y \leq 1 .\end{cases}$
c. $F_{Z}(z)=P(Z \leq z)=P(10(Y-1) \leq z)=P(Y \leq(z / 10)+1)=F_{Y}((z / 10)+1)$. Thus,

$$
F_{Z}(z)= \begin{cases}0 & \text { if } z \leq 0 \\ 1-\left(\frac{1}{[(z / 10)+1]^{2}}\right) & \text { if } z>0\end{cases}
$$

1.54 a. $\int_{0}^{\pi / 2} \sin x d x=1$. Thus, $c=1 / 1=1$.
b. $\int_{-\infty}^{\infty} e^{-|x|} d x=\int_{-\infty}^{0} e^{x} d x+\int_{0}^{\infty} e^{-x} d x=1+1=2$. Thus, $c=1 / 2$.
1.55

$$
P(V \leq 5)=P(T<3)=\int_{0}^{3} \frac{1}{1.5} e^{-t / 1.5} d t=1-e^{-2}
$$

For $v \geq 6$,

$$
P(V \leq v)=P(2 T \leq v)=P\left(T \leq \frac{v}{2}\right)=\int_{0}^{\frac{v}{2}} \frac{1}{1.5} e^{-t / 1.5} d t=1-e^{-v / 3}
$$

Therefore,

$$
P(V \leq v)=\left\{\begin{array}{ll}
0 & -\infty<v<0 \\
1-e^{-2} & 0 \leq v<6 \\
1-e^{-v / 3} & 6 \leq v
\end{array} .\right.
$$

## Chapter 2

## Transformations and Expectations

2.1 a. $f_{x}(x)=42 x^{5}(1-x), 0<x<1 ; y=x^{3}=g(x)$, monotone, and $\mathcal{Y}=(0,1)$. Use Theorem 2.1.5.

$$
\begin{aligned}
f_{Y}(y) & =f_{x}\left(g^{-1}(y)\right)\left|\frac{d}{d y} g^{-1}(y)\right|=f_{x}\left(y^{1 / 3}\right) \frac{d}{d y}\left(y^{1 / 3}\right)=42 y^{5 / 3}\left(1-y^{1 / 3}\right)\left(\frac{1}{3} y^{-2 / 3}\right) \\
& =14 y\left(1-y^{1 / 3}\right)=14 y-14 y^{4 / 3}, \quad 0<y<1
\end{aligned}
$$

To check the integral,

$$
\int_{0}^{1}\left(14 y-14 y^{4 / 3}\right) d y=7 y^{2}-\left.14 \frac{y^{7 / 3}}{7 / 3}\right|_{0} ^{1}=7 y^{2}-\left.6 y^{7 / 3}\right|_{0} ^{1}=1-0=1
$$

b. $f_{x}(x)=7 e^{-7 x}, 0<x<\infty, y=4 x+3$, monotone, and $\mathcal{Y}=(3, \infty)$. Use Theorem 2.1.5.

$$
f_{Y}(y)=f_{x}\left(\frac{y-3}{4}\right)\left|\frac{d}{d y}\left(\frac{y-3}{4}\right)\right|=7 e^{-(7 / 4)(y-3)}\left|\frac{1}{4}\right|=\frac{7}{4} e^{-(7 / 4)(y-3)}, 3<y<\infty .
$$

To check the integral,

$$
\int_{3}^{\infty} \frac{7}{4} e^{-(7 / 4)(y-3)} d y=-\left.e^{-(7 / 4)(y-3)}\right|_{3} ^{\infty}=0-(-1)=1
$$

c. $F_{Y}(y)=P(0 \leq X \leq \sqrt{y})=F_{X}(\sqrt{y})$. Then $f_{Y}(y)=\frac{1}{2 \sqrt{y}} f_{X}(\sqrt{y})$. Therefore

$$
f_{Y}(y)=\frac{1}{2 \sqrt{y}} 30(\sqrt{y})^{2}(1-\sqrt{y})^{2}=15 y^{\frac{1}{2}}(1-\sqrt{y})^{2}, \quad 0<y<1 .
$$

To check the integral,

$$
\int_{0}^{1} 15 y^{\frac{1}{2}}(1-\sqrt{y})^{2} d y=\int_{0}^{1}\left(15 y^{\frac{1}{2}}-30 y+15 y^{\frac{3}{2}}\right) d y=15\left(\frac{2}{3}\right)-30\left(\frac{1}{2}\right)+15\left(\frac{2}{5}\right)=1 .
$$

2.2 In all three cases, Theorem 2.1.5 is applicable and yields the following answers.
a. $f_{Y}(y)=\frac{1}{2} y^{-1 / 2}, 0<y<1$.
b. $f_{Y}(y)=\frac{(n+m+1)!}{n!m!} e^{-y(n+1)}\left(1-e^{-y}\right)^{m}, 0<y<\infty$.
c. $f_{Y}(y)=\frac{1}{\sigma^{2}} \frac{\log y}{y} e^{-(1 / 2)((\log y) / \sigma)^{2}}, 0<y<\infty$.
2.3 $P(Y=y)=P\left(\frac{X}{X+1}=y\right)=P\left(X=\frac{y}{1-y}\right)=\frac{1}{3}\left(\frac{2}{3}\right)^{y /(1-y)}$, where $y=0, \frac{1}{2}, \frac{2}{3}, \frac{3}{4}, \ldots, \frac{x}{x+1}, \ldots$.
2.4 a. $f(x)$ is a pdf since it is positive and

$$
\int_{-\infty}^{\infty} f(x) d x=\int_{-\infty}^{0} \frac{1}{2} \lambda e^{\lambda x} d x+\int_{0}^{\infty} \frac{1}{2} \lambda e^{-\lambda x} d x=\frac{1}{2}+\frac{1}{2}=1 .
$$

b. Let $X$ be a random variable with density $f(x)$.

$$
P(X<t)= \begin{cases}\int_{-\infty}^{t} \frac{1}{2} \lambda e^{\lambda x} d x & \text { if } t<0 \\ \int_{-\infty}^{0} \frac{1}{2} \lambda e^{\lambda x} d x+\int_{0}^{t} \frac{1}{2} \lambda e^{-\lambda x} d x & \text { if } t \geq 0\end{cases}
$$

where, $\int_{-\infty}^{t} \frac{1}{2} \lambda e^{\lambda x} d x=\left.\frac{1}{2} e^{\lambda x}\right|_{-\infty} ^{t}=\frac{1}{2} e^{\lambda t}$ and $\int_{0}^{t} \frac{1}{2} \lambda e^{-\lambda x} d x=-\left.\frac{1}{2} e^{-\lambda x}\right|_{0} ^{t}=-\frac{1}{2} e^{-\lambda t}+\frac{1}{2}$.
Therefore,

$$
P(X<t)= \begin{cases}\frac{1}{2} e^{\lambda t} & \text { if } t<0 \\ 1-\frac{1}{2} e^{-\lambda t} d x & \text { if } t \geq 0\end{cases}
$$

c. $P(|X|<t)=0$ for $t<0$, and for $t \geq 0$,

$$
\begin{aligned}
P(|X|<t) & =P(-t<X<t)=\int_{-t}^{0} \frac{1}{2} \lambda e^{\lambda x} d x+\int_{0}^{t} \frac{1}{2} \lambda e^{-\lambda x} d x \\
& =\frac{1}{2}\left[1-e^{-\lambda t}\right]+\frac{1}{2}\left[-e^{-\lambda t}+1\right]=1-e^{-\lambda t}
\end{aligned}
$$

2.5 To apply Theorem 2.1.8. Let $A_{0}=\{0\}, A_{1}=\left(0, \frac{\pi}{2}\right), A_{3}=\left(\pi, \frac{3 \pi}{2}\right)$ and $A_{4}=\left(\frac{3 \pi}{2}, 2 \pi\right)$. Then $g_{i}(x)=\sin ^{2}(x)$ on $A_{i}$ for $i=1,2,3,4$. Therefore $g_{1}^{-1}(y)=\sin ^{-1}(\sqrt{y}), g_{2}^{-1}(y)=\pi-\sin ^{-1}(\sqrt{y})$, $g_{3}^{-1}(y)=\sin ^{-1}(\sqrt{y})+\pi$ and $g_{4}^{-1}(y)=2 \pi-\sin ^{-1}(\sqrt{y})$. Thus

$$
\begin{aligned}
f_{Y}(y) & =\frac{1}{2 \pi}\left|\frac{1}{\sqrt{1-y}} \frac{1}{2 \sqrt{y}}\right|+\frac{1}{2 \pi}\left|-\frac{1}{\sqrt{1-y}} \frac{1}{2 \sqrt{y}}\right|+\frac{1}{2 \pi}\left|\frac{1}{\sqrt{1-y}} \frac{1}{2 \sqrt{y}}\right|+\frac{1}{2 \pi}\left|-\frac{1}{\sqrt{1-y}} \frac{1}{2 \sqrt{y}}\right| \\
& =\frac{1}{\pi \sqrt{y(1-y)}}, \quad 0 \leq y \leq 1
\end{aligned}
$$

To use the cdf given in (2.1.6) we have that $x_{1}=\sin ^{-1}(\sqrt{y})$ and $x_{2}=\pi-\sin ^{-1}(\sqrt{y})$. Then by differentiating (2.1.6) we obtain that

$$
\begin{aligned}
f_{Y}(y) & =2 f_{X}\left(\operatorname { s i n } ^ { - 1 } ( \sqrt { y } ) \frac { d } { d y } \left(\sin ^{-1}(\sqrt{y})-2 f_{X}\left(\pi-\sin ^{-1}(\sqrt{y}) \frac{d}{d y}\left(\pi-\sin ^{-1}(\sqrt{y})\right.\right.\right.\right. \\
& =2\left(\frac{1}{2 \pi} \frac{1}{\sqrt{1-y}} \frac{1}{2 \sqrt{y}}\right)-2\left(\frac{1}{2 \pi} \frac{-1}{\sqrt{1-y}} \frac{1}{2 \sqrt{y}}\right) \\
& =\frac{1}{\pi \sqrt{y(1-y)}}
\end{aligned}
$$

2.6 Theorem 2.1.8 can be used for all three parts.
a. Let $A_{0}=\{0\}, A_{1}=(-\infty, 0)$ and $A_{2}=(0, \infty)$. Then $g_{1}(x)=|x|^{3}=-x^{3}$ on $A_{1}$ and $g_{2}(x)=|x|^{3}=x^{3}$ on $A_{2}$. Use Theorem 2.1.8 to obtain

$$
f_{Y}(y)=\frac{1}{3} e^{-y^{1 / 3}} y^{-2 / 3}, \quad 0<y<\infty
$$

b. Let $A_{0}=\{0\}, A_{1}=(-1,0)$ and $A_{2}=(0,1)$. Then $g_{1}(x)=1-x^{2}$ on $A_{1}$ and $g_{2}(x)=1-x^{2}$ on $A_{2}$. Use Theorem 2.1.8 to obtain

$$
f_{Y}(y)=\frac{3}{8}(1-y)^{-1 / 2}+\frac{3}{8}(1-y)^{1 / 2}, \quad 0<y<1
$$

c. Let $A_{0}=\{0\}, A_{1}=(-1,0)$ and $A_{2}=(0,1)$. Then $g_{1}(x)=1-x^{2}$ on $A_{1}$ and $g_{2}(x)=1-x$ on $A_{2}$. Use Theorem 2.1.8 to obtain

$$
f_{Y}(y)=\frac{3}{16}(1-\sqrt{1-y})^{2} \frac{1}{\sqrt{1-y}}+\frac{3}{8}(2-y)^{2}, \quad 0<y<1
$$

2.7 Theorem 2.1.8 does not directly apply.
a. Theorem 2.1.8 does not directly apply. Instead write

$$
\begin{aligned}
P(Y \leq y) & =P\left(X^{2} \leq y\right) \\
& = \begin{cases}P(-\sqrt{y} \leq X \leq \sqrt{y}) & \text { if }|x| \leq 1 \\
P(1 \leq X \leq \sqrt{y}) & \text { if } x \geq 1\end{cases} \\
& = \begin{cases}\int_{-\sqrt{y}}^{\sqrt{y}} f_{X}(x) d x & \text { if }|x| \leq 1 \\
\int_{1}^{\sqrt{y}} f_{X}(x) d x & \text { if } x \geq 1\end{cases}
\end{aligned}
$$

Differentiation gives

$$
f_{y}(y)=\left\{\begin{array}{ll}
\frac{2}{9} \frac{1}{\sqrt{y}} & \text { if } y \leq 1 \\
\frac{1}{9}+\frac{1}{9} \frac{1}{\sqrt{y}} & \text { if } y \geq 1
\end{array} .\right.
$$

b. If the sets $B_{1}, B_{2}, \ldots, B_{K}$ are a partition of the range of $Y$, we can write

$$
f_{Y}(y)=\sum_{k} f_{Y}(y) I\left(y \in B_{k}\right)
$$

and do the transformation on each of the $B_{k}$. So this says that we can apply Theorem 2.1.8 on each of the $B_{k}$ and add up the pieces. For $A_{1}=(-1,1)$ and $A_{2}=(1,2)$ the calculations are identical to those in part (a). (Note that on $A_{1}$ we are essentially using Example 2.1.7).
2.8 For each function we check the conditions of Theorem 1.5.3.
a. (i) $\lim _{x \rightarrow 0} F(x)=1-e^{-0}=0, \lim _{x \rightarrow-\infty} F(x)=1-e^{-\infty}=1$.
(ii) $1-e^{-x}$ is increasing in $x$.
(iii) $1-e^{-x}$ is continuous.
(iv) $F_{x}^{-1}(y)=-\log (1-y)$.
b. (i) $\lim _{x \rightarrow-\infty} F(x)=e^{-\infty} / 2=0, \lim _{x \rightarrow \infty} F(x)=1-\left(e^{1-\infty} / 2\right)=1$.
(ii) $e^{-x / 2}$ is increasing, $1 / 2$ is nondecreasing, $1-\left(e^{1-x} / 2\right)$ is increasing.
(iii) For continuity we only need check $x=0$ and $x=1$, and $\lim _{x \rightarrow 0} F(x)=1 / 2$, $\lim _{x \rightarrow 1} F(x)=1 / 2$, so $F$ is continuous.
(iv)

$$
F_{X}^{-1}(y)= \begin{cases}\log (2 y) & 0 \leq y<\frac{1}{2} \leq y<1 \\ 1-\log (2(1-y)) & \frac{1}{2} \leq y<1\end{cases}
$$

c. (i) $\lim _{x \rightarrow-\infty} F(x)=e^{-\infty} / 4=0, \lim _{x \rightarrow \infty} F(x)=1-e^{-\infty} / 4=1$.
(ii) $e^{-x} / 4$ and $1-e^{-x} / 4$ are both increasing in $x$.
(iii) $\lim _{x \downarrow 0} F(x)=1-e^{-0} / 4=\frac{3}{4}=F(0)$, so $F$ is right-continuous.
(iv) $F_{X}^{-1}(y)= \begin{cases}\log (4 y) & 0 \leq y<\frac{1}{4} \\ -\log (4(1-y)) & \frac{1}{4} \leq y<1\end{cases}$
2.9 From the probability integral transformation, Theorem 2.1.10, we know that if $u(x)=F_{x}(x)$, then $F_{x}(X) \sim$ uniform $(0,1)$. Therefore, for the given pdf, calculate

$$
u(x)=F_{x}(x)= \begin{cases}0 & \text { if } x \leq 1 \\ (x-1)^{2} / 4 & \text { if } 1<x<3 \\ 1 & \text { if } 3 \leq x\end{cases}
$$

2.10 a. We prove part b), which is equivalent to part a).
b. Let $A_{y}=\left\{x: F_{x}(x) \leq y\right\}$. Since $F_{x}$ is nondecreasing, $A_{y}$ is a half infinite interval, either open, say $\left(-\infty, x_{y}\right)$, or closed, say $\left(-\infty, x_{y}\right]$. If $A_{y}$ is closed, then

$$
F_{Y}(y)=P(Y \leq y)=P\left(F_{x}(X) \leq y\right)=P\left(X \in A_{y}\right)=F_{x}\left(x_{y}\right) \leq y
$$

The last inequality is true because $x_{y} \in A_{y}$, and $F_{x}(x) \leq y$ for every $x \in A_{y}$. If $A_{y}$ is open, then

$$
F_{Y}(y)=P(Y \leq y)=P\left(F_{x}(X) \leq y\right)=P\left(X \in A_{y}\right),
$$

as before. But now we have

$$
P\left(X \in A_{y}\right)=P\left(X \in\left(-\infty, x_{y}\right)\right)=\lim _{x \uparrow y} P(X \in(-\infty, x]),
$$

Use the Axiom of Continuity, Exercise 1.12, and this equals $\lim _{x \uparrow y} F_{X}(x) \leq y$. The last inequality is true since $F_{x}(x) \leq y$ for every $x \in A_{y}$, that is, for every $x<x_{y}$. Thus, $F_{Y}(y) \leq y$ for every $y$. To get strict inequality for some $y$, let $y$ be a value that is "jumped over" by $F_{x}$. That is, let $y$ be such that, for some $x_{y}$,

$$
\lim _{x \uparrow y} F_{X}(x)<y<F_{X}\left(x_{y}\right)
$$

For such a $y, A_{y}=\left(-\infty, x_{y}\right)$, and $F_{Y}(y)=\lim _{x \uparrow y} F_{X}(x)<y$.
2.11 a. Using integration by parts with $u=x$ and $d v=x e^{\frac{-x^{2}}{2}} d x$ then

$$
\mathrm{E} X^{2}=\int_{-\infty}^{\infty} x^{2} \frac{1}{2 \pi} e^{\frac{-x^{2}}{2}} d x=\frac{1}{2 \pi}\left[-\left.x e^{\frac{-x^{2}}{2}}\right|_{-\infty} ^{\infty}+\int_{-\infty}^{\infty} e^{\frac{-x^{2}}{2}} d x\right]=\frac{1}{2 \pi}(2 \pi)=1
$$

Using example 2.1.7 let $Y=X^{2}$. Then

$$
f_{Y}(y)=\frac{1}{2 \sqrt{y}}\left[\frac{1}{\sqrt{2 \pi}} e^{\frac{-y}{2}}+\frac{1}{\sqrt{2 \pi}} e^{\frac{-y}{2}}\right]=\frac{1}{\sqrt{2 \pi y}} e^{\frac{-y}{2}} .
$$

Therefore,

$$
\mathrm{E} Y=\int_{0}^{\infty} \frac{y}{\sqrt{2 \pi y}} e^{\frac{-y}{2}} d y=\frac{1}{\sqrt{2 \pi}}\left[-\left.2 y^{\frac{1}{2}} e^{\frac{-y}{2}}\right|_{0} ^{\infty}+\int_{0}^{\infty} y^{\frac{-1}{2}} e^{\frac{-y}{2}} d y\right]=\frac{1}{\sqrt{2 \pi}}(\sqrt{2 \pi})=1
$$

This was obtained using integration by parts with $u=2 y^{\frac{1}{2}}$ and $d v=\frac{1}{2} e^{\frac{-y}{2}}$ and the fact the $f_{Y}(y)$ integrates to 1.
b. $Y=|X|$ where $-\infty<x<\infty$. Therefore $0<y<\infty$. Then

$$
\begin{aligned}
F_{Y}(y) & =P(Y \leq y)=P(|X| \leq y)=P(-y \leq X \leq y) \\
& =P(x \leq y)-P(X \leq-y)=F_{X}(y)-F_{X}(-y)
\end{aligned}
$$

Therefore,

$$
F_{Y}(y)=\frac{d}{d y} F_{Y}(y)=f_{X}(y)+f_{X}(-y)=\frac{1}{\sqrt{2 \pi}} e^{\frac{-y}{2}}+\frac{1}{\sqrt{2 \pi}} e^{\frac{-y}{2}}=\sqrt{\frac{2}{\pi}} e^{\frac{-y}{2}}
$$

Thus,

$$
\mathrm{E} Y=\int_{0}^{\infty} y \sqrt{\frac{2}{\pi}} e^{\frac{-y}{2}} d y=\sqrt{\frac{2}{\pi}} \int_{0}^{\infty} e^{-u} d u=\sqrt{\frac{2}{\pi}}\left[-\left.e^{-u}\right|_{0} ^{\infty}\right]=\sqrt{\frac{2}{\pi}}
$$

where $u=\frac{y^{2}}{2}$.

$$
\mathrm{E} Y^{2}=\int_{0}^{\infty} y^{2} \sqrt{\frac{2}{\pi}} e^{\frac{-y}{2}} d y=\sqrt{\frac{2}{\pi}}\left[-\left.y e^{\frac{-y}{2}}\right|_{0} ^{\infty}+\int_{0}^{\infty} e^{\frac{-y}{2}} d y\right]=\sqrt{\frac{2}{\pi}} \sqrt{\frac{\pi}{2}}=1
$$

This was done using integration by part with $u=y$ and $d v=y e^{\frac{-y}{2}} d y$. Then $\operatorname{Var}(Y)=1-\frac{2}{\pi}$.
2.12 We have $\tan x=y / d$, therefore $\tan ^{-1}(y / d)=x$ and $\frac{d}{d y} \tan ^{-1}(y / d)=\frac{1}{1+(y / d)^{2}} \frac{1}{d} d y=d x$. Thus,

$$
f_{Y}(y)=\frac{2}{\pi d} \frac{1}{1+(y / d)^{2}}, \quad 0<y<\infty
$$

This is the Cauchy distribution restricted to $(0, \infty)$, and the mean is infinite.
2.13 $P(X=k)=(1-p)^{k} p+p^{k}(1-p), k=1,2, \ldots$. Therefore,

$$
\begin{aligned}
\mathrm{E} X & =\sum_{k=1}^{\infty} k\left[(1-p)^{k} p+p^{k}(1-p)\right]=(1-p) p\left[\sum_{k=1}^{\infty} k(1-p)^{k-1}+\sum_{k=1}^{\infty} k p^{k-1}\right] \\
& =(1-p) p\left[\frac{1}{p^{2}}+\frac{1}{(1-p)^{2}}\right]=\frac{1-2 p+2 p^{2}}{p(1-p)}
\end{aligned}
$$

2.14

$$
\begin{aligned}
\int_{0}^{\infty}\left(1-F_{X}(x)\right) d x & =\int_{0}^{\infty} P(X>x) d x \\
& =\int_{0}^{\infty} \int_{x}^{\infty} f_{X}(y) d y d x \\
& =\int_{0}^{\infty} \int_{0}^{y} d x f_{X}(y) d y \\
& =\int_{0}^{\infty} y f_{X}(y) d y=\mathrm{E} X
\end{aligned}
$$

where the last equality follows from changing the order of integration.
2.15 Assume without loss of generality that $X \leq Y$. Then $X \vee Y=Y$ and $X \wedge Y=X$. Thus $X+Y=(X \wedge Y)+(X \vee Y)$. Taking expectations

$$
\mathrm{E}[X+Y]=\mathrm{E}[(X \wedge Y)+(X \vee Y)]=\mathrm{E}(X \wedge Y)+\mathrm{E}(X \vee Y)
$$

Therefore $\mathrm{E}(X \vee Y)=\mathrm{E} X+\mathrm{E} Y-\mathrm{E}(X \wedge Y)$.
2.16 From Exercise 2.14,

$$
\mathrm{E} T=\int_{0}^{\infty}\left[a e^{-\lambda t}+(1-a) e^{-\mu t}\right] d t=\frac{-a e^{-\lambda t}}{\lambda}-\left.\frac{(1-a) e^{-\mu t}}{\mu}\right|_{0} ^{\infty}=\frac{a}{\lambda}+\frac{1-a}{\mu}
$$

2.17 a. $\int_{0}^{m} 3 x^{2} d x=m^{3} \stackrel{\text { set }}{=} \frac{1}{2} \Rightarrow m=\left(\frac{1}{2}\right)^{1 / 3}=.794$.
b. The function is symmetric about zero, therefore $m=0$ as long as the integral is finite.

$$
\frac{1}{\pi} \int_{-\infty}^{\infty} \frac{1}{1+x^{2}} d x=\left.\frac{1}{\pi} \tan ^{-1}(x)\right|_{-\infty} ^{\infty}=\frac{1}{\pi}\left(\frac{\pi}{2}+\frac{\pi}{2}\right)=1
$$

This is the Cauchy pdf.
$2.18 \mathrm{E}|X-a|=\int_{-\infty}^{\infty}|x-a| f(x) d x=\int_{-\infty}^{a}-(x-a) f(x) d x+\int_{a}^{\infty}(x-a) f(x) d x$. Then,

$$
\frac{d}{d a} \mathrm{E}|X-a|=\int_{-\infty}^{a} f(x) d x-\int_{a}^{\infty} f(x) d x \stackrel{\text { set }}{=} 0
$$

The solution to this equation is $a=$ median. This is a minimum since $d^{2} / d a^{2} \mathrm{E}|X-a|=2 f(a)>$ 0.
2.19

$$
\begin{aligned}
\frac{d}{d a} \mathrm{E}(X-a)^{2} & =\frac{d}{d a} \int_{-\infty}^{\infty}(x-a)^{2} f_{X}(x) d x=\int_{-\infty}^{\infty} \frac{d}{d a}(x-a)^{2} f_{X}(x) d x \\
& =\int_{-\infty}^{\infty}-2(x-a) f_{X}(x) d x=-2\left[\int_{-\infty}^{\infty} x f_{X}(x) d x-a \int_{-\infty}^{\infty} f_{X}(x) d x\right] \\
& =-2[\mathrm{E} X-a]
\end{aligned}
$$

Therefore if $\frac{d}{d a} \mathrm{E}(X-a)^{2}=0$ then $-2[\mathrm{E} X-a]=0$ which implies that $\mathrm{E} X=a$. If $\mathrm{E} X=a$ then $\frac{d}{d a} \mathrm{E}(X-a)^{2}=-2[\mathrm{E} X-a]=-2[a-a]=0 . \mathrm{E} X=a$ is a minimum since $d^{2} / d a^{2} \mathrm{E}(X-a)^{2}=$ $2>0$. The assumptions that are needed are the ones listed in Theorem 2.4.3.
2.20 From Example 1.5.4, if $X=$ number of children until the first daughter, then

$$
P(X=k)=(1-p)^{k-1} p,
$$

where $\mathrm{p}=$ probability of a daughter. Thus $X$ is a geometric random variable, and

$$
\begin{aligned}
\mathrm{E} X & =\sum_{k=1}^{\infty} k(1-p)^{k-1} p=p-\sum_{k=1}^{\infty} \frac{d}{d p}(1-p)^{k}=-p \frac{d}{d p}\left[\sum_{k=0}^{\infty}(1-p)^{k}-1\right] \\
& =-p \frac{d}{d p}\left[\frac{1}{p}-1\right]=\frac{1}{p} .
\end{aligned}
$$

Therefore, if $\mathrm{p}=\frac{1}{2}$, the expected number of children is two.
2.21 Since $g(x)$ is monotone

$$
\mathrm{E} g(X)=\int_{-\infty}^{\infty} g(x) f_{X}(x) d x=\int_{-\infty}^{\infty} y f_{X}\left(g^{-1}(y)\right) \frac{d}{d y} g^{-1}(y) d y=\int_{-\infty}^{\infty} y f_{Y}(y) d y=\mathrm{E} Y
$$

where the second equality follows from the change of variable $y=g(x), x=g^{-1}(y)$ and $d x=\frac{d}{d y} g^{-1}(y) d y$.
2.22 a. Using integration by parts with $u=x$ and $d v=x e^{-x^{2} / \beta^{2}}$ we obtain that

$$
\int_{0}^{\infty} x^{2} e^{-x^{2} / \beta^{2}} d x^{2}=\frac{\beta^{2}}{2} \int_{0}^{\infty} e^{-x^{2} / \beta^{2}} d x
$$

The integral can be evaluated using the argument on pages 104-105 (see 3.3.14) or by transforming to a gamma kernel (use $y=-\lambda^{2} / \beta^{2}$ ). Therefore, $\int_{0}^{\infty} e^{-x^{2} / \beta^{2}} d x=\sqrt{\pi} \beta / 2$ and hence the function integrates to 1 .
b. $\mathrm{E} X=2 \beta / \sqrt{\pi} \quad \mathrm{E} X^{2}=3 \beta^{2} / 2 \quad \operatorname{Var} X=\beta^{2}\left[\frac{3}{2}-\frac{4}{\pi}\right]$.
2.23 a. Use Theorem 2.1 .8 with $A_{0}=\{0\}, A_{1}=(-1,0)$ and $A_{2}=(0,1)$. Then $g_{1}(x)=x^{2}$ on $A_{1}$ and $g_{2}(x)=x^{2}$ on $A_{2}$. Then

$$
f_{Y}(y)=\frac{1}{2} y^{-1 / 2}, \quad 0<y<1
$$

b. $\mathrm{E} Y=\int_{0}^{1} y f_{Y}(y) d y=\frac{1}{3}$
$\mathrm{E} Y^{2}=\int_{0}^{1} y^{2} f_{Y}(y) d y=\frac{1}{5}$
$\operatorname{Var} Y=\frac{1}{5}-\left(\frac{1}{3}\right)^{2}=\frac{4}{45}$.
2.24 a. $\mathrm{E} X=\int_{0}^{1} x a x^{a-1} d x=\int_{0}^{1} a x^{a} d x=\left.\frac{a x^{a+1}}{a+1}\right|_{0} ^{1}=\frac{a}{a+1}$.
$\mathrm{E} X^{2}=\int_{0}^{1} x^{2} a x^{a-1} d x=\int_{0}^{1} a x^{a+1} d x=\left.\frac{a x^{a+2}}{a+2}\right|_{0} ^{1}=\frac{a}{a+2}$.
$\operatorname{Var} X=\frac{a}{a+2}-\left(\frac{a}{a+1}\right)^{2}=\frac{a}{(a+2)(a+1)^{2}}$.
b. $\mathrm{E} X=\sum_{x=1}^{n} \frac{x}{n}=\frac{1}{n} \sum_{x=1}^{n} x=\frac{1}{n} \frac{n(n+1)}{2}=\frac{n+1}{2}$.
$\mathrm{E} X^{2}=\sum_{i=1}^{n} \frac{x^{2}}{n}=\frac{1}{n} \sum_{i=1}^{n} x^{2}=\frac{1}{n} \frac{n(n+1)(2 n+1)}{6}=\frac{(n+1)(2 n+1)}{6}$.
$\operatorname{Var} X=\frac{(n+1)(2 n+1)}{6}-\left(\frac{n+1}{2}\right)^{2}=\frac{2 n^{2}+3 n+1}{6}-\frac{n^{2}+2 n+1}{4}=\frac{n^{2}+1}{12}$.
c. $\mathrm{E} X=\int_{0}^{2} x \frac{3}{2}(x-1)^{2} d x=\frac{3}{2} \int_{0}^{2}\left(x^{3}-2 x^{2}+x\right) d x=1$.
$\mathrm{E} X^{2}=\int_{0}^{2} x^{2} \frac{3}{2}(x-1)^{2} d x=\frac{3}{2} \int_{0}^{2}\left(x^{4}-2 x^{3}+x^{2}\right) d x=\frac{8}{5}$.
$\operatorname{Var} X=\frac{8}{5}-1^{2}=\frac{3}{5}$.
2.25 a. $Y=-X$ and $g^{-1}(y)=-y$. Thus $f_{Y}(y)=f_{X}\left(g^{-1}(y)\right)\left|\frac{d}{d y} g^{-1}(y)\right|=f_{X}(-y)|-1|=f_{X}(y)$ for every $y$.
b. To show that $M_{X}(t)$ is symmetric about 0 we must show that $M_{X}(0+\epsilon)=M_{X}(0-\epsilon)$ for all $\epsilon>0$.

$$
\begin{aligned}
M_{X}(0+\epsilon) & =\int_{-\infty}^{\infty} e^{(0+\epsilon) x} f_{X}(x) d x=\int_{-\infty}^{0} e^{\epsilon x} f_{X}(x) d x+\int_{0}^{\infty} e^{\epsilon x} f_{X}(x) d x \\
& =\int_{0}^{\infty} e^{\epsilon(-x)} f_{X}(-x) d x+\int_{-\infty}^{0} e^{\epsilon(-x)} f_{X}(-x) d x=\int_{-\infty}^{\infty} e^{-\epsilon x} f_{X}(x) d x \\
& =\int_{-\infty}^{\infty} e^{(0-\epsilon) x} f_{X}(x) d x=M_{X}(0-\epsilon)
\end{aligned}
$$

2.26 a. There are many examples; here are three. The standard normal pdf (Example 2.1.9) is symmetric about $a=0$ because $(0-\epsilon)^{2}=(0+\epsilon)^{2}$. The Cauchy pdf (Example 2.2.4) is symmetric about $a=0$ because $(0-\epsilon)^{2}=(0+\epsilon)^{2}$. The uniform $(0,1)$ pdf (Example 2.1.4) is symmetric about $a=1 / 2$ because

$$
f((1 / 2)+\epsilon)=f((1 / 2)-\epsilon)= \begin{cases}1 & \text { if } 0<\epsilon<\frac{1}{2} \\ 0 & \text { if } \frac{1}{2} \leq \epsilon<\infty\end{cases}
$$

b.

$$
\begin{aligned}
\int_{a}^{\infty} f(x) d x & =\int_{0}^{\infty} f(a+\epsilon) d \epsilon & & \text { (change variable, } \epsilon=x-a) \\
& =\int_{0}^{\infty} f(a-\epsilon) d \epsilon & & (f(a+\epsilon)=f(a-\epsilon) \text { for all } \epsilon>0) \\
& =\int_{-\infty}^{a} f(x) d x . & & \text { (change variable, } x=a-\epsilon)
\end{aligned}
$$

Since

$$
\int_{-\infty}^{a} f(x) d x+\int_{a}^{\infty} f(x) d x=\int_{-\infty}^{\infty} f(x) d x=1
$$

it must be that

$$
\int_{-\infty}^{a} f(x) d x=\int_{a}^{\infty} f(x) d x=1 / 2
$$

Therefore, $a$ is a median.
c.

$$
\begin{aligned}
\mathrm{E} X-a & =\mathrm{E}(X-a)=\int_{-\infty}^{\infty}(x-a) f(x) d x \\
& =\int_{-\infty}^{a}(x-a) f(x) d x+\int_{a}^{\infty}(x-a) f(x) d x \\
& =\int_{0}^{\infty}(-\epsilon) f(a-\epsilon) d \epsilon+\int_{0}^{\infty} \epsilon f(a+\epsilon) d \epsilon
\end{aligned}
$$

With a change of variable, $\epsilon=a-x$ in the first integral, and $\epsilon=x-a$ in the second integral we obtain that

$$
\begin{aligned}
\mathrm{E} X-a & =\mathrm{E}(X-a) \\
& =-\int_{0}^{\infty} \epsilon f(a-\epsilon) d \epsilon+\int_{0}^{\infty} \epsilon f(a-\epsilon) d \epsilon \quad(f(a+\epsilon)=f(a-\epsilon) \text { for all } \epsilon>0) \\
& =0 . \quad \text { (two integrals are same) }
\end{aligned}
$$

Therefore, $\mathrm{E} X=a$.
d. If $a>\epsilon>0$,

$$
f(a-\epsilon)=e^{-(a-\epsilon)}>e^{-(a+\epsilon)}=f(a+\epsilon)
$$

Therefore, $f(x)$ is not symmetric about $a>0$. If $-\epsilon<a \leq 0$,

$$
f(a-\epsilon)=0<e^{-(a+\epsilon)}=f(a+\epsilon) .
$$

Therefore, $f(x)$ is not symmetric about $a \leq 0$, either.
e. The median of $X=\log 2<1=\mathrm{E} X$.
2.27 a. The standard normal pdf.
b. The uniform on the interval $(0,1)$.
c. For the case when the mode is unique. Let $a$ be the point of symmetry and $b$ be the mode. Let assume that $a$ is not the mode and without loss of generality that $a=b+\epsilon>b$ for $\epsilon>0$. Since $b$ is the mode then $f(b)>f(b+\epsilon) \geq f(b+2 \epsilon)$ which implies that $f(a-\epsilon)>f(a) \geq f(a+\epsilon)$ which contradict the fact the $f(x)$ is symmetric. Thus $a$ is the mode.
For the case when the mode is not unique, there must exist an interval $\left(x_{1}, x_{2}\right)$ such that $f(x)$ has the same value in the whole interval, i.e, $f(x)$ is flat in this interval and for all $b \in\left(x_{1}, x_{2}\right), b$ is a mode. Let assume that $a \notin\left(x_{1}, x_{2}\right)$, thus $a$ is not a mode. Let also assume without loss of generality that $a=(b+\epsilon)>b$. Since $b$ is a mode and $a=(b+\epsilon) \notin\left(x_{1}, x_{2}\right)$ then $f(b)>f(b+\epsilon) \geq f(b+2 \epsilon)$ which contradict the fact the $f(x)$ is symmetric. Thus $a \in\left(x_{1}, x_{2}\right)$ and is a mode.
d. $f(x)$ is decreasing for $x \geq 0$, with $f(0)>f(x)>f(y)$ for all $0<x<y$. Thus $f(x)$ is unimodal and 0 is the mode.
2.28 a.

$$
\begin{aligned}
& \mu_{3}=\int_{-\infty}^{\infty}(x-a)^{3} f(x) d x=\int_{-\infty}^{a}(x-a)^{3} f(x) d x+\int_{a}^{\infty}(x-a)^{3} f(x) d x \\
&\left.=\int_{-\infty}^{0} y^{3} f(y+a) d y+\int_{0}^{\infty} y^{3} f(y+a) d y \quad \quad \text { (change variable } y=x-a\right) \\
&=\int_{0}^{\infty}-y^{3} f(-y+a) d y+\int_{0}^{\infty} y^{3} f(y+a) d y \\
&=0 . \\
& \quad(f(-y+a)=f(y+a))
\end{aligned}
$$

b. For $f(x)=e^{-x}, \mu_{1}=\mu_{2}=1$, therefore $\alpha_{3}=\mu_{3}$.

$$
\begin{aligned}
\mu_{3} & =\int_{0}^{\infty}(x-1)^{3} e^{-x} d x=\int_{0}^{\infty}\left(x^{3}-3 x^{2}+3 x-1\right) e^{-x} d x \\
& =\Gamma(4)-3 \Gamma(3)+3 \Gamma(2)-\Gamma(1)=3!-3 \times 2!+3 \times 1-1=3
\end{aligned}
$$

c. Each distribution has $\mu_{1}=0$, therefore we must calculate $\mu_{2}=\mathrm{E} X^{2}$ and $\mu_{4}=\mathrm{E} X^{4}$.
(i) $f(x)=\frac{1}{\sqrt{2 \pi}} e^{-x^{2} / 2}, \quad \mu_{2}=1, \quad \mu_{4}=3, \quad \alpha_{4}=3$.
(ii) $f(x)=\frac{1}{2},-1<x<1, \quad \mu_{2}=\frac{1}{3}, \quad \mu_{4}=\frac{1}{5}, \quad \alpha_{4}=\frac{9}{5}$.
(iii) $f(x)=\frac{1}{2} e^{-|x|},-\infty<x<\infty, \quad \mu_{2}=2, \quad \mu_{4}=24, \quad \alpha_{4}=6$.

As a graph will show, (iii) is most peaked, (i) is next, and (ii) is least peaked.
2.29 a. For the binomial

$$
\begin{aligned}
\mathrm{E} X(X-1) & =\sum_{x=2}^{n} x(x-1)\binom{n}{x} p^{x}(1-p)^{n-x} \\
& =n(n-1) p^{2} \sum_{x=2}^{n}\binom{n-2}{x} p^{x-2}(1-p)^{n-x} \\
& =n(n-1) p^{2} \sum_{y=0}^{n-2}\binom{n-2}{y} p^{y}(1-p)^{n-2-y}=n(n-1) p^{2}
\end{aligned}
$$

where we use the identity $x(x-1)\binom{n}{x}=n(n-1)\binom{n-2}{x}$, substitute $y=x-2$ and recognize that the new sum is equal to 1 . Similarly, for the Poisson

$$
\mathrm{E} X(X-1)=\sum_{x=2}^{\infty} x(x-1) \frac{e^{-\lambda} \lambda^{x}}{x!}=\lambda^{2} \sum_{y=0}^{\infty} \frac{e^{-\lambda} \lambda^{y}}{y!}=\lambda^{2}
$$

where we substitute $y=x-2$.
b. $\operatorname{Var}(X)=\mathrm{E}[X(X-1)]+\mathrm{E} X-(\mathrm{E} X)^{2}$. For the binomial

$$
\operatorname{Var}(X)=n(n-1) p^{2}+n p-(n p)^{2}=n p(1-p)
$$

For the Poisson

$$
\operatorname{Var}(X)=\lambda^{2}+\lambda-\lambda^{2}=\lambda
$$

c.

$$
\mathrm{E} Y=\sum_{y=0}^{n} y \frac{a}{y+a}\binom{n}{y} \frac{\binom{a+b-1}{a}}{\binom{n+a+b-1}{y+a}}=\sum_{y=1}^{n} n \frac{a}{(y-1)+(a+1)}\binom{n-1}{y-1} \frac{\binom{a+b-1}{a}}{\binom{n-1)+(a+1)+b-1}{(y-1)+(a+1)}}
$$

$$
\begin{aligned}
& =\sum_{y=1}^{n} n \frac{a}{(y-1)+(a+1)}\binom{n-1}{y-1} \frac{\binom{a+b-1}{a}}{\binom{n-1)+(a+1)+b-1}{(y-1)+(a+1)}} \\
& =\frac{\frac{n a}{a+1}\binom{a+b-1}{a}}{\binom{a+1+b-1}{a+1}} \sum_{y=1}^{n} \frac{a+1}{(y-1)+(a+1)}\binom{n-1}{y-1} \frac{\binom{a+1+b-1}{a+1}}{\binom{n-1)+(a+1)+b-1}{(y-1)+(a+1)}} \\
& =\frac{n a}{a+b} \sum_{j=0}^{n-1} \frac{a+1}{j+(a+1)}\binom{n-1}{j} \frac{\binom{a+1+b-1}{a+1}}{\binom{(n-1)+(a+1)+b-1}{(j+(a+1)}}=\frac{n a}{a+b},
\end{aligned}
$$

since the last summation is 1 , being the sum over all possible values of a beta-binomial $(n-$ $1, a+1, b) . \mathrm{E}[Y(Y-1)]=\frac{n(n-1) a(a+1)}{(a+b)(a+b+1)}$ is calculated similar to EY, but using the identity $y(y-1)\binom{n}{y}=n(n-1)\binom{n-2}{y-2}$ and adding 2 instead of 1 to the parameter $a$. The sum over all possible values of $a$ beta-binomial $(n-2, a+2, b)$ will appear in the calculation. Therefore

$$
\operatorname{Var}(Y)=\mathrm{E}[Y(Y-1)]+\mathrm{E} Y-(\mathrm{E} Y)^{2}=\frac{n a b(n+a+b)}{(a+b)^{2}(a+b+1)}
$$

2.30 a. $\mathrm{E}\left(e^{t X}\right)=\int_{0}^{c} e^{t x} \frac{1}{c} d x=\left.\frac{1}{c t} e^{t x}\right|_{0} ^{c}=\frac{1}{c t} e^{t c}-\frac{1}{c t} 1=\frac{1}{c t}\left(e^{t c}-1\right)$.
b. $\mathrm{E}\left(e^{t X}\right)=\int_{0}^{c} \frac{2 x}{c^{2}} e^{t x} d x=\frac{2}{c^{2} t^{2}}\left(c t e^{t c}-e^{t c}+1\right)$.
(integration-by-parts)
c.

$$
\begin{aligned}
\mathrm{E}\left(e^{t x}\right) & =\int_{-\infty}^{\alpha} \frac{1}{2 \beta} e^{(x-\alpha) / \beta} e^{t x} d x+\int_{\alpha}^{\infty} \frac{1}{2 \beta} e^{-(x-\alpha) / \beta} e^{t x} d x \\
& =\left.\frac{e^{-\alpha / \beta}}{2 \beta} \frac{1}{\left(\frac{1}{\beta}+t\right)} e^{x\left(\frac{1}{\beta}+t\right)}\right|_{-\infty} ^{\alpha}+-\left.\frac{e^{\alpha / \beta}}{2 \beta} \frac{1}{\left(\frac{1}{\beta}-t\right)} e^{-x\left(\frac{1}{\beta}-t\right)}\right|_{\alpha} ^{\infty} \\
& =\frac{4 e^{\alpha t}}{4-\beta^{2} t^{2}}, \quad-2 / \beta<t<2 / \beta
\end{aligned}
$$

d. $\mathrm{E}\left(e^{t X}\right)=\sum_{x=0}^{\infty} e^{t x}\binom{r+x-1}{x} p^{r}(1-p)^{x}=p^{r} \sum_{x=0}^{\infty}\binom{r+x-1}{x}\left((1-p) e^{t}\right)^{x}$. Now use the fact that $\sum_{x=0}^{\infty}\binom{r+x-1}{x}\left((1-p) e^{t}\right)^{x}\left(1-(1-p) e^{t}\right)^{r}=1$ for $(1-p) e^{t}<1$, since this is just the sum of this pmf, to get $\mathrm{E}\left(e^{t X}\right)=\left(\frac{p}{1-(1-p) e^{t}}\right)^{r}, t<-\log (1-p)$.
2.31 Since the mgf is defined as $M_{X}(t)=\mathrm{E} e^{t X}$, we necessarily have $M_{X}(0)=\mathrm{E} e^{0}=1$. But $t /(1-t)$ is 0 at $t=0$, therefore it cannot be an mgf.
2.32

$$
\begin{gathered}
\left.\frac{d}{d t} S(t)\right|_{t=0}=\frac{d}{d t}\left(\left.\log \left(M_{x}(t)\right)\right|_{t=0}=\left.\frac{\frac{d}{d t} M_{x}(t)}{M_{x}(t)}\right|_{t=0} \quad=\frac{\mathrm{E} X}{1}=\mathrm{E} X \quad\left(\text { since } M_{X}(0)=\mathrm{E} e^{0}=1\right)\right. \\
\left.\frac{d^{2}}{d t^{2}} S(t)\right|_{t=0} \\
=\left.\frac{d}{d t}\left(\frac{M_{x}^{\prime}(t)}{M_{x}(t)}\right)\right|_{t=0} \\
=\frac{1 \cdot \mathrm{E} X^{2}-(\mathrm{E} X)^{2}}{1}=\operatorname{Var} X
\end{gathered}
$$

2.33 a. $M_{X}(t)=\sum_{x=0}^{\infty} e^{t x} \frac{e^{-\lambda} \lambda^{x}}{x!}=e^{-\lambda} \sum_{x=1}^{\infty} \frac{\left(e^{t} \lambda\right)^{x}}{x!}=e^{-\lambda} e^{\lambda e^{t}}=e^{\lambda\left(e^{t}-1\right)}$.

$$
\mathrm{E} X=\left.\frac{d}{d t} M_{x}(t)\right|_{t=0}=\left.e^{\lambda\left(e^{t}-1\right)} \lambda e^{t}\right|_{t=0}=\lambda
$$

$$
\begin{aligned}
& \mathrm{E} X^{2}=\left.\frac{d^{2}}{d t^{2}} M_{x}(t)\right|_{t=0}=\lambda e^{t} e^{\lambda\left(e^{t}-1\right)} \lambda e^{t}+\left.\lambda e^{t} e^{\lambda\left(e^{t}-1\right)}\right|_{t=0}=\lambda^{2}+\lambda . \\
& \operatorname{Var} X=\mathrm{E} X^{2}-(\mathrm{E} X)^{2}=\lambda^{2}+\lambda-\lambda^{2}=\lambda .
\end{aligned}
$$

b.

$$
\begin{aligned}
M_{x}(t) & =\sum_{x=0}^{\infty} e^{t x} p(1-p)^{x}=p \sum_{x=0}^{\infty}\left((1-p) e^{t}\right)^{x} \\
& =p \frac{1}{1-(1-p) e^{t}}=\frac{p}{1-(1-p) e^{t}}, \quad t<-\log (1-p) \\
\mathrm{E} X & =\left.\frac{d}{d t} M_{x}(t)\right|_{t=0}=\left.\frac{-p}{\left(1-(1-p) e^{t}\right)^{2}}\left(-(1-p) e^{t}\right)\right|_{t=0} \\
& =\frac{p(1-p)}{p^{2}}=\frac{1-p}{p} . \\
\mathrm{E} X^{2} & =\left.\frac{d^{2}}{d t^{2}} M_{x}(t)\right|_{t=0} \\
& =\left.\frac{\left(1-(1-p) e^{t}\right)^{2}\left(p(1-p) e^{t}\right)+p(1-p) e^{t} 2\left(1-(1-p) e^{t}\right)(1-p) e^{t}}{\left(1-(1-p) e^{t}\right)^{4}}\right|_{t=0} \\
& =\frac{p^{3}(1-p)+2 p^{2}(1-p)^{2}}{p^{4}}=\frac{p(1-p)+2(1-p)^{2}}{p^{2}} \\
\operatorname{Var} X & =\frac{p(1-p)+2(1-p)^{2}}{p^{2}}-\frac{(1-p)^{2}}{p^{2}}=\frac{1-p}{p^{2}}
\end{aligned}
$$

c. $M_{x}(t)=\int_{-\infty}^{\infty} e^{t x} \frac{1}{\sqrt{2 \pi} \sigma} e^{-(x-\mu)^{2} / 2 \sigma^{2}} d x=\frac{1}{\sqrt{2 \pi} \sigma} \int_{-\infty}^{\infty} e^{-\left(x^{2}-2 \mu x-2 \sigma^{2} t x+\mu^{2}\right) / 2 \sigma^{2}} d x$. Now complete the square in the numerator by writing

$$
\begin{aligned}
x^{2}-2 \mu x-2 \sigma^{2} t x+\mu^{2} & =x^{2}-2\left(\mu+\sigma^{2} t\right) x \pm\left(\mu+\sigma^{2} t\right)^{2}+\mu^{2} \\
& =\left(x-\left(\mu+\sigma^{2} t\right)\right)^{2}-\left(\mu+\sigma^{2} t\right)^{2}+\mu^{2} \\
& =\left(x-\left(\mu+\sigma^{2} t\right)\right)^{2}-\left[2 \mu \sigma^{2} t+\left(\sigma^{2} t\right)^{2}\right] .
\end{aligned}
$$

Then we have $M_{x}(t)=e^{\left[2 \mu \sigma^{2} t+\left(\sigma^{2} t\right)^{2}\right] / 2 \sigma^{2}} \frac{1}{\sqrt{2 \pi} \sigma} \int_{-\infty}^{\infty} e^{-\frac{1}{2 \sigma^{2}}\left(x-\left(\mu+\sigma^{2} t\right)\right)^{2}} d x=e^{\mu t+\frac{\sigma^{2} t^{2}}{2}}$.
$\mathrm{E} X=\left.\frac{d}{d t} M_{x}(t)\right|_{t=0}=\left.\left(\mu+\sigma^{2} t\right) e^{\mu t+\sigma^{2} t^{2} / 2}\right|_{t=0}=\mu$.
$\mathrm{E} X^{2}=\left.\frac{d^{2}}{d t^{2}} M_{x}(t)\right|_{t=0}=\left(\mu+\sigma^{2} t\right)^{2} e^{\mu t+\sigma^{2} t^{2} / 2}+\left.\sigma^{2} e^{\mu t+\sigma^{2} t / 2}\right|_{t=0}=\mu^{2}+\sigma^{2}$.
$\operatorname{Var} X=\mu^{2}+\sigma^{2}-\mu^{2}=\sigma^{2}$.
2.35 a.

$$
\begin{aligned}
\mathrm{E} X_{1}^{r} & =\int_{0}^{\infty} x^{r} \frac{1}{\sqrt{2 \pi x}} e^{-(\log x)^{2} / 2} d x \quad \quad\left(f_{1} \text { is lognormal with } \mu=0, \sigma_{2}=1\right) \\
& \left.=\frac{1}{\sqrt{2 \pi}} \int_{-\infty}^{\infty} e^{y(r-1)} e^{-y^{2} / 2} e^{y} d y \quad \quad \quad \text { (substitute } y=\log x, d y=(1 / x) d x\right) \\
& =\frac{1}{\sqrt{2 \pi}} \int_{-\infty}^{\infty} e^{-y^{2} / 2+r y} d y=\frac{1}{\sqrt{2 \pi}} \int_{-\infty}^{\infty} e^{-\left(y^{2}-2 r y+r^{2}\right) / 2} e^{r^{2} / 2} d y \\
& =e^{r^{2} / 2}
\end{aligned}
$$

b.

$$
\begin{aligned}
\int_{0}^{\infty} x^{r} f_{1}(x) \sin (2 \pi \log x) d x & =\int_{0}^{\infty} x^{r} \frac{1}{\sqrt{2 \pi} x} e^{-(\log x)^{2} / 2} \sin (2 \pi \log x) d x \\
& =\int_{-\infty}^{\infty} e^{(y+r) r} \frac{1}{\sqrt{2 \pi}} e^{-(y+r)^{2} / 2} \sin (2 \pi y+2 \pi r) d y \\
& =\int_{-\infty}^{\infty} \frac{1}{\sqrt{2 \pi}} e^{\left(r^{2}-y^{2}\right) / 2} \sin (2 \pi y) d y \\
& =0
\end{aligned}
$$

because $e^{\left(r^{2}-y^{2}\right) / 2} \sin (2 \pi y)=-e^{\left(r^{2}-(-y)^{2}\right) / 2} \sin (2 \pi(-y))$; the integrand is an odd function so the negative integral cancels the positive one.
2.36 First, it can be shown that

$$
\lim _{x \rightarrow \infty} e^{t x-(\log x)^{2}}=\infty
$$

by using l'Hôpital's rule to show

$$
\lim _{x \rightarrow \infty} \frac{t x-(\log x)^{2}}{t x}=1
$$

and, hence,

$$
\lim _{x \rightarrow \infty} t x-(\log x)^{2}=\lim _{x \rightarrow \infty} t x=\infty
$$

Then for any $k>0$, there is a constant $c$ such that

$$
\int_{k}^{\infty} \frac{1}{x} e^{t x} e^{(\log x)^{2} / 2} d x \geq c \int_{k}^{\infty} \frac{1}{x} d x=\left.c \log x\right|_{k} ^{\infty}=\infty
$$

Hence $M_{x}(t)$ does not exist.
2.37 a. The graph looks very similar to Figure 2.3.2 except that $f_{1}$ is symmetric around 0 (since it is standard normal).
b. The functions look like $t^{2} / 2$ - it is impossible to see any difference.
c. The mgf of $f_{1}$ is $e^{K_{1}(t)}$. The mgf of $f_{2}$ is $e^{K_{2}(t)}$.
d. Make the transformation $y=e^{x}$ to get the densities in Example 2.3.10.
2.39 a. $\frac{d}{d x} \int_{0}^{x} e^{-\lambda t} d t=e^{-\lambda x}$. Verify

$$
\frac{d}{d x}\left[\int_{0}^{x} e^{-\lambda t} d t\right]=\frac{d}{d x}\left[-\left.\frac{1}{\lambda} e^{-\lambda t}\right|_{0} ^{x}\right]=\frac{d}{d x}\left(-\frac{1}{\lambda} e^{-\lambda x}+\frac{1}{\lambda}\right)=e^{-\lambda x}
$$

b. $\frac{d}{d \lambda} \int_{0}^{\infty} e^{-\lambda t} d t=\int_{0}^{\infty} \frac{d}{d \lambda} e^{-\lambda t} d t=\int_{0}^{\infty}-t e^{-\lambda t} d t=-\frac{\Gamma(2)}{\lambda^{2}}=-\frac{1}{\lambda^{2}}$. Verify

$$
\frac{d}{d \lambda} \int_{0}^{\infty} e^{-\lambda t} d t=\frac{d}{d \lambda} \frac{1}{\lambda}=-\frac{1}{\lambda^{2}}
$$

c. $\frac{d}{d t} \int_{t}^{1} \frac{1}{x^{2}} d x=-\frac{1}{t^{2}}$. Verify

$$
\frac{d}{d t}\left[\int_{t}^{1} \frac{1}{x^{2}} d x\right]=\frac{d}{d t}\left(-\left.\frac{1}{x}\right|_{t} ^{1}\right)=\frac{d}{d t}\left(-1+\frac{1}{t}\right)=-\frac{1}{t^{2}}
$$

d. $\frac{d}{d t} \int_{1}^{\infty} \frac{1}{(x-t)^{2}} d x=\int_{1}^{\infty} \frac{d}{d t}\left(\frac{1}{(x-t)^{2}}\right) d x=\int_{1}^{\infty} 2(x-t)^{-3} d x=-\left.(x-t)^{-2}\right|_{1} ^{\infty}=\frac{1}{(1-t)^{2}}$. Verify

$$
\frac{d}{d t} \int_{1}^{\infty}(x-t)^{-2} d x=\frac{d}{d t}\left[-\left.(x-t)^{-1}\right|_{1} ^{\infty}\right]=\frac{d}{d t} \frac{1}{1-t}=\frac{1}{(1-t)^{2}}
$$

## Common Families of Distributions

3.1 The pmf of $X$ is $f(x)=\frac{1}{N_{1}-N_{0}+1}, x=N_{0}, N_{0}+1, \ldots, N_{1}$. Then

$$
\begin{aligned}
\mathrm{E} X & =\sum_{x=N_{0}}^{N_{1}} x \frac{1}{N_{1}-N_{0}+1}=\frac{1}{N_{1}-N_{0}+1}\left(\sum_{x=1}^{N_{1}} x-\sum_{x=1}^{N_{0}-1} x\right) \\
& =\frac{1}{N_{1}-N_{0}+1}\left(\frac{N_{1}\left(N_{1}+1\right)}{2}-\frac{\left(N_{0}-1\right)\left(N_{0}-1+1\right)}{2}\right) \\
& =\frac{N_{1}+N_{0}}{2}
\end{aligned}
$$

Similarly, using the formula for $\sum_{1}^{N} x^{2}$, we obtain

$$
\begin{aligned}
\mathrm{E} x^{2} & =\frac{1}{N_{1}-N_{0}+1}\left(\frac{N_{1}\left(N_{1}+1\right)\left(2 N_{1}+1\right)-N_{0}\left(N_{0}-1\right)\left(2 N_{0}-1\right)}{6}\right) \\
\operatorname{Var} X & =\mathrm{E} X^{2}-\mathrm{E} X=\frac{\left(N_{1}-N_{0}\right)\left(N_{1}-N_{0}+2\right)}{12}
\end{aligned}
$$

3.2 Let $X=$ number of defective parts in the sample. Then $X \sim \operatorname{hypergeometric}(N=100, M, K)$ where $M=$ number of defectives in the lot and $K=$ sample size.
a. If there are 6 or more defectives in the lot, then the probability that the lot is accepted $(X=0)$ is at most

$$
P(X=0 \mid M=100, N=6, K)=\frac{\binom{6}{0}\binom{94}{K}}{\binom{100}{K}}=\frac{(100-K) \cdot \cdots \cdot(100-K-5)}{100 \cdots \cdots \cdot 95}
$$

By trial and error we find $P(X=0)=.10056$ for $K=31$ and $P(X=0)=.09182$ for $K=32$. So the sample size must be at least 32 .
b. Now $P($ accept lot $)=P(X=0$ or 1$)$, and, for 6 or more defectives, the probability is at most

$$
P(X=0 \text { or } 1 \mid M=100, N=6, K)=\frac{\binom{6}{0}\binom{94}{K}}{\binom{100}{K}}+\frac{\binom{6}{1}\binom{94}{K-1}}{\binom{100}{K}} .
$$

By trial and error we find $P(X=0$ or 1$)=.10220$ for $K=50$ and $P(X=0$ or 1$)=.09331$ for $K=51$. So the sample size must be at least 51 .
3.3 In the seven seconds for the event, no car must pass in the last three seconds, an event with probability $(1-p)^{3}$. The only occurrence in the first four seconds, for which the pedestrian does not wait the entire four seconds, is to have a car pass in the first second and no other car pass. This has probability $p(1-p)^{3}$. Thus the probability of waiting exactly four seconds before starting to cross is $\left[1-p(1-p)^{3}\right](1-p)^{3}$.
3.5 Let $X=$ number of effective cases. If the new and old drugs are equally effective, then the probability that the new drug is effective on a case is .8. If the cases are independent then $X \sim$ binomial $(100, .8)$, and

$$
P(X \geq 85)=\sum_{x=85}^{100}\binom{100}{x} \cdot 8^{x} \cdot 2^{100-x}=.1285
$$

So, even if the new drug is no better than the old, the chance of 85 or more effective cases is not too small. Hence, we cannot conclude the new drug is better. Note that using a normal approximation to calculate this binomial probability yields $P(X \geq 85) \approx P(Z \geq 1.125)=$ . 1303.
3.7 Let $X \sim \operatorname{Poisson}(\lambda)$. We want $P(X \geq 2) \geq .99$, that is,

$$
P(X \leq 1)=e^{-\lambda}+\lambda e^{-\lambda} \leq .01
$$

Solving $e^{-\lambda}+\lambda e^{-\lambda}=.01$ by trial and error (numerical bisection method) yields $\lambda=6.6384$.
3.8 a. We want $P(X>N)<.01$ where $X \sim \operatorname{binomial}(1000,1 / 2)$. Since the 1000 customers choose randomly, we take $p=1 / 2$. We thus require

$$
P(X>N)=\sum_{x=N+1}^{1000}\binom{1000}{x}\left(\frac{1}{2}\right)^{x}\left(1-\frac{1}{2}\right)^{1000-x}<.01
$$

which implies that

$$
\left(\frac{1}{2}\right)^{1000} \sum_{x=N+1}^{1000}\binom{1000}{x}<.01
$$

This last inequality can be used to solve for $N$, that is, $N$ is the smallest integer that satisfies

$$
\left(\frac{1}{2}\right)^{1000} \sum_{x=N+1}^{1000}\binom{1000}{x}<.01 .
$$

The solution is $N=537$.
b. To use the normal approximation we take $X \sim \mathrm{n}(500,250)$, where we used $\mu=1000\left(\frac{1}{2}\right)=500$ and $\sigma^{2}=1000\left(\frac{1}{2}\right)\left(\frac{1}{2}\right)=250$.Then

$$
P(X>N)=P\left(\frac{X-500}{\sqrt{250}}>\frac{N-500}{\sqrt{250}}\right)<.01
$$

thus,

$$
P\left(Z>\frac{N-500}{\sqrt{250}}\right)<.01
$$

where $Z \sim \mathrm{n}(0,1)$. From the normal table we get

$$
\begin{aligned}
P(Z>2.33) \approx .0099<.01 & \Rightarrow \frac{N-500}{\sqrt{250}}=2.33 \\
& \Rightarrow N \approx 537
\end{aligned}
$$

Therefore, each theater should have at least 537 seats, and the answer based on the approximation equals the exact answer.
3.9 a. We can think of each one of the 60 children entering kindergarten as 60 independent Bernoulli trials with probability of success (a twin birth) of approximately $\frac{1}{90}$. The probability of having 5 or more successes approximates the probability of having 5 or more sets of twins entering kindergarten. Then $X \sim \operatorname{binomial}\left(60, \frac{1}{90}\right)$ and

$$
P(X \geq 5)=1-\sum_{x=0}^{4}\binom{60}{x}\left(\frac{1}{90}\right)^{x}\left(1-\frac{1}{90}\right)^{60-x}=.0006
$$

which is small and may be rare enough to be newsworthy.
b. Let $X$ be the number of elementary schools in New York state that have 5 or more sets of twins entering kindergarten. Then the probability of interest is $P(X \geq 1)$ where $X \sim$ binomial(310,.0006). Therefore $P(X \geq 1)=1-P(X=0)=.1698$.
c. Let $X$ be the number of States that have 5 or more sets of twins entering kindergarten during any of the last ten years. Then the probability of interest is $P(X \geq 1)$ where $X \sim$ $\operatorname{binomial}(500, .1698)$. Therefore $P(X \geq 1)=1-P(X=0)=1-3.90 \times 10^{-41} \approx 1$.
3.11 a.

$$
\begin{aligned}
& \lim _{M / N \rightarrow p, M \rightarrow \infty, N \rightarrow \infty} \frac{\binom{M}{x}\binom{N-M}{K-x}}{\binom{N}{K}} \\
& = \\
& \quad \frac{K!}{x!(K-x)!} \lim _{M / N \rightarrow p, M \rightarrow \infty, N \rightarrow \infty} \frac{M!(N-M)!(N-K)!}{N!(M-x)!(N-M-(K-x))!}
\end{aligned}
$$

In the limit, each of the factorial terms can be replaced by the approximation from Stirling's formula because, for example,

$$
M!=\left(M!/\left(\sqrt{2 \pi} M^{M+1 / 2} e^{-M}\right)\right) \sqrt{2 \pi} M^{M+1 / 2} e^{-M}
$$

and $M!/\left(\sqrt{2 \pi} M^{M+1 / 2} e^{-M}\right) \rightarrow 1$. When this replacement is made, all the $\sqrt{2 \pi}$ and exponential terms cancel. Thus,

$$
\begin{aligned}
& \quad \lim _{M / N \rightarrow p, M \rightarrow \infty, N \rightarrow \infty} \frac{\binom{M}{x}\binom{N-M}{K-x}}{\binom{N}{K}} \\
& =\binom{K}{x}_{M / N \rightarrow p, M \rightarrow \infty, N \rightarrow \infty} \lim _{N \rightarrow \infty} \frac{M^{M+1 / 2}(N-M)^{N-M+1 / 2}(N-K)^{N-K+1 / 2}}{N^{N+1 / 2}(M-x)^{M-x+1 / 2}(N-M-K+x)^{N-M-(K-x)+1 / 2}} .
\end{aligned}
$$

We can evaluate the limit by breaking the ratio into seven terms, each of which has a finite limit we can evaluate. In some limits we use the fact that $M \rightarrow \infty, N \rightarrow \infty$ and $M / N \rightarrow p$ imply $N-M \rightarrow \infty$. The first term (of the seven terms) is

$$
\lim _{M \rightarrow \infty}\left(\frac{M}{M-x}\right)^{M}=\lim _{M \rightarrow \infty} \frac{1}{\left(\frac{M-x}{M}\right)^{M}}=\lim _{M \rightarrow \infty} \frac{1}{\left(1+\frac{-x}{M}\right)^{M}}=\frac{1}{e^{-x}}=e^{x}
$$

Lemma 2.3.14 is used to get the penultimate equality. Similarly we get two more terms,

$$
\lim _{N-M \rightarrow \infty}\left(\frac{N-M}{N-M-(K-x)}\right)^{N-M}=e^{K-x}
$$

and

$$
\lim _{N \rightarrow \infty}\left(\frac{N-K}{N}\right)^{N}=e^{-K}
$$

Note, the product of these three limits is one. Three other terms are

$$
\begin{aligned}
\lim M \rightarrow \infty\left(\frac{M}{M-x}\right)^{1 / 2} & =1 \\
\lim _{N-M \rightarrow \infty}\left(\frac{N-M}{N-M-(K-x)}\right)^{1 / 2} & =1
\end{aligned}
$$

and

$$
\lim _{N \rightarrow \infty}\left(\frac{N-K}{N}\right)^{1 / 2}=1
$$

The only term left is

$$
\begin{aligned}
M / N \rightarrow p, M \rightarrow \infty, N \rightarrow \infty & \frac{(M-x)^{x}(N-M-(K-x))^{K-x}}{(N-K)^{K}} \\
& \lim _{M / N \rightarrow p, M \rightarrow \infty, N \rightarrow \infty}\left(\frac{M-x}{N-K}\right)^{x}\left(\frac{N-M-(K-x)}{N-K}\right)^{K-x} \\
& =p^{x}(1-p)^{K-x} .
\end{aligned}
$$

b. If in (a) we in addition have $K \rightarrow \infty, p \rightarrow 0, M K / N \rightarrow p K \rightarrow \lambda$, by the Poisson approximation to the binomial, we heuristically get

$$
\frac{\binom{M}{x}\binom{N-M}{K-x}}{\binom{N}{K}} \rightarrow\binom{K}{x} p^{x}(1-p)^{K-x} \rightarrow \frac{e^{-\lambda} \lambda^{x}}{x!} .
$$

c. Using Stirling's formula as in (a), we get

$$
\begin{aligned}
N, M, K \rightarrow \infty, \frac{M}{N} \rightarrow 0, \frac{K M}{N} \rightarrow \lambda
\end{aligned} \lim \frac{\binom{M}{x}\binom{N-M}{K-x}}{\binom{N}{K}}
$$

3.12 Consider a sequence of Bernoulli trials with success probability $p$. Define $X=$ number of successes in first $n$ trials and $Y=$ number of failures before the $r$ th success. Then $X$ and $Y$ have the specified binomial and hypergeometric distributions, respectively. And we have

$$
\begin{aligned}
F_{x}(r-1) & =P(X \leq r-1) \\
& =P(r \text { th success on }(n+1) \text { st or later trial }) \\
& =P(\text { at least } n+1-r \text { failures before the } r \text { th success }) \\
& =P(Y \geq n-r+1) \\
& =1-P(Y \leq n-r) \\
& =1-F_{Y}(n-r)
\end{aligned}
$$

3.13 For any $X$ with support $0,1, \ldots$, we have the mean and variance of the 0 -truncated $X_{T}$ are given by

$$
\begin{aligned}
\mathrm{E} X_{T} & =\sum_{x=1}^{\infty} x P\left(X_{T}=x\right)=\sum_{x=1}^{\infty} x \frac{P(X=x)}{P(X>0)} \\
& =\frac{1}{P(X>0)} \sum_{x=1}^{\infty} x P(X=x)=\frac{1}{P(X>0)} \sum_{x=0}^{\infty} x P(X=x)=\frac{\mathrm{E} X}{P(X>0)} .
\end{aligned}
$$

In a similar way we get $\mathrm{E} X_{T}^{2}=\frac{\mathrm{E} X^{2}}{P(X>0)}$. Thus,

$$
\operatorname{Var} X_{T}=\frac{\mathrm{E} X^{2}}{P(X>0)}-\left(\frac{\mathrm{E} X}{P(X>0)}\right)^{2}
$$

a. For $\operatorname{Poisson}(\lambda), P(X>0)=1-P(X=0)=1-\frac{e^{-\lambda} \lambda^{0}}{0!}=1-e^{-\lambda}$, therefore

$$
\begin{aligned}
P\left(X_{T}=x\right) & =\frac{e^{-\lambda} \lambda^{x}}{x!\left(1-e^{-\lambda}\right)} \quad x=1,2, \ldots \\
\mathrm{E} X_{T} & =\lambda /\left(1-e^{-\lambda}\right) \\
\operatorname{Var} X_{T} & =\left(\lambda^{2}+\lambda\right) /\left(1-e^{-\lambda}\right)-\left(\lambda /\left(1-e^{-\lambda}\right)\right)^{2}
\end{aligned}
$$

b. For negative $\operatorname{binomial}(r, p), P(X>0)=1-P(X=0)=1-\binom{r-1}{0} p^{r}(1-p)^{0}=1-p^{r}$. Then

$$
\begin{aligned}
P\left(X_{T}=x\right) & =\frac{\binom{r+x-1}{x} p^{r}(1-p)^{x}}{1-p^{r}}, \quad x=1,2, \ldots \\
\mathrm{E} X_{T} & =\frac{r(1-p)}{p\left(1-p^{r}\right)} \\
\operatorname{Var} X_{T} & =\frac{r(1-p)+r^{2}(1-p)^{2}}{p^{2}\left(1-p^{r}\right)}-\left[\frac{r(1-p)}{p\left(1-p^{r}\right)^{2}}\right] .
\end{aligned}
$$

3.14 a. $\sum_{x=1}^{\infty} \frac{-(1-p)^{x}}{x \log p}=\frac{1}{\log p} \sum_{x=1}^{\infty} \frac{-(1-p)^{x}}{x}=1$, since the sum is the Taylor series for $\log p$.
b.

$$
\mathrm{E} X=\frac{-1}{\log p}\left[\sum_{x=1}^{\infty}(1-p)^{x}\right]=\frac{-1}{\log p}\left[\sum_{x=0}^{\infty}(1-p)^{x}-1\right]==\frac{-1}{\log p}\left[\frac{1}{p}-1\right]=\frac{-1}{\log p}\left(\frac{1-p}{p}\right)
$$

Since the geometric series converges uniformly,

$$
\begin{aligned}
\mathrm{E} X^{2} & =\frac{-1}{\log p} \sum_{x=1}^{\infty} x(1-p)^{x}=\frac{(1-p)}{\log p} \sum_{x=1}^{\infty} \frac{d}{d p}(1-p)^{x} \\
& =\frac{(1-p)}{\log p} \frac{d}{d p} \sum_{x=1}^{\infty}(1-p)^{x}=\frac{(1-p)}{\log p} \frac{d}{d p}\left[\frac{1-p}{p}\right]=\frac{-(1-p)}{p^{2} \log p}
\end{aligned}
$$

Thus

$$
\operatorname{Var} X=\frac{-(1-p)}{p^{2} \log p}\left[1+\frac{(1-p)}{\log p}\right]
$$

Alternatively, the mgf can be calculated,

$$
M_{x}(t)=\frac{-1}{\log p} \sum_{x=1}^{\infty}\left[(1-p) e^{t}\right]^{x}=\frac{\log \left(1+p e^{t}-e^{t}\right)}{\log p}
$$

and can be differentiated to obtain the moments.
3.15 The moment generating function for the negative binomial is

$$
M(t)=\left(\frac{p}{1-(1-p) e^{t}}\right)^{r}=\left(1+\frac{1}{r} \frac{r(1-p)\left(e^{t}-1\right)}{1-(1-p) e^{t}}\right)^{r}
$$

the term

$$
\frac{r(1-p)\left(e^{t}-1\right)}{1-(1-p) e^{t}} \rightarrow \frac{\lambda\left(e^{t}-1\right)}{1}=\lambda\left(e^{t}-1\right) \quad \text { as } r \rightarrow \infty, p \rightarrow 1 \text { and } r(p-1) \rightarrow \lambda
$$

Thus by Lemma 2.3.14, the negative binomial moment generating function converges to $e^{\lambda\left(e^{t}-1\right)}$, the Poisson moment generating function.
3.16 a. Using integration by parts with, $u=t^{\alpha}$ and $d v=e^{-t} d t$, we obtain

$$
\Gamma(\alpha+1)=\int_{0}^{\infty} t^{(\alpha+1)-1} e^{-t} d t=\left.t^{\alpha}\left(-e^{-t}\right)\right|_{0} ^{\infty}-\int_{0}^{\infty} \alpha t^{\alpha-1}\left(-e^{-t}\right) d t=0+\alpha \Gamma(\alpha)=\alpha \Gamma(\alpha)
$$

b. Making the change of variable $z=\sqrt{2 t}$, i.e., $t=z^{2} / 2$, we obtain

$$
\Gamma(1 / 2)=\int_{0}^{\infty} t^{-1 / 2} e^{-t} d t=\int_{0}^{\infty} \frac{\sqrt{2}}{z} e^{-z^{2} / 2} z d z=\sqrt{2} \int_{0}^{\infty} e^{-z^{2} / 2} d z=\sqrt{2} \frac{\sqrt{\pi}}{\sqrt{2}}=\sqrt{\pi}
$$

where the penultimate equality uses (3.3.14).
3.17

$$
\begin{aligned}
\mathrm{E} X^{\nu} & =\int_{0}^{\infty} x^{\nu} \frac{1}{\Gamma(\alpha) \beta^{\alpha}} x^{\alpha-1} e^{-x / \beta} d x=\frac{1}{\Gamma(\alpha) \beta^{\alpha}} \int_{0}^{\infty} x^{(\nu+\alpha)-1} e^{-x / \beta} d x \\
& =\frac{\Gamma(\nu+\alpha) \beta^{\nu+\alpha}}{\Gamma(\alpha) \beta^{\alpha}}=\frac{\beta^{\nu} \Gamma(\nu+\alpha)}{\Gamma(\alpha)}
\end{aligned}
$$

Note, this formula is valid for all $\nu>-\alpha$. The expectation does not exist for $\nu \leq-\alpha$.
3.18 If $Y \sim$ negative $\operatorname{binomial}(r, p)$, its moment generating function is $M_{Y}(t)=\left(\frac{p}{1-(1-p) e^{t}}\right)^{r}$, and, from Theorem 2.3.15, $M_{p Y}(t)=\left(\frac{p}{1-(1-p) e^{p t}}\right)^{r}$. Now use L'Hôpital's rule to calculate

$$
\lim _{p \rightarrow 0}\left(\frac{p}{1-(1-p) e^{p t}}\right)=\lim _{p \rightarrow 0} \frac{1}{(p-1) t e^{p t}+e^{p t}}=\frac{1}{1-t}
$$

so the moment generating function converges to $(1-t)^{-r}$, the moment generating function of a $\operatorname{gamma}(r, 1)$.
3.19 Repeatedly apply the integration-by-parts formula

$$
\frac{1}{\Gamma(n)} \int_{x}^{\infty} z^{n-1} z^{-z} d z=\frac{x^{n-1} e^{-x}}{(n-1)!}+\frac{1}{\Gamma(n-1)} \int_{x}^{\infty} z^{n-2} z^{-z} d z
$$

until the exponent on the second integral is zero. This will establish the formula. If $X \sim$ $\operatorname{gamma}(\alpha, 1)$ and $Y \sim \operatorname{Poisson}(x)$. The probabilistic relationship is $P(X \geq x)=P(Y \leq \alpha-1)$.
3.21 The moment generating function would be defined by $\frac{1}{\pi} \int_{-\infty}^{\infty} \frac{e^{t x}}{1+x^{2}} d x$. On $(0, \infty), e^{t x}>x$, hence

$$
\int_{0}^{\infty} \frac{e^{t x}}{1+x^{2}} d x>\int_{0}^{\infty} \frac{x}{1+x^{2}} d x=\infty
$$

thus the moment generating function does not exist.
3.22 a.

$$
\begin{aligned}
\mathrm{E}(X(X-1)) & =\sum_{x=0}^{\infty} x(x-1) \frac{e^{-\lambda} \lambda^{x}}{x!} \\
& =e^{-\lambda} \lambda^{2} \sum_{x=2}^{\infty} \frac{\lambda^{x-2}}{(x-2)!} \quad(\text { let } y=x-2) \\
& =e^{-\lambda} \lambda^{2} \sum_{y=0}^{\infty} \frac{\lambda^{y}}{y!}=e^{-\lambda} \lambda^{2} e^{\lambda}=\lambda^{2} \\
\mathrm{E} X^{2} & =\lambda^{2}+\mathrm{E} X=\lambda^{2}+\lambda \\
\operatorname{Var} X & =\mathrm{E} X^{2}-(\mathrm{E} X)^{2}=\lambda^{2}+\lambda-\lambda^{2}=\lambda .
\end{aligned}
$$

b.

$$
\begin{aligned}
\mathrm{E}(X(X-1)) & =\sum_{x=0}^{\infty} x(x-1)\binom{r+x-1}{x} p r(1-p)^{x} \\
& =\sum_{x=2}^{\infty} r(r+1)\binom{r+x-1}{x-2} p r(1-p)^{x} \\
& =r(r+1) \frac{(1-p)^{2}}{p^{2}} \sum_{y=0}^{\infty}\binom{r+2+y-1}{y} p r+2(1-p)^{y} \\
& =r(r-1) \frac{(1-p)^{2}}{p^{2}},
\end{aligned}
$$

where in the second equality we substituted $y=x-2$, and in the third equality we use the fact that we are summing over a negative $\operatorname{binomial}(r+2, p)$ pmf. Thus,

$$
\begin{aligned}
\operatorname{Var} X & =\mathrm{E} X(X-1)+\mathrm{E} X-(\mathrm{E} X)^{2} \\
& =r(r+1) \frac{(1-p)^{2}}{p^{2}}+\frac{r(1-p)}{p}-\frac{r^{2}(1-p)^{2}}{p^{2}} \\
& =\frac{r(1-p)}{p^{2}}
\end{aligned}
$$

c.

$$
\begin{aligned}
\mathrm{E} X^{2} & =\int_{0}^{\infty} x^{2} \frac{1}{\Gamma(\alpha) \beta^{\alpha}} x^{\alpha-1} e^{-x / \beta} d x=\frac{1}{\Gamma(\alpha) \beta^{\alpha}} \int_{0}^{\infty} x^{\alpha+1} e^{-x / \beta} d x \\
& =\frac{1}{\Gamma(\alpha) \beta^{\alpha}} \Gamma(\alpha+2) \beta^{\alpha+2}=\alpha(\alpha+1) \beta^{2} . \\
\operatorname{Var} X & =\mathrm{E} X^{2}-(\mathrm{E} X)^{2}=\alpha(\alpha+1) \beta^{2}-\alpha^{2} \beta^{2}=\alpha \beta^{2} .
\end{aligned}
$$

d. (Use 3.3.18)

$$
\begin{aligned}
\mathrm{E} X & =\frac{\Gamma(\alpha+1) \Gamma(\alpha+\beta)}{\Gamma(\alpha+\beta+1) \Gamma(\alpha)}=\frac{\alpha \Gamma(\alpha) \Gamma(\alpha+\beta)}{(\alpha+\beta) \Gamma(\alpha+\beta) \Gamma(\alpha)}=\frac{\alpha}{\alpha+\beta} . \\
\mathrm{E} X^{2} & =\frac{\Gamma(\alpha+2) \Gamma(\alpha+\beta)}{\Gamma(\alpha+\beta+2) \Gamma(\alpha)}=\frac{(\alpha+1) \alpha \Gamma(\alpha) \Gamma(\alpha+\beta)}{(\alpha+\beta+1)(\alpha+\beta) \Gamma(\alpha+\beta) \Gamma(\alpha)}=\frac{\alpha(\alpha+1)}{(\alpha+\beta)(\alpha+\beta+1)} . \\
\operatorname{Var} X & =\mathrm{E} X^{2}-(\mathrm{E} X)^{2}=\frac{\alpha(\alpha+1)}{(\alpha+\beta)(\alpha+\beta+1)}-\frac{\alpha^{2}}{(\alpha+\beta)^{2}}=\frac{\alpha \beta}{(\alpha+\beta)^{2}(\alpha+\beta+1)} .
\end{aligned}
$$

e. The double exponential $(\mu, \sigma)$ pdf is symmetric about $\mu$. Thus, by Exercise $2.26, \mathrm{E} X=\mu$.

$$
\begin{aligned}
\operatorname{Var} X & =\int_{-\infty}^{\infty}(x-\mu)^{2} \frac{1}{2 \sigma} e^{-|x-\mu| / \sigma} d x=\int_{-\infty}^{\infty} \sigma z^{2} \frac{1}{2} e^{-|z|} \sigma d z \\
& =\sigma^{2} \int_{0}^{\infty} z^{2} e^{-z} d z=\sigma^{2} \Gamma(3)=2 \sigma^{2}
\end{aligned}
$$

3.23 a.

$$
\int_{\alpha}^{\infty} x^{-\beta-1} d x=\left.\frac{-1}{\beta} x^{-\beta}\right|_{\alpha} ^{\infty}=\frac{1}{\beta \alpha^{\beta}},
$$

thus $f(x)$ integrates to 1 .
b. $\mathrm{E} X^{n}=\frac{\beta \alpha^{n}}{(n-\beta)}$, therefore

$$
\begin{aligned}
\mathrm{E} X & =\frac{\alpha \beta}{(1-\beta)} \\
\mathrm{E} X^{2} & =\frac{\alpha \beta^{2}}{(2-\beta)} \\
\operatorname{Var} X & =\frac{\alpha \beta^{2}}{2-\beta}-\frac{(\alpha \beta)^{2}}{(1-\beta)^{2}}
\end{aligned}
$$

c. If $\beta<2$ the integral of the second moment is infinite.
3.24 a. $f_{x}(x)=\frac{1}{\beta} e^{-x / \beta}, x>0$. For $Y=X^{1 / \gamma}, f_{Y}(y)=\frac{\gamma}{\beta} e^{-y^{\gamma} / \beta} y^{\gamma-1}, y>0$. Using the transformation $z=y^{\gamma} / \beta$, we calculate

$$
\mathrm{E} Y^{n}=\frac{\gamma}{\beta} \int_{0}^{\infty} y^{\gamma+n-1} e^{-y^{\gamma} / \beta} d y=\beta^{n / \gamma} \int_{0}^{\infty} z^{n / \gamma} e^{-z} d z=\beta^{n / \gamma} \Gamma\left(\frac{n}{\gamma}+1\right)
$$

Thus E $Y=\beta^{1 / \gamma} \Gamma\left(\frac{1}{\gamma}+1\right)$ and $\operatorname{Var} Y=\beta^{2 / \gamma}\left[\Gamma\left(\frac{2}{\gamma}+1\right)-\Gamma^{2}\left(\frac{1}{\gamma}+1\right)\right]$.
b. $f_{x}(x)=\frac{1}{\beta} e^{-x / \beta}, x>0$. For $Y=(2 X / \beta)^{1 / 2}, f_{Y}(y)=y e^{-y^{2} / 2}, y>0$. We now notice that

$$
\mathrm{E} Y=\int_{0}^{\infty} y^{2} e^{-y^{2} / 2} d y=\frac{\sqrt{2 \pi}}{2}
$$

since $\frac{1}{\sqrt{2 \pi}} \int_{-\infty}^{\infty} y^{2} e^{-y^{2} / 2}=1$, the variance of a standard normal, and the integrand is symmetric. Use integration-by-parts to calculate the second moment

$$
\mathrm{E} Y^{2}=\int_{0}^{\infty} y^{3} e^{-y^{2} / 2} d y=2 \int_{0}^{\infty} y e^{-y^{2} / 2} d y=2
$$

where we take $u=y^{2}, d v=y e^{-y^{2} / 2}$. Thus $\operatorname{Var} Y=2(1-\pi / 4)$.
c. The gamma $(a, b)$ density is

$$
f_{X}(x)=\frac{1}{\Gamma(a) b^{a}} x^{a-1} e^{-x / b}
$$

Make the transformation $y=1 / x$ with $d x=-d y / y^{2}$ to get

$$
f_{Y}(y)=f_{X}(1 / y)\left|1 / y^{2}\right|=\frac{1}{\Gamma(a) b^{a}}\left(\frac{1}{y}\right)^{a+1} e^{-1 / b y}
$$

The first two moments are

$$
\begin{aligned}
\mathrm{E} Y & =\frac{1}{\Gamma(a) b^{a}} \int_{0}^{\infty}\left(\frac{1}{y}\right)^{a} e^{-1 / b y}=\frac{\Gamma(a-1) b^{a-1}}{\Gamma(a) b^{a}}=\frac{1}{(a-1) b} \\
\mathrm{E}^{2} & =\frac{\Gamma(a-2) b^{a-2}}{\Gamma(a) b^{a}}=\frac{1}{(a-1)(a-2) b^{2}}
\end{aligned}
$$

and so $\operatorname{Var} Y=\frac{1}{(a-1)^{2}(a-2) b^{2}}$.
d. $f_{x}(x)=\frac{1}{\Gamma(3 / 2) \beta^{3 / 2}} x^{3 / 2-1} e^{-x / \beta}, x>0$. For $Y=(X / \beta)^{1 / 2}, f_{Y}(y)=\frac{2}{\Gamma(3 / 2)} y^{2} e^{-y^{2}}, y>0$. To calculate the moments we use integration-by-parts with $u=y^{2}, d v=y e^{-y^{2}}$ to obtain

$$
\mathrm{E} Y=\frac{2}{\Gamma(3 / 2)} \int_{0}^{\infty} y^{3} e^{-y^{2}} d y=\frac{2}{\Gamma(3 / 2)} \int_{0}^{\infty} y e^{-y^{2}} d y=\frac{1}{\Gamma(3 / 2)}
$$

and with $u=y^{3}, d v=y e^{-y^{2}}$ to obtain

$$
\mathrm{E} Y^{2}=\frac{2}{\Gamma(3 / 2)} \int_{0}^{\infty} y^{4} e^{-y^{2}} d y=\frac{3}{\Gamma(3 / 2)} \int_{0}^{\infty} y^{2} e^{-y^{2}} d y=\frac{3}{\Gamma(3 / 2)} \sqrt{\pi}
$$

Using the fact that $\frac{1}{2 \sqrt{\pi}} \int_{-\infty}^{\infty} y^{2} e^{-y^{2}}=1$, since it is the variance of a $n(0,2)$, symmetry yields $\int_{0}^{\infty} y^{2} e^{-y^{2}} d y=\sqrt{\pi}$. Thus, $\operatorname{Var} Y=6-4 / \pi$, using $\Gamma(3 / 2)=\frac{1}{2} \sqrt{\pi}$.
e. $f_{x}(x)=e^{-x}, x>0$. For $Y=\alpha-\gamma \log X, f_{Y}(y)=e^{-e \frac{\alpha-y}{\gamma}} e^{\frac{\alpha-y}{\gamma}} \frac{1}{\gamma},-\infty<y<\infty$. Calculation of $\mathrm{E} Y$ and $\mathrm{E} Y^{2}$ cannot be done in closed form. If we define

$$
I_{1}=\int_{0}^{\infty} \log x e^{-x} d x, \quad I_{2}=\int_{0}^{\infty}(\log x)^{2} e^{-x} d x
$$

then $\mathrm{E} Y=\mathrm{E}(\alpha-\gamma \log x)=\alpha-\gamma I_{1}$, and $\mathrm{E} Y^{2}=\mathrm{E}(\alpha-\gamma \log x)^{2}=\alpha^{2}-2 \alpha \gamma I_{1}+\gamma^{2} I_{2}$. The constant $I_{1}=.5772157$ is called Euler's constant.
3.25 Note that if T is continuous then,

$$
\begin{aligned}
P(t \leq T \leq t+\delta \mid t \leq T) & =\frac{P(t \leq T \leq t+\delta, t \leq T)}{P(t \leq T)} \\
& =\frac{P(t \leq T \leq t+\delta)}{P(t \leq T)} \\
& =\frac{F_{T}(t+\delta)-F_{T}(t)}{1-F_{T}(t)}
\end{aligned}
$$

Therefore from the definition of derivative,

$$
h_{T}(t)=\frac{1}{1-F_{T}(t)}=\lim _{\delta \rightarrow 0} \frac{F_{T}(t+\delta)-F_{T}(t)}{\delta}=\frac{F_{T}^{\prime}(t)}{1-F_{T}(t)}=\frac{f_{T}(t)}{1-F_{T}(t)}
$$

Also,

$$
-\frac{d}{d t}\left(\log \left[1-F_{T}(t)\right]\right)=-\frac{1}{1-F_{T}(t)}\left(-f_{T}(t)\right)=h_{T}(t)
$$

3.26 a. $f_{T}(t)=\frac{1}{\beta} e^{-t / \beta}$ and $F_{T}(t)=\int_{0}^{t} \frac{1}{\beta} e^{-x / \beta} d x=-\left.e^{-x / \beta}\right|_{0} ^{t}=1-e^{-t / \beta}$. Thus,

$$
h_{T}(t)=\frac{f_{T}(t)}{1-F_{T}(t)}=\frac{(1 / \beta) e^{-t / \beta}}{1-\left(1-e^{-t / \beta}\right)}=\frac{1}{\beta} .
$$

b. $f_{T}(t)=\frac{\gamma}{\beta} t^{\gamma-1} e^{-t^{\gamma} / \beta}, t \geq 0$ and $F_{T}(t)=\int_{0}^{t} \frac{\gamma}{\beta} x^{\gamma-1} e^{-x^{\gamma} / \beta} d x=\int_{0}^{t^{\gamma / \beta}} e^{-u} d u=-\left.e^{-u}\right|_{0} ^{t^{\gamma / \beta}}=$ $1-e^{-t^{\gamma} / \beta}$, where $u=x^{\gamma / \beta}$. Thus,

$$
h_{T}(t)=\frac{(\gamma / \beta) t^{\gamma-1} e^{-t^{\gamma} / \beta}}{e^{-t^{\gamma} / \beta}}=\frac{\gamma}{\beta} t^{\gamma-1}
$$

c. $F_{T}(t)=\frac{1}{1+e^{-(t-\mu) / \beta}}$ and $f_{T}(t)=\frac{e^{-(t-\mu) / \beta}}{\left(1+e^{-(t-\mu) / \beta}\right)^{2}}$. Thus,

$$
h_{T}(t)=\frac{1}{\beta} e^{-(t-\mu) / \beta\left(1+e^{-(t-\mu) / \beta}\right)^{2}} \frac{1}{\frac{e^{-(t-\mu) / \beta}}{1+e^{-(t-\mu) / \beta}}}=\frac{1}{\beta} F_{T}(t)
$$

3.27 a. The uniform pdf satisfies the inequalities of Exercise 2.27, hence is unimodal.
b. For the gamma $(\alpha, \beta) \operatorname{pdf} f(x)$, ignoring constants, $\frac{d}{d x} f(x)=\frac{x^{\alpha-2} e^{-x / \beta}}{\beta}[\beta(\alpha-1)-x]$, which only has one sign change. Hence the pdf is unimodal with mode $\beta(\alpha-1)$.
c. For the $\mathrm{n}\left(\mu, \sigma^{2}\right)$ pdf $f(x)$, ignoring constants, $\frac{d}{d x} f(x)=\frac{x-\mu}{\sigma^{2}} e^{-(-x / \beta)^{2} / 2 \sigma^{2}}$, which only has one sign change. Hence the pdf is unimodal with mode $\mu$.
d. For the beta $(\alpha, \beta)$ pdf $f(x)$, ignoring constants,

$$
\frac{d}{d x} f(x)=x^{\alpha-2}(1-x)^{\beta-2}[(\alpha-1)-x(\alpha+\beta-2)]
$$

which only has one sign change. Hence the pdf is unimodal with mode $\frac{\alpha-1}{\alpha+\beta-2}$.
3.28 a. (i) $\mu$ known,

$$
f\left(x \mid \sigma^{2}\right)=\frac{1}{\sqrt{2 \pi} \sigma} \exp \left(\frac{-1}{2 \sigma^{2}}(x-\mu)^{2}\right)
$$

$h(x)=1, \quad c\left(\sigma^{2}\right)=\frac{1}{\sqrt{2 \pi \sigma^{2}}} I_{(0, \infty)}\left(\sigma^{2}\right), \quad w_{1}\left(\sigma^{2}\right)=-\frac{1}{2 \sigma^{2}}, \quad t_{1}(x)=(x-\mu)^{2}$.
(ii) $\sigma^{2}$ known,

$$
\begin{array}{r}
f(x \mid \mu)=\frac{1}{\sqrt{2 \pi} \sigma} \exp \left(-\frac{x^{2}}{2 \sigma^{2}}\right) \exp \left(-\frac{\mu^{2}}{2 \sigma^{2}}\right) \exp \left(\mu \frac{x}{\sigma^{2}}\right) \\
h(x)=\exp \left(\frac{-x^{2}}{2 \sigma^{2}}\right), \quad c(\mu)=\frac{1}{\sqrt{2 \pi} \sigma} \exp \left(\frac{-\mu^{2}}{2 \sigma^{2}}\right), \quad w_{1}(\mu)=\mu, \quad t_{1}(x)=\frac{x}{\sigma^{2}}
\end{array}
$$

b. (i) $\alpha$ known,

$$
f(x \mid \beta)=\frac{1}{\Gamma(\alpha) \beta^{\alpha}} x^{\alpha-1} e^{\frac{-x}{\beta}}
$$

$h(x)=\frac{x^{\alpha-1}}{\Gamma(\alpha)}, x>0, \quad c(\beta)=\frac{1}{\beta^{\alpha}}, \quad w_{1}(\beta)=\frac{1}{\beta}, \quad t_{1}(x)=-x$.
(ii) $\beta$ known,

$$
f(x \mid \alpha)=e^{-x / \beta} \frac{1}{\Gamma(\alpha) \beta^{\alpha}} \exp ((\alpha-1) \log x)
$$

$h(x)=e^{-x / \beta}, x>0, \quad c(\alpha)=\frac{1}{\Gamma(\alpha) \beta^{\alpha}} \quad w_{1}(\alpha)=\alpha-1, \quad t_{1}(x)=\log x$.
(iii) $\alpha, \beta$ unknown,

$$
f(x \mid \alpha, \beta)=\frac{1}{\Gamma(\alpha) \beta^{\alpha}} \exp \left((\alpha-1) \log x-\frac{x}{\beta}\right)
$$

$h(x)=I_{\{x>0\}}(x), \quad c(\alpha, \beta)=\frac{1}{\Gamma(\alpha) \beta^{\alpha}}, \quad w_{1}(\alpha)=\alpha-1, \quad t_{1}(x)=\log x$, $w_{2}(\alpha, \beta)=-1 / \beta, \quad t_{2}(x)=x$.
c. (i) $\alpha$ known, $h(x)=x^{\alpha-1} I_{[0,1]}(x), \quad c(\beta)=\frac{1}{B(\alpha, \beta)}, \quad w_{1}(\beta)=\beta-1, \quad t_{1}(x)=\log (1-x)$.
(ii) $\beta$ known, $h(x)=(1-x)^{\beta-1} I_{[0,1]}(x), \quad c(\alpha)=\frac{1}{B(\alpha, \beta)}, \quad w_{1}(x)=\alpha-1, \quad t_{1}(x)=\log x$.
(iii) $\alpha, \beta$ unknown,

$$
\begin{aligned}
& h(x)=I_{[0,1]}(x), c(\alpha, \beta)=\frac{1}{B(\alpha, \beta)}, \quad w_{1}(\alpha)=\alpha-1, \quad t_{1}(x)=\log x, \\
& w_{2}(\beta)=\beta-1, t_{2}(x)=\log (1-x)
\end{aligned}
$$

d. $h(x)=\frac{1}{x!} I_{\{0,1,2, \ldots\}}(x), \quad c(\theta)=e^{-\theta}, \quad w_{1}(\theta)=\log \theta, \quad t_{1}(x)=x$.
e. $h(x)=\binom{x-1}{r-1} I_{\{r, r+1, \ldots\}}(x), \quad c(p)=\left(\frac{p}{1-p}\right)^{r}, \quad w_{1}(p)=\log (1-p), \quad t_{1}(x)=x$.
3.29 a. For the $\mathrm{n}\left(\mu, \sigma^{2}\right)$

$$
f(x)=\left(\frac{1}{\sqrt{2 \pi}}\right)\left(\frac{e^{-\mu^{2} / 2 \sigma^{2}}}{\sigma}\right)\left(e^{-x^{2} / 2 \sigma^{2}+x \mu / \sigma^{2}}\right)
$$

so the natural parameter is $\left(\eta_{1}, \eta_{2}\right)=\left(-1 / 2 \sigma^{2}, \mu / \sigma^{2}\right)$ with natural parameter space $\left\{\left(\eta_{1}, \eta_{2}\right): \eta_{1}<0,-\infty<\eta_{2}<\infty\right\}$.
b. For the $\operatorname{gamma}(\alpha, \beta)$,

$$
f(x)=\left(\frac{1}{\Gamma(\alpha) \beta^{\alpha}}\right)\left(e^{(\alpha-1) \log x-x / \beta}\right)
$$

so the natural parameter is $\left(\eta_{1}, \eta_{2}\right)=(\alpha-1,-1 / \beta)$ with natural parameter space $\left\{\left(\eta_{1}, \eta_{2}\right): \eta_{1}>-1, \eta_{2}<0\right\}$.
c. For the $\operatorname{beta}(\alpha, \beta)$,

$$
f(x)=\left(\frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha) \Gamma(\beta)}\right)\left(e^{(\alpha-1) \log x+(\beta-1) \log (1-x)}\right)
$$

so the natural parameter is $\left(\eta_{1}, \eta_{2}\right)=(\alpha-1, \beta-1)$ and the natural parameter space is $\left\{\left(\eta_{1}, \eta_{2}\right): \eta_{1}>-1, \eta_{2}>-1\right\}$.
d. For the Poisson

$$
f(x)=\left(\frac{1}{x!}\right)\left(e^{-\theta}\right) e^{x \log \theta}
$$

so the natural parameter is $\eta=\log \theta$ and the natural parameter space is $\{\eta:-\infty<\eta<\infty\}$.
e. For the negative $\operatorname{binomial}(r, p), r$ known,

$$
P(X=x)=\binom{r+x-1}{x}\left(p^{r}\right)\left(e^{x \log (1-p)}\right)
$$

so the natural parameter is $\eta=\log (1-p)$ with natural parameter space $\{\eta: \eta<0\}$.
3.31 a.

$$
\begin{aligned}
0= & \frac{\partial}{\partial \theta} \int h(x) c(\theta) \exp \left(\sum_{i=1}^{k} w_{i}(\theta) t_{i}(x)\right) d x \\
= & \int h(x) c^{\prime}(\theta) \exp \left(\sum_{i=1}^{k} w_{i}(\theta) t_{i}(x)\right) d x \\
& +\int h(x) c(\theta) \exp \left(\sum_{i=1}^{k} w_{i}(\theta) t_{i}(x)\right)\left(\sum_{i=1}^{k} \frac{\partial w_{i}(\theta)}{\partial \theta_{j}} t_{i}(x)\right) d x \\
= & \int h(x)\left[\frac{\partial}{\partial \theta_{j}} \log c(\theta)\right] c(\theta) \exp \left(\sum_{i=1}^{k} w_{i}(\theta) t_{i}(x)\right) d x+\mathrm{E}\left[\sum_{i=1}^{k} \frac{\partial w_{i}(\theta)}{\partial \theta_{j}} t_{i}(x)\right] \\
= & \frac{\partial}{\partial \theta_{j}} \log c(\theta)+\mathrm{E}\left[\sum_{i=1}^{k} \frac{\partial w_{i}(\theta)}{\partial \theta_{j}} t_{i}(x)\right]
\end{aligned}
$$

Therefore $\mathrm{E}\left[\sum_{i=1}^{k} \frac{\partial w_{i}(\theta)}{\partial \theta_{j}} t_{i}(x)\right]=-\frac{\partial}{\partial \theta_{j}} \log c(\theta)$.
b.

$$
\begin{aligned}
& 0=\frac{\partial^{2}}{\partial \theta^{2}} \int h(x) c(\theta) \exp \left(\sum_{i=1}^{k} w_{i}(\theta) t_{i}(x)\right) d x \\
& =\int h(x) c^{\prime \prime}(\theta) \exp \left(\sum_{i=1}^{k} w_{i}(\theta) t_{i}(x)\right) d x \\
& +\int h(x) c^{\prime}(\theta) \exp \left(\sum_{i=1}^{k} w_{i}(\theta) t_{i}(x)\right)\left(\sum_{i=1}^{k} \frac{\partial w_{i}(\theta)}{\partial \theta_{j}} t_{i}(x)\right) d x \\
& +\int h(x) c^{\prime}(\theta) \exp \left(\sum_{i=1}^{k} w_{i}(\theta) t_{i}(x)\right)\left(\sum_{i=1}^{k} \frac{\partial w_{i}(\theta)}{\partial \theta_{j}} t_{i}(x)\right) d x \\
& +\int h(x) c(\theta) \exp \left(\sum_{i=1}^{k} w_{i}(\theta) t_{i}(x)\right)\left(\sum_{i=1}^{k} \frac{\partial w_{i}(\theta)}{\partial \theta_{j}} t_{i}(x)\right)^{2} d x \\
& +\int h(x) c(\theta) \exp \left(\sum_{i=1}^{k} w_{i}(\theta) t_{i}(x)\right)\left(\sum_{i=1}^{k} \frac{\partial^{2} w_{i}(\theta)}{\partial \theta_{j}^{2}} t_{i}(x)\right) d x \\
& =\int h(x)\left[\frac{\partial^{2}}{\partial \theta_{j}^{2}} \log c(\theta)\right] c(\theta) \exp \left(\sum_{i=1}^{k} w_{i}(\theta) t_{i}(x)\right) d x \\
& +\int h(x)\left[\frac{c^{\prime}(\theta)}{c(\theta)}\right]^{2} c(\theta) \exp \left(\sum_{i=1}^{k} w_{i}(\theta) t_{i}(x)\right) d x \\
& +2\left(\frac{\partial}{\partial \theta_{j}} \log c(\theta)\right) \mathrm{E}\left[\sum_{i=1}^{k} \frac{\partial w_{i}(\theta)}{\partial \theta_{j}} t_{i}(x)\right] \\
& +\mathrm{E}\left[\left(\sum_{i=1}^{k} \frac{\partial w_{i}(\theta)}{\partial \theta_{j}} t_{i}(x)\right)^{2}\right]+\mathrm{E}\left[\sum_{i=1}^{k} \frac{\partial^{2} w_{i}(\theta)}{\partial \theta_{j}^{2}} t_{i}(x)\right] \\
& =\frac{\partial^{2}}{\partial \theta_{j}^{2}} \log c(\theta)+\left[\frac{\partial}{\partial \theta_{j}} \log c(\theta)\right]^{2} \\
& -2 \mathrm{E}\left[\sum_{i=1}^{k} \frac{\partial w_{i}(\theta)}{\partial \theta_{j}} t_{i}(x)\right] \mathrm{E}\left[\sum_{i=1}^{k} \frac{\partial w_{i}(\theta)}{\partial \theta_{j}} t_{i}(x)\right] \\
& +\mathrm{E}\left[\left(\sum_{i=1}^{k} \frac{\partial w_{i}(\theta)}{\partial \theta_{j}} t_{i}(x)\right)^{2}\right]+\mathrm{E}\left[\sum_{i=1}^{k} \frac{\partial^{2} w_{i}(\theta)}{\partial \theta_{j}^{2}} t_{i}(x)\right] \\
& =\frac{\partial^{2}}{\partial \theta_{j}^{2}} \log c(\theta)+\operatorname{Var}\left(\sum_{i=1}^{k} \frac{\partial w_{i}(\theta)}{\partial \theta_{j}} t_{i}(x)\right)+\mathrm{E}\left[\sum_{i=1}^{k} \frac{\partial^{2} w_{i}(\theta)}{\partial \theta_{j}^{2}} t_{i}(x)\right] .
\end{aligned}
$$

Therefore $\operatorname{Var}\left(\sum_{i=1}^{k} \frac{\partial w_{i}(\theta)}{\partial \theta_{j}} t_{i}(x)\right)=-\frac{\partial^{2}}{\partial \theta_{j}^{2}} \log c(\theta)-\mathrm{E}\left[\sum_{i=1}^{k} \frac{\partial^{2} w_{i}(\theta)}{\partial \theta_{j}^{2}} t_{i}(x)\right]$.
3.33 a. (i) $h(x)=e^{x} I_{\{-\infty<x<\infty\}}(x), \quad c(\theta)=\frac{1}{\sqrt{2 \pi \theta}} \exp \left(\frac{-\theta}{2}\right) \theta>0, \quad w_{1}(\theta)=\frac{1}{2 \theta}, \quad t_{1}(x)=-x^{2}$.
(ii) The nonnegative real line.
b. (i) $h(x)=I_{\{-\infty<x<\infty\}}(x), \quad c(\theta)=\frac{1}{\sqrt{2 \pi a \theta^{2}}} \exp \left(\frac{-1}{2 a}\right)-\infty<\theta<\infty, a>0$, $w_{1}(\theta)=\frac{1}{2 a \theta^{2}}, \quad w_{2}(\theta)=\frac{1}{a \theta}, \quad t_{1}(x)=-x^{2}, \quad t_{2}(x)=x$.
(ii) A parabola.
c. (i) $h(x)=\frac{1}{x} I_{\{0<x<\infty\}}(x), \quad c(\alpha)=\frac{\alpha^{\alpha}}{\Gamma(\alpha)} \alpha>0, \quad w_{1}(\alpha)=\alpha, \quad w_{2}(\alpha)=\alpha$, $t_{1}(x)=\log (x), \quad t_{2}(x)=-x$.
(ii) A line.
d. (i) $h(x)=C \exp \left(x^{4}\right) I_{\{-\infty<x<\infty\}}(x), \quad c(\theta)=\exp \left(\theta^{4}\right)-\infty<\theta<\infty, \quad w_{1}(\theta)=\theta$, $w_{2}(\theta)=\theta^{2}, \quad w_{3}(\theta)=\theta^{3}, \quad t_{1}(x)=-4 x^{3}, \quad t_{2}(x)=6 x^{2}, \quad t_{3}(x)=-4 x$.
(ii) The curve is a spiral in 3 -space.
(iii) A good picture can be generated with the Mathematica statement
3.35 a. In Exercise 3.34(a) $w_{1}(\lambda)=\frac{1}{2 \lambda}$ and for a $\mathrm{n}\left(e^{\theta}, e^{\theta}\right), w_{1}(\theta)=\frac{1}{2 e^{\theta}}$.
b. $\mathrm{E} X=\mu=\alpha \beta$, then $\beta=\frac{\mu}{\alpha}$. Therefore $h(x)=\frac{1}{x} I_{\{0<x<\infty\}}(x)$,
$c(\alpha)=\frac{\alpha^{\alpha}}{\Gamma(\alpha)\left(\frac{\mu}{\alpha}\right)^{\alpha}}, \alpha>0, \quad w_{1}(\alpha)=\alpha, \quad w_{2}(\alpha)=\frac{\alpha}{\mu}, \quad t_{1}(x)=\log (x), \quad t_{2}(x)=-x$.
c. From (b) then $\left(\alpha_{1}, \ldots, \alpha_{n}, \beta_{1}, \ldots, \beta_{n}\right)=\left(\alpha_{1}, \ldots, \alpha_{n}, \frac{\alpha_{1}}{\mu}, \ldots, \frac{\alpha_{n}}{\mu}\right)$
3.37 The pdf $\left(\frac{1}{\sigma}\right) f\left(\frac{(x-\mu)}{\sigma}\right)$ is symmetric about $\mu$ because, for any $\epsilon>0$,

$$
\frac{1}{\sigma} f\left(\frac{(\mu+\epsilon)-\mu}{\sigma}\right)=\frac{1}{\sigma} f\left(\frac{\epsilon}{\sigma}\right)=\frac{1}{\sigma} f\left(-\frac{\epsilon}{\sigma}\right)=\frac{1}{\sigma} f\left(\frac{(\mu-\epsilon)-\mu}{\sigma}\right)
$$

Thus, by Exercise $2.26 \mathrm{~b}, \mu$ is the median.
3.38 $P\left(X>x_{\alpha}\right)=P\left(\sigma Z+\mu>\sigma z_{\alpha}+\mu\right)=P\left(Z>z_{\alpha}\right)$ by Theorem 3.5.6.
3.39 First take $\mu=0$ and $\sigma=1$.
a. The pdf is symmetric about 0 , so 0 must be the median. Verifying this, write

$$
P(Z \geq 0)=\int_{0}^{\infty} \frac{1}{\pi} \frac{1}{1+z^{2}} d z=\left.\frac{1}{\pi} \tan ^{-1}(z)\right|_{0} ^{\infty}=\frac{1}{\pi}\left(\frac{\pi}{2}-0\right)=\frac{1}{2} .
$$

b. $P(Z \geq 1)=\left.\frac{1}{\pi} \tan ^{-1}(z)\right|_{1} ^{\infty}=\frac{1}{\pi}\left(\frac{\pi}{2}-\frac{\pi}{4}\right)=\frac{1}{4}$. By symmetry this is also equal to $P(Z \leq-1)$. Writing $z=(x-\mu) / \sigma$ establishes $P(X \geq \mu)=\frac{1}{2}$ and $P(X \geq \mu+\sigma)=\frac{1}{4}$.
3.40 Let $X \sim f(x)$ have mean $\mu$ and variance $\sigma^{2}$. Let $Z=\frac{X-\mu}{\sigma}$. Then

$$
\mathrm{E} Z=\left(\frac{1}{\sigma}\right) \mathrm{E}(X-\mu)=0
$$

and

$$
\operatorname{Var} Z=\operatorname{Var}\left(\frac{X-\mu}{\sigma}\right)=\left(\frac{1}{\sigma^{2}}\right) \operatorname{Var}(X-\mu)=\left(\frac{1}{\sigma^{2}}\right) \operatorname{Var} X=\frac{\sigma^{2}}{\sigma^{2}}=1
$$

Then compute the pdf of $Z, f_{Z}(z)=f_{x}(\sigma z+\mu) \cdot \sigma=\sigma f_{x}(\sigma z+\mu)$ and use $f_{Z}(z)$ as the standard pdf.
3.41 a. This is a special case of Exercise 3.42a.
b. This is a special case of Exercise 3.42b.
3.42 a. Let $\theta_{1}>\theta_{2}$. Let $X_{1} \sim f\left(x-\theta_{1}\right)$ and $X_{2} \sim f\left(x-\theta_{2}\right)$. Let $F(z)$ be the cdf corresponding to $f(z)$ and let $Z \sim f(z)$.Then

$$
\begin{aligned}
F\left(x \mid \theta_{1}\right) & =P\left(X_{1} \leq x\right)=P\left(Z+\theta_{1} \leq x\right)=P\left(Z \leq x-\theta_{1}\right)=F\left(x-\theta_{1}\right) \\
& \leq F\left(x-\theta_{2}\right)=P\left(Z \leq x-\theta_{2}\right)=P\left(Z+\theta_{2} \leq x\right)=P\left(X_{2} \leq x\right) \\
& =F\left(x \mid \theta_{2}\right)
\end{aligned}
$$

The inequality is because $x-\theta_{2}>x-\theta_{1}$, and $F$ is nondecreasing. To get strict inequality for some $x$, let $(a, b]$ be an interval of length $\theta_{1}-\theta_{2}$ with $P(a<Z \leq b)=F(b)-F(a)>0$. Let $x=a+\theta_{1}$. Then

$$
\begin{aligned}
F\left(x \mid \theta_{1}\right) & =F\left(x-\theta_{1}\right)=F\left(a+\theta_{1}-\theta_{1}\right)=F(a) \\
& <F(b)=F\left(a+\theta_{1}-\theta_{2}\right)=F\left(x-\theta_{2}\right)=F\left(x \mid \theta_{2}\right)
\end{aligned}
$$

b. Let $\sigma_{1}>\sigma_{2}$. Let $X_{1} \sim f\left(x / \sigma_{1}\right)$ and $X_{2} \sim f\left(x / \sigma_{2}\right)$. Let $F(z)$ be the cdf corresponding to $f(z)$ and let $Z \sim f(z)$. Then, for $x>0$,

$$
\begin{aligned}
F\left(x \mid \sigma_{1}\right) & =P\left(X_{1} \leq x\right)=P\left(\sigma_{1} Z \leq x\right)=P\left(Z \leq x / \sigma_{1}\right)=F\left(x / \sigma_{1}\right) \\
& \leq F\left(x / \sigma_{2}\right)=P\left(Z \leq x / \sigma_{2}\right)=P\left(\sigma_{2} Z \leq x\right)=P\left(X_{2} \leq x\right) \\
& =F\left(x \mid \sigma_{2}\right)
\end{aligned}
$$

The inequality is because $x / \sigma_{2}>x / \sigma_{1}$ (because $x>0$ and $\sigma_{1}>\sigma_{2}>0$ ), and $F$ is nondecreasing. For $x \leq 0, F\left(x \mid \sigma_{1}\right)=P\left(X_{1} \leq x\right)=0=P\left(X_{2} \leq x\right)=F\left(x \mid \sigma_{2}\right)$. To get strict inequality for some $x$, let $(a, b]$ be an interval such that $a>0, b / a=\sigma_{1} / \sigma_{2}$ and $P(a<Z \leq b)=F(b)-F(a)>0$. Let $x=a \sigma_{1}$. Then

$$
\begin{aligned}
F\left(x \mid \sigma_{1}\right) & =F\left(x / \sigma_{1}\right)=F\left(a \sigma_{1} / \sigma_{1}\right)=F(a) \\
& <F(b)=F\left(a \sigma_{1} / \sigma_{2}\right)=F\left(x / \sigma_{2}\right) \\
& =F\left(x \mid \sigma_{2}\right)
\end{aligned}
$$

3.43 a. $F_{Y}(y \mid \theta)=1-F_{X}\left(\left.\frac{1}{y} \right\rvert\, \theta\right) y>0$, by Theorem 2.1.3. For $\theta_{1}>\theta_{2}$,

$$
F_{Y}\left(y \mid \theta_{1}\right)=1-F_{X}\left(\left.\frac{1}{y} \right\rvert\, \theta_{1}\right) \leq 1-F_{X}\left(\left.\frac{1}{y} \right\rvert\, \theta_{2}\right)=F_{Y}\left(y \mid \theta_{2}\right)
$$

for all $y$, since $F_{X}(x \mid \theta)$ is stochastically increasing and if $\theta_{1}>\theta_{2}, F_{X}\left(x \mid \theta_{2}\right) \leq F_{X}\left(x \mid \theta_{1}\right)$ for all $x$. Similarly, $F_{Y}\left(y \mid \theta_{1}\right)=1-F_{X}\left(\left.\frac{1}{y} \right\rvert\, \theta_{1}\right)<1-F_{X}\left(\left.\frac{1}{y} \right\rvert\, \theta_{2}\right)=F_{Y}\left(y \mid \theta_{2}\right)$ for some $y$, since if $\theta_{1}>\theta_{2}, F_{X}\left(x \mid \theta_{2}\right)<F_{X}\left(x \mid \theta_{1}\right)$ for some $x$. Thus $F_{Y}(y \mid \theta)$ is stochastically decreasing in $\theta$.
b. $F_{X}(x \mid \theta)$ is stochastically increasing in $\theta$. If $\theta_{1}>\theta_{2}$ and $\theta_{1}, \theta_{2}>0$ then $\frac{1}{\theta_{2}}>\frac{1}{\theta_{1}}$. Therefore $F_{X}\left(x \left\lvert\, \frac{1}{\theta_{1}}\right.\right) \leq F_{X}\left(x \left\lvert\, \frac{1}{\theta_{2}}\right.\right.$ ) for all $x$ and $F_{X}\left(x \left\lvert\, \frac{1}{\theta_{1}}\right.\right)<F_{X}\left(x \left\lvert\, \frac{1}{\theta_{2}}\right.\right)$ for some $x$. Thus $F_{X}\left(x \left\lvert\, \frac{1}{\theta}\right.\right)$ is stochastically decreasing in $\theta$.
3.44 The function $g(x)=|x|$ is a nonnegative function. So by Chebychev's Inequality,

$$
P(|X| \geq b) \leq \mathrm{E}|X| / b
$$

Also, $P(|X| \geq b)=P\left(X^{2} \geq b^{2}\right)$. Since $g(x)=x^{2}$ is also nonnegative, again by Chebychev's Inequality we have

$$
P(|X| \geq b)=P\left(X^{2} \geq b^{2}\right) \leq \mathrm{E} X^{2} / b^{2}
$$

For $X \sim \operatorname{exponential(1),~} \mathrm{E}|X|=\mathrm{E} X=1$ and $\mathrm{E} X^{2}=\operatorname{Var} X+(\mathrm{E} X)^{2}=2$. For $b=3$,

$$
\mathrm{E}|X| / b=1 / 3>2 / 9=\mathrm{E} X^{2} / b^{2}
$$

Thus $\mathrm{E} X^{2} / b^{2}$ is a better bound. But for $b=\sqrt{2}$,

$$
\mathrm{E}|X| / b=1 / \sqrt{2}<1=\mathrm{E} X^{2} / b^{2}
$$

Thus $\mathrm{E}|X| / b$ is a better bound.
3.45 a.

$$
\begin{aligned}
M_{X}(t) & =\int_{-\infty}^{\infty} e^{t x} f_{X}(x) d x \geq \int_{a}^{\infty} e^{t x} f_{X}(x) d x \\
& \geq e^{t a} \int_{a}^{\infty} f_{X}(x) d x=e^{t a} P(X \geq a)
\end{aligned}
$$

where we use the fact that $e^{t x}$ is increasing in $x$ for $t>0$.
b.

$$
\begin{aligned}
M_{X}(t) & =\int_{-\infty}^{\infty} e^{t x} f_{X}(x) d x \geq \int_{-\infty}^{a} e^{t x} f_{X}(x) d x \\
& \geq e^{t a} \int_{-\infty}^{a} f_{X}(x) d x=e^{t a} P(X \leq a)
\end{aligned}
$$

where we use the fact that $e^{t x}$ is decreasing in $x$ for $t<0$.
c. $h(t, x)$ must be nonnegative.
3.46 For $X \sim \operatorname{uniform}(0,1), \mu=\frac{1}{2}$ and $\sigma^{2}=\frac{1}{12}$, thus

$$
P(|X-\mu|>k \sigma)=1-P\left(\frac{1}{2}-\frac{k}{\sqrt{12}} \leq X \leq \frac{1}{2}+\frac{k}{\sqrt{12}}\right)= \begin{cases}1-\frac{2 k}{\sqrt{12}} & k<\sqrt{3} \\ 0 & k \geq \sqrt{3}\end{cases}
$$

For $X \sim \operatorname{exponential}(\lambda), \mu=\lambda$ and $\sigma^{2}=\lambda^{2}$, thus

$$
P(|X-\mu|>k \sigma)=1-P(\lambda-k \lambda \leq X \leq \lambda+k \lambda)= \begin{cases}1+e^{-(k+1)}-e^{k-1} & k \leq 1 \\ e^{-(k+1)} & k>1\end{cases}
$$

From Example 3.6.2, Chebychev's Inequality gives the bound $P(|X-\mu|>k \sigma) \leq 1 / k^{2}$.

| Comparison of probabilities |  |  |  |
| :---: | :---: | :---: | :---: |
| $k$ | $\mathrm{u}(0,1)$ <br> exact | $\exp (\lambda)$ <br> exact | Chebychev |
| .1 | .942 | .926 | 100 |
| .5 | .711 | .617 | 4 |
| 1 | .423 | .135 | 1 |
| 1.5 | .134 | .0821 | .44 |
| $\sqrt{3}$ | 0 | 0.0651 | .33 |
| 2 | 0 | 0.0498 | .25 |
| 4 | 0 | 0.00674 | .0625 |
| 10 | 0 | 0.0000167 | .01 |

So we see that Chebychev's Inequality is quite conservative.
3.47

$$
\begin{aligned}
P(|Z|>t) & =2 P(Z>t)=2 \frac{1}{\sqrt{2 \pi}} \int_{t}^{\infty} e^{-x^{2} / 2} d x \\
& =\sqrt{\frac{2}{\pi}} \int_{t}^{\infty} \frac{1+x^{2}}{1+x^{2}} e^{-x^{2} / 2} d x \\
& =\sqrt{\frac{2}{\pi}}\left[\int_{t}^{\infty} \frac{1}{1+x^{2}} e^{-x^{2} / 2} d x+\int_{t}^{\infty} \frac{x^{2}}{1+x^{2}} e^{-x^{2} / 2} d x\right]
\end{aligned}
$$

To evaluate the second term, let $u=\frac{x}{1+x^{2}}, d v=x e^{-x^{2} / 2} d x, v=-e^{-x^{2} / 2}, d u=\frac{1-x^{2}}{\left(1+x^{2}\right)^{2}}$, to obtain

$$
\begin{aligned}
\int_{t}^{\infty} \frac{x^{2}}{1+x^{2}} e^{-x^{2} / 2} d x & =\left.\frac{x}{1+x^{2}}\left(-e^{-x^{2} / 2}\right)\right|_{t} ^{\infty}-\int_{t}^{\infty} \frac{1-x^{2}}{\left(1+x^{2}\right)^{2}}\left(-e^{-x^{2} / 2}\right) d x \\
& =\frac{t}{1+t^{2}} e^{-t^{2} / 2}+\int_{t}^{\infty} \frac{1-x^{2}}{\left(1+x^{2}\right)^{2}} e^{-x^{2} / 2} d x
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
P(Z \geq t) & =\sqrt{\frac{2}{\pi}} \frac{t}{1+t^{2}} e^{-t^{2} / 2}+\sqrt{\frac{2}{\pi}} \int_{t}^{\infty}\left(\frac{1}{1+x^{2}}+\frac{1-x^{2}}{\left(1+x^{2}\right)^{2}}\right) e^{-x^{2} / 2} d x \\
& =\sqrt{\frac{2}{\pi}} \frac{t}{1+t^{2}} e^{-t^{2} / 2}+\sqrt{\frac{2}{\pi}} \int_{t}^{\infty}\left(\frac{2}{\left(1+x^{2}\right)^{2}}\right) e^{-x^{2} / 2} d x \\
& \geq \sqrt{\frac{2}{\pi}} \frac{t}{1+t^{2}} e^{-t^{2} / 2}
\end{aligned}
$$

3.48 For the negative binomial

$$
P(X=x+1)=\binom{r+x+1-1}{x+1} p^{r}(1-p)^{x+1}=\left(\frac{r+x}{x+1}\right)(1-p) P(X=x)
$$

For the hypergeometric

$$
P(X=x+1)= \begin{cases}\frac{(M-x)(k-x+x+1)(x+1)}{P(X=x)} & \text { if } x<k, x<M, x \geq M-(N-k) \\
\frac{\binom{M}{x+1}\left(\begin{array}{l}
N-M-x) \\
k-x-1) \\
k
\end{array}\right)}{0} & \text { if } x=M-(N-k)-1 \\
0 & \text { otherwise } .\end{cases}
$$

3.49 a.

$$
\mathrm{E}(g(X)(X-\alpha \beta))=\int_{0}^{\infty} g(x)(x-\alpha \beta) \frac{1}{\Gamma(\alpha)} \beta^{\alpha} x^{\alpha-1} e^{-x / \beta} d x
$$

Let $u=g(x), d u=g^{\prime}(x), d v=(x-\alpha \beta) x^{\alpha-1} e^{-x / \beta}, v=-\beta x^{\alpha} e^{-x / \beta}$. Then

$$
\mathrm{E} g(X)(X-\alpha \beta)=\frac{1}{\Gamma(\alpha) \beta^{\alpha}}\left[-\left.g(x) \beta x^{\alpha} e^{-x / \beta}\right|_{0} ^{\infty}+\beta \int_{0}^{\infty} g^{\prime}(x) x^{\alpha} e^{-x / \beta} d x\right]
$$

Assuming $g(x)$ to be differentiable, $\mathrm{E}\left|X g^{\prime}(X)\right|<\infty$ and $\lim _{x \rightarrow \infty} g(x) x^{\alpha} e^{-x / \beta}=0$, the first term is zero, and the second term is $\beta \mathrm{E}\left(X g^{\prime}(X)\right)$.
b.

$$
\mathrm{E}\left[g(X)\left(\beta-(\alpha-1) \frac{1-X}{x}\right)\right]=\frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha) \Gamma(\beta)} \int_{0}^{1} g(x)\left(\beta-(\alpha-1) \frac{1-x}{x}\right) x^{\alpha-1}(1-x)^{\beta-1} d x
$$

Let $u=g(x)$ and $d v=\left(\beta-(\alpha-1) \frac{1-x}{x}\right) x^{\alpha-1}(1-x)^{\beta}$. The expectation is

$$
\frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha) \Gamma(\beta)}\left[\left.g(x) x^{\alpha-1}(1-x)^{\beta}\right|_{0} ^{1}+\int_{0}^{1}(1-x) g^{\prime}(x) x^{\alpha-1}(1-x)^{\beta-1} d x\right]=\mathrm{E}\left((1-X) g^{\prime}(X)\right)
$$

assuming the first term is zero and the integral exists.
3.50 The proof is similar to that of part a) of Theorem 3.6.8. For $X \sim$ negative $\operatorname{binomial}(r, p)$,

$$
\begin{aligned}
\mathrm{E} g & (X) \\
& =\sum_{x=0}^{\infty} g(x)\binom{r+x-1}{x} p^{r}(1-p)^{x} \\
& =\sum_{y=1}^{\infty} g(y-1)\binom{r+y-2}{y-1} p^{r}(1-p)^{y-1} \quad(\text { set } y=x+1) \\
& =\sum_{y=1}^{\infty} g(y-1)\left(\frac{y}{r+y-1}\right)\binom{r+y-1}{y} p^{r}(1-p)^{y-1} \\
& \left.=\sum_{y=0}^{\infty}\left[\frac{y}{r+y-1} \frac{g(y-1)}{1-p}\right]\left[\binom{r+y-1}{y} p^{r}(1-p)^{y}\right] \quad \text { (the summand is zero at } \mathrm{y}=0\right) \\
& =\mathrm{E}\left(\frac{X}{r+X-1} \frac{g(X-1)}{1-p}\right),
\end{aligned}
$$

where in the third equality we use the fact that $\binom{r+y-2}{y-1}=\left(\frac{y}{r+y-1}\right)\binom{r+y-1}{y}$.

## Chapter 4

## Multiple Random Variables

4.1 Since the distribution is uniform, the easiest way to calculate these probabilities is as the ratio of areas, the total area being 4 .
a. The circle $x^{2}+y^{2} \leq 1$ has area $\pi$, so $P\left(X^{2}+Y^{2} \leq 1\right)=\frac{\pi}{4}$.
b. The area below the line $y=2 x$ is half of the area of the square, so $P(2 X-Y>0)=\frac{2}{4}$.
c. Clearly $P(|X+Y|<2)=1$.
4.2 These are all fundamental properties of integrals. The proof is the same as for Theorem 2.2.5 with bivariate integrals replacing univariate integrals.
4.3 For the experiment of tossing two fair dice, each of the points in the 36 -point sample space are equally likely. So the probability of an event is (number of points in the event)/36. The given probabilities are obtained by noting the following equivalences of events.

$$
\begin{aligned}
& P(\{X=0, Y=0\})=P(\{(1,1),(2,1),(1,3),(2,3),(1,5),(2,5)\})=\frac{6}{36}=\frac{1}{6} \\
& P(\{X=0, Y=1\})=P(\{(1,2),(2,2),(1,4),(2,4),(1,6),(2,6)\})=\frac{6}{36}=\frac{1}{6} \\
& P(\{X=1, Y=0\}) \\
& \quad=P(\{(3,1),(4,1),(5,1),(6,1),(3,3),(4,3),(5,3),(6,3),(3,5),(4,5),(5,5),(6,5)\}) \\
& \quad=\frac{12}{36}=\frac{1}{3} \\
& P(\{X=1, Y=1\}) \\
& \quad=P(\{(3,2),(4,2),(5,2),(6,2),(3,4),(4,4),(5,4),(6,4),(3,6),(4,6),(5,6),(6,6)\}) \\
& \quad=\frac{12}{36}=\frac{1}{3}
\end{aligned}
$$

4.4 a. $\int_{0}^{1} \int_{0}^{2} C(x+2 y) d x d y=4 C=1$, thus $C=\frac{1}{4}$.
b. $f_{X}(x)= \begin{cases}\int_{0}^{1} \frac{1}{4}(x+2 y) d y=\frac{1}{4}(x+1) & 0<x<2 \\ 0 & \text { otherwise }\end{cases}$
c. $F_{X Y}(x, y)=P(X \leq x, Y \leq y)=\int_{-\infty}^{x} \int_{-\infty}^{y} f(v, u) d v d u$. The way this integral is calculated depends on the values of $x$ and $y$. For example, for $0<x<2$ and $0<y<1$,

$$
F_{X Y}(x, y)=\int_{-\infty}^{x} \int_{-\infty}^{y} f(u, v) d v d u=\int_{0}^{x} \int_{0}^{y} \frac{1}{4}(u+2 v) d v d u=\frac{x^{2} y}{8}+\frac{y^{2} x}{4} .
$$

But for $0<x<2$ and $1 \leq y$,

$$
F_{X Y}(x, y)=\int_{-\infty}^{x} \int_{-\infty}^{y} f(u, v) d v d u=\int_{0}^{x} \int_{0}^{1} \frac{1}{4}(u+2 v) d v d u=\frac{x^{2}}{8}+\frac{x}{4}
$$

The complete definition of $F_{X Y}$ is

$$
F_{X Y}(x, y)= \begin{cases}0 & x \leq 0 \text { or } y \leq 0 \\ x^{2} y / 8+y^{2} x / 4 & 0<x<2 \text { and } 0<y<1 \\ y / 2+y^{2} / 2 & 2 \leq x \text { and } 0<y<1 \\ x^{2} / 8+x / 4 & 0<x<2 \text { and } 1 \leq y \\ 1 & 2 \leq x \text { and } 1 \leq y\end{cases}
$$

d. The function $z=g(x)=9 /(x+1)^{2}$ is monotone on $0<x<2$, so use Theorem 2.1.5 to obtain $f_{Z}(z)=9 /\left(8 z^{2}\right), 1<z<9$.
4.5 a. $P(X>\sqrt{Y})=\int_{0}^{1} \int_{\sqrt{y}}^{1}(x+y) d x d y=\frac{7}{20}$.
b. $P\left(X^{2}<Y<X\right)=\int_{0}^{1} \int_{y}^{\sqrt{y}} 2 x d x d y=\frac{1}{6}$.
4.6 Let $A=$ time that $A$ arrives and $B=$ time that $B$ arrives. The random variables $A$ and $B$ are independent uniform $(1,2)$ variables. So their joint pdf is uniform on the square $(1,2) \times(1,2)$. Let $X=$ amount of time $A$ waits for $B$. Then, $F_{X}(x)=P(X \leq x)=0$ for $x<0$, and $F_{X}(x)=P(X \leq x)=1$ for $1 \leq x$. For $x=0$, we have

$$
F_{X}(0)=P(X \leq 0)=P(X=0)=P(B \leq A)=\int_{1}^{2} \int_{1}^{a} 1 d b d a=\frac{1}{2}
$$

And for $0<x<1$,
$F_{X}(x)=P(X \leq x)=1-P(X>x)=1-P(B-A>x)=1-\int_{1}^{2-x} \int_{a+x}^{2} 1 d b d a=\frac{1}{2}+x-\frac{x^{2}}{2}$.
4.7 We will measure time in minutes past 8 A.M. So $X \sim$ uniform $(0,30), Y \sim$ uniform $(40,50)$ and the joint pdf is $1 / 300$ on the rectangle $(0,30) \times(40,50)$.

$$
P(\text { arrive before } 9 \text { A.M. })=P(X+Y<60)=\int_{40}^{50} \int_{0}^{60-y} \frac{1}{300} d x d y=\frac{1}{2}
$$

4.9

$$
\begin{aligned}
& P(a \leq X \leq b, c \leq Y \leq d) \\
& \quad=P(X \leq b, c \leq Y \leq d)-P(X \leq a, c \leq Y \leq d) \\
& \quad=P(X \leq b, Y \leq d)-P(X \leq b, Y \leq c)-P(X \leq a, Y \leq d)+P(X \leq a, Y \leq c) \\
& \quad=F(b, d)-F(b, c)-F(a, d)-F(a, c) \\
& \quad=F_{X}(b) F_{Y}(d)-F_{X}(b) F_{Y}(c)-F_{X}(a) F_{Y}(d)-F_{X}(a) F_{Y}(c) \\
& \quad=P(X \leq b)[P(Y \leq d)-P(Y \leq c)]-P(X \leq a)[P(Y \leq d)-P(Y \leq c)] \\
& \quad=P(X \leq b) P(c \leq Y \leq d)-P(X \leq a) P(c \leq Y \leq d) \\
& \\
& =P(a \leq X \leq b) P(c \leq Y \leq d) .
\end{aligned}
$$

4.10 a. The marginal distribution of $X$ is $P(X=1)=P(X=3)=\frac{1}{4}$ and $P(X=2)=\frac{1}{2}$. The marginal distribution of $Y$ is $P(Y=2)=P(Y=3)=P(Y=4)=\frac{1}{3}$. But

$$
P(X=2, Y=3)=0 \neq\left(\frac{1}{2}\right)\left(\frac{1}{3}\right)=P(X=2) P(Y=3)
$$

Therefore the random variables are not independent.
b. The distribution that satisfies $P(U=x, V=y)=P(U=x) P(V=y)$ where $U \sim X$ and $V \sim Y$ is

|  | $U$ |  |  |
| :---: | :---: | :---: | :---: |
|  | 1 | 2 | 3 |
| 2 | $\frac{1}{12}$ | $\frac{1}{6}$ | $\frac{1}{12}$ |
| V 3 | $\frac{1}{12}$ | $\frac{1}{6}$ | $\frac{1}{12}$ |
| 4 | $\frac{1}{12}$ | $\frac{1}{6}$ | $\frac{1}{12}$ |

4.11 The support of the distribution of $(U, V)$ is $\{(u, v): u=1,2, \ldots ; v=u+1, u+2, \ldots\}$. This is not a cross-product set. Therefore, $U$ and $V$ are not independent. More simply, if we know $U=u$, then we know $V>u$.
4.12 One interpretation of "a stick is broken at random into three pieces" is this. Suppose the length of the stick is 1 . Let $X$ and $Y$ denote the two points where the stick is broken. Let $X$ and $Y$ both have uniform $(0,1)$ distributions, and assume $X$ and Y are independent. Then the joint distribution of $X$ and $Y$ is uniform on the unit square. In order for the three pieces to form a triangle, the sum of the lengths of any two pieces must be greater than the length of the third. This will be true if and only if the length of each piece is less than $1 / 2$. To calculate the probability of this, we need to identify the sample points $(x, y)$ such that the length of each piece is less than $1 / 2$. If $y>x$, this will be true if $x<1 / 2, y-x<1 / 2$ and $1-y<1 / 2$. These three inequalities define the triangle with vertices $(0,1 / 2),(1 / 2,1 / 2)$ and $(1 / 2,1)$. (Draw a graph of this set.) Because of the uniform distribution, the probability that $(X, Y)$ falls in the triangle is the area of the triangle, which is $1 / 8$. Similarly, if $x>y$, each piece will have length less than $1 / 2$ if $y<1 / 2, x-y<1 / 2$ and $1-x<1 / 2$. These three inequalities define the triangle with vertices $(1 / 2,0),(1 / 2,1 / 2)$ and $(1,1 / 2)$. The probability that $(X, Y)$ is in this triangle is also $1 / 8$. So the probability that the pieces form a triangle is $1 / 8+1 / 8=1 / 4$.
4.13 а.

$$
\begin{aligned}
& \mathrm{E}(Y-g(X))^{2} \\
& \quad=\mathrm{E}((Y-\mathrm{E}(Y \mid X))+(\mathrm{E}(Y \mid X)-g(X)))^{2} \\
& \quad=\mathrm{E}(Y-\mathrm{E}(Y \mid X))^{2}+\mathrm{E}(\mathrm{E}(Y \mid X)-g(X))^{2}+2 \mathrm{E}[(Y-\mathrm{E}(Y \mid X))(\mathrm{E}(Y \mid X)-g(X))]
\end{aligned}
$$

The cross term can be shown to be zero by iterating the expectation. Thus

$$
\mathrm{E}(Y-g(X))^{2}=\mathrm{E}(Y-\mathrm{E}(Y \mid X))^{2}+\mathrm{E}(\mathrm{E}(Y \mid X)-g(X))^{2} \geq \mathrm{E}(Y-\mathrm{E}(Y \mid X))^{2}, \text { for all } \mathrm{g}(\cdot)
$$

The choice $g(X)=\mathrm{E}(Y \mid X)$ will give equality.
b. Equation (2.2.3) is the special case of a) where we take the random variable $X$ to be a constant. Then, $g(X)$ is a constant, say $b$, and $\mathrm{E}(Y \mid X)=\mathrm{E} Y$.
4.15 We will find the conditional distribution of $Y \mid X+Y$. The derivation of the conditional distribution of $X \mid X+Y$ is similar. Let $U=X+Y$ and $V=Y$. In Example 4.3.1, we found the joint pmf of $(U, V)$. Note that for fixed $u, f(u, v)$ is positive for $v=0, \ldots, u$. Therefore the conditional pmf is

$$
f(v \mid u)=\frac{f(u, v)}{f(u)}=\frac{\frac{\theta^{u-v} e^{-\theta}}{(u-v)^{v}} \frac{\lambda^{v} e^{-\lambda}}{v!}}{\frac{(\theta+\lambda)^{u} e^{-(\theta+\lambda)}}{u!}}=\binom{u}{v}\left(\frac{\lambda}{\theta+\lambda}\right)^{v}\left(\frac{\theta}{\theta+\lambda}\right)^{u-v}, v=0, \ldots, u .
$$

That is $V \mid U \sim \operatorname{binomial}(U, \lambda /(\theta+\lambda))$.
4.16 a. The support of the distribution of $(U, V)$ is $\{(u, v): u=1,2, \ldots ; v=0, \pm 1, \pm 2, \ldots\}$.

If $V>0$, then $X>Y$. So for $v=1,2, \ldots$, the joint pmf is

$$
\begin{aligned}
f_{U, V}(u, v) & =P(U=u, V=v)=P(Y=u, X=u+v) \\
& =p(1-p)^{u+v-1} p(1-p)^{u-1}=p^{2}(1-p)^{2 u+v-2}
\end{aligned}
$$

If $V<0$, then $X<Y$. So for $v=-1,-2, \ldots$, the joint pmf is

$$
\begin{aligned}
f_{U, V}(u, v) & =P(U=u, V=v)=P(X=u, Y=u-v) \\
& =p(1-p)^{u-1} p(1-p)^{u-v-1}=p^{2}(1-p)^{2 u-v-2}
\end{aligned}
$$

If $V=0$, then $X=Y$. So for $v=0$, the joint pmf is
$f_{U, V}(u, 0)=P(U=u, V=0)=P(X=Y=u)=p(1-p)^{u-1} p(1-p)^{u-1}=p^{2}(1-p)^{2 u-2}$.
In all three cases, we can write the joint pmf as
$f_{U, V}(u, v)=p^{2}(1-p)^{2 u+|v|-2}=\left(p^{2}(1-p)^{2 u}\right)(1-p)^{|v|-2}, u=1,2, \ldots ; v=0, \pm 1, \pm 2, \ldots$.
Since the joint pmf factors into a function of $u$ and a function of $v, U$ and $V$ are independent.
b. The possible values of $Z$ are all the fractions of the form $r / s$, where $r$ and $s$ are positive integers and $r<s$. Consider one such value, $r / s$, where the fraction is in reduced form. That is, $r$ and $s$ have no common factors. We need to identify all the pairs $(x, y)$ such that $x$ and $y$ are positive integers and $x /(x+y)=r / s$. All such pairs are $(i r, i(s-r)), i=1,2, \ldots$. Therefore,

$$
\begin{aligned}
P\left(Z=\frac{r}{s}\right) & =\sum_{i=1}^{\infty} P(X=i r, Y=i(s-r))=\sum_{i=1}^{\infty} p(1-p)^{i r-1} p(1-p)^{i(s-r)-1} \\
& =\frac{p^{2}}{(1-p)^{2}} \sum_{i=1}^{\infty}\left((1-p)^{s}\right)^{i}=\frac{p^{2}}{(1-p)^{2}} \frac{(1-p)^{s}}{1-(1-p)^{s}}=\frac{p^{2}(1-p)^{s-2}}{1-(1-p)^{s}}
\end{aligned}
$$

c.

$$
P(X=x, X+Y=t)=P(X=x, Y=t-x)=P(X=x) P(Y=t-x)=p^{2}(1-p)^{t-2} .
$$

4.17 a. $P(Y=i+1)=\int_{i}^{i+1} e^{-x} d x=e^{-i}\left(1-e^{-1}\right)$, which is geometric with $p=1-e^{-1}$.
b. Since $Y \geq 5$ if and only if $X \geq 4$,

$$
P(X-4 \leq x \mid Y \geq 5)=P(X-4 \leq x \mid X \geq 4)=P(X \leq x)=e^{-x}
$$

since the exponential distribution is memoryless.
4.18 We need to show $f(x, y)$ is nonnegative and integrates to 1. $f(x, y) \geq 0$, because the numerator is nonnegative since $g(x) \geq 0$, and the denominator is positive for all $x>0, y>0$. Changing to polar coordinates, $x=r \cos \theta$ and $y=r \sin \theta$, we obtain

$$
\int_{0}^{\infty} \int_{0}^{\infty} f(x, y) d x d y=\int_{0}^{\pi / 2} \int_{0}^{\infty} \frac{2 g(r)}{\pi r} r d r d \theta=\frac{2}{\pi} \int_{0}^{\pi / 2} \int_{0}^{\infty} g(r) d r d \theta=\frac{2}{\pi} \int_{0}^{\pi / 2} 1 d \theta=1
$$

4.19 a. Since $\left(X_{1}-X_{2}\right) / \sqrt{2} \sim \mathrm{n}(0,1),\left(X_{1}-X_{2}\right)^{2} / 2 \sim \chi_{1}^{2}$ (see Example 2.1.9).
b. Make the transformation $y_{1}=\frac{x_{1}}{x_{1}+x_{2}}, y_{2}=x_{1}+x_{2}$ then $x_{1}=y_{1} y_{2}, x_{2}=y_{2}\left(1-y_{1}\right)$ and $|J|=y_{2}$. Then

$$
f\left(y_{1}, y_{2}\right)=\left[\frac{\Gamma\left(\alpha_{1}+\alpha_{2}\right)}{\Gamma\left(\alpha_{1}\right) \Gamma\left(\alpha_{2}\right)} y_{1}^{\alpha_{1}-1}\left(1-y_{1}\right)^{\alpha_{2}-1}\right]\left[\frac{1}{\Gamma\left(\alpha_{1}+\alpha_{2}\right)} y_{2}^{\alpha_{1}+\alpha_{2}-1} e^{-y_{2}}\right],
$$

thus $Y_{1} \sim \operatorname{beta}\left(\alpha_{1}, \alpha_{2}\right), Y_{2} \sim \operatorname{gamma}\left(\alpha_{1}+\alpha_{1}, 1\right)$ and are independent.
4.20 a. This transformation is not one-to-one because you cannot determine the sign of $X_{2}$ from $Y_{1}$ and $Y_{2}$. So partition the support of ( $X_{1}, X_{2}$ ) into $\mathcal{A}_{0}=\left\{-\infty<x_{1}<\infty, x_{2}=0\right\}$, $\mathcal{A}_{1}=\left\{-\infty<x_{1}<\infty, x_{2}>0\right\}$ and $\mathcal{A}_{2}=\left\{-\infty<x_{1}<\infty, x_{2}<0\right\}$. The support of $\left(Y_{1}, Y_{2}\right)$ is $\mathcal{B}=\left\{0<y_{1}<\infty,-1<y_{2}<1\right\}$. The inverse transformation from $\mathcal{B}$ to $\mathcal{A}_{1}$ is $x_{1}=y_{2} \sqrt{y_{1}}$ and $x_{2}=\sqrt{y_{1}-y_{1} y_{2}^{2}}$ with Jacobian

$$
J_{1}=\left|\begin{array}{cc}
\frac{1}{2} \frac{y_{2}}{\sqrt{y_{1}}} & \sqrt{y_{1}} \\
\frac{1}{2} \frac{\sqrt{1-y_{2}^{2}}}{\sqrt{y_{1}}} & \frac{y_{2} \sqrt{y_{1}}}{\sqrt{1-y_{2}^{2}}}
\end{array}\right|=\frac{1}{2 \sqrt{1-y_{2}^{2}}} .
$$

The inverse transformation from $\mathcal{B}$ to $\mathcal{A}_{2}$ is $x_{1}=y_{2} \sqrt{y_{1}}$ and $x_{2}=-\sqrt{y_{1}-y_{1} y_{2}^{2}}$ with $J_{2}=$ $-J_{1}$. From (4.3.6), $f_{Y_{1}, Y_{2}}\left(y_{1}, y_{2}\right)$ is the sum of two terms, both of which are the same in this case. Then

$$
\begin{aligned}
f_{Y_{1}, Y_{2}}\left(y_{1}, y_{2}\right) & =2\left[\frac{1}{2 \pi \sigma^{2}} e^{-y_{1} /\left(2 \sigma^{2}\right)} \frac{1}{2 \sqrt{1-y_{2}^{2}}}\right] \\
& =\frac{1}{2 \pi \sigma^{2}} e^{-y_{1} /\left(2 \sigma^{2}\right)} \frac{1}{\sqrt{1-y_{2}^{2}}},
\end{aligned} \quad 0<y_{1}<\infty,-1<y_{2}<1 .
$$

b. We see in the above expression that the joint pdf factors into a function of $y_{1}$ and a function of $y_{2}$. So $Y_{1}$ and $Y_{2}$ are independent. $Y_{1}$ is the square of the distance from $\left(X_{1}, X_{2}\right)$ to the origin. $Y_{2}$ is the cosine of the angle between the positive $x_{1}$-axis and the line from $\left(X_{1}, X_{2}\right)$ to the origin. So independence says the distance from the origin is independent of the orientation (as measured by the angle).
4.21 Since $R$ and $\theta$ are independent, the joint pdf of $T=R^{2}$ and $\theta$ is

$$
f_{T, \theta}(t, \theta)=\frac{1}{4 \pi} e^{-t / 2}, \quad 0<t<\infty, \quad 0<\theta<2 \pi
$$

Make the transformation $x=\sqrt{t} \cos \theta, y=\sqrt{t} \sin \theta$. Then $t=x^{2}+y^{2}, \theta=\tan ^{-1}(y / x)$, and

$$
J=\left|\begin{array}{cc}
2 x & 2 y \\
\frac{-y}{x^{2}+y^{2}} & \frac{-x}{x^{2}+y^{2}}
\end{array}\right|=2 .
$$

Therefore

$$
f_{X, Y}(x, y)=\frac{2}{4 \pi} e^{-\frac{1}{2}\left(x^{2}+y^{2}\right)}, \quad 0<x^{2}+y^{2}<\infty, \quad 0<\tan ^{-1} y / x<2 \pi
$$

Thus,

$$
f_{X, Y}(x, y)=\frac{1}{2 \pi} e^{-\frac{1}{2}\left(x^{2}+y^{2}\right)}, \quad-\infty<x, y<\infty
$$

So $X$ and $Y$ are independent standard normals.
4.23 a. Let $y=v, x=u / y=u / v$ then

$$
\begin{gathered}
J=\left|\begin{array}{cc}
\frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\
\frac{\partial y}{\partial u} & \frac{\partial y}{\partial v}
\end{array}\right|=\left|\begin{array}{cc}
\frac{1}{v} & -\frac{u}{v^{2}} \\
0 & 1
\end{array}\right|=\frac{1}{v} . \\
f_{U, V}(u, v)=\frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha) \Gamma(\beta)} \frac{\Gamma(\alpha+\beta+\gamma)}{\Gamma(\alpha+\beta) \Gamma(\gamma)}\left(\frac{u}{v}\right)^{\alpha-1}\left(1-\frac{u}{v}\right)^{\beta-1} v^{\alpha+\beta-1}(1-v)^{\gamma-1} \frac{1}{v}, 0<u<v<1 .
\end{gathered}
$$

Then,

$$
\begin{aligned}
f_{U}(u) & =\frac{\Gamma(\alpha+\beta+\gamma)}{\Gamma(\alpha) \Gamma(\beta) \Gamma(\gamma)} u^{\alpha-1} \int_{u}^{1} v^{\beta-1}(1-v)^{\gamma-1}\left(\frac{v-u}{v}\right)^{\beta-1} d v \\
& =\frac{\Gamma(\alpha+\beta+\gamma)}{\Gamma(\alpha) \Gamma(\beta) \Gamma(\gamma)} u^{\alpha-1}(1-u)^{\beta+\gamma-1} \int_{0}^{1} y^{\beta-1}(1-y)^{\gamma-1} d y\left(y=\frac{v-u}{1-u}, d y=\frac{d v}{1-u}\right) \\
& =\frac{\Gamma(\alpha+\beta+\gamma)}{\Gamma(\alpha) \Gamma(\beta) \Gamma(\gamma)} u^{\alpha-1}(1-u)^{\beta+\gamma-1} \frac{\Gamma(\beta) \Gamma(\gamma)}{\Gamma(\beta+\gamma)} \\
& =\frac{\Gamma(\alpha+\beta+\gamma)}{\Gamma(\alpha) \Gamma(\beta+\gamma)} u^{\alpha-1}(1-u)^{\beta+\gamma-1}, \quad 0<u<1 .
\end{aligned}
$$

Thus, $U \sim \operatorname{gamma}(\alpha, \beta+\gamma)$.
b. Let $x=\sqrt{u v}, y=\sqrt{\frac{u}{v}}$ then

$$
\begin{gathered}
J=\left|\begin{array}{cc}
\frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\
\frac{\partial y}{\partial u} & \frac{\partial x}{\partial v}
\end{array}\right|=\left|\begin{array}{cc}
\frac{1}{2} v^{1 / 2} u^{-1 / 2} & \frac{1}{2} u^{1 / 2} v^{-1 / 2} \\
\frac{1}{2} v^{-1 / 2} u^{-1 / 2} & -\frac{1}{2} u^{1 / 2} v^{-3 / 2}
\end{array}\right|=\frac{1}{2 v} . \\
f_{U, V}(u, v)=\frac{\Gamma(\alpha+\beta+\gamma)}{\Gamma(\alpha) \Gamma(\beta) \Gamma(\gamma)}\left(\sqrt{u v}^{\alpha-1}(1-\sqrt{u v})^{\beta-1}\left(\sqrt{\frac{u}{v}}\right)^{\alpha+\beta-1}\left(1-\sqrt{\frac{u}{v}}\right)^{\gamma-1} \frac{1}{2 v} .\right.
\end{gathered}
$$

The set $\{0<x<1,0<y<1\}$ is mapped onto the set $\left\{0<u<v<\frac{1}{u}, 0<u<1\right\}$. Then, $f_{U}(u)$

$$
\begin{aligned}
& =\int_{u}^{1 / u} f_{U, V}(u, v) d v \\
& =\underbrace{\frac{\Gamma(\alpha+\beta+\gamma)}{\Gamma(\alpha) \Gamma(\beta) \Gamma(\gamma)} u^{\alpha-1}(1-u)^{\beta+\gamma-1}} \int_{u}^{1 / u}\left(\frac{1-\sqrt{u v}}{1-u}\right)^{\beta-1}\left(\frac{1-\sqrt{u / v}}{1-u}\right)^{\gamma-1} \frac{(\sqrt{u / v})^{\beta}}{2 v(1-u)} d v .
\end{aligned}
$$

## Call it A

To simplify, let $z=\frac{\sqrt{u / v}-u}{1-u}$. Then $v=u \Rightarrow z=1, v=1 / u \Rightarrow z=0$ and $d z=-\frac{\sqrt{u / v}}{2(1-u) v} d v$.
Thus,

$$
\begin{aligned}
f_{U}(u) & =A \int z^{\beta-1}(1-z)^{\gamma-1} d z \quad(\text { kernel of } \operatorname{beta}(\beta, \gamma)) \\
& =\frac{\Gamma(\alpha+\beta+\gamma)}{\Gamma(\alpha) \Gamma(\beta) \Gamma(\gamma)} u^{\alpha-1}(1-u)^{\beta+\gamma-1} \frac{\Gamma(\beta) \Gamma(\gamma)}{\Gamma(\beta+\gamma)} \\
& =\frac{\Gamma(\alpha+\beta+\gamma)}{\Gamma(\alpha) \Gamma(\beta+\gamma)} u^{\alpha-1}(1-u)^{\beta+\gamma-1}, \quad 0<u<1
\end{aligned}
$$

That is, $U \sim \operatorname{beta}(\alpha, \beta+\gamma)$, as in a).
4.24 Let $z_{1}=x+y, z_{2}=\frac{x}{x+y}$, then $x=z_{1} z_{2}, y=z_{1}\left(1-z_{2}\right)$ and

$$
|J|=\left|\begin{array}{cc}
\frac{\partial x}{\partial z_{1}} & \frac{\partial x}{\partial z_{2}} \\
\frac{\partial y}{\partial z_{1}} & \frac{\partial y}{\partial z_{2}}
\end{array}\right|=\left|\begin{array}{cc}
z_{2} & z_{1} \\
1-z_{2} & -z_{1}
\end{array}\right|=z_{1} .
$$

The set $\{x>0, y>0\}$ is mapped onto the set $\left\{z_{1}>0,0<z_{2}<1\right\}$.

$$
\begin{aligned}
f_{Z_{1}, Z_{2}}\left(z_{1}, z_{2}\right) & =\frac{1}{\Gamma(r)}\left(z_{1} z_{2}\right)^{r-1} e^{-z_{1} z_{2}} \cdot \frac{1}{\Gamma(s)}\left(z_{1}-z_{1} z_{2}\right)^{s-1} e^{-z_{1}+z_{1} z_{2}} z_{1} \\
& =\frac{1}{\Gamma(r+s)} z_{1}^{r+s-1} e^{-z_{1}} \cdot \frac{\Gamma(r+s)}{\Gamma(r) \Gamma(s)} z_{2}^{r-1}\left(1-z_{2}\right)^{s-1}, \quad 0<z_{1}, 0<z_{2}<1
\end{aligned}
$$

$f_{Z_{1}, Z_{2}}\left(z_{1}, z_{2}\right)$ can be factored into two densities. Therefore $Z_{1}$ and $Z_{2}$ are independent and $Z_{1} \sim \operatorname{gamma}(r+s, 1), Z_{2} \sim \operatorname{beta}(r, s)$.
4.25 For $X$ and $Z$ independent, and $Y=X+Z, f_{X Y}(x, y)=f_{X}(x) f_{Z}(y-x)$. In Example 4.5.8,

$$
f_{X Y}(x, y)=I_{(0,1)}(x) \frac{1}{10} I_{(0,1 / 10)}(y-x)
$$

In Example 4.5.9, $Y=X^{2}+Z$ and

$$
f_{X Y}(x, y)=f_{X}(x) f_{Z}\left(y-x^{2}\right)=\frac{1}{2} I_{(-1,1)}(x) \frac{1}{10} I_{(0,1 / 10)}\left(y-x^{2}\right)
$$

4.26 a.

$$
\begin{aligned}
P(Z \leq z, W=0) & =P(\min (X, Y) \leq z, Y \leq X)=P(Y \leq z, Y \leq X) \\
& =\int_{0}^{z} \int_{y}^{\infty} \frac{1}{\lambda} e^{-x / \lambda} \frac{1}{\mu} e^{-y / \mu} d x d y \\
& =\frac{\lambda}{\mu+\lambda}\left(1-\exp \left\{-\left(\frac{1}{\mu}+\frac{1}{\lambda}\right) z\right\}\right)
\end{aligned}
$$

Similarly,

$$
\begin{aligned}
P(Z \leq z, W=1) & =P(\min (X, Y) \leq z, X \leq Y) \quad P(X \leq z, X \leq Y) \\
& =\int_{0}^{z} \int_{x}^{\infty} \frac{1}{\lambda} e^{-x / \lambda} \frac{1}{\mu} e^{-y / \mu} d y d x=\frac{\mu}{\mu+\lambda}\left(1-\exp \left\{-\left(\frac{1}{\mu}+\frac{1}{\lambda}\right) z\right\}\right) .
\end{aligned}
$$

b.

$$
\begin{gathered}
P(W=0)=P(Y \leq X)=\int_{0}^{\infty} \int_{y}^{\infty} \frac{1}{\lambda} e^{-x / \lambda} \frac{1}{\mu} e^{-y / \mu} d x d y=\frac{\lambda}{\mu+\lambda} . \\
P(W=1)=1-P(W=0)=\frac{\mu}{\mu+\lambda} . \\
P(Z \leq z)=P(Z \leq z, W=0)+P(Z \leq z, W=1)=1-\exp \left\{-\left(\frac{1}{\mu}+\frac{1}{\lambda}\right) z\right\} .
\end{gathered}
$$

Therefore, $P(Z \leq z, W=i)=P(Z \leq z) P(W=i)$, for $i=0,1, z>0$. So $Z$ and $W$ are independent.
4.27 From Theorem 4.2.14 we know $U \sim \mathrm{n}\left(\mu+\gamma, 2 \sigma^{2}\right)$ and $V \sim \mathrm{n}\left(\mu-\gamma, 2 \sigma^{2}\right)$. It remains to show that they are independent. Proceed as in Exercise 4.24.

$$
f_{X Y}(x, y)=\frac{1}{2 \pi \sigma^{2}} e^{-\frac{1}{2 \sigma^{2}}\left[(x-\mu)^{2}+(y-\gamma)^{2}\right]} \quad\left(\text { by independence, so } f_{X Y}=f_{X} f_{Y}\right)
$$

Let $u=x+y, v=x-y$, then $x=\frac{1}{2}(u+v), y=\frac{1}{2}(u-v)$ and

$$
|J|=\left|\begin{array}{cc}
1 / 2 & 1 / 2 \\
1 / 2 & -1 / 2
\end{array}\right|=\frac{1}{2}
$$

The set $\{-\infty<x<\infty,-\infty<y<\infty\}$ is mapped onto the set $\{-\infty<u<\infty,-\infty<v<\infty\}$.
Therefore

$$
\begin{aligned}
f_{U V}(u, v) & =\frac{1}{2 \pi \sigma^{2}} e^{-\frac{1}{2 \sigma^{2}}\left[\left(\left(\frac{u+v}{2}\right)-\mu\right)^{2}+\left(\left(\frac{u-v}{2}\right)-\gamma\right)^{2}\right]} \cdot \frac{1}{2} \\
& =\frac{1}{4 \pi \sigma^{2}} e^{-\frac{1}{2 \sigma^{2}}\left[2\left(\frac{u}{2}\right)^{2}-u(\mu+\gamma)+\frac{(\mu+\gamma)^{2}}{2}+2\left(\frac{v}{2}\right)^{2}-v(\mu-\gamma)+\frac{(\mu+\gamma)^{2}}{2}\right]} \\
& =g(u) \frac{1}{4 \pi \sigma^{2}} e^{-\frac{1}{2\left(2 \sigma^{2}\right)}}(u-(\mu+\gamma))^{2} \cdot h(v) e^{-\frac{1}{2\left(2 \sigma^{2}\right)}}(v-(\mu-\gamma))^{2} .
\end{aligned}
$$

By the factorization theorem, $U$ and $V$ are independent.
4.29 a. $\frac{X}{Y}=\frac{R \cos \theta}{R \sin \theta}=\cot \theta$. Let $Z=\cot \theta$. Let $A_{1}=(0, \pi), g_{1}(\theta)=\cot \theta, g_{1}^{-1}(z)=\cot ^{-1} z$, $A_{2}=(\pi, 2 \pi), g_{2}(\theta)=\cot \theta, g_{2}^{-1}(z)=\pi+\cot ^{-1} z$. By Theorem 2.1.8

$$
f_{Z}(z)=\frac{1}{2 \pi}\left|\frac{-1}{1+z^{2}}\right|+\frac{1}{2 \pi}\left|\frac{-1}{1+z^{2}}\right|=\frac{1}{\pi} \frac{1}{1+z^{2}}, \quad-\infty<z<\infty
$$

b. $X Y=R^{2} \cos \theta \sin \theta$ then $2 X Y=R^{2} 2 \cos \theta \sin \theta=R^{2} \sin 2 \theta$. Therefore $\frac{2 X Y}{R}=R \sin 2 \theta$. Since $R=\sqrt{X^{2}+Y^{2}}$ then $\frac{2 X Y}{\sqrt{X^{2}+Y^{2}}}=R \sin 2 \theta$. Thus $\frac{2 X Y}{\sqrt{X^{2}+Y^{2}}}$ is distributed as $\sin 2 \theta$ which is distributed as $\sin \theta$. To see this let $\sin \theta \sim f_{\sin \theta}$. For the function $\sin 2 \theta$ the values of the function $\sin \theta$ are repeated over each of the 2 intervals $(0, \pi)$ and $(\pi, 2 \pi)$. Therefore the distribution in each of these intervals is the distribution of $\sin \theta$. The probability of choosing between each one of these intervals is $\frac{1}{2}$. Thus $f_{2 \sin \theta}=\frac{1}{2} f_{\sin \theta}+\frac{1}{2} f_{\sin \theta}=f_{\sin \theta}$. Therefore $\frac{2 X Y}{\sqrt{X^{2}+Y^{2}}}$ has the same distribution as $Y=\sin \theta$. In addition, $\frac{2 X Y}{\sqrt{X^{2}+Y^{2}}}$ has the same distribution as $X=\cos \theta \operatorname{since} \sin \theta$ has the same distribution as $\cos \theta$. To see this let consider the distribution of $W=\cos \theta$ and $V=\sin \theta$ where $\theta \sim$ uniform $(0,2 \pi)$. To derive the distribution of $W=\cos \theta$ let $A_{1}=(0, \pi), g_{1}(\theta)=\cos \theta, g_{1}^{-1}(w)=\cos ^{-1} w, A_{2}=(\pi, 2 \pi)$, $g_{2}(\theta)=\cos \theta, g_{2}^{-1}(w)=2 \pi-\cos ^{-1} w$. By Theorem 2.1.8

$$
f_{W}(w)=\frac{1}{2 \pi}\left|\frac{-1}{\sqrt{1-w^{2}}}\right|+\frac{1}{2 \pi}\left|\frac{1}{\sqrt{1-w^{2}}}\right|=\frac{1}{\pi} \frac{1}{\sqrt{1-w^{2}}},-1 \leq w \leq 1
$$

To derive the distribution of $V=\sin \theta$, first consider the interval $\left(\frac{\pi}{2}, \frac{3 \pi}{2}\right)$. Let $g_{1}(\theta)=\sin \theta$, $4 g_{1}^{-1}(v)=\pi-\sin ^{-1} v$, then

$$
f_{V}(v)=\frac{1}{\pi} \frac{1}{\sqrt{1-v^{2}}}, \quad-1 \leq v \leq 1
$$

Second, consider the set $\left\{\left(0, \frac{\pi}{2}\right) \cup\left(\frac{3 \pi}{2}, 2 \pi\right)\right\}$, for which the function $\sin \theta$ has the same values as it does in the interval $\left(\frac{-\pi}{2}, \frac{\pi}{2}\right)$. Therefore the distribution of $V$ in $\left\{\left(0, \frac{\pi}{2}\right) \cup\left(\frac{3 \pi}{2}, 2 \pi\right)\right\}$ is the same as the distribution of $V$ in $\left(\frac{-\pi}{2}, \frac{\pi}{2}\right)$ which is $\frac{1}{\pi} \frac{1}{\sqrt{1-v^{2}}},-1 \leq v \leq 1$. On $(0,2 \pi)$ each of the sets $\left(\frac{\pi}{2}, \frac{3 \pi}{2}\right),\left\{\left(0, \frac{\pi}{2}\right) \cup\left(\frac{3 \pi}{2}, 2 \pi\right)\right\}$ has probability $\frac{1}{2}$ of being chosen. Therefore

$$
f_{V}(v)=\frac{1}{2} \frac{1}{\pi} \frac{1}{\sqrt{1-v^{2}}}+\frac{1}{2} \frac{1}{\pi} \frac{1}{\sqrt{1-v^{2}}}=\frac{1}{\pi} \frac{1}{\sqrt{1-v^{2}}}, \quad-1 \leq v \leq 1
$$

Thus $W$ and $V$ has the same distribution.
Let $X$ and $Y$ be iid $\mathrm{n}(0,1)$. Then $X^{2}+Y^{2} \sim \chi_{2}^{2}$ is a positive random variable. Therefore with $X=R \cos \theta$ and $Y=R \sin \theta, R=\sqrt{X^{2}+Y^{2}}$ is a positive random variable and $\theta=\tan ^{-1}\left(\frac{Y}{X}\right) \sim$ uniform $(0,1)$. Thus $\frac{2 X Y}{\sqrt{X^{2}+Y^{2}}} \sim X \sim \mathrm{n}(0,1)$.
4.30 a.

$$
\begin{aligned}
\mathrm{E} Y & =\mathrm{E}\{\mathrm{E}(Y \mid X)\}=\mathrm{E} X=\frac{1}{2} . \\
\operatorname{Var} Y & =\operatorname{Var}(\mathrm{E}(Y \mid X))+\mathrm{E}(\operatorname{Var}(Y \mid X))=\operatorname{Var} X+\mathrm{E} X^{2}=\frac{1}{12}+\frac{1}{3}=\frac{5}{12} . \\
\mathrm{E} X Y & =\mathrm{E}[\mathrm{E}(X Y \mid X)]=\mathrm{E}[X \mathrm{E}(Y \mid X)]=\mathrm{E} X^{2}=\frac{1}{3} \\
\operatorname{Cov}(X, Y) & =\mathrm{E} X Y-\mathrm{E} X \mathrm{E} Y=\frac{1}{3}-\left(\frac{1}{2}\right)^{2}=\frac{1}{12} .
\end{aligned}
$$

b. The quick proof is to note that the distribution of $Y \mid X=x$ is $\mathrm{n}(1,1)$, hence is independent of $X$. The bivariate transformation $t=y / x, u=x$ will also show that the joint density factors.
4.31 a.

$$
\begin{gathered}
\mathrm{E} Y=\mathrm{E}\{\mathrm{E}(Y \mid X)\}=\mathrm{E} n X=\frac{n}{2} \\
\operatorname{Var} Y=\operatorname{Var}(\mathrm{E}(Y \mid X))+\mathrm{E}(\operatorname{Var}(Y \mid X))=\operatorname{Var}(n X)+\mathrm{E} n X(1-X)=\frac{n^{2}}{12}+\frac{n}{6}
\end{gathered}
$$

b.

$$
P(Y=y, X \leq x)=\binom{n}{y} x^{y}(1-x)^{n-y}, \quad y=0,1, \ldots, n, \quad 0<x<1
$$

c.

$$
P(y=y)=\binom{n}{y} \frac{\Gamma(y+1) \Gamma(n-y+1)}{\Gamma(n+2)} .
$$

4.32 a. The pmf of $Y$, for $y=0,1, \ldots$, is

$$
\begin{aligned}
f_{Y}(y) & =\int_{0}^{\infty} f_{Y}(y \mid \lambda) f_{\Lambda}(\lambda) d \lambda=\int_{0}^{\infty} \frac{\lambda^{y} e^{-\lambda}}{y!} \frac{1}{\Gamma(\alpha) \beta^{\alpha}} \lambda^{\alpha-1} e^{-\lambda / \beta} d \lambda \\
& =\frac{1}{y!\Gamma(\alpha) \beta^{\alpha}} \int_{0}^{\infty} \lambda^{(y+\alpha)-1} \exp \left\{\frac{-\lambda}{\left(\frac{\beta}{1+\beta}\right)}\right\} d \lambda \\
& =\frac{1}{y!\Gamma(\alpha) \beta^{\alpha}} \Gamma(y+\alpha)\left(\frac{\beta}{1+\beta}\right)^{y+\alpha} .
\end{aligned}
$$

If $\alpha$ is a positive integer,

$$
f_{Y}(y)=\binom{y+\alpha-1}{y}\left(\frac{\beta}{1+\beta}\right)^{y}\left(\frac{1}{1+\beta}\right)^{\alpha}
$$

the negative $\operatorname{binomial}(\alpha, 1 /(1+\beta)) \mathrm{pmf}$. Then

$$
\begin{aligned}
\mathrm{E} Y & =\mathrm{E}(\mathrm{E}(Y \mid \Lambda))=\mathrm{E} \Lambda=\alpha \beta \\
\operatorname{Var} Y & =\operatorname{Var}(\mathrm{E}(Y \mid \Lambda))+\mathrm{E}(\operatorname{Var}(Y \mid \Lambda))=\operatorname{Var} \Lambda+\mathrm{E} \Lambda=\alpha \beta^{2}+\alpha \beta=\alpha \beta(\beta+1) .
\end{aligned}
$$

b. For $y=0,1, \ldots$, we have

$$
\begin{aligned}
P(Y=y \mid \lambda) & =\sum_{n=y}^{\infty} P(Y=y \mid N=n, \lambda) P(N=n \mid \lambda) \\
& =\sum_{n=y}^{\infty}\binom{n}{y} p^{y}(1-p)^{n-y} \frac{e^{-\lambda} \lambda^{n}}{n!} \\
& =\sum_{n=y}^{\infty} \frac{1}{y!(n-y)!}\left(\frac{p}{1-p}\right)^{y}[(1-p) \lambda]^{n} e^{-\lambda} \\
& =e^{-\lambda} \sum_{m=0}^{\infty} \frac{1}{y!m!}\left(\frac{p}{1-p}\right)^{y}[(1-p) \lambda]^{m+y} \quad(\text { let } m=n-y) \\
& =\frac{e^{-\lambda}}{y!}\left(\frac{p}{1-p}\right)^{y}[(1-p) \lambda]^{y}\left[\sum_{m=0}^{\infty} \frac{[(1-p) \lambda]^{m}}{m!}\right] \\
& =e^{-\lambda}(p \lambda)^{y} e^{(1-p) \lambda} \\
& =\frac{(p \lambda)^{y} e^{-p \lambda}}{y!},
\end{aligned}
$$

the $\operatorname{Poisson}(p \lambda)$ pmf. Thus $Y \mid \Lambda \sim \operatorname{Poisson}(p \lambda)$. Now calculations like those in a) yield the pmf of $Y$, for $y=0,1, \ldots$, is

$$
f_{Y}(y)=\frac{1}{\Gamma(\alpha) y!(p \beta)^{\alpha}} \Gamma(y+\alpha)\left(\frac{p \beta}{1+p \beta}\right)^{y+\alpha}
$$

Again, if $\alpha$ is a positive integer, $Y \sim$ negative $\operatorname{binomial}(\alpha, 1 /(1+p \beta))$.
4.33 We can show that $H$ has a negative binomial distribution by computing the mgf of $H$.

$$
\mathrm{E} e^{H t}=\mathrm{EE}\left(e^{H t} \mid N\right)=\mathrm{EE}\left(e^{\left(X_{1}+\cdots+X_{N}\right) t} \mid N\right)=\mathrm{E}\left\{\left[\mathrm{E}\left(e^{X_{1} t} \mid N\right)\right]^{N}\right\}
$$

because, by Theorem 4.6.7, the mgf of a sum of independent random variables is equal to the product of the individual mgfs. Now,

$$
\mathrm{E} e^{X_{1} t}=\sum_{x_{1}=1}^{\infty} e^{x_{1} t} \frac{-1}{\log p} \frac{(1-p)^{x_{1}}}{x_{1}}=\frac{-1}{\log p} \sum_{x_{1}=1}^{\infty} \frac{\left(e^{t}(1-p)\right)^{x_{1}}}{x_{1}}=\frac{-1}{\log p}\left(-\log \left\{1-e^{t}(1-p)\right\}\right)
$$

Then

$$
\begin{aligned}
\mathrm{E}\left(\frac{\log \left\{1-e^{t}(1-p)\right\}}{\log p}\right)^{N} & =\sum_{n=0}^{\infty}\left(\frac{\log \left\{1-e^{t}(1-p)\right\}}{\log p}\right)^{n} \frac{e^{-\lambda} \lambda^{n}}{n!} \quad \quad \text { (since } N \sim \text { Poisson) } \\
& =e^{-\lambda} e^{\frac{\lambda \log \left(1-e^{t}(1-p)\right)}{\log p}} \sum_{n=0}^{\infty} \frac{e^{\frac{-\lambda \log \left(1-e^{t}(1-p)\right)}{\log p}}\left(\frac{\lambda \log \left(1-e^{t}(1-p)\right)}{\log p}\right)^{n}}{n!} .
\end{aligned}
$$

The sum equals 1. It is the sum of a Poisson $\left(\left[\lambda \log \left(1-e^{t}(1-p)\right)\right] /[\log p]\right)$ pmf. Therefore,

$$
\begin{aligned}
\mathrm{E}\left(e^{H t}\right) & =e^{-\lambda}\left[e^{\log \left(1-e^{t}(1-p)\right)}\right]^{\lambda / \log p}=\left(e^{\log p}\right)^{-\lambda / \log p}\left(\frac{1}{1-e^{t}(1-p)}\right)^{-\lambda / \log p} \\
& =\left(\frac{p}{1-e^{t}(1-p)}\right)^{-\lambda / \log p}
\end{aligned}
$$

This is the mgf of a negative $\operatorname{binomial}(r, p)$, with $r=-\lambda / \log p$, if $r$ is an integer.
4.34 a .

$$
\begin{aligned}
P(Y=y) & =\int_{0}^{1} P(Y=y \mid p) f_{p}(p) d p \\
& =\int_{0}^{1}\binom{n}{y} p^{y}(1-p)^{n-y} \frac{1}{B(\alpha, \beta)} p^{\alpha-1}(1-p)^{\beta-1} d p \\
& =\binom{n}{y} \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha) \Gamma(\beta)} \int_{0}^{1} p^{y+\alpha-1}(1-p)^{n+\beta-y-1} d p \\
& =\binom{n}{y} \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha) \Gamma(\beta)} \frac{\Gamma(y+\alpha) \Gamma(n+\beta-y)}{\Gamma(\alpha+n+\beta)}, \quad y=0,1, \ldots, n
\end{aligned}
$$

b.

$$
\begin{aligned}
P(X=x) & =\int_{0}^{1} P(X=x \mid p) f_{P}(p) d p \\
& =\int_{0}^{1}\binom{r+x-1}{x} p^{r}(1-p)^{x} \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha) \Gamma(\beta)} p^{\alpha-1}(1-p)^{\beta-1} d p
\end{aligned}
$$

$$
\begin{aligned}
& =\binom{r+x-1}{x} \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha) \Gamma(\beta)} \int_{0}^{1} p^{(r+\alpha)-1}(1-p)^{(x+\beta)-1} d p \\
& =\binom{r+x-1}{x} \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha) \Gamma(\beta)} \frac{\Gamma(r+\alpha) \Gamma(x+\beta)}{\Gamma(r+x+\alpha+\beta)} \quad x=0,1, \ldots
\end{aligned}
$$

Therefore,

$$
\mathrm{E} X=\mathrm{E}[\mathrm{E}(X \mid P)]=\mathrm{E}\left[\frac{r(1-P)}{P}\right]=\frac{r \beta}{\alpha-1},
$$

since

$$
\begin{aligned}
\mathrm{E}\left[\frac{1-P}{P}\right] & =\int_{0}^{1}\left(\frac{1-P}{P}\right) \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha) \Gamma(\beta)} p^{\alpha-1}(1-p)^{\beta-1} d p \\
& =\frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha) \Gamma(\beta)} \int_{0}^{1} p^{(\alpha-1)-1}(1-p)^{(\beta+1)-1} d p=\frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha) \Gamma(\beta)} \frac{\Gamma(\alpha-1) \Gamma(\beta+1)}{\Gamma(\alpha+\beta)} \\
& =\frac{\beta}{\alpha-1} .
\end{aligned}
$$

$$
\begin{aligned}
\operatorname{Var}(X) & =\mathrm{E}(\operatorname{Var}(X \mid P))+\operatorname{Var}(\mathrm{E}(X \mid P))=\mathrm{E}\left[\frac{r(1-P)}{P^{2}}\right]+\operatorname{Var}\left(\frac{r(1-P)}{P}\right) \\
& =r \frac{(\beta+1)(\alpha+\beta)}{\alpha(\alpha-1)}+r^{2} \frac{\beta(\alpha+\beta-1)}{(\alpha-1)^{2}(\alpha-2)},
\end{aligned}
$$

since

$$
\begin{aligned}
\mathrm{E}\left[\frac{1-P}{P^{2}}\right] & =\int_{0}^{1} \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha) \Gamma(\beta)} p^{(\alpha-2)-1}(1-p)^{(\beta+1)-1} d p=\frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha) \Gamma(\beta)} \frac{\Gamma(\alpha-2) \Gamma(\beta+1)}{\Gamma(\alpha+\beta-1)} \\
& =\frac{(\beta+1)(\alpha+\beta)}{\alpha(\alpha-1)}
\end{aligned}
$$

and

$$
\begin{aligned}
\operatorname{Var}\left(\frac{1-P}{P}\right) & =\mathrm{E}\left[\left(\frac{1-P}{P}\right)^{2}\right]-\left(\mathrm{E}\left[\frac{1-P}{P}\right]\right)^{2}=\frac{\beta(\beta+1)}{(\alpha-2)(\alpha-1)}-\left(\frac{\beta}{\alpha-1}\right)^{2} \\
& =\frac{\beta(\alpha+\beta-1)}{(\alpha-1)^{2}(\alpha-2)}
\end{aligned}
$$

where

$$
\begin{aligned}
\mathrm{E}\left[\left(\frac{1-P}{P}\right)^{2}\right] & =\int_{0}^{1} \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha) \Gamma(\beta)} p^{(\alpha-2)-1}(1-p)^{(\beta+2)-1} d p \\
& =\frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha) \Gamma(\beta)} \frac{\Gamma(\alpha-2) \Gamma(\beta+2)}{\Gamma(\alpha-2+\beta+2)}=\frac{\beta(\beta+1)}{(\alpha-2)(\alpha-1)} .
\end{aligned}
$$

4.35 a. $\operatorname{Var}(X)=\mathrm{E}(\operatorname{Var}(X \mid P))+\operatorname{Var}(\mathrm{E}(X \mid P))$. Therefore,

$$
\begin{aligned}
\operatorname{Var}(X) & =\mathrm{E}[n P(1-P)]+\operatorname{Var}(n P) \\
& =n \frac{\alpha \beta}{(\alpha+\beta)(\alpha+\beta+1)}+n^{2} \operatorname{Var} P \\
& =n \frac{\alpha \beta(\alpha+\beta+1-1)}{\left(\alpha+\beta^{2}\right)(\alpha+\beta+1)}+n^{2} \operatorname{Var} P
\end{aligned}
$$

$$
\begin{aligned}
& =\frac{n \alpha \beta(\alpha+\beta+1)}{\left(\alpha+\beta^{2}\right)(\alpha+\beta+1)}-\frac{n \alpha \beta}{\left(\alpha+\beta^{2}\right)(\alpha+\beta+1)}+n^{2} \operatorname{Var} P \\
& =n \frac{\alpha}{\alpha+\beta} \frac{\beta}{\alpha+\beta}-n \operatorname{Var} P+n^{2} \operatorname{Var} P \\
& =n \mathrm{E} P(1-\mathrm{E} P)+n(n-1) \operatorname{Var} P .
\end{aligned}
$$

b. $\operatorname{Var}(Y)=\mathrm{E}(\operatorname{Var}(Y \mid \Lambda))+\operatorname{Var}(\mathrm{E}(Y \mid \Lambda))=\mathrm{E} \Lambda+\operatorname{Var}(\Lambda)=\mu+\frac{1}{\alpha} \mu^{2}$ since $\mathrm{E} \Lambda=\mu=\alpha \beta$ and $\operatorname{Var}(\Lambda)=\alpha \beta^{2}=\frac{(\alpha \beta)^{2}}{\alpha}=\frac{\mu^{2}}{\alpha}$. The "extra-Poisson" variation is $\frac{1}{\alpha} \mu^{2}$.
4.37 a. Let $Y=\sum X_{i}$.

$$
\begin{aligned}
P(Y=k) & =P\left(Y=k, \frac{1}{2}<c=\frac{1}{2}(1+p)<1\right) \\
& =\int_{0}^{1}\left(Y=k \left\lvert\, c=\frac{1}{2}(1+p)\right.\right) P(P=p) d p \\
& =\int_{0}^{1}\binom{n}{k}\left[\frac{1}{2}(1+p)\right]^{k}\left[1-\frac{1}{2}(1+p)\right]^{n-k} \frac{\Gamma(a+b)}{\Gamma(a) \Gamma(b)} p^{a-1}(1-p)^{b-1} d p \\
& =\int_{0}^{1}\binom{n}{k} \frac{(1+p)^{k}}{2^{k}} \frac{(1-p)^{n-k}}{2^{n-k}} \frac{\Gamma(a+b)}{\Gamma(a) \Gamma(b)} p^{a-1}(1-p)^{b-1} d p \\
& =\binom{n}{k} \frac{\Gamma(a+b)}{2^{n} \Gamma(a) \Gamma(b)} \sum_{j=0}^{k} \int_{0}^{1} p^{k+a-1}(1-p)^{n-k+b-1} d p \\
& =\binom{n}{k} \frac{\Gamma(a+b)}{2^{n} \Gamma(a) \Gamma(b)} \sum_{j=0}^{k}\binom{k}{j} \frac{\Gamma(k+a) \Gamma(n-k+b)}{\Gamma(n+a+b)} \\
& =\sum_{j=0}^{k}\left[\binom{\binom{k}{j}}{2^{n}}\left(\binom{n}{k} \frac{\Gamma(a+b)}{\Gamma(a) \Gamma(b)} \frac{\Gamma(k+a) \Gamma(n-k+b)}{\Gamma(n+a+b)}\right)\right] .
\end{aligned}
$$

A mixture of beta-binomial.
b.

$$
\mathrm{E} Y=\mathrm{E}(\mathrm{E}(Y \mid c))=\mathrm{E}[n c]=\mathrm{E}\left[n\left(\frac{1}{2}(1+p)\right)\right]=\frac{n}{2}\left(1+\frac{a}{a+b}\right)
$$

Using the results in Exercise 4.35(a),

$$
\operatorname{Var}(Y)=n \mathrm{E} C(1-\mathrm{E} C)+n(n-1) \operatorname{Var} C
$$

Therefore,

$$
\begin{aligned}
\operatorname{Var}(Y) & =n \mathrm{E}\left[\frac{1}{2}(1+P)\right]\left(1-\mathrm{E}\left[\frac{1}{2}(1+P)\right]\right)+n(n-1) \operatorname{Var}\left(\frac{1}{2}(1+P)\right) \\
& =\frac{n}{4}(1+\mathrm{E} P)(1-\mathrm{E} P)+\frac{n(n-1)}{4} \operatorname{Var} P \\
& =\frac{n}{4}\left(1-\left(\frac{a}{a+b}\right)^{2}\right)+\frac{n(n-1)}{4} \frac{a b}{(a+b)^{2}(a+b+1)} .
\end{aligned}
$$

4.38 a. Make the transformation $u=\frac{x}{\nu}-\frac{x}{\lambda}, d u=\frac{-x}{\nu^{2}} d \nu, \frac{\nu}{\lambda-\nu}=\frac{x}{\lambda u}$. Then

$$
\int_{0}^{\lambda} \frac{1}{\nu} e^{-x / \nu} \frac{1}{\Gamma(r) \Gamma(1-r)} \frac{\nu^{r-1}}{(\lambda-\nu)^{r}} d \nu
$$

$$
\begin{aligned}
& =\frac{1}{\Gamma(r) \Gamma(1-r)} \int_{0}^{\infty} \frac{1}{x}\left(\frac{x}{\lambda u}\right)^{r} e^{-(u+x / \lambda)} d u \\
& =\frac{x^{r-1} e^{-x / \lambda}}{\lambda^{r} \Gamma(r) \Gamma(1-r)} \int_{0}^{\infty}\left(\frac{1}{u}\right)^{r} e^{-u} d u=\frac{x^{r-1} e^{-x / \lambda}}{\Gamma(r) \lambda^{r}}
\end{aligned}
$$

since the integral is equal to $\Gamma(1-r)$ if $r<1$.
b. Use the transformation $t=\nu / \lambda$ to get

$$
\int_{0}^{\lambda} p_{\lambda}(\nu) d \nu=\frac{1}{\Gamma(r) \Gamma(1-r)} \int_{0}^{\lambda} \nu^{r-1}(\lambda-\nu)^{-r} d \nu=\frac{1}{\Gamma(r) \Gamma(1-r)} \int_{0}^{1} t^{r-1}(1-t)^{-r} d t=1
$$

since this is a $\operatorname{beta}(r, 1-r)$.
c.

$$
\frac{d}{d x} \log f(x)=\frac{d}{d x}\left[\log \frac{1}{\Gamma(r) \lambda^{r}}+(r-1) \log x-x / \lambda\right]=\frac{r-1}{x}-\frac{1}{\lambda}>0
$$

for some $x$, if $r>1$. But,

$$
\frac{d}{d x}\left[\log \int_{0}^{\infty} \frac{e^{-x / \nu}}{\nu} q_{\lambda}(\nu) d \nu\right]=\frac{-\int_{0}^{\infty} \frac{1}{\nu^{2}} e^{-x / \nu} q_{\lambda}(\nu) d \nu}{\int_{0}^{\infty} \frac{1}{\nu} e^{-x / \nu} q_{\lambda}(\nu) d \nu}<0 \quad \forall x
$$

4.39 a. Without loss of generality lets assume that $i<j$. From the discussion in the text we have that

$$
\begin{aligned}
& f\left(x_{1}, \ldots, x_{j-1}, x_{j+1}, \ldots, x_{n} \mid x_{j}\right) \\
&= \frac{\left(m-x_{j}\right)!}{x_{1}!\cdots \cdots x_{j-1}!\cdot x_{j+1}!\cdots \cdots x_{n}!} \\
& \quad \times\left(\frac{p_{1}}{1-p_{j}}\right)^{x_{1}} \cdots \cdots\left(\frac{p_{j-1}}{1-p_{j}}\right)^{x_{j-1}}\left(\frac{p_{j+1}}{1-p_{j}}\right)^{x_{j+1}} \cdots \cdots\left(\frac{p_{n}}{1-p_{j}}\right)^{x_{n}}
\end{aligned}
$$

Then,

$$
\begin{aligned}
& f\left(x_{i} \mid x_{j}\right) \\
& =\sum_{\left(x_{1}, \ldots, x_{i-1}, x_{i+1}, \ldots, x_{j-1}, x_{j+1}, \ldots, x_{n}\right)} f\left(x_{1}, \ldots, x_{j-1}, x_{j+1}, \ldots, x_{n} \mid x_{j}\right) \\
& =\sum_{\left(x_{k} \neq x_{i}, x_{j}\right)} \frac{\left(m-x_{j}\right)!}{x_{1}!\cdots \cdots x_{j-1}!\cdot x_{j+1}!\cdots \cdot x_{n}!} \\
& \times\left(\frac{p_{1}}{1-p_{j}}\right)^{x_{1}} \cdots \cdots\left(\frac{p_{j-1}}{1-p_{j}}\right)^{x_{j-1}}\left(\frac{p_{j+1}}{1-p_{j}}\right)^{x_{j+1}} \cdots \cdots\left(\frac{p_{n}}{1-p_{j}}\right)^{x_{n}} \\
& \times \frac{\left(m-x_{i}-x_{j}\right)!\left(1-\frac{p_{i}}{1-p_{j}}\right)^{m-x_{i}-x_{j}}}{\left(m-x_{i}-x_{j}\right)!\left(1-\frac{p_{i}}{1-p_{j}}\right)^{m-x_{i}-x_{j}}} \\
& =\frac{\left(m-x_{j}\right)!}{x_{i}!\left(m-x_{i}-x_{j}\right)!}\left(\frac{p_{i}}{1-p_{j}}\right)^{x_{i}}\left(1-\frac{p_{i}}{1-p_{j}}\right)^{m-x_{i}-x_{j}} \\
& \times \sum_{\left(x_{k} \neq x_{i}, x_{j}\right)} \frac{\left(m-x_{i}-x_{j}\right)!}{x_{1}!\cdots x_{i-1}!, x_{i+1}!\cdots \cdots x_{j-1}!, x_{j+1}!\cdots \cdots x_{n}!} \\
& \times\left(\frac{p_{1}}{1-p_{j}-p_{i}}\right)^{x_{1}} \cdots \cdot\left(\frac{p_{i-1}}{1-p_{j}-p_{i}}\right)^{x_{i-1}}\left(\frac{p_{i+1}}{1-p_{j}-p_{i}}\right)^{x_{i+1}}
\end{aligned}
$$

$$
\begin{aligned}
& \times\left(\frac{p_{j-1}}{1-p_{j}-p_{i}}\right)^{x_{j-1}}\left(\frac{p_{j+1}}{1-p_{j}-p_{i}}\right)^{x_{j+1}} \cdots \cdot\left(\frac{p_{n}}{1-p_{j}-p_{i}}\right)^{x_{n}} \\
= & \frac{\left(m-x_{j}\right)!}{x_{i}!\left(m-x_{i}-x_{j}\right)!}\left(\frac{p_{i}}{1-p_{j}}\right)^{x_{i}}\left(1-\frac{p_{i}}{1-p_{j}}\right)^{m-x_{i}-x_{j}} .
\end{aligned}
$$

Thus $X_{i} \left\lvert\, X_{j}=x_{j} \sim \operatorname{binomial}\left(m-x_{j}, \frac{p_{i}}{1-p_{j}}\right)\right.$.
b.

$$
f\left(x_{i}, x_{j}\right)=f\left(x_{i} \mid x_{j}\right) f\left(x_{j}\right)=\frac{m!}{x_{i}!x_{j}!\left(m-x_{j}-x_{i}\right)!} p_{i}^{x_{i}} p_{j}^{x_{j}}\left(1-p_{j}-p_{i}\right)^{m-x_{j}-x_{i}}
$$

Using this result it can be shown that $X_{i}+X_{j} \sim \operatorname{binomial}\left(m, p_{i}+p_{j}\right)$. Therefore,

$$
\operatorname{Var}\left(X_{i}+X_{j}\right)=m\left(p_{i}+p_{j}\right)\left(1-p_{i}-p_{j}\right)
$$

By Theorem 4.5.6 $\operatorname{Var}\left(X_{i}+X_{j}\right)=\operatorname{Var}\left(X_{i}\right)+\operatorname{Var}\left(X_{j}\right)+2 \operatorname{Cov}\left(X_{i}, X_{j}\right)$. Therefore,
$\operatorname{Cov}\left(X_{i}, X_{j}\right)=\frac{1}{2}\left[m\left(p_{i}+p_{j}\right)\left(1-p_{i}-p_{j}\right)-m p_{i}\left(1-p_{i}\right)-m p_{i}\left(1-p_{i}\right)\right]=\frac{1}{2}\left(-2 m p_{i} p_{j}\right)=-m p_{i} p_{j}$.
4.41 Let $a$ be a constant. $\operatorname{Cov}(a, X)=\mathrm{E}(a X)-\mathrm{E} a \mathrm{E} X=a \mathrm{E} X-a \mathrm{E} X=0$.
4.42

$$
\rho_{X Y, Y}=\frac{\operatorname{Cov}(X Y, Y)}{\sigma_{X Y} \sigma_{Y}}=\frac{\mathrm{E}\left(X Y^{2}\right)-\mu_{X Y} \mu_{Y}}{\sigma_{X Y} \sigma_{Y}}=\frac{\mathrm{E} X \mathrm{E} Y^{2}-\mu_{X} \mu_{Y} \mu_{Y}}{\sigma_{X Y} \sigma_{Y}}
$$

where the last step follows from the independence of X and Y . Now compute

$$
\begin{aligned}
\sigma_{X Y}^{2} & =\mathrm{E}(X Y)^{2}-[\mathrm{E}(X Y)]^{2}=\mathrm{E} X^{2} \mathrm{E} Y^{2}-(\mathrm{E} X)^{2}(\mathrm{E} Y)^{2} \\
& =\left(\sigma_{X}^{2}+\mu_{X}^{2}\right)\left(\sigma_{Y}^{2}+\mu_{Y}^{2}\right)-\mu_{X}^{2} \mu_{Y}^{2}=\sigma_{X}^{2} \sigma_{Y}^{2}+\sigma_{X}^{2} \mu_{Y}^{2}+\sigma_{Y}^{2} \mu_{X}^{2}
\end{aligned}
$$

Therefore,

$$
\rho_{X Y, Y}=\frac{\mu_{X}\left(\sigma_{Y}^{2}+\mu_{Y}^{2}\right)-\mu_{X} \mu_{Y}^{2}}{\left(\sigma_{X}^{2} \sigma_{Y}^{2}+\sigma_{X}^{2} \mu_{Y}^{2}+\sigma_{Y}^{2} \mu_{X}^{2}\right)^{1 / 2} \sigma_{Y}}=\frac{\mu_{X} \sigma_{Y}}{\left(\mu_{X}^{2} \sigma_{Y}^{2}+\mu_{Y}^{2} \sigma_{X}^{2}+\sigma_{X}^{2} \sigma_{Y}^{2}\right)^{1 / 2}}
$$

4.43

$$
\begin{aligned}
\operatorname{Cov}\left(X_{1}+X_{2}, X_{2}+X_{3}\right) & =\mathrm{E}\left(X_{1}+X_{2}\right)\left(X_{2}+X_{3}\right)-\mathrm{E}\left(X_{1}+X_{2}\right) \mathrm{E}\left(X_{2}+X_{3}\right) \\
& =\left(4 \mu^{2}+\sigma^{2}\right)-4 \mu^{2}=\sigma^{2} \\
\operatorname{Cov}\left(X_{1}+X_{2}\right)\left(X_{1}-X_{2}\right) & =\mathrm{E}\left(X_{1}+X_{2}\right)\left(X_{1}-X_{2}\right)=\mathrm{E} X_{1}^{2}-X_{2}^{2}=0 .
\end{aligned}
$$

4.44 Let $\mu_{i}=\mathrm{E}\left(X_{i}\right)$. Then

$$
\begin{aligned}
\operatorname{Var}\left(\sum_{i=1}^{n} X_{i}\right) & =\operatorname{Var}\left(X_{1}+X_{2}+\cdots+X_{n}\right) \\
& =\mathrm{E}\left[\left(X_{1}+X_{2}+\cdots+X_{n}\right)-\left(\mu_{1}+\mu_{2}+\cdots+\mu_{n}\right)\right]^{2} \\
& =\mathrm{E}\left[\left(X_{1}-\mu_{1}\right)+\left(X_{2}-\mu_{2}\right)+\cdots+\left(X_{n}-\mu_{n}\right)\right]^{2} \\
& =\sum_{i=1}^{n} \mathrm{E}\left(X_{i}-\mu_{i}\right)^{2}+2 \sum_{1 \leq i<j \leq n} \mathrm{E}\left(X_{i}-\mu_{i}\right)\left(X_{j}-\mu_{j}\right) \\
& =\sum_{i=1}^{n} \operatorname{Var} X_{i}+2 \sum_{1 \leq i<j \leq n} \operatorname{Cov}\left(X_{i}, X_{j}\right)
\end{aligned}
$$

4.45 a. We will compute the marginal of $X$. The calculation for $Y$ is similar. Start with

$$
\begin{aligned}
f_{X Y}(x, y) & =\frac{1}{2 \pi \sigma_{X} \sigma_{Y} \sqrt{1-\rho^{2}}} \\
& \times \exp \left[-\frac{1}{2\left(1-\rho^{2}\right)}\left\{\left(\frac{x-\mu_{X}}{\sigma_{X}}\right)^{2}-2 \rho\left(\frac{x-\mu_{X}}{\sigma_{X}}\right)\left(\frac{y-\mu_{Y}}{\sigma_{Y}}\right)+\left(\frac{y-\mu_{Y}}{\sigma_{Y}}\right)^{2}\right\}\right]
\end{aligned}
$$

and compute

$$
f_{X}(x)=\int_{-\infty}^{\infty} f_{X Y}(x, y) d y=\int_{-\infty}^{\infty} \frac{1}{2 \pi \sigma_{X} \sigma_{Y} \sqrt{1-\rho^{2}}} e^{-\frac{1}{2\left(1-\rho^{2}\right)}\left(\omega^{2}-2 \rho \omega z+z^{2}\right) \sigma_{Y} d z}
$$

where we make the substitution $z=\frac{y-\mu_{Y}}{\sigma_{Y}}, d y=\sigma_{Y} d z, \omega=\frac{x-\mu_{X}}{\sigma_{X}}$. Now the part of the exponent involving $\omega^{2}$ can be removed from the integral, and we complete the square in $z$ to get

$$
\begin{aligned}
f_{X}(x) & =\frac{e^{-\frac{\omega^{2}}{2\left(1-\rho^{2}\right)}}}{2 \pi \sigma_{X} \sqrt{1-\rho^{2}}} \int_{-\infty}^{\infty} e^{-\frac{1}{2\left(1-\rho^{2}\right)}\left[\left(z^{2}-2 \rho \omega z+\rho^{2} \omega^{2}\right)-\rho^{2} \omega^{2}\right]} d z \\
& =\frac{e^{-\omega^{2} / 2\left(1-\rho^{2}\right)} e^{\rho^{2} \omega^{2} / 2\left(1-\rho^{2}\right)}}{2 \pi \sigma_{X} \sqrt{1-\rho^{2}}} \int_{-\infty}^{\infty} e^{-\frac{1}{2\left(1-\rho^{2}\right)}(z-\rho \omega)^{2}} d z
\end{aligned}
$$

The integrand is the kernel of normal pdf with $\sigma^{2}=\left(1-\rho^{2}\right)$, and $\mu=\rho \omega$, so it integrates to $\sqrt{2 \pi} \sqrt{1-\rho^{2}}$. Also note that $e^{-\omega^{2} / 2\left(1-\rho^{2}\right)} e^{\rho^{2} \omega^{2} / 2\left(1-\rho^{2}\right)}=e^{-\omega^{2} / 2}$. Thus,

$$
f_{X}(x)=\frac{e^{-\omega^{2} / 2}}{2 \pi \sigma_{X} \sqrt{1-\rho^{2}}} \sqrt{2 \pi} \sqrt{1-\rho^{2}}=\frac{1}{\sqrt{2 \pi} \sigma_{X}} e^{-\frac{1}{2}\left(\frac{x-\mu_{X}}{\sigma_{X}}\right)^{2}}
$$

the pdf of $\mathrm{n}\left(\mu_{X}, \sigma_{X}^{2}\right)$.
b.

$$
\begin{aligned}
& f_{Y \mid X}(y \mid x) \\
& =\frac{\frac{1}{2 \pi \sigma_{X} \sigma_{Y} \sqrt{1-\rho^{2}}} e^{-\frac{1}{2\left(1-\rho^{2}\right)}\left[\left(\frac{x-\mu_{X}}{\sigma_{X}}\right)^{2}-2 \rho\left(\frac{x-\mu_{X}}{\sigma_{X}}\right)\left(\frac{y-\mu_{Y}}{\sigma_{Y}}\right)+\left(\frac{y-\mu_{Y}}{\sigma_{Y}}\right)^{2}\right]}}{\frac{1}{\sqrt{2 \pi \sigma_{X}}} e^{-\frac{1}{2 \sigma_{X}^{2}}\left(x-\mu_{X}\right)^{2}}} \\
& =\frac{1}{\sqrt{2 \pi} \sigma_{Y} \sqrt{1-\rho^{2}}} e^{-\frac{1}{2\left(1-\rho^{2}\right)}\left[\left(\frac{x-\mu_{X}}{\sigma_{X}}\right)^{2}-\left(1-\rho^{2}\right)\left(\frac{x-\mu_{X}}{\sigma_{X}}\right)^{2}-2 \rho\left(\frac{x-\mu_{X}}{\sigma_{X}}\right)\left(\frac{y-\mu_{Y}}{\sigma_{Y}}\right)+\left(\frac{y-\mu_{Y}}{\sigma_{Y}}\right)^{2}\right]} \\
& =\frac{1}{\sqrt{2 \pi} \sigma_{Y} \sqrt{1-\rho^{2}}} e^{-\frac{1}{2\left(1-\rho^{2}\right)}\left[\rho^{2}\left(\frac{x-\mu_{X}}{\sigma_{X}}\right)^{2}-2 \rho\left(\frac{x-\mu_{X}}{\sigma_{X}}\right)\left(\frac{y-\mu_{Y}}{\sigma_{Y}}\right)+\left(\frac{y-\mu_{Y}}{\sigma_{Y}}\right)^{2}\right]} \\
& =\frac{1}{\sqrt{2 \pi} \sigma_{Y} \sqrt{1-\rho^{2}}} e^{-\frac{1}{2 \sigma_{Y}^{2} \sqrt{\left(1-\rho^{2}\right.}}\left[\left(y-\mu_{Y}\right)-\left(\rho \frac{\sigma_{Y}}{\sigma_{X}}\left(x-\mu_{X}\right)\right)\right]^{2}},
\end{aligned}
$$

which is the pdf of $\mathrm{n}\left(\left(\mu_{Y}-\rho\left(\sigma_{Y} / \sigma_{X}\right)\left(x-\mu_{X}\right), \sigma_{Y} \sqrt{1-\rho^{2}}\right)\right.$.
c. The mean is easy to check,

$$
\mathrm{E}(a X+b Y)=a \mathrm{E} X+b \mathrm{E} Y=a \mu_{X}+b \mu_{Y}
$$

as is the variance,

$$
\operatorname{Var}(a X+b Y)=a^{2} \operatorname{Var} X+b^{2} \operatorname{Var} Y+2 a b \operatorname{Cov}(X, Y)=a^{2} \sigma_{X}^{2}+b^{2} \sigma_{Y}^{2}+2 a b \rho \sigma_{X} \sigma_{Y}
$$

To show that $a X+b Y$ is normal we have to do a bivariate transform. One possibility is $U=a X+b Y, V=Y$, then get $f_{U, V}(u, v)$ and show that $f_{U}(u)$ is normal. We will do this in the standard case. Make the indicated transformation and write $x=\frac{1}{a}(u-b v), y=v$ and obtain

$$
|J|=\left|\begin{array}{cc}
1 / a & -b / a \\
0 & 1
\end{array}\right|=\frac{1}{a}
$$

Then

$$
f_{U V}(u, v)=\frac{1}{2 \pi a \sqrt{1-\rho^{2}}} e^{-\frac{1}{2\left(1-\rho^{2}\right)}\left[\left[\frac{1}{a}(u-b v)\right]^{2}-2 \frac{\rho}{a}(u-b v)+v^{2}\right]}
$$

Now factor the exponent to get a square in $u$. The result is

$$
-\frac{1}{2\left(1-\rho^{2}\right)}\left[\frac{b^{2}+2 \rho a b+a^{2}}{a^{2}}\right]\left[\frac{u^{2}}{b^{2}+2 \rho a b+a^{2}}-2\left(\frac{b+a \rho}{b^{2}+2 \rho a b+a^{2}}\right) u v+v^{2}\right] .
$$

Note that this is joint bivariate normal form since $\mu_{U}=\mu_{V}=0, \sigma_{v}^{2}=1, \sigma_{u}^{2}=a^{2}+b^{2}+2 a b \rho$ and

$$
\rho^{*}=\frac{\operatorname{Cov}(U, V)}{\sigma_{U} \sigma_{V}}=\frac{\mathrm{E}\left(a X Y+b Y^{2}\right)}{\sigma_{U} \sigma_{V}}=\frac{a \rho+b}{\sqrt{a^{2}+b^{2}+a b \rho}},
$$

thus

$$
\left(1-\rho^{* 2}\right)=1-\frac{a^{2} \rho^{2}+a b \rho+b^{2}}{a^{2}+b^{2}+2 a b \rho}=\frac{\left(1-\rho^{2}\right) a^{2}}{a^{2}+b^{2}+2 a b \rho}=\frac{\left(1-\rho^{2}\right) a^{2}}{\sigma_{u}^{2}}
$$

where $a \sqrt{1-\rho^{2}}=\sigma_{U} \sqrt{1-\rho^{* 2}}$. We can then write

$$
f_{U V}(u, v)=\frac{1}{2 \pi \sigma_{U} \sigma_{V} \sqrt{1-\rho^{* 2}}} \exp \left[-\frac{1}{2 \sqrt{1-\rho^{* 2}}}\left(\frac{u^{2}}{\sigma_{U}^{2}}-2 \rho \frac{u v}{\sigma_{U} \sigma_{V}}+\frac{v^{2}}{\sigma_{V}^{2}}\right)\right]
$$

which is in the exact form of a bivariate normal distribution. Thus, by part a), $U$ is normal. 4.46 а.

$$
\begin{aligned}
\mathrm{E} X & =a_{X} \mathrm{E} Z_{1}+b_{X} \mathrm{E} Z_{2}+\mathrm{E} c_{X}=a_{X} 0+b_{X} 0+c_{X}=c_{X} \\
\operatorname{Var} X & =a_{X}^{2} \operatorname{Var} Z_{1}+b_{X}^{2} \operatorname{Var} Z_{2}+\operatorname{Var} c_{X}=a_{X}^{2}+b_{X}^{2} \\
\mathrm{E} Y & =a_{Y} 0+b_{Y} 0+c_{Y}=c_{Y} \\
\operatorname{Var} Y & =a_{Y}^{2} \operatorname{Var} Z_{1}+b_{Y}^{2} \operatorname{Var} Z_{2}+\operatorname{Var} c_{Y}=a_{Y}^{2}+b_{Y}^{2} \\
\operatorname{Cov}(X, Y)= & \mathrm{E} X Y-\mathrm{E} X \cdot \mathrm{E} Y \\
= & \mathrm{E}\left[\left(a_{X} a_{Y} Z_{1}^{2}+b_{X} b_{Y} Z_{2}^{2}+c_{X} c_{Y}+a_{X} b_{Y} Z_{1} Z_{2}+a_{X} c_{Y} Z_{1}+b_{X} a_{Y} Z_{2} Z_{1}\right.\right. \\
& \left.\left.\quad+b_{X} c_{Y} Z_{2}+c_{X} a_{Y} Z_{1}+c_{X} b_{Y} Z_{2}\right)-c_{X} c_{Y}\right] \\
= & a_{X} a_{Y}+b_{X} b_{Y}
\end{aligned}
$$

since $\mathrm{E} Z_{1}^{2}=\mathrm{E} Z_{2}^{2}=1$, and expectations of other terms are all zero.
b. Simply plug the expressions for $a_{X}, b_{X}$, etc. into the equalities in a) and simplify.
c. Let $D=a_{X} b_{Y}-a_{Y} b_{X}=-\sqrt{1-\rho^{2}} \sigma_{X} \sigma_{Y}$ and solve for $Z_{1}$ and $Z_{2}$,

$$
\begin{aligned}
Z_{1} & =\frac{b_{Y}\left(X-c_{X}\right)-b_{X}\left(Y-c_{Y}\right)}{D}=\frac{\sigma_{Y}\left(X-\mu_{X}\right)+\sigma_{X}\left(Y-\mu_{Y}\right)}{\sqrt{2(1+\rho)} \sigma_{X} \sigma_{Y}} \\
Z_{2} & =\frac{\sigma_{Y}\left(X-\mu_{X}\right)+\sigma_{X}\left(Y-\mu_{Y}\right)}{\sqrt{2(1-\rho)} \sigma_{X} \sigma_{Y}}
\end{aligned}
$$

Then the Jacobian is

$$
J=\left(\begin{array}{ll}
\frac{\partial z_{1}}{\partial x_{1}} & \frac{\partial z_{1}}{\partial y} \\
\frac{\partial z_{2}}{\partial x} & \frac{\partial z_{2}}{\partial y}
\end{array}\right)=\left(\begin{array}{cc}
\frac{b_{Y}}{D} & \frac{-b_{X}}{D} \\
\frac{-a_{Y}}{D} & \frac{a_{X}}{D}
\end{array}\right)=\frac{a_{X} b_{Y}}{D^{2}}-\frac{a_{Y} b_{X}}{D^{2}}=\frac{1}{D}=\frac{1}{-\sqrt{1-\rho^{2}} \sigma_{X} \sigma_{Y}},
$$

and we have that

$$
\begin{aligned}
f_{X, Y}(x, y) & =\frac{1}{\sqrt{2 \pi}} e^{-\frac{1}{2} \frac{\left(\sigma_{Y}\left(x-\mu_{X}\right)+\sigma_{X}\left(y-\mu_{Y}\right)\right)^{2}}{2(1+\rho) \sigma_{X}^{2} \sigma_{Y}^{2}}} \frac{1}{\sqrt{2 \pi}} e^{-\frac{1}{2} \frac{\left(\sigma_{Y}\left(x-\mu_{X}\right)+\sigma_{X}\left(y-\mu_{Y}\right)\right)^{2}}{2\left(1-\rho \sigma_{X}^{2} \sigma_{Y}^{2}\right.}} \frac{1}{\sqrt{1-\rho^{2}} \sigma_{X} \sigma_{Y}} \\
& =\left(2 \pi \sigma_{X} \sigma_{Y} \sqrt{1-\rho^{2}}\right)^{-1} \exp \left(-\frac{1}{2\left(1-\rho^{2}\right)}\left(\frac{x-\mu_{X}}{\sigma_{X}}\right)^{2}\right) \\
& -2 \rho \frac{x-\mu_{X}}{\sigma_{X}}\left(\frac{y-\mu_{Y}}{\sigma_{Y}}\right)+\left(\frac{y-\mu_{Y}}{\sigma_{Y}}\right)^{2}, \quad-\infty<x<\infty,-\infty<y<\infty,
\end{aligned}
$$

a bivariate normal pdf.
d. Another solution is

$$
\begin{aligned}
a_{X} & =\rho \sigma_{X} b_{X}=\sqrt{\left(1-\rho^{2}\right)} \sigma_{X} \\
a_{Y} & =\sigma_{Y} b_{Y}=0 \\
c_{X} & =\mu_{X} \\
c_{Y} & =\mu_{Y} .
\end{aligned}
$$

There are an infinite number of solutions. Write $b_{X}= \pm \sqrt{\sigma_{X}^{2}-a_{X}^{2}}, b_{Y}= \pm \sqrt{\sigma_{Y}^{2}-a_{Y}^{2}}$, and substitute $b_{X}, b_{Y}$ into $a_{X} a_{Y}=\rho \sigma_{X} \sigma_{Y}$. We get

$$
a_{X} a_{Y}+\left( \pm \sqrt{\sigma_{X}^{2}-a_{X}^{2}}\right)\left( \pm \sqrt{\sigma_{Y}^{2}-a_{Y}^{2}}\right)=\rho \sigma_{X} \sigma_{Y}
$$

Square both sides and simplify to get

$$
\left(1-\rho^{2}\right) \sigma_{X}^{2} \sigma_{Y}^{2}=\sigma_{X}^{2} a_{Y}^{2}-2 \rho \sigma_{X} \sigma_{Y} a_{X} a_{Y}+\sigma_{Y}^{2} a_{X}^{2}
$$

This is an ellipse for $\rho \neq \pm 1$, a line for $\rho= \pm 1$. In either case there are an infinite number of points satisfying the equations.
4.47 a. By definition of $Z$, for $z<0$,

$$
\begin{aligned}
P(Z \leq z) & =P(X \leq z \text { and } X Y>0)+P(-X \leq z \text { and } X Y<0) \\
& =P(X \leq z \text { and } Y<0)+P(X \geq-z \text { and } Y<0) \quad(\text { since } z<0) \\
& =P(X \leq z) P(Y<0)+P(X \geq-z) P(Y<0) \quad \quad \text { (independence) } \\
& =P(X \leq z) P(Y<0)+P(X \leq z) P(Y>0) \quad \quad \text { (symmetry of } X \text { and } Y) \\
& =P(X \leq z)(P(Y<0)+P(Y>0)) \\
& =P(X \leq z) .
\end{aligned}
$$

By a similar argument, for $z>0$, we get $P(Z>z)=P(X>z)$, and hence, $P(Z \leq z)=$ $P(X \leq z)$. Thus, $Z \sim X \sim \mathrm{n}(0,1)$.
b. By definition of $Z, Z>0 \Leftrightarrow$ either (i) $X<0$ and $Y>0$ or (ii) $X>0$ and $Y>0$. So $Z$ and $Y$ always have the same sign, hence they cannot be bivariate normal.
4.49 а.

$$
\begin{aligned}
f_{X}(x) & =\int\left(a f_{1}(x) g_{1}(y)+(1-a) f_{2}(x) g_{2}(y)\right) d y \\
& =a f_{1}(x) \int g_{1}(y) d y+(1-a) f_{2}(x) \int g_{2}(y) d y \\
& =a f_{1}(x)+(1-a) f_{2}(x) \\
f_{Y}(y) & =\int\left(a f_{1}(x) g_{1}(y)+(1-a) f_{2}(x) g_{2}(y)\right) d x \\
& =a g_{1}(y) \int f_{1}(x) d x+(1-a) g_{2}(y) \int f_{2}(x) d x \\
& =a g_{1}(y)+(1-a) g_{2}(y)
\end{aligned}
$$

b. $(\Rightarrow)$ If $X$ and $Y$ are independent then $f(x, y)=f_{X}(x) f_{Y}(y)$. Then,

$$
\begin{aligned}
& f(x, y)-f_{X}(x) f_{Y}(y) \\
& =\quad a f_{1}(x) g_{1}(y)+(1-a) f_{2}(x) g_{2}(y) \\
& \quad-\left[a f_{1}(x)+(1-a) f_{2}(x)\right]\left[a g_{1}(y)+(1-a) g_{2}(y)\right] \\
& \quad=a(1-a)\left[f_{1}(x) g_{1}(y)-f_{1}(x) g_{2}(y)-f_{2}(x) g_{1}(y)+f_{2}(x) g_{2}(y)\right] \\
& = \\
& =a(1-a)\left[f_{1}(x)-f_{2}(x)\right]\left[g_{1}(y)-g_{2}(y)\right] \\
& =
\end{aligned}
$$

Thus $\left[f_{1}(x)-f_{2}(x)\right]\left[g_{1}(y)-g_{2}(y)\right]=0$ since $0<a<1$.
$(\Leftarrow)$ if $\left[f_{1}(x)-f_{2}(x)\right]\left[g_{1}(y)-g_{2}(y)\right]=0$ then

$$
f_{1}(x) g_{1}(y)+f_{2}(x) g_{2}(y)=f_{1}(x) g_{2}(y)+f_{2}(x) g_{1}(y)
$$

Therefore

$$
\begin{aligned}
& f_{X}(x) f_{Y}(y) \\
& \quad=a^{2} f_{1}(x) g_{1}(y)+a(1-a) f_{1}(x) g_{2}(y)+a(1-a) f_{2}(x) g_{1}(y)+(1-a)^{2} f_{2}(x) g_{2}(y) \\
& \quad=a^{2} f_{1}(x) g_{1}(y)+a(1-a)\left[f_{1}(x) g_{2}(y)+f_{2}(x) g_{1}(y)\right]+(1-a)^{2} f_{2}(x) g_{2}(y) \\
& \quad=a^{2} f_{1}(x) g_{1}(y)+a(1-a)\left[f_{1}(x) g_{1}(y)+f_{2}(x) g_{2}(y)\right]+(1-a)^{2} f_{2}(x) g_{2}(y) \\
& \quad=a f_{1}(x) g_{1}(y)+(1-a) f_{2}(x) g_{2}(y)=f(x, y)
\end{aligned}
$$

Thus $X$ and $Y$ are independent.
c.

$$
\begin{aligned}
\operatorname{Cov}(X, Y) & =a \mu_{1} \xi_{1}+(1-a) \mu_{2} \xi_{2}-\left[a \mu_{1}+(1-a) \mu_{2}\right]\left[a \xi_{1}+(1-a) \xi_{2}\right] \\
& =a(1-a)\left[\mu_{1} \xi_{1}-\mu_{1} \xi_{2}-\mu_{2} \xi_{1}+\mu_{2} \xi_{2}\right] \\
& =a(1-a)\left[\mu_{1}-\mu_{2}\right]\left[\xi_{1}-\xi_{2}\right]
\end{aligned}
$$

To construct dependent uncorrelated random variables let $(X, Y) \sim a f_{1}(x) g_{1}(y)+(1-$ a) $f_{2}(x) g_{2}(y)$ where $f_{1}, f_{2}, g_{1}, g_{2}$ are such that $f_{1}-f_{2} \neq 0$ and $g_{1}-g_{2} \neq 0$ with $\mu_{1}=\mu_{2}$ or $\xi_{1}=\xi_{2}$.
d. (i) $f_{1} \sim \operatorname{binomial}(n, p), f_{2} \sim \operatorname{binomial}(n, p), g_{1} \sim \operatorname{binomial}(n, p), g_{2} \sim \operatorname{binomial}(n, 1-p)$.
(ii) $f_{1} \sim \operatorname{binomial}\left(n, p_{1}\right), f_{2} \sim \operatorname{binomial}\left(n, p_{2}\right), g_{1} \sim \operatorname{binomial}\left(n, p_{1}\right), g_{2} \sim \operatorname{binomial}\left(n, p_{2}\right)$.
(iii) $f_{1} \sim \operatorname{binomial}\left(n_{1}, \frac{p}{n_{1}}\right), f_{2} \sim \operatorname{binomial}\left(n_{2}, \frac{p}{n_{2}}\right), g_{1} \sim \operatorname{binomial}\left(n_{1}, p\right), g_{2} \sim \operatorname{binomial}\left(n_{2}, p\right)$.
4.51 a.

$$
\begin{array}{rll}
P(X / Y \leq t) & = \begin{cases}\frac{1}{2} t & t>1 \\
\frac{1}{2}+(1-t) & t \leq 1\end{cases} \\
P(X Y \leq t) & =t-t \log t & 0<t<1
\end{array}
$$

b.

$$
\begin{aligned}
P(X Y / Z \leq t) & =\int_{0}^{1} P(X Y \leq z t) d z \\
& = \begin{cases}\int_{0}^{1}\left[\frac{z t}{2}+(1-z t)\right] d z & \text { if } t \leq 1 \\
\int_{0}^{\frac{1}{t}}\left[\frac{z t}{2}+(1-z t)\right] d z+\int_{\frac{1}{t}}^{1} \frac{1}{2 z t} d z & \text { if } t \leq 1\end{cases} \\
& = \begin{cases}1-t / 4 & \text { if } t \leq 1 \\
t-\frac{1}{4 t}+\frac{1}{2 t} \log t & \text { if } t>1\end{cases}
\end{aligned}
$$

4.53

$$
\begin{aligned}
P(\text { Real Roots }) & =P\left(B^{2}>4 A C\right) \\
& =P(2 \log B>\log 4+\log A+\log C) \\
& =P(-2 \log B \leq-\log 4-\log A-\log C) \\
& =P(-2 \log B \leq-\log 4+(-\log A-\log C))
\end{aligned}
$$

Let $X=-2 \log B, Y=-\log A-\log C$. Then $X \sim \operatorname{exponential(2),~} Y \sim \operatorname{gamma}(2,1)$, independent, and

$$
\begin{aligned}
P(\text { Real Roots }) & =P(X<-\log 4+Y) \\
& =\int_{\log 4}^{\infty} P(X<-\log 4+y) f_{Y}(y) d y \\
& =\int_{\log 4}^{\infty} \int_{0}^{-\log 4+y} \frac{1}{2} e^{-x / 2} d x y e^{-y} d y \\
& =\int_{\log 4}^{\infty}\left(1-e^{-\frac{1}{2} \log 4} e^{-y / 2}\right) y e^{-y} d y
\end{aligned}
$$

Integration-by-parts will show that $\int_{a}^{\infty} y e^{-y / b}=b(a+b) e^{-a / b}$ and hence

$$
P(\text { Real Roots })=\frac{1}{4}(1+\log 4)-\frac{1}{24}\left(\frac{2}{3}+\log 4\right)=.511 .
$$

4.54 Let $Y=\prod_{i=1}^{n} X_{i}$. Then $P(Y \leq y)=P\left(\prod_{i=1}^{n} X_{i} \leq y\right)=P\left(\sum_{i=1}^{n}-\log X_{i} \geq-\log y\right)$. Now, $-\log X_{i} \sim \operatorname{exponential}(1)=\operatorname{gamma}(1,1)$. By Example 4.6.8, $\sum_{i=1}^{n}-\log X_{i} \sim \operatorname{gamma}(n, 1)$. Therefore,

$$
P(Y \leq y)=\int_{-\log y}^{\infty} \frac{1}{\Gamma(n)} z^{n-1} e^{-z} d z
$$

and

$$
\begin{aligned}
f_{Y}(y) & =\frac{d}{d y} \int_{-\log y}^{\infty} \frac{1}{\Gamma(n)} z^{n-1} e^{-z} d z \\
& =-\frac{1}{\Gamma(n)}(-\log y)^{n-1} e^{-(-\log y)} \frac{d}{d y}(-\log y) \\
& =\frac{1}{\Gamma(n)}(-\log y)^{n-1}, \quad 0<y<1 .
\end{aligned}
$$

4.55 Let $X_{1}, X_{2}, X_{3}$ be independent exponential $(\lambda)$ random variables, and let $Y=\max \left(X_{1}, X_{2}, X_{3}\right)$, the lifetime of the system. Then

$$
\begin{aligned}
P(Y \leq y) & =P\left(\max \left(X_{1}, X_{2}, X_{3}\right) \leq y\right) \\
& =P\left(X_{1} \leq y \text { and } X_{2} \leq y \text { and } X_{3} \leq y\right) \\
& =P\left(X_{1} \leq y\right) P\left(X_{2} \leq y\right) P\left(X_{3} \leq y\right)
\end{aligned}
$$

by the independence of $X_{1}, X_{2}$ and $X_{3}$. Now each probability is $P\left(X_{1} \leq y\right)=\int_{0}^{y} \frac{1}{\lambda} e^{-x / \lambda} d x=$ $1-e^{-y / \lambda}$, so

$$
P(Y \leq y)=\left(1-e^{-y / \lambda}\right)^{3}, \quad 0<y<\infty
$$

and the pdf is

$$
f_{Y}(y)= \begin{cases}3\left(1-e^{-y / \lambda}\right)^{2} e^{-y / \lambda} & y>0 \\ 0 & y \leq 0\end{cases}
$$

4.57 a.

$$
\begin{aligned}
A_{1} & =\left[\frac{1}{n} \sum_{x=1}^{n} x_{i}^{1}\right]^{\frac{1}{1}}=\frac{1}{n} \sum_{x=1}^{n} x_{i}, \quad \text { the arithmetic mean. } \\
A_{-1} & =\left[\frac{1}{n} \sum_{x=1}^{n} x_{i}^{-1}\right]^{-1}=\frac{1}{\frac{1}{n}\left(\frac{1}{x_{1}}+\cdots+\frac{1}{x_{n}}\right)}, \quad \text { the harmonic mean. } \\
\lim _{r \rightarrow 0} \log A_{r} & =\lim _{r \rightarrow 0} \log \left[\frac{1}{n} \sum_{x=1}^{n} x_{i}^{r}\right]^{\frac{1}{r}}=\lim _{r \rightarrow 0} \frac{1}{r} \log \left[\frac{1}{n} \sum_{x=1}^{n} x_{i}^{r}\right]=\lim _{r \rightarrow 0} \frac{\frac{1}{n} \sum_{i=1}^{n} r x_{i}^{r-1}}{\frac{1}{n} \sum_{i=1}^{n} x_{i}^{r}} \\
& =\lim _{r \rightarrow 0} \frac{\frac{1}{n} \sum_{i=1}^{n} x_{i}^{r} \log x_{i}}{\frac{1}{n} \sum_{i=1}^{n} x_{i}^{r}}=\frac{1}{n} \sum_{i=1}^{n} \log x_{i}=\frac{1}{n} \log \left(\prod_{i=1}^{n} x_{i}\right) .
\end{aligned}
$$

Thus $A_{0}=\lim _{r \rightarrow 0} A_{r}=\exp \left(\frac{1}{n} \log \left(\prod_{i=1}^{n} x_{i}\right)\right)=\left(\prod_{i=1}^{n} x_{i}\right)^{\frac{1}{n}}$, the geometric mean. The term $r x_{i}^{r-1}=x_{i}^{r} \log x_{i}$ since $r x_{i}^{r-1}=\frac{d}{d r} x_{i}^{r}=\frac{d}{d r} \exp \left(r \log x_{i}\right)=\exp \left(r \log x_{i}\right) \log x_{i}=x_{i}^{r} \log x_{i}$.
b. (i) if $\log A_{r}$ is nondecreasing then for $r \leq r^{\prime} \log A_{r} \leq \log A_{r^{\prime}}$, then $e^{\log A_{r}} \leq e^{\log A_{r^{\prime}}}$. Therefore $A_{r} \leq A_{r^{\prime}}$. Thus $A_{r}$ is nondecreasing in $r$.
(ii) $\frac{d}{d r} \log A_{r}=\frac{-1}{r^{2}} \log \left(\frac{1}{n} \sum_{x=1}^{n} x_{i}^{r}\right)+\frac{1}{r} \frac{\frac{1}{n} \sum_{i=1}^{n} r x_{i}^{r-1}}{\frac{1}{n} \sum_{i=1}^{n} x_{i}^{r}}=\frac{1}{r^{2}}\left[\frac{r \sum_{i=1}^{n} x_{i}^{r} \log x_{i}}{\sum_{x=1}^{n} x_{i}^{r}}-\log \left(\frac{1}{n} \sum_{x=1}^{n} x_{i}^{r}\right)\right]$, where we use the identity for $r x_{i}^{r-1}$ showed in a).
(iii)

$$
\begin{aligned}
& \frac{r \sum_{i=1}^{n} x_{i}^{r} \log x_{i}}{\sum_{x=1}^{n} x_{i}^{r}}-\log \left(\frac{1}{n} \sum_{x=1}^{n} x_{i}^{r}\right) \\
& \quad=\log (n)+\frac{r \sum_{i=1}^{n} x_{i}^{r} \log x_{i}}{\sum_{x=1}^{n} x_{i}^{r}}-\log \left(\sum_{x=1}^{n} x_{i}^{r}\right) \\
& \quad=\log (n)+\sum_{i=1}^{n}\left[\frac{x_{i}^{r}}{\sum_{i=1}^{n} x_{i}^{r}} r \log x_{i}-\frac{x_{i}^{r}}{\sum_{i=1}^{n} x_{i}^{r}} \log \left(\sum_{x=1}^{n} x_{i}^{r}\right)\right] \\
& \quad=\log (n)+\sum_{i=1}^{n}\left[\frac{x_{i}^{r}}{\sum_{i=1}^{n} x_{i}^{r}}\left(r \log x_{i}-\log \left(\sum_{x=1}^{n} x_{i}^{r}\right)\right)\right] \\
& \quad=\log (n)-\sum_{i=1}^{n} \frac{x_{i}^{r}}{\sum_{i=1}^{n} x_{i}^{r}} \log \left(\frac{\sum_{x=1}^{n} x_{i}^{r}}{x_{i}^{r}}\right)=\log (n)-\sum_{i=1}^{n} a_{i} \log \left(\frac{1}{a_{i}}\right)
\end{aligned}
$$

We need to prove that $\log (n) \geq \sum_{i=1}^{n} a_{i} \log \left(\frac{1}{a_{i}}\right)$. Using Jensen inequality we have that $\mathrm{E} \log \left(\frac{1}{a}\right)=\sum_{i=1}^{n} a_{i} \log \left(\frac{1}{a_{i}}\right) \leq \log \left(\mathrm{E} \frac{1}{a}\right)=\log \left(\sum_{i=1}^{n} a_{i} \frac{1}{a_{i}}\right)=\log (n)$ which establish the result.
4.59 Assume that $\mathrm{E} X=0, \mathrm{E} Y=0$, and $\mathrm{E} Z=0$. This can be done without loss of generality because we could work with the quantities $X-\mathrm{E} X$, etc. By iterating the expectation we have

$$
\operatorname{Cov}(X, Y)=\mathrm{E} X Y=\mathrm{E}[\mathrm{E}(X Y \mid Z)]
$$

Adding and subtracting $\mathrm{E}(X \mid Z) \mathrm{E}(Y \mid Z)$ gives

$$
\operatorname{Cov}(X, Y)=\mathrm{E}[\mathrm{E}(X Y \mid Z)-\mathrm{E}(X \mid Z) \mathrm{E}(Y \mid Z)]+\mathrm{E}[\mathrm{E}(X \mid Z) \mathrm{E}(Y \mid Z)]
$$

Since $\mathrm{E}[\mathrm{E}(X \mid Z)]=\mathrm{E} X=0$, the second term above is $\operatorname{Cov}[\mathrm{E}(X \mid Z) \mathrm{E}(Y \mid Z)]$. For the first term write

$$
\mathrm{E}[\mathrm{E}(X Y \mid Z)-\mathrm{E}(X \mid Z) \mathrm{E}(Y \mid Z)]=\mathrm{E}[\mathrm{E}\{X Y-\mathrm{E}(X \mid Z) \mathrm{E}(Y \mid Z) \mid Z\}]
$$

where we have brought $\mathrm{E}(X \mid Z)$ and $\mathrm{E}(Y \mid Z)$ inside the conditional expectation. This can now be recognized as $\operatorname{ECov}(X, Y \mid Z)$, establishing the identity.
4.61 a. To find the distribution of $f\left(X_{1} \mid Z\right)$, let $U=\frac{X_{2}-1}{X_{1}}$ and $V=X_{1}$. Then $x_{2}=h_{1}(u, v)=u v+1$, $x_{1}=h_{2}(u, v)=v$. Therefore

$$
f_{U, V}(u, v)=f_{X, Y}\left(h_{1}(u, v), h_{2}(u, v)\right)|J|=e^{-(u v+1)} e^{-v} v
$$

and

$$
f_{U}(u)=\int_{0}^{\infty} v e^{-(u v+1)} e^{-v} d v=\frac{e^{-1}}{(u+1)^{2}}
$$

Thus $V \mid U=0$ has distribution $v e^{-v}$. The distribution of $X_{1} \mid X_{2}$ is $e^{-x_{1}}$ since $X_{1}$ and $X_{2}$ are independent.
b. The following Mathematica code will draw the picture; the solid lines are $B_{1}$ and the dashed lines are $B_{2}$. Note that the solid lines increase with $x 1$, while the dashed lines are constant. Thus $B_{1}$ is informative, as the range of $X_{2}$ changes.

```
e = 1/10;
Plot[{-e*x1 + 1, e*x1 + 1, 1-e, 1 + e}, {x1, 0, 5},
PlotStyle -> {Dashing[{}], Dashing[{}],Dashing[{0.15, 0.05}],
    Dashing[{0.15, 0.05}]}]
```

c.

$$
\begin{aligned}
P\left(X_{1} \leq x \mid B_{1}\right) & =P\left(V \leq v^{*} \mid-\epsilon<U<\epsilon\right)=\frac{\int_{0}^{v^{*}} \int_{-\epsilon}^{\epsilon} v e^{-(u v+1)} e^{-v} d u d v}{\int_{0}^{\infty} \int_{-\epsilon}^{\epsilon} v e^{-(u v+1)} e^{-v} d u d v} \\
& =\frac{e^{-1}\left[\frac{e^{-v^{*}(1+\epsilon)}}{1+\epsilon}-\frac{1}{1+\epsilon}-\frac{e^{-v^{*}(1-\epsilon)}}{1-\epsilon}+\frac{1}{1-\epsilon}\right]}{e^{-1}\left[-\frac{1}{1+\epsilon}+\frac{1}{1-\epsilon}\right]}
\end{aligned}
$$

Thus $\lim _{\epsilon \rightarrow 0} P\left(X_{1} \leq x \mid B_{1}\right)=1-e^{-v^{*}}-v^{*} e^{-v^{*}}=\int_{0}^{v^{*}} v e^{-v} d v=P\left(V \leq v^{*} \mid U=0\right)$.

$$
P\left(X_{1} \leq x \mid B_{2}\right)=\frac{\int_{0}^{x} \int_{0}^{1+\epsilon} e^{-\left(x_{1}+x_{2}\right)} d x_{2} d x_{1}}{\int_{0}^{1+\epsilon} e^{-x_{2}} d x_{2}}=\frac{e^{-(x+1+\epsilon)}-e^{-(1+\epsilon)}-e^{-x}+1}{1-e^{-(1+\epsilon)}}
$$

Thus $\lim _{\epsilon \rightarrow 0} P\left(X_{1} \leq x \mid B_{2}\right)=1-e^{x}=\int_{0}^{x} e^{x_{1}} d x_{1}=P\left(X_{1} \leq x \mid X_{2}=1\right)$.
4.63 Since $X=e^{Z}$ and $g(z)=e^{z}$ is convex, by Jensen's Inequality $\mathrm{E} X=\mathrm{E} g(Z) \geq g(\mathrm{E} Z)=e^{0}=1$. In fact, there is equality in Jensen's Inequality if and only if there is an interval $I$ with $P(Z \in$ $I)=1$ and $g(z)$ is linear on $I$. But $e^{z}$ is linear on an interval only if the interval is a single point. So $\mathrm{E} X>1$, unless $P(Z=\mathrm{E} Z=0)=1$.
4.64 a. Let $a$ and $b$ be real numbers. Then,

$$
|a+b|^{2}=(a+b)(a+b)=a^{2}+2 a b+b^{2} \leq|a|^{2}+2|a b|+|b|^{2}=(|a|+|b|)^{2} .
$$

Take the square root of both sides to get $|a+b| \leq|a|+|b|$.
b. $|X+Y| \leq|X|+|Y| \Rightarrow \mathrm{E}|X+Y| \leq \mathrm{E}(|X|+|Y|)=\mathrm{E}|X|+\mathrm{E}|Y|$.
4.65 Without loss of generality let us assume that $\mathrm{E} g(X)=\mathrm{E} h(X)=0$. For part (a)

$$
\begin{aligned}
\mathrm{E}(g(X) h(X)) & =\int_{-\infty}^{\infty} g(x) h(x) f_{X}(x) d x \\
& =\int_{\{x: h(x) \leq 0\}} g(x) h(x) f_{X}(x) d x+\int_{\{x: h(x) \geq 0\}} g(x) h(x) f_{X}(x) d x \\
& \leq g\left(x_{0}\right) \int_{\{x: h(x) \leq 0\}} h(x) f_{X}(x) d x+g\left(x_{0}\right) \int_{\{x: h(x) \geq 0\}} h(x) f_{X}(x) d x \\
& =\int_{-\infty}^{\infty} h(x) f_{X}(x) d x \\
& =g\left(x_{0}\right) \operatorname{E} h(X)=0 .
\end{aligned}
$$

where $x_{0}$ is the number such that $h\left(x_{0}\right)=0$. Note that $g\left(x_{0}\right)$ is a maximum in $\{x: h(x) \leq 0\}$ and a minimum in $\{x: h(x) \geq 0\}$ since $g(x)$ is nondecreasing. For part (b) where $g(x)$ and $h(x)$ are both nondecreasing

$$
\begin{aligned}
\mathrm{E}(g(X) h(X)) & =\int_{-\infty}^{\infty} g(x) h(x) f_{X}(x) d x \\
& =\int_{\{x: h(x) \leq 0\}} g(x) h(x) f_{X}(x) d x+\int_{\{x: h(x) \geq 0\}} g(x) h(x) f_{X}(x) d x \\
& \geq g\left(x_{0}\right) \int_{\{x: h(x) \leq 0\}} h(x) f_{X}(x) d x+g\left(x_{0}\right) \int_{\{x: h(x) \geq 0\}} h(x) f_{X}(x) d x \\
& =\int_{-\infty}^{\infty} h(x) f_{X}(x) d x \\
& =g\left(x_{0}\right) \operatorname{Eh}(X)=0 .
\end{aligned}
$$

The case when $g(x)$ and $h(x)$ are both nonincreasing can be proved similarly.

## Chapter 5

## Properties of a Random Sample

5.1 Let $X=\#$ color blind people in a sample of size $n$. Then $X \sim \operatorname{binomial}(n, p)$, where $p=.01$. The probability that a sample contains a color blind person is $P(X>0)=1-P(X=0)$, where $P(X=0)=\binom{n}{0}(.01)^{0}(.99)^{n}=.99^{n}$. Thus,

$$
P(X>0)=1-.99^{n}>.95 \Leftrightarrow n>\log (.05) / \log (.99) \approx 299 .
$$

5.3 Note that $Y_{i} \sim$ Bernoulli with $p_{i}=P\left(X_{i} \geq \mu\right)=1-F(\mu)$ for each $i$. Since the $Y_{i}$ 's are iid Bernoulli, $\sum_{i=1}^{n} Y_{i} \sim \operatorname{binomial}(n, p=1-F(\mu))$.
5.5 Let $Y=X_{1}+\cdots+X_{n}$. Then $\bar{X}=(1 / n) Y$, a scale transformation. Therefore the pdf of $\bar{X}$ is $f_{\bar{X}}(x)=\frac{1}{1 / n} f_{Y}\left(\frac{x}{1 / n}\right)=n f_{Y}(n x)$.
5.6 a. For $Z=X-Y$, set $W=X$. Then $Y=W-Z, X=W$, and $|J|=\left|\begin{array}{cc}0 & 1 \\ -1 & 1\end{array}\right|=1$. Then $f_{Z, W}(z, w)=f_{X}(w) f_{Y}(w-z) \cdot 1$, thus $f_{Z}(z)=\int_{-\infty}^{\infty} f_{X}(w) f_{Y}(w-z) d w$.
b. For $Z=X Y$, set $W=X$. Then $Y=Z / W$ and $|J|=\left|\begin{array}{cc}0 & 1 \\ 1 / w & -z / w^{2}\end{array}\right|=-1 / w$. Then $f_{Z, W}(z, w)=f_{X}(w) f_{Y}(z / w) \cdot|-1 / w|$, thus $f_{Z}(z)=\int_{-\infty}^{\infty}|-1 / w| f_{X}(w) f_{Y}(z / w) d w$.
c. For $Z=X / Y$, set $W=X$. Then $\mathrm{Y}=\mathrm{W} / \mathrm{Z}$ and $|J|=\left|\begin{array}{cc}0 & 1 \\ -w / z^{2} & 1 / z\end{array}\right|=w / z^{2}$. Then $f_{Z, W}(z, w)=f_{X}(w) f_{Y}(w / z) \cdot\left|w / z^{2}\right|$, thus $f_{Z}(z)=\int_{-\infty}^{\infty}\left|w / z^{2}\right| f_{X}(w) f_{Y}(w / z) d w$.
5.7 It is, perhaps, easiest to recover the constants by doing the integrations. We have

$$
\int_{-\infty}^{\infty} \frac{B}{1+\left(\frac{\omega}{\sigma}\right)^{2}} d \omega=\sigma \pi B, \quad \int_{-\infty}^{\infty} \frac{D}{1+\left(\frac{\omega-z}{\tau}\right)^{2}} d \omega=\tau \pi D
$$

and

$$
\begin{aligned}
& \int_{-\infty}^{\infty}\left[\frac{A \omega}{1+\left(\frac{\omega}{\sigma}\right)^{2}}-\frac{C \omega}{1+\left(\frac{\omega-z}{\tau}\right)^{2}}\right] d \omega \\
& \quad=\int_{-\infty}^{\infty}\left[\frac{A \omega}{1+\left(\frac{\omega}{\sigma}\right)^{2}}-\frac{C(\omega-z)}{1+\left(\frac{\omega-z}{\tau}\right)^{2}}\right] d \omega-C z \int_{-\infty}^{\infty} \frac{1}{1+\left(\frac{\omega-z}{\tau}\right)^{2}} d \omega \\
& \quad=A \frac{\sigma^{2}}{2} \log \left[1+\left(\frac{\omega}{\sigma}\right)^{2}\right]-\left.\frac{C \tau^{2}}{2} \log \left[1+\left(\frac{\omega-z}{\tau}\right)^{2}\right]\right|_{-\infty} ^{\infty}-\tau \pi C z
\end{aligned}
$$

The integral is finite and equal to zero if $A=M \frac{2}{\sigma^{2}}, C=M \frac{2}{\tau^{2}}$ for some constant $M$. Hence

$$
f_{Z}(z)=\frac{1}{\pi^{2} \sigma \tau}\left[\sigma \pi B-\tau \pi D-\frac{2 \pi M z}{\tau}\right]=\frac{1}{\pi(\sigma+\tau)} \frac{1}{1+(z /(\sigma+\tau))^{2}}
$$

if $B=\frac{\tau}{\sigma+\tau}, D=\frac{\sigma}{\sigma+\tau)}, M=\frac{-\sigma \tau^{2}}{2 z(\sigma+\tau)} \frac{1}{1+\left(\frac{z}{\sigma+\tau}\right)^{2}}$.
5.8 a.

$$
\begin{aligned}
& \frac{1}{2 n(n-1)} \sum_{i=1}^{n} \sum_{j=1}^{n}\left(X_{i}-X_{j}\right)^{2} \\
& \quad=\frac{1}{2 n(n-1)} \sum_{i=1}^{n} \sum_{j=1}^{n}\left(X_{i}-\bar{X}+\bar{X}-X_{j}\right)^{2} \\
& =\frac{1}{2 n(n-1)} \sum_{i=1}^{n} \sum_{j=1}^{n}\left[\left(X_{i}-\bar{X}\right)^{2}-2\left(X_{i}-\bar{X}\right)\left(X_{j}-\bar{X}\right)+\left(X_{j}-\bar{X}\right)^{2}\right] \\
& \quad=\frac{1}{2 n(n-1)}[\sum_{i=1}^{n} n\left(X_{i}-\bar{X}\right)^{2}-2 \sum_{i=1}^{n}\left(X_{i}-\bar{X}\right) \underbrace{\sum_{j=1}^{n}\left(X_{j}-\bar{X}\right)}_{=0}+n \sum_{j=1}^{n}\left(X_{j}-\bar{X}\right)^{2}] \\
& \quad=\frac{n}{2 n(n-1)} \sum_{i=1}^{n}\left(X_{i}-\bar{X}\right)^{2}+\frac{n}{2 n(n-1)} \sum_{j=1}^{n}\left(X_{j}-\bar{X}\right)^{2} \\
& \quad=\frac{1}{n-1} \sum_{i=1}^{n}\left(X_{i}-\bar{X}\right)^{2}=S^{2} .
\end{aligned}
$$

b. Although all of the calculations here are straightforward, there is a tedious amount of bookkeeping needed. It seems that induction is the easiest route. (Note: Without loss of generality we can assume $\theta_{1}=0$, so $\mathrm{E} X_{i}=0$.)
(i) Prove the equation for $n=4$. We have $S^{2}=\frac{1}{24} \sum_{i=1}^{4} \sum_{j=1}^{4}\left(X_{i}-X_{j}\right)^{2}$, and to calculate $\operatorname{Var}\left(S^{2}\right)$ we need to calculate $\mathrm{E}\left(S^{2}\right)^{2}$ and $\mathrm{E}\left(S^{2}\right)$. The latter expectation is straightforward and we get $\mathrm{E}\left(S^{2}\right)=24 \theta_{2}$. The expected value $\mathrm{E}\left(S^{2}\right)^{2}=\mathrm{E}\left(S^{4}\right)$ contains $256\left(=4^{4}\right)$ terms of which $112\left(=4 \times 16+4 \times 16-4^{2}\right)$ are zero, whenever $i=j$. Of the remaining terms,

- 24 are of the form $\mathrm{E}\left(X_{i}-X_{j}\right)^{4}=2\left(\theta_{4}+3 \theta_{2}^{2}\right)$
- 96 are of the form $\mathrm{E}\left(X_{i}-X_{j}\right)^{2}\left(X_{i}-X_{k}\right)^{2}=\theta_{4}+3 \theta_{2}^{2}$
- 24 are of the form $\mathrm{E}\left(X_{i}-X_{j}\right)^{2}\left(X_{k}-X_{\ell}\right)^{2}=4 \theta_{2}^{2}$

Thus,

$$
\operatorname{Var}\left(S^{2}\right)=\frac{1}{24^{2}}\left[24 \times 2\left(\theta_{4}+3 \theta_{2}^{2}\right)+96\left(\theta_{4}+3 \theta_{2}^{2}\right)+24 \times 4 \theta_{4}-\left(24 \theta_{2}\right)^{2}\right]=\frac{1}{4}\left[\theta_{4}-\frac{1}{3} \theta_{2}^{2}\right]
$$

(ii) Assume that the formula holds for $n$, and establish it for $n+1$. (Let $S_{n}$ denote the variance based on $n$ observations.) Straightforward algebra will establish

$$
\begin{aligned}
S_{n+1}^{2} & =\frac{1}{2 n(n+1)}\left[\sum_{i=1}^{n} \sum_{j=1}^{n}\left(X_{i}-X_{j}\right)^{2}+2 \sum_{k=1}^{n}\left(X_{k}-X_{n+1}\right)^{2}\right] \\
& \stackrel{\text { deffn }}{=} \frac{1}{2 n(n+1)}[A+2 B]
\end{aligned}
$$

where

$$
\begin{array}{rlr}
\operatorname{Var}(A) & =4 n(n-1)^{2}\left[\theta_{4}-\frac{n-3}{n-1} \theta_{2}^{2}\right] & \\
\operatorname{Var}(B) & =n(n+1) \theta_{4}-n(n-3) \theta_{2}^{2} & \\
\operatorname{Cov}(A, B) & =2 n(n-1)\left[\theta_{k}-\theta_{2}^{2}\right] & \text { (some minor } X_{n+1} \text { are independention hypothesis) } \\
\text { (soeping needed) }
\end{array}
$$

Hence,

$$
\operatorname{Var}\left(S_{n+1}^{2}\right)=\frac{1}{4 n^{2}(n+1)^{2}}[\operatorname{Var}(A)+4 \operatorname{Var}(B)+4 \operatorname{Cov}(A, B)]=\frac{1}{n+1}\left[\theta_{4}-\frac{n-2}{n} \theta_{2}^{2}\right]
$$

establishing the induction and verifying the result.
c. Again assume that $\theta_{1}=0$. Then

$$
\operatorname{Cov}\left(\bar{X}, S^{2}\right)=\frac{1}{2 n^{2}(n-1)} \mathrm{E}\left\{\sum_{k=1}^{n} X_{k} \sum_{i=1}^{n} \sum_{j=1}^{n}\left(X_{i}-X_{j}\right)^{2}\right\}
$$

The double sum over $i$ and $j$ has $n(n-1)$ nonzero terms. For each of these, the entire expectation is nonzero for only two values of $k$ (when $k$ matches either $i$ or $j$ ). Thus

$$
\operatorname{Cov}\left(\bar{X}, S^{2}\right)=\frac{2 n(n-1)}{2 n^{2}(n-1)} \mathrm{E} X_{i}\left(X_{i}-X_{j}\right)^{2}=\frac{1}{n} \theta_{3}
$$

and $\bar{X}$ and $S^{2}$ are uncorrelated if $\theta_{3}=0$.
5.9 To establish the Lagrange Identity consider the case when $n=2$,

$$
\begin{aligned}
\left(a_{1} b_{2}-a_{2} b_{1}\right)^{2} & =a_{1}^{2} b_{2}^{2}+a_{2}^{2} b_{1}^{2}-2 a_{1} b_{2} a_{2} b_{1} \\
& =a_{1}^{2} b_{2}^{2}+a_{2}^{2} b_{1}^{2}-2 a_{1} b_{2} a_{2} b_{1}+a_{1}^{2} b_{1}^{2}+a_{2}^{2} b_{2}^{2}-a_{1}^{2} b_{1}^{2}-a_{2}^{2} b_{2}^{2} \\
& =\left(a_{1}^{2}+a_{2}^{2}\right)\left(b_{1}^{2}+b_{2}^{2}\right)-\left(a_{1} b_{1}+a_{2} b_{2}\right)^{2}
\end{aligned}
$$

Assume that is true for $n$, then

$$
\begin{aligned}
\left(\sum_{i=1}^{n+1} a_{i}^{2}\right) & \left(\sum_{i=1}^{n+1} b_{i}^{2}\right)-\left(\sum_{i=1}^{n+1} a_{i} b_{i}\right)^{2} \\
= & \left(\sum_{i=1}^{n} a_{i}^{2}+a_{n+1}^{2}\right)\left(\sum_{i=1}^{n} b_{i}^{2}+b_{n+1}^{2}\right)-\left(\sum_{i=1}^{n} a_{i} b_{i}+a_{n+1} b_{n+1}\right)^{2} \\
= & \left(\sum_{i=1}^{n} a_{i}^{2}\right)\left(\sum_{i=1}^{n} b_{i}^{2}\right)-\left(\sum_{i=1}^{n} a_{i} b_{i}\right)^{2} \\
& +\left(\sum_{i=1}^{n} a_{i}^{2}\right) b_{n+1}^{2}+a_{n+1}^{2}\left(\sum_{i=1}^{n} b_{i}^{2}\right)-2\left(\sum_{i=1}^{n} a_{i} b_{i}\right) a_{n+1} b_{n+1} \\
= & \sum_{i=1}^{n-1} \sum_{j=i+1}^{n}\left(a_{i} b_{j}-a_{j} b_{i}\right)^{2}+\sum_{i=1}^{n}\left(a_{i} b_{n+1}-a_{n+1} b_{i}\right)^{2} \\
= & \sum_{i=1}^{n} \sum_{j=i+1}^{n+1}\left(a_{i} b_{j}-a_{j} b_{i}\right)^{2} .
\end{aligned}
$$

If all the points lie on a straight line then $Y-\mu_{y}=c\left(X-\mu_{x}\right)$, for some constant $c \neq 0$. Let $b_{i}=Y-\mu_{y}$ and $a_{i}=\left(X-\mu_{x}\right)$, then $b_{i}=c a_{i}$. Therefore $\sum_{i=1}^{n} \sum_{j=i+1}^{n+1}\left(a_{i} b_{j}-a_{j} b_{i}\right)^{2}=0$. Thus the correlation coefficient is equal to 1 .
5.10 a.

$$
\theta_{1}=\mathrm{E} X_{i}=\mu
$$

$$
\begin{aligned}
\theta_{2} & =\mathrm{E}\left(X_{i}-\mu\right)^{2}=\sigma^{2} \\
\theta_{3} & =\mathrm{E}\left(X_{i}-\mu\right)^{3} \\
& \left.=\mathrm{E}\left(X_{i}-\mu\right)^{2}\left(X_{i}-\mu\right) \quad \text { (Stein's lemma: } \mathrm{E} g(X)(X-\theta)=\sigma^{2} \mathrm{E} g^{\prime}(X)\right) \\
& =2 \sigma^{2} \mathrm{E}\left(X_{i}-\mu\right)=0 \\
\theta_{4} & =\mathrm{E}\left(X_{i}-\mu\right)^{4}=\mathrm{E}\left(X_{i}-\mu\right)^{3}\left(X_{i}-\mu\right)=3 \sigma^{2} \mathrm{E}\left(X_{i}-\mu\right)^{2}=3 \sigma^{4}
\end{aligned}
$$

b. $\operatorname{Var} S^{2}=\frac{1}{n}\left(\theta_{4}-\frac{n-3}{n-1} \theta_{2}^{2}\right)=\frac{1}{n}\left(3 \sigma^{4}-\frac{n-3}{n-1} \sigma^{4}\right)=\frac{2 \sigma^{4}}{n-1}$.
c. Use the fact that $(n-1) S^{2} / \sigma^{2} \sim \chi_{n-1}^{2}$ and $\operatorname{Var} \chi_{n-1}^{2}=2(n-1)$ to get

$$
\operatorname{Var}\left(\frac{(n-1) S^{2}}{\sigma^{2}}\right)=2(n-1)
$$

which implies $\left(\frac{(n-1)^{2}}{\sigma^{4}}\right) \operatorname{Var} S^{2}=2(n-1)$ and hence

$$
\operatorname{Var} S^{2}=\frac{2(n-1)}{(n-1)^{2} / \sigma^{4}}=\frac{2 \sigma^{4}}{n-1}
$$

Remark: Another approach to b), not using the $\chi^{2}$ distribution, is to use linear model theory. For any matrix $A \operatorname{Var}\left(X^{\prime} A X\right)=2 \mu_{2}^{2} \operatorname{tr} A^{2}+4 \mu_{2} \theta^{\prime} A \theta$, where $\mu_{2}$ is $\sigma^{2}, \theta=\mathrm{E} X=\mu 1$. Write $S^{2}=\frac{1}{n-1} \sum_{i=1}^{n}\left(X_{i}-\bar{X}\right)=\frac{1}{n-1} X^{\prime}\left(I-\bar{J}_{n}\right) X$. Where

$$
I-\bar{J}_{n}=\left(\begin{array}{cccc}
1-\frac{1}{n} & -\frac{1}{n} & \cdots & -\frac{1}{n} \\
-\frac{1}{n} & 1-\frac{1}{n} & & \vdots \\
\vdots & & \ddots & \vdots \\
-\frac{1}{n} & \cdots & \cdots & 1-\frac{1}{n}
\end{array}\right)
$$

Notice that $\operatorname{tr} A^{2}=\operatorname{tr} A=n-1, A \theta=0$. So

$$
\operatorname{Var} S^{2}=\frac{1}{(n-1)^{2}} \operatorname{Var}\left(X^{\prime} A X\right)=\frac{1}{(n-1)^{2}}\left(2 \sigma^{4}(n-1)+0\right)=\frac{2 \sigma^{4}}{n-1}
$$

5.11 Let $g(s)=s^{2}$. Since $g(\cdot)$ is a convex function, we know from Jensen's inequality that $\mathrm{E} g(S) \geq$ $g(\mathrm{E} S)$, which implies $\sigma^{2}=\mathrm{E} S^{2} \geq(\mathrm{E} S)^{2}$. Taking square roots, $\sigma \geq \mathrm{E} S$. From the proof of Jensen's Inequality, it is clear that, in fact, the inequality will be strict unless there is an interval I such that g is linear on I and $P(X \in I)=1$. Since $s^{2}$ is "linear" only on single points, we have $\mathrm{E} T^{2}>(\mathrm{E} T)^{2}$ for any random variable $T$, unless $P(T=\mathrm{E} T)=1$.
5.13

$$
\begin{aligned}
\mathrm{E}\left(c \sqrt{S^{2}}\right) & =c \sqrt{\frac{\sigma^{2}}{n-1}} \mathrm{E}\left(\sqrt{\frac{S^{2}(n-1)}{\sigma^{2}}}\right) \\
& =c \sqrt{\frac{\sigma^{2}}{n-1}} \int_{0}^{\infty} \sqrt{q} \frac{1}{\Gamma\left(\frac{n-1}{2}\right) 2^{(n-1) / 2}} q^{\left(\frac{n-1}{2}\right)-1} e^{-q / 2} d q
\end{aligned}
$$

Since $\sqrt{S^{2}(n-1) / \sigma^{2}}$ is the square root of a $\chi^{2}$ random variable. Now adjust the integrand to be another $\chi^{2}$ pdf and get

$$
\mathrm{E}\left(c \sqrt{S^{2}}\right)=c \sqrt{\frac{\sigma^{2}}{n-1}} \cdot \frac{\Gamma(n / 2) 2^{n / 2}}{\Gamma((n-1) / 2) 2^{((n-1) / 2}} \underbrace{\int_{0}^{\infty} \frac{1}{\Gamma(n / 2) 2^{n / 2}} q^{(n-1) / 2}-\frac{1}{2} e^{-q / 2} d q}_{=1 \text { since } \chi_{n}^{2} \mathrm{pdf}}
$$

So $c=\frac{\Gamma\left(\frac{n-1}{2}\right) \sqrt{n-1}}{\sqrt{2} \Gamma\left(\frac{n}{2}\right)}$ gives $\mathrm{E}(c S)=\sigma$.
5.15 a.

$$
\bar{X}_{n+1}=\frac{\sum_{i=1}^{n+1} X_{i}}{n+1}=\frac{X_{n+1}+\sum_{i=1}^{n} X_{i}}{n+1}=\frac{X_{n+1}+n \bar{X}_{n}}{n+1}
$$

b.

$$
\begin{aligned}
n S_{n+1}^{2} & =\frac{n}{(n+1)-1} \sum_{i=1}^{n+1}\left(X_{i}-\bar{X}_{n+1}\right)^{2} \\
& =\sum_{i=1}^{n+1}\left(X_{i}-\frac{X_{n+1}+n \bar{X}_{n}}{n+1}\right)^{2} \\
& =\sum_{i=1}^{n+1}\left(X_{i}-\frac{X_{n+1}}{n+1}-\frac{n \bar{X}_{n}}{n+1}\right)^{2} \\
& =\sum_{i=1}^{n+1}\left[\left(X_{i}-\bar{X}_{n}\right)-\left(\frac{X_{n+1}}{n+1}-\frac{\bar{X}_{n}}{n+1}\right)\right]^{2} \quad \quad \text { use (a)) } \\
& =\sum_{i=1}^{n+1}\left[\left(X_{i}-\bar{X}_{n}\right)^{2}-2\left(X_{i}-\bar{X}_{n}\right)\left(\frac{X_{n+1}-\bar{X}_{n}}{n+1}\right)+\frac{1}{(n+1)^{2}}\left(X_{n+1}-\bar{X}_{n}\right)^{2}\right] \\
& =\sum_{i=1}^{n}\left(X_{i}-\bar{X}_{n}\right)^{2}+\left(X_{n+1}-\bar{X}_{n}\right)^{2}-2 \frac{\left(X_{n+1}-\bar{X}_{n}\right)^{2}}{n+1}+\frac{n+1}{(n+1)^{2}}\left(X_{n+1}-\bar{X}_{n}\right)^{2}
\end{aligned}
$$

$$
=(n-1) S_{n}^{2}+\frac{n}{n+1}\left(X_{n+1}-\bar{X}_{n}\right)^{2} .
$$

5.16 a. $\sum_{i=1}^{3}\left(\frac{X_{i}-i}{i}\right)^{2} \sim \chi_{3}^{2}$
b. $\left(\frac{X_{i}-1}{i}\right) / \sqrt{\sum_{i=2}^{3}\left(\frac{X_{i}-i}{i}\right)^{2}} / 2 \sim t_{2}$
c. Square the random variable in part b).
5.17 a. Let $U \sim \chi_{p}^{2}$ and $V \sim \chi_{q}^{2}$, independent. Their joint pdf is

$$
\frac{1}{\Gamma\left(\frac{p}{2}\right) \Gamma\left(\frac{q}{2}\right) 2^{(p+q) / 2}} u^{\frac{p}{2}-1} v^{\frac{q}{2}-1} e^{\frac{-(u+v)}{2}} .
$$

From Definition 5.3.6, the random variable $X=(U / p) /(V / q)$ has an $F$ distribution, so we make the transformation $x=(u / p) /(v / q)$ and $y=u+v$. (Of course, many choices of $y$ will do, but this one makes calculations easy. The choice is prompted by the exponential term in the pdf.) Solving for $u$ and $v$ yields

$$
u=\frac{\frac{p}{q} x y}{1+\frac{q}{p} x}, \quad v=\frac{y}{1+\frac{q}{p} x}, \text { and }|J|=\frac{\frac{q}{p} y}{\left(1+\frac{q}{p} x\right)^{2}} .
$$

We then substitute into $f_{U, V}(u, v)$ to obtain

$$
f_{X, Y}(x, y)=\frac{1}{\Gamma\left(\frac{p}{2}\right) \Gamma\left(\frac{q}{2}\right) 2^{(p+q) / 2}}\left(\frac{\frac{p}{q} x y}{1+\frac{q}{p} x}\right)^{\frac{p}{2}-1}\left(\frac{y}{1+\frac{q}{p} x}\right)^{\frac{q}{2}-1} e^{\frac{-y}{2}} \frac{\frac{q}{p} y}{\left(1+\frac{q}{p} x\right)^{2}} .
$$

Note that the pdf factors, showing that $X$ and $Y$ are independent, and we can read off the pdfs of each: $X$ has the $F$ distribution and $Y$ is $\chi_{p+q}^{2}$. If we integrate out $y$ to recover the proper constant, we get the $F$ pdf

$$
f_{X}(x)=\frac{\Gamma\left(\frac{p+q}{2}\right)}{\Gamma\left(\frac{p}{2}\right) \Gamma\left(\frac{q}{2}\right)}\left(\frac{q}{p}\right)^{p / 2} \frac{x^{p / 2-1}}{\left(1+\frac{q}{p} x\right)^{\frac{p+q}{2}}}
$$

b. Since $F_{p, q}=\frac{\chi_{p}^{2} / p}{\chi_{q}^{2} / q}$, let $U \sim \chi_{p}^{2}, V \sim \chi_{q}^{2}$ and $U$ and $V$ are independent. Then we have

$$
\begin{aligned}
\mathrm{E} F_{p, q} & =\mathrm{E}\left(\frac{U / p}{V / q}\right)=\mathrm{E}\left(\frac{U}{p}\right) \mathrm{E}\left(\frac{q}{V}\right) & & \text { (by independence) } \\
& =\frac{p}{p} q \mathrm{E}\left(\frac{1}{V}\right) & & (\mathrm{E} U=p)
\end{aligned}
$$

Then

$$
\begin{aligned}
\mathrm{E}\left(\frac{1}{V}\right) & =\int_{0}^{\infty} \frac{1}{v} \frac{1}{\Gamma\left(\frac{q}{2}\right) 2^{q / 2}} v^{\frac{q}{2}-1} e^{-\frac{v}{2}} d v=\frac{1}{\Gamma\left(\frac{q}{2}\right) 2^{q / 2}} \int_{0}^{\infty} v^{\frac{q-2}{2}-1} e^{-\frac{v}{2}} d v \\
& =\frac{1}{\Gamma\left(\frac{q}{2}\right) 2^{q / 2}} \Gamma\left(\frac{q-2}{2}\right) 2^{(q-2) / 2}=\frac{\Gamma\left(\frac{q-2}{2}\right) 2^{(q-2) / 2}}{\Gamma\left(\frac{q-2}{2}\right)\left(\frac{q-2}{2}\right) 2^{q / 2}}=\frac{1}{q-2} .
\end{aligned}
$$

Hence, $\mathrm{E} F_{p, q}=\frac{p}{p} \frac{q}{q-2}=\frac{q}{q-2}$, if $q>2$. To calculate the variance, first calculate

$$
\mathrm{E}\left(F_{p, q}^{2}\right)=\mathrm{E}\left(\frac{U^{2}}{p^{2}} \frac{q^{2}}{V^{2}}\right)=\frac{q^{2}}{p^{2}} \mathrm{E}\left(U^{2}\right) \mathrm{E}\left(\frac{1}{V^{2}}\right)
$$

Now

$$
\mathrm{E}\left(U^{2}\right)=\operatorname{Var}(U)+(\mathrm{E} U)^{2}=2 p+p^{2}
$$

and

$$
\mathrm{E}\left(\frac{1}{V^{2}}\right)=\int_{0}^{\infty} \frac{1}{v^{2}} \frac{1}{\Gamma(q / 2) 2^{q / 2}} v^{(q / 2)-1} e^{-v / 2} d v=\frac{1}{(q-2)(q-4)}
$$

Therefore,

$$
\mathrm{E} F_{p, q}^{2}=\frac{q^{2}}{p^{2}} p(2+p) \frac{1}{(q-2)(q-4)}=\frac{q^{2}}{p} \frac{(p+2)}{(q-2)(q-4)},
$$

and, hence

$$
\operatorname{Var}\left(F_{p, q}\right)=\frac{q^{2}(p+2)}{p(q-2)(q-4)}-\frac{q^{2}}{(q-2)^{2}}=2\left(\frac{q}{q-2}\right)^{2}\left(\frac{q+p-2}{p(q-4)}\right), q>4
$$

c. Write $X=\frac{U / p}{V / p}$ then $\frac{1}{X}=\frac{V / q}{U / p} \sim F_{q, p}$, since $U \sim \chi_{p}^{2}, V \sim \chi_{q}^{2}$ and $U$ and $V$ are independent.
d. Let $Y=\frac{(p / q) X}{1+(p / q) X}=\frac{p X}{q+p X}$, so $X=\frac{q Y}{p(1-Y)}$ and $\left|\frac{d x}{d y}\right|=\frac{q}{p}(1-y)^{-2}$. Thus, $Y$ has pdf

$$
\begin{aligned}
f_{Y}(y) & =\frac{\Gamma\left(\frac{q+p}{2}\right)}{\Gamma\left(\frac{p}{2}\right) \Gamma\left(\frac{q}{2}\right)}\left(\frac{p}{q}\right)^{\frac{p}{2}} \frac{\left(\frac{q y}{p(1-y)}\right)^{\frac{p-2}{2}}}{\left(1+\frac{p}{q} \frac{q y}{p(1-y)}\right)^{\frac{p+q}{2}}} \frac{q}{p(1-y)^{2}} \\
& =\left[B\left(\frac{p}{2}, \frac{q}{2}\right)\right]^{-1} y^{\frac{p}{2}-1}(1-y)^{\frac{q}{2}-1} \sim \operatorname{beta}\left(\frac{p}{2}, \frac{q}{2}\right)
\end{aligned}
$$

5.18 If $X \sim t_{p}$, then $X=Z / \sqrt{V / p}$ where $Z \sim \mathrm{n}(0,1), V \sim \chi_{p}^{2}$ and $Z$ and $V$ are independent.
a. $\mathrm{E} X=\mathrm{E} Z / \sqrt{V / p}=(\mathrm{E} Z)(\mathrm{E} 1 / \sqrt{V / p})=0$, since $\mathrm{E} Z=0$, as long as the other expectation is finite. This is so if $p>1$. From part b), $X^{2} \sim F_{1, p}$. Thus $\operatorname{Var} X=\mathrm{E} X^{2}=p /(p-2)$, if $p>2$ (from Exercise 5.17b).
b. $X^{2}=Z^{2} /(V / p) . Z^{2} \sim \chi_{1}^{2}$, so the ratio is distributed $F_{1, p}$.
c. The pdf of $X$ is

$$
f_{X}(x)=\left[\frac{\Gamma\left(\frac{p+1}{2}\right)}{\Gamma(p / 2) \sqrt{p \pi}}\right] \frac{1}{\left(1+x^{2} / p\right)^{(p+1) / 2}} .
$$

Denote the quantity in square brackets by $C_{p}$. From an extension of Stirling's formula (Exercise 1.28) we have

$$
\begin{aligned}
\lim _{p \rightarrow \infty} C_{p} & =\lim _{p \rightarrow \infty} \frac{\sqrt{2 \pi}\left(\frac{p-1}{2}\right)^{\frac{p-1}{2}+\frac{1}{2}} e^{-\frac{p-1}{2}}}{\sqrt{2 \pi}\left(\frac{p-2}{2}\right)^{\frac{p-2}{2}+\frac{1}{2}} e^{-\frac{p-2}{2}}} \frac{1}{\sqrt{p \pi}} \\
& =\frac{e^{-1 / 2}}{\sqrt{\pi}} \lim _{p \rightarrow \infty} \frac{\left(\frac{p-1}{2}\right)^{\frac{p-1}{2}+\frac{1}{2}}}{\left(\frac{p-2}{2}\right)^{\frac{p-2}{2}+\frac{1}{2}} \sqrt{p}}=\frac{e^{-1 / 2}}{\sqrt{\pi}} \frac{e^{1 / 2}}{\sqrt{2}}
\end{aligned}
$$

by an application of Lemma 2.3.14. Applying the lemma again shows that for each $x$

$$
\lim _{p \rightarrow \infty}\left(1+x^{2} / p\right)^{(p+1) / 2}=e^{x^{2} / 2}
$$

establishing the result.
d. As the random variable $F_{1, p}$ is the square of a $t_{p}$, we conjecture that it would converge to the square of a $n(0,1)$ random variable, a $\chi_{1}^{2}$.
e. The random variable $q F_{q, p}$ can be thought of as the sum of $q$ random variables, each a $t_{p}$ squared. Thus, by all of the above, we expect it to converge to a $\chi_{q}^{2}$ random variable as $p \rightarrow \infty$.
5.19 a. $\chi_{p}^{2} \sim \chi_{q}^{2}+\chi_{d}^{2}$ where $\chi_{q}^{2}$ and $\chi_{d}^{2}$ are independent $\chi^{2}$ random variables with $q$ and $d=p-q$ degrees of freedom. Since $\chi_{d}^{2}$ is a positive random variable, for any $a>0$,

$$
P\left(\chi_{p}>a\right)=P\left(\chi_{q}^{2}+\chi_{d}^{2}>a\right)>P\left(\chi_{q}^{2}>a\right)
$$

b. For $k_{1}>k_{2}, k_{1} \mathrm{~F}_{k_{1}, \nu} \sim(U+V) /(W / \nu)$, where $U, V$ and $W$ are independent and $U \sim \chi_{k_{2}}^{2}$, $V \sim \chi_{k_{1}-k_{2}}^{2}$ and $W \sim \chi_{\nu}^{2}$. For any $a>0$, because $V /(W / \nu)$ is a positive random variable, we have

$$
P\left(k_{1} F_{k_{1}, \nu}>a\right)=P((U+V) /(W / \nu)>a)>P(U /(W / \nu)>a)=P\left(k_{2} F_{k_{2}, \nu}>a\right)
$$

c. $\alpha=P\left(F_{k, \nu}>F_{\alpha, k, \nu}\right)=P\left(k F_{k, \nu}>k F_{\alpha, k, \nu}\right)$. So, $k F_{\alpha, k, \nu}$ is the $\alpha$ cutoff point for the random variable $k F_{k, \nu}$. Because $k F_{k, \nu}$ is stochastically larger that $(k-1) F_{k-1, \nu}$, the $\alpha$ cutoff for $k F_{k, \nu}$ is larger than the $\alpha$ cutoff for $(k-1) F_{k-1, \nu}$, that is $k F_{\alpha, k, \nu}>(k-1) F_{\alpha, k-1, \nu}$.
5.20 a. The given integral is

$$
\begin{aligned}
& \int_{0}^{\infty} \frac{1}{\sqrt{2 \pi}} e^{-t^{2} x / 2} \nu \sqrt{x} \frac{1}{\Gamma(\nu / 2) 2^{\nu / 2}}(\nu x)^{(\nu / 2)-1} e^{-\nu x / 2} d x \\
& \quad=\frac{1}{\sqrt{2 \pi}} \frac{\nu^{\nu / 2}}{\Gamma(\nu / 2) 2^{\nu / 2}} \int_{0}^{\infty} e^{-t^{2} x / 2} x^{((\nu+1) / 2)-1} e^{-\nu x / 2} d x
\end{aligned}
$$

$$
\begin{aligned}
& =\frac{1}{\sqrt{2 \pi}} \frac{\nu^{\nu / 2}}{\Gamma(\nu / 2) 2^{\nu / 2}} \int_{0}^{\infty} x^{((\nu+1) / 2)-1} e^{-\left(\nu+t^{2}\right) x / 2} d x \quad\binom{\text { integrand is kernel of }}{\operatorname{gamma}\left((\nu+1) / 2,2 /\left(\nu+t^{2}\right)\right.} \\
& =\frac{1}{\sqrt{2 \pi}} \frac{\nu^{\nu / 2}}{\Gamma(\nu / 2) 2^{\nu / 2}} \Gamma((\nu+1) / 2)\left(\frac{2}{\nu+t^{2}}\right)^{(\nu+1) / 2} \\
& =\frac{1}{\sqrt{\nu \pi}} \frac{\Gamma((\nu+1) / 2)}{\Gamma(\nu / 2)} \frac{1}{\left(1+t^{2} / \nu\right)^{(\nu+1) / 2}}
\end{aligned}
$$

the pdf of a $t_{\nu}$ distribution.
b. Differentiate both sides with respect to $t$ to obtain

$$
\nu f_{F}(\nu t)=\int_{0}^{\infty} y f_{1}(t y) f_{\nu}(y) d y
$$

where $f_{F}$ is the $F$ pdf. Now write out the two chi-squared pdfs and collect terms to get

$$
\begin{aligned}
\nu f_{F}(\nu t) & =\frac{t^{-1 / 2}}{\Gamma(1 / 2) \Gamma(\nu / 2) 2^{(\nu+1) / 2}} \int_{0}^{\infty} y^{(\nu-1) / 2} e^{-(1+t) y / 2} d y \\
& =\frac{t^{-1 / 2}}{\Gamma(1 / 2) \Gamma(\nu / 2) 2^{(\nu+1) / 2}} \frac{\Gamma\left(\frac{\nu+1}{2}\right) 2^{(\nu+1) / 2}}{(1+t)^{(\nu+1) / 2}}
\end{aligned}
$$

Now define $y=\nu t$ to get

$$
f_{F}(y)=\frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\nu \Gamma(1 / 2) \Gamma(\nu / 2)} \frac{(y / \nu)^{-1 / 2}}{(1+y / \nu)^{(\nu+1) / 2}}
$$

the pdf of an $F_{1, \nu}$.
c. Again differentiate both sides with respect to $t$, write out the chi-squared pdfs, and collect terms to obtain

$$
(\nu / m) f_{F}((\nu / m) t)=\frac{t^{-m / 2}}{\Gamma(m / 2) \Gamma(\nu / 2) 2^{(\nu+m) / 2}} \int_{0}^{\infty} y^{(m+\nu-2) / 2} e^{-(1+t) y / 2} d y
$$

Now, as before, integrate the gamma kernel, collect terms, and define $y=(\nu / m) t$ to get

$$
f_{F}(y)=\frac{\Gamma\left(\frac{\nu+m}{2}\right)}{\Gamma(m / 2) \Gamma(\nu / 2)}\left(\frac{m}{\nu}\right)^{m / 2} \frac{y^{m / 2-1}}{(1+(m / \nu) y)^{(\nu+m) / 2}}
$$

the pdf of an $F_{m, \nu}$.
5.21 Let $m$ denote the median. Then, for general $n$ we have

$$
\begin{aligned}
P\left(\max \left(X_{1}, \ldots, X_{n}\right)>m\right) & =1-P\left(X_{i} \leq m \text { for } i=1,2, \ldots, n\right) \\
& =1-\left[P\left(X_{1} \leq m\right)\right]^{n}=1-\left(\frac{1}{2}\right)^{n}
\end{aligned}
$$

5.22 Calculating the cdf of $Z^{2}$, we obtain

$$
\begin{aligned}
F_{Z^{2}}(z) & =P\left((\min (X, Y))^{2} \leq z\right)=P(-z \leq \min (X, Y) \leq \sqrt{z}) \\
& =P(\min (X, Y) \leq \sqrt{z})-P(\min (X, Y) \leq-\sqrt{z}) \\
& =[1-P(\min (X, Y)>\sqrt{z})]-[1-P(\min (X, Y)>-\sqrt{z})] \\
& =P(\min (X, Y)>-\sqrt{z})-P(\min (X, Y)>\sqrt{z}) \\
& =P(X>-\sqrt{z}) P(Y>-\sqrt{z})-P(X>\sqrt{z}) P(Y>\sqrt{z})
\end{aligned}
$$

where we use the independence of $X$ and $Y$. Since $X$ and $Y$ are identically distributed, $P(X>$ $a)=P(Y>a)=1-F_{X}(a)$, so

$$
F_{Z^{2}}(z)=\left(1-F_{X}(-\sqrt{z})\right)^{2}-\left(1-F_{X}(\sqrt{z})\right)^{2}=1-2 F_{X}(-\sqrt{z})
$$

since $1-F_{X}(\sqrt{z})=F_{X}(-\sqrt{z})$. Differentiating and substituting gives

$$
f_{Z^{2}}(z)=\frac{d}{d z} F_{Z^{2}}(z)=f_{X}(-\sqrt{z}) \frac{1}{\sqrt{z}}=\frac{1}{\sqrt{2 \pi}} e^{-z / 2} z^{-1 / 2}
$$

the pdf of a $\chi_{1}^{2}$ random variable. Alternatively,

$$
\begin{aligned}
P\left(Z^{2} \leq z\right)= & P\left([\min (X, Y)]^{2} \leq z\right) \\
= & P(-\sqrt{z} \leq \min (X, Y) \leq \sqrt{z}) \\
= & P(-\sqrt{z} \leq X \leq \sqrt{z}, X \leq Y)+P(-\sqrt{z} \leq Y \leq \sqrt{z}, Y \leq X) \\
= & P(-\sqrt{z} \leq X \leq \sqrt{z} \mid X \leq Y) P(X \leq Y) \\
& +P(-\sqrt{z} \leq Y \leq \sqrt{z} \mid Y \leq X) P(Y \leq X) \\
= & \frac{1}{2} P(-\sqrt{z} \leq X \leq \sqrt{z})+\frac{1}{2} P(-\sqrt{z} \leq Y \leq \sqrt{z})
\end{aligned}
$$

using the facts that $X$ and $Y$ are independent, and $P(Y \leq X)=P(X \leq Y)=\frac{1}{2}$. Moreover, since $X$ and $Y$ are identically distributed

$$
P\left(Z^{2} \leq z\right)=P(-\sqrt{z} \leq X \leq \sqrt{z})
$$

and

$$
\begin{aligned}
f_{Z^{2}}(z) & =\frac{d}{d z} P(-\sqrt{z} \leq X \leq \sqrt{z})=\frac{1}{\sqrt{2 \pi}}\left(e^{-z / 2} \frac{1}{2} z^{-1 / 2}+e^{-z / 2} \frac{1}{2} z^{-1 / 2}\right) \\
& =\frac{1}{\sqrt{2 \pi}} z^{-1 / 2} e^{-z / 2}
\end{aligned}
$$

the pdf of a $\chi_{1}^{2}$.
5.23

$$
\begin{aligned}
P(Z>z) & =\sum_{x=1}^{\infty} P(Z>z \mid x) P(X=x)=\sum_{x=1}^{\infty} P\left(U_{1}>z, \ldots, U_{x}>z \mid x\right) P(X=x) \\
& \left.=\sum_{x=1}^{\infty} \prod_{i=1}^{x} P\left(U_{i}>z\right) P(X=x) \quad \quad \quad \text { (by independence of the } U_{i} ' \text { s }\right) \\
& =\sum_{x=1}^{\infty} P\left(U_{i}>z\right)^{x} P(X=x)=\sum_{x=1}^{\infty}(1-z)^{x} \frac{1}{(e-1) x!} \\
& =\frac{1}{(e-1)} \sum_{x=1}^{\infty} \frac{(1-z)^{x}}{x!}=\frac{e^{1-z}-1}{e-1} \quad 0<z<1 .
\end{aligned}
$$

5.24 Use $f_{X}(x)=1 / \theta, F_{X}(x)=x / \theta, 0<x<\theta$. Let $Y=X_{(n)}, Z=X_{(1)}$. Then, from Theorem 5.4.6,
$f_{Z, Y}(z, y)=\frac{n!}{0!(n-2)!0!} \frac{1}{\theta} \frac{1}{\theta}\left(\frac{z}{\theta}\right)^{0}\left(\frac{y-z}{\theta}\right)^{n-2}\left(1-\frac{y}{\theta}\right)^{0}=\frac{n(n-1)}{\theta^{n}}(y-z)^{n-2}, 0<z<y<\theta$.

Now let $W=Z / Y, Q=Y$. Then $Y=Q, Z=W Q$, and $|J|=q$. Therefore

$$
f_{W, Q}(w, q)=\frac{n(n-1)}{\theta^{n}}(q-w q)^{n-2} q=\frac{n(n-1)}{\theta^{n}}(1-w)^{n-2} q^{n-1}, 0<w<1,0<q<\theta
$$

The joint pdf factors into functions of $w$ and $q$, and, hence, $W$ and $Q$ are independent.
5.25 The joint pdf of $X_{(1)}, \ldots, X_{(n)}$ is

$$
f\left(u_{1}, \ldots, u_{n}\right)=\frac{n!a^{n}}{\theta^{a n}} u_{1}^{a-1} \cdots u_{n}^{a-1}, \quad 0<u_{1}<\cdots<u_{n}<\theta
$$

Make the one-to-one transformation to $Y_{1}=X_{(1)} / X_{(2)}, \ldots, Y_{n-1}=X_{(n-1)} / X_{(n)}, Y_{n}=X_{(n)}$. The Jacobian is $J=y_{2} y_{3}^{2} \cdots y_{n}^{n-1}$. So the joint pdf of $Y_{1}, \ldots, Y_{n}$ is

$$
\begin{aligned}
f\left(y_{1}, \ldots, y_{n}\right) & =\frac{n!a^{n}}{\theta^{a n}}\left(y_{1} \cdots y_{n}\right)^{a-1}\left(y_{2} \cdots y_{n}\right)^{a-1} \cdots\left(y_{n}\right)^{a-1}\left(y_{2} y_{3}^{2} \cdots y_{n}^{n-1}\right) \\
& =\frac{n!a^{n}}{\theta^{a n}} y_{1}^{a-1} y_{2}^{2 a-1} \cdots y_{n}^{n a-1}, \quad 0<y_{i}<1 ; i=1, \ldots, n-1, \quad 0<y_{n}<\theta
\end{aligned}
$$

We see that $f\left(y_{1}, \ldots, y_{n}\right)$ factors so $Y_{1}, \ldots, Y_{n}$ are mutually independent. To get the pdf of $Y_{1}$, integrate out the other variables and obtain that $f_{Y_{1}}\left(y_{1}\right)=c_{1} y_{1}^{a-1}, 0<y_{1}<1$, for some constant $c_{1}$. To have this pdf integrate to 1 , it must be that $c_{1}=a$. Thus $f_{Y_{1}}\left(y_{1}\right)=a y_{1}^{a-1}$, $0<y_{1}<1$. Similarly, for $i=2, \ldots, n-1$, we obtain $f_{Y_{i}}\left(y_{i}\right)=i a y_{i}^{i a-1}, 0<y_{i}<1$. From Theorem 5.4.4, the pdf of $Y_{n}$ is $f_{Y_{n}}\left(y_{n}\right)=\frac{n a}{\theta^{n a}} y_{n}^{n a-1}, 0<y_{n}<\theta$. It can be checked that the product of these marginal pdfs is the joint pdf given above.
5.27 a. $f_{X_{(i)} \mid X_{(j)}}(u \mid v)=f_{X_{(i)}, X_{(j)}}(u, v) / f_{X_{(j)}}(v)$. Consider two cases, depending on which of $i$ or $j$ is greater. Using the formulas from Theorems 5.4.4 and 5.4.6, and after cancellation, we obtain the following.
(i) If $i<j$,

$$
\begin{aligned}
f_{X_{(i)} \mid X_{(j)}}(u \mid v) & =\frac{(j-1)!}{(i-1)!(j-1-i)!} f_{X}(u) F_{X}^{i-1}(u)\left[F_{X}(v)-F_{X}(u)\right]^{j-i-1} F_{X}^{1-j}(v) \\
& =\frac{(j-1)!}{(i-1)!(j-1-i)!} \frac{f_{X}(u)}{F_{X}(v)}\left[\frac{F_{X}(u)}{F_{X}(v)}\right]^{i-1}\left[1-\frac{F_{X}(u)}{F_{X}(v)}\right]^{j-i-1}, \quad u<v
\end{aligned}
$$

Note this interpretation. This is the pdf of the $i$ th order statistic from a sample of size $j-1$, from a population with pdf given by the truncated distribution, $f(u)=f_{X}(u) / F_{X}(v)$, $u<v$.
(ii) If $j<i$ and $u>v$,

$$
\begin{aligned}
& f_{X_{(i)} \mid X_{(j)}}(u \mid v) \\
& \quad=\frac{(n-j)!}{(n-1)!(i-1-j)!} f_{X}(u)\left[1-F_{X}(u)\right]^{n-i}\left[F_{X}(u)-F_{X}(v)\right]^{i-1-j}\left[1-F_{X}(v)\right]^{j-n} \\
& \quad=\frac{(n-j)!}{(i-j-1)!(n-i)!} \frac{f_{X}(u)}{1-F_{X}(v)}\left[\frac{F_{X}(u)-F_{X}(v)}{1-F_{X}(v)}\right]^{i-j-1}\left[1-\frac{F_{X}(u)-F_{X}(v)}{1-F_{X}(v)}\right]^{n-i} .
\end{aligned}
$$

This is the pdf of the $(i-j)$ th order statistic from a sample of size $n-j$, from a population with pdf given by the truncated distribution, $f(u)=f_{X}(u) /\left(1-F_{X}(v)\right), u>v$.
b. From Example 5.4.7,

$$
f_{V \mid R}(v \mid r)=\frac{n(n-1) r^{n-2} / a^{n}}{n(n-1) r^{n-2}(a-r) / a^{n}}=\frac{1}{a-r}, \quad r / 2<v<a-r / 2 .
$$

5.29 Let $X_{i}=$ weight of $i$ th booklet in package. The $X_{i} \mathrm{~s}$ are iid with $E X_{i}=1$ and $\operatorname{Var} X_{i}=.05^{2}$. We want to approximate $P\left(\sum_{i=1}^{100} X_{i}>100.4\right)=P\left(\sum_{i=1}^{100} X_{i} / 100>1.004\right)=P(\bar{X}>1.004)$. By the CLT, $P(\bar{X}>1.004) \approx P(Z>(1.004-1) /(.05 / 10))=P(Z>.8)=.2119$.
5.30 From the CLT we have, approximately, $\bar{X}_{1} \sim \mathrm{n}\left(\mu, \sigma^{2} / n\right), \bar{X}_{2} \sim \mathrm{n}\left(\mu, \sigma^{2} / n\right)$. Since $\bar{X}_{1}$ and $\bar{X}_{2}$ are independent, $\bar{X}_{1}-\bar{X}_{2} \sim \mathrm{n}\left(0,2 \sigma^{2} / n\right)$. Thus, we want

$$
\begin{aligned}
.99 & \approx P\left(\left|\bar{X}_{1}-\bar{X}_{2}\right|<\sigma / 5\right) \\
& =P\left(\frac{-\sigma / 5}{\sigma / \sqrt{n / 2}}<\frac{\bar{X}_{1}-\bar{X}_{2}}{\sigma / \sqrt{n / 2}}<\frac{\sigma / 5}{\sigma / \sqrt{n / 2}}\right) \\
& \approx P\left(-\frac{1}{5} \sqrt{\frac{n}{2}}<Z<\frac{1}{5} \sqrt{\frac{n}{2}}\right)
\end{aligned}
$$

where $Z \sim \mathrm{n}(0,1)$. Thus we need $P(Z \geq \sqrt{n} / 5(\sqrt{2})) \approx .005$. From Table $1, \sqrt{n} / 5 \sqrt{2}=2.576$, which implies $n=50(2.576)^{2} \approx 332$.
5.31 We know that $\sigma_{\bar{X}}^{2}=9 / 100$. Use Chebyshev's Inequality to get

$$
P(-3 k / 10<\bar{X}-\mu<3 k / 10) \geq 1-1 / k^{2} .
$$

We need $1-1 / k^{2} \geq .9$ which implies $k \geq \sqrt{10}=3.16$ and $3 k / 10=.9487$. Thus

$$
P(-.9487<\bar{X}-\mu<.9487) \geq .9
$$

by Chebychev's Inequality. Using the CLT, $\bar{X}$ is approximately $\mathrm{n}\left(\mu, \sigma_{\bar{X}}^{2}\right)$ with $\sigma_{\bar{X}}=\sqrt{.09}=.3$ and $(\bar{X}-\mu) / .3 \sim \mathrm{n}(0,1)$. Thus

$$
.9=P\left(-1.645<\frac{\bar{X}-\mu}{.3}<1.645\right)=P(-.4935<\bar{X}-\mu<.4935)
$$

Thus, we again see the conservativeness of Chebychev's Inequality, yielding bounds on $\bar{X}-\mu$ that are almost twice as big as the normal approximation. Moreover, with a sample of size 100, $\bar{X}$ is probably very close to normally distributed, even if the underlying $X$ distribution is not close to normal.
5.32 a. For any $\epsilon>0$,

$$
\begin{aligned}
P\left(\left|\sqrt{X_{n}}-\sqrt{a}\right|>\epsilon\right) & =P\left(\left|\sqrt{X_{n}}-\sqrt{a}\right|\left|\sqrt{X_{n}}+\sqrt{a}\right|>\epsilon\left|\sqrt{X_{n}}+\sqrt{a}\right|\right) \\
& =P\left(\left|X_{n}-a\right|>\epsilon\left|\sqrt{X_{n}}+\sqrt{a}\right|\right) \\
& \leq P\left(\left|X_{n}-a\right|>\epsilon \sqrt{a}\right) \rightarrow 0
\end{aligned}
$$

as $n \rightarrow \infty$, since $X_{n} \rightarrow$ a in probability. Thus $\sqrt{X_{n}} \rightarrow \sqrt{a}$ in probability.
b. For any $\epsilon>0$,

$$
\begin{aligned}
P\left(\left|\frac{a}{X_{n}}-1\right| \leq \epsilon\right) & =P\left(\frac{a}{1+\epsilon} \leq X_{n} \leq \frac{a}{1-\epsilon}\right) \\
& =P\left(a-\frac{a \epsilon}{1+\epsilon} \leq X_{n} \leq a+\frac{a \epsilon}{1-\epsilon}\right) \\
& \geq P\left(a-\frac{a \epsilon}{1+\epsilon} \leq X_{n} \leq a+\frac{a \epsilon}{1+\epsilon}\right) \quad\left(a+\frac{a \epsilon}{1+\epsilon}<a+\frac{a \epsilon}{1-\epsilon}\right) \\
& =P\left(\left|X_{n}-a\right| \leq \frac{a \epsilon}{1+\epsilon}\right) \rightarrow 1,
\end{aligned}
$$

as $n \rightarrow \infty$, since $X_{n} \rightarrow$ a in probability. Thus $a / X_{n} \rightarrow 1$ in probability.
c. $S_{n}^{2} \rightarrow \sigma^{2}$ in probability. By a), $S_{n}=\sqrt{S_{n}^{2}} \rightarrow \sqrt{\sigma^{2}}=\sigma$ in probability. By b), $\sigma / S_{n} \rightarrow 1$ in probability.
5.33 For all $\epsilon>0$ there exist $N$ such that if $n>N$, then $P\left(X_{n}+Y_{n}>c\right)>1-\epsilon$. Choose $N_{1}$ such that $P\left(X_{n}>-m\right)>1-\epsilon / 2$ and $N_{2}$ such that $P\left(Y_{n}>c+m\right)>1-\epsilon / 2$. Then

$$
P\left(X_{n}+Y_{n}>c\right) \geq P\left(X_{n}>-m,+Y_{n}>c+m\right) \geq P\left(X_{n}>-m\right)+P\left(Y_{n}>c+m\right)-1=1-\epsilon
$$

5.34 Using $\mathrm{E} \bar{X}_{n}=\mu$ and $\operatorname{Var} \bar{X}_{n}=\sigma^{2} / n$, we obtain

$$
\begin{gathered}
\mathrm{E} \frac{\sqrt{n}\left(\bar{X}_{n}-\mu\right)}{\sigma}=\frac{\sqrt{n}}{\sigma} \mathrm{E}\left(\bar{X}_{n}-\mu\right)=\frac{\sqrt{n}}{\sigma}(\mu-\mu)=0 . \\
\operatorname{Var} \frac{\sqrt{n}\left(\bar{X}_{n}-\mu\right)}{\sigma}=\frac{n}{\sigma^{2}} \operatorname{Var}\left(\bar{X}_{n}-\mu\right)=\frac{n}{\sigma^{2}} \operatorname{Var} \bar{X}=\frac{n}{\sigma^{2}} \frac{\sigma^{2}}{n}=1 .
\end{gathered}
$$

5.35 a. $X_{i} \sim$ exponential(1). $\mu_{X}=1, \operatorname{Var} X=1$. From the CLT, $\bar{X}_{n}$ is approximately $\mathrm{n}(1,1 / n)$. So

$$
\frac{\bar{X}_{n}-1}{1 / \sqrt{n}} \rightarrow Z \sim \mathrm{n}(0,1) \quad \text { and } \quad P\left(\frac{\bar{X}_{n}-1}{1 / \sqrt{n}} \leq x\right) \rightarrow P(Z \leq x)
$$

b.

$$
\begin{gathered}
\frac{d}{d x} P(Z \leq x)=\frac{d}{d x} F_{Z}(x)=f_{Z}(x)=\frac{1}{\sqrt{2 \pi}} e^{-x^{2} / 2} . \\
\frac{d}{d x} P\left(\frac{\bar{X}_{n}-1}{1 / \sqrt{n}} \leq x\right) \\
=\frac{d}{d x}\left(\sum_{i=1}^{n} X_{i} \leq x \sqrt{n}+n\right) \quad\left(W=\sum_{i=1}^{n} X_{i} \sim \operatorname{gamma}(n, 1)\right) \\
=\frac{d}{d x} F_{W}(x \sqrt{n}+n)=f_{W}(x \sqrt{n}+n) \cdot \sqrt{n}=\frac{1}{\Gamma(n)}(x \sqrt{n}+n)^{n-1} e^{-(x \sqrt{n}+n)} \sqrt{n} .
\end{gathered}
$$

Therefore, $(1 / \Gamma(n))(x \sqrt{n}+n)^{n-1} e^{-(x \sqrt{n}+n)} \sqrt{n} \approx \frac{1}{\sqrt{2 \pi}} e^{-x^{2} / 2}$ as $n \rightarrow \infty$. Substituting $x=0$ yields $n!\approx n^{n+1 / 2} e^{-n} \sqrt{2 \pi}$.
5.37 a. For the exact calculations, use the fact that $V_{n}$ is itself distributed negative binomial $(10 r, p)$. The results are summarized in the following table. Note that the recursion relation of problem 3.48 can be used to simplify calculations.

|  | $P\left(V_{n}=v\right)$ |  |  |
| :---: | :---: | :---: | :---: |
|  | (a) | (b) | (c) |
| $v$ | Exact | Normal App. | Normal w/cont. |
| 0 | . 0008 | . 0071 | . 0056 |
| 1 | . 0048 | . 0083 | . 0113 |
| 2 | . 0151 | . 0147 | . 0201 |
| 3 | . 0332 | . 0258 | . 0263 |
| 4 | . 0572 | . 0392 | . 0549 |
| 5 | . 0824 | . 0588 | . 0664 |
| 6 | . 1030 | . 0788 | . 0882 |
| 7 | . 1148 | . 0937 | . 1007 |
| 8 | . 1162 | . 1100 | . 1137 |
| 9 | . 1085 | . 1114 | . 1144 |
| 10 | . 0944 | . 1113 | . 1024 |

b. Using the normal approximation, we have $\mu_{v}=r(1-p) / p=20(.3) / .7=8.57$ and

$$
\sigma_{v}=\sqrt{r(1-p) / p^{2}}=\sqrt{(20)(.3) / .49}=3.5
$$

Then,

$$
P\left(V_{n}=0\right)=1-P\left(V_{n} \geq 1\right)=1-P\left(\frac{V_{n}-8.57}{3.5} \geq \frac{1-8.57}{3.5}\right)=1-P(Z \geq-2.16)=.0154
$$

Another way to approximate this probability is

$$
P\left(V_{n}=0\right)=P\left(V_{n} \leq 0\right)=P\left(\frac{V-8.57}{3.5} \leq \frac{0-8.57}{3.5}\right)=P(Z \leq-2.45)=.0071 .
$$

Continuing in this way we have $P(V=1)=P(V \leq 1)-P(V \leq 0)=.0154-.0071=.0083$, etc.
c. With the continuity correction, compute $P(V=k)$ by $P\left(\frac{(k-.5)-8.57}{3.5} \leq Z \leq \frac{(k+.5)-8.57}{3.5}\right)$, so $P(V=0)=P(-9.07 / 3.5 \leq Z \leq-8.07 / 3.5)=.0104-.0048=.0056$, etc. Notice that the continuity correction gives some improvement over the uncorrected normal approximation.
5.39 a. If $h$ is continuous given $\epsilon>0$ there exits $\delta$ such that $\left|h\left(x_{n}\right)-h(x)\right|<\epsilon$ for $\left|x_{n}-x\right|<\delta$. Since $X_{1}, \ldots, X_{n}$ converges in probability to the random variable $X$, then $\lim _{n \rightarrow \infty} P\left(\left|X_{n}-X\right|<\right.$ $\delta)=1$. Thus $\lim _{n \rightarrow \infty} P\left(\left|h\left(X_{n}\right)-h(X)\right|<\epsilon\right)=1$.
b. Define the subsequence $X_{j}(s)=s+I_{[a, b]}(s)$ such that in $I_{[a, b]}, a$ is always 0 , i.e, the subsequence $X_{1}, X_{2}, X_{4}, X_{7}, \ldots$ For this subsequence

$$
X_{j}(s) \rightarrow \begin{cases}s & \text { if } s>0 \\ s+1 & \text { if } s=0\end{cases}
$$

5.41 a. Let $\epsilon=|x-\mu|$.
(i) For $x-\mu \geq 0$

$$
\begin{aligned}
P\left(\left|X_{n}-\mu\right|>\epsilon\right) & =P\left(\left|X_{n}-\mu\right|>x-\mu\right) \\
& =P\left(X_{n}-\mu<-(x-\mu)\right)+P\left(X_{n}-\mu>x-\mu\right) \\
& \geq P\left(X_{n}-\mu>x-\mu\right) \\
& =P\left(X_{n}>x\right)=1-P\left(X_{n} \leq x\right)
\end{aligned}
$$

Therefore, $0=\lim _{n \rightarrow \infty} P\left(\left|X_{n}-\mu\right|>\epsilon\right) \geq \lim _{n \rightarrow \infty} 1-P\left(X_{n} \leq x\right)$. Thus $\lim _{n \rightarrow \infty} P\left(X_{n} \leq\right.$ $x) \geq 1$.
(ii) For $x-\mu<0$

$$
\begin{aligned}
P\left(\left|X_{n}-\mu\right|>\epsilon\right) & =P\left(\left|X_{n}-\mu\right|>-(x-\mu)\right) \\
& =P\left(X_{n}-\mu<x-\mu\right)+P\left(X_{n}-\mu>-(x-\mu)\right) \\
& \geq P\left(X_{n}-\mu<x-\mu\right) \\
& =P\left(X_{n} \leq x\right) .
\end{aligned}
$$

Therefore, $0=\lim _{n \rightarrow \infty} P\left(\left|X_{n}-\mu\right|>\epsilon\right) \geq \lim _{n \rightarrow \infty} P\left(X_{n} \leq x\right)$.
By (i) and (ii) the results follows.
b. For every $\epsilon>0$,

$$
\begin{aligned}
P\left(\left|X_{n}-\mu\right|>\epsilon\right) & \leq P\left(X_{n}-\mu<-\epsilon\right)+P\left(X_{n}-\mu>\epsilon\right) \\
& =P\left(X_{n}<\mu-\epsilon\right)+1-P\left(X_{n} \leq \mu+\epsilon\right) \quad \rightarrow \quad 0 \quad \text { as } n \rightarrow \infty
\end{aligned}
$$

5.43 a. $\left.P\left(\left|Y_{n}-\theta\right|<\epsilon\right)=P(\mid \sqrt{( } n)\left(Y_{n}-\theta\right) \mid<\sqrt{(n) \epsilon}\right)$. Therefore,

$$
\left.\left.\lim _{n \rightarrow \infty} P\left(\left|Y_{n}-\theta\right|<\epsilon\right)=\lim _{n \rightarrow \infty} P(\mid \sqrt{( } n)\left(Y_{n}-\theta\right) \mid<\sqrt{( } n\right) \epsilon\right)=P(|Z|<\infty)=1
$$

where $Z \sim \mathrm{n}\left(0, \sigma^{2}\right)$. Thus $Y_{n} \rightarrow \theta$ in probability.
b. By Slutsky's Theorem (a), $g^{\prime}(\theta) \sqrt{n}\left(Y_{n}-\theta\right) \rightarrow g^{\prime}(\theta) X$ where $X \sim \mathrm{n}\left(0, \sigma^{2}\right)$. Therefore $\sqrt{n}\left[g\left(Y_{n}\right)-g(\theta)\right]=g^{\prime}(\theta) \sqrt{n}\left(Y_{n}-\theta\right) \rightarrow \mathrm{n}\left(0, \sigma^{2}\left[g^{\prime}(\theta)\right]^{2}\right)$.
5.45 We do part (a), the other parts are similar. Using Mathematica, the exact calculation is

```
In[120]:=
f1[x_]=PDF[GammaDistribution[4,25],x]
p1=Integrate[f1[x],{x,100,\[Infinity]}]//N
1-CDF[BinomialDistribution[300,p1],149]
Out[120]=
e^(-x/25) x^3/2343750
Out [121]=
0.43347
Out [122] =
0.0119389 .
```

The answer can also be simulated in Mathematica or in R. Here is the R code for simulating the same probability

```
p1<-mean(rgamma(10000,4,scale=25)>100)
mean(rbinom(10000, 300, p1)>149)
```

In each case 10,000 random variables were simulated. We obtained $p 1=0.438$ and a binomial probability of 0.0108 .
5.47 a. $-2 \log \left(U_{j}\right) \sim \operatorname{exponential}(2) \sim \chi_{2}^{2}$. Thus $Y$ is the sum of $\nu$ independent $\chi_{2}^{2}$ random variables. By Lemma 5.3.2(b), $Y \sim \chi_{2 \nu}^{2}$.
b. $\beta \log \left(U_{j}\right) \sim \operatorname{exponential}(2) \sim \operatorname{gamma}(1, \beta)$. Thus $Y$ is the sum of independent gamma random variables. By Example 4.6.8, $Y \sim \operatorname{gamma}(a, \beta)$
c. Let $V=\sum_{j=1}^{a} \log \left(U_{j}\right) \sim \operatorname{gamma}(a, 1)$. Similarly $W=\sum_{j=1}^{b} \log \left(U_{j}\right) \sim \operatorname{gamma}(b, 1)$. By Exercise 4.24, $\frac{V}{V+W} \sim \operatorname{beta}(a, b)$.
5.49 a. See Example 2.1.4.
b. $X=g(U)=-\log \frac{1-U}{U}$. Then $g^{-1}(x)=\frac{1}{1+e^{-y}}$. Thus

$$
f_{X}(x)=1 \times\left|\frac{e^{-y}}{\left(1+e^{-y}\right)^{2}}\right|=\frac{e^{-y}}{\left(1+e^{-y}\right)^{2}} \quad-\infty<y<\infty
$$

which is the density of a logistic $(0,1)$ random variable.
c. Let $Y \sim \operatorname{logistic}(\mu, \beta)$ then $f_{Y}(y)=\frac{1}{\beta} f_{Z}\left(\frac{-(y-\mu)}{\beta}\right)$ where $f_{Z}$ is the density of a $\operatorname{logistic}(0,1)$. Then $Y=\beta Z+\mu$. To generate a $\operatorname{logistic}(\mu, \beta)$ random variable generate (i) generate $U \sim$ uniform $(0,1)$, (ii) Set $Y=\beta \log \frac{U}{1-U}+\mu$.
5.51 a. For $U_{i} \sim \operatorname{uniform}(0,1), \mathrm{E} U_{i}=1 / 2, \operatorname{Var} U_{i}=1 / 12$. Then

$$
X=\sum_{i=1}^{12} U_{i}-6=12 \bar{U}-6=\sqrt{12}\left(\frac{\bar{U}-1 / 2}{1 / \sqrt{12}}\right)
$$

is in the form $\sqrt{n}((\bar{U}-\mathrm{E} U) / \sigma)$ with $n=12$, so $X$ is approximately $\mathrm{n}(0,1)$ by the Central Limit Theorem.
b. The approximation does not have the same range as $Z \sim \mathrm{n}(0,1)$ where $-\infty<Z<+\infty$, since $-6<X<6$.
c.

$$
\begin{gathered}
\mathrm{E} X=\mathrm{E}\left(\sum_{i=1}^{12} U_{i}-6\right)=\sum_{i=1}^{12} \mathrm{E} U_{i}-6=\left(\sum_{i=1}^{12} \frac{1}{2}\right)-6=6-6=0 \\
\operatorname{Var} X=\operatorname{Var}\left(\sum_{i=1}^{12} U_{i}-6\right)=\operatorname{Var} \sum_{i=1}^{12} U_{i}=12 \operatorname{Var} U_{1}=1
\end{gathered}
$$

$\mathrm{E} X^{3}=0$ since $X$ is symmetric about 0 . (In fact, all odd moments of $X$ are 0 .) Thus, the first three moments of $X$ all agree with the first three moments of a $n(0,1)$. The fourth moment is not easy to get, one way to do it is to get the mgf of $X$. Since $\mathrm{E} e^{t U}=\left(e^{t}-1\right) / t$,

$$
\mathrm{E}\left[e^{t\left(\sum_{i=1}^{12} U_{i}-6\right)}\right]=e^{-6 t}\left(\frac{e^{t}-1}{t}\right)^{12}=\left(\frac{e^{t / 2}-e^{-t / 2}}{t}\right)^{12}
$$

Computing the fourth derivative and evaluating it at $t=0$ gives us $\mathrm{E} X^{4}$. This is a lengthy calculation. The answer is $\mathrm{E} X^{4}=29 / 10$, slightly smaller than $\mathrm{E} Z^{4}=3$, where $Z \sim \mathrm{n}(0,1)$.
5.53 The R code is the following:
a. obs <- rbinom $(1000,8,2 / 3)$
meanobs <- mean(obs)
variance <- var (obs)
hist(obs)
Output:
> meanobs
[1] 5.231
> variance
[1] 1.707346
b. obs<- rhyper $(1000,8,2,4)$
meanobs <- mean(obs)
variance <- var (obs)
hist(obs)
Output:
> meanobs
[1] 3.169
> variance
[1] 0.4488879
c. obs <- rnbinom ( $1000,5,1 / 3$ )
meanobs <- mean(obs)
variance <- var(obs)
hist (obs)
Output:
> meanobs
[1] 10.308
> variance
[1] 29.51665
5.55 Let $X$ denote the number of comparisons. Then

$$
\begin{aligned}
\mathrm{E} X & =\sum_{k=0}^{\infty} P(X>k)=1+\sum_{k=1}^{\infty} P\left(U>F_{y}\left(y_{k-1}\right)\right) \\
& =1+\sum_{k=1}^{\infty}\left(1-F_{y}\left(y_{k-1}\right)\right)=1+\sum_{k=0}^{\infty}\left(1-F_{y}\left(y_{i}\right)\right)=1+\mathrm{E} Y
\end{aligned}
$$

5.57 a. $\operatorname{Cov}\left(Y_{1}, Y_{2}\right)=\operatorname{Cov}\left(X_{1}+X_{3}, X_{2}+X_{3}\right)=\operatorname{Cov}\left(X_{3}, X_{3}\right)=\lambda_{3}$ since $X_{1}, X_{2}$ and $X_{3}$ are independent.
b.

$$
Z_{i}= \begin{cases}1 & \text { if } X_{i}=X_{3}=0 \\ 0 & \text { otherwise }\end{cases}
$$

$p_{i}=P\left(Z_{i}=0\right)=P\left(Y_{i}=0\right)=P\left(X_{i}=0, X_{3}=0\right)=e^{-\left(\lambda_{i}+\lambda_{3}\right)}$. Therefore $Z_{i}$ are $\operatorname{Bernoulli}\left(p_{i}\right)$ with $\mathrm{E}\left[Z_{i}\right]=p_{i}, \operatorname{Var}\left(Z_{i}\right)=p_{i}\left(1-p_{i}\right)$ and

$$
\begin{aligned}
\mathrm{E}\left[Z_{1} Z_{2}\right] & =P\left(Z_{1}=1, Z_{2}=1\right)=P\left(Y_{1}=0, Y_{2}=0\right) \\
& =P\left(X_{1}+X_{3}=0, X_{2}+X_{3}=0\right)=P\left(X_{1}=0\right) P\left(X_{2}=0\right) P\left(X_{3}=0\right) \\
& =e^{-\lambda_{1}} e^{-\lambda_{2}} e^{-\lambda_{3}}
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
\operatorname{Cov}\left(Z_{1}, Z_{2}\right) & =\mathrm{E}\left[Z_{1} Z_{2}\right]-\mathrm{E}\left[Z_{1}\right] \mathrm{E}\left[Z_{2}\right] \\
& =e^{-\lambda_{1}} e^{-\lambda_{2}} e^{-\lambda_{3}}-e^{-\left(\lambda_{i}+\lambda_{3}\right)} e^{-\left(\lambda_{2}+\lambda_{3}\right)}=e^{-\left(\lambda_{i}+\lambda_{3}\right)} e^{-\left(\lambda_{2}+\lambda_{3}\right)}\left(e^{\lambda_{3}}-1\right) \\
& =p_{1} p_{2}\left(e^{\lambda_{3}}-1\right)
\end{aligned}
$$

Thus $\operatorname{Corr}\left(Z_{1}, Z_{2}\right)=\frac{p_{1} p_{2}\left(e^{\lambda_{3}}-1\right)}{\sqrt{p_{1}\left(1-p_{1}\right)} \sqrt{p_{2}\left(1-p_{2}\right)}}$.
c. $\mathrm{E}\left[Z_{1} Z_{2}\right] \leq p_{i}$, therefore

$$
\begin{aligned}
& \operatorname{Cov}\left(Z_{1}, Z_{2}\right)=\mathrm{E}\left[Z_{1} Z_{2}\right]-\mathrm{E}\left[Z_{1}\right] \mathrm{E}\left[Z_{2}\right] \leq p_{1}-p_{1} p_{2}=p_{1}\left(1-p_{2}\right), \text { and } \\
& \operatorname{Cov}\left(Z_{1}, Z_{2}\right) \leq p_{2}\left(1-p_{1}\right)
\end{aligned}
$$

Therefore,

$$
\operatorname{Corr}\left(Z_{1}, Z_{2}\right) \leq \frac{p_{1}\left(1-p_{2}\right)}{\sqrt{p_{1}\left(1-p_{1}\right)} \sqrt{p_{2}\left(1-p_{2}\right)}}=\frac{\sqrt{p_{1}\left(1-p_{2}\right)}}{\sqrt{p_{2}\left(1-p_{1}\right)}}
$$

and

$$
\operatorname{Corr}\left(Z_{1}, Z_{2}\right) \leq \frac{p_{2}\left(1-p_{1}\right)}{\sqrt{p_{1}\left(1-p_{1}\right)} \sqrt{p_{2}\left(1-p_{2}\right)}}=\frac{\sqrt{p_{2}\left(1-p_{1}\right)}}{\sqrt{p_{1}\left(1-p_{2}\right)}}
$$

which implies the result.

$$
\begin{aligned}
P(Y \leq y) & =P\left(V \leq y \left\lvert\, U<\frac{1}{c} f_{Y}(V)\right.\right)=\frac{P\left(V \leq y, U<\frac{1}{c} f_{Y}(V)\right)}{P\left(U<\frac{1}{c} f_{Y}(V)\right)} \\
& =\frac{\int_{0}^{y} \int_{0}^{\frac{1}{c} f_{Y}(v)} d u d v}{\frac{1}{c}}=\frac{\frac{1}{c} \int_{0}^{y} f_{Y}(v) d v}{\frac{1}{c}}=\int_{0}^{y} f_{Y}(v) d v
\end{aligned}
$$

5.61 a. $M=\sup _{y} \frac{\frac{\Gamma(a+b)}{\Gamma(a, \Gamma(b)} y^{a-1}(1-y)^{b-1}}{\Gamma(a] \mid(b))}\left[y^{[a]-1}(1-y)^{[b]-1}\right)$, since $a-[a]>0$ and $b-[b]>0$ and $y \in(0,1)$.
b. $M=\sup _{y} \frac{\frac{\Gamma(a+b)}{\Gamma(a) \Gamma(b)} y^{a-1}(1-y)^{b-1}}{\Gamma([a+b)}<\infty$, since $a-[a]>0$ and $y \in(0,1)$.
c. $M=\sup _{y} \frac{\frac{\Gamma(a+b)}{\Gamma(a) \Gamma(b)} y^{a-1}(1-y)^{b-1}}{\Gamma(a+1+\beta)} y^{[(a]+1-1}(1-y)^{b^{\prime}-1}<\infty$, since $a-[a]-1<0$ and $y \in(0,1) . b-b^{\prime}>0$ when $b^{\prime}=[b]$ and will be equal to zero when $b^{\prime}=b$, thus it does not affect the result.
d. Let $f(y)=y^{\alpha}(1-y)^{\beta}$. Then

$$
\frac{d f(y)}{d y}=\alpha y^{\alpha-1}(1-y)^{\beta}-y^{\alpha} \beta(1-y)^{\beta-1}=y^{\alpha-1}(1-y)^{\beta-1}[\alpha(1-y)+\beta y]
$$

which is maximize at $y=\frac{\alpha}{\alpha+\beta}$. Therefore for, $\alpha=a-a^{\prime}$ and $\beta=b-b^{\prime}$

$$
M=\frac{\frac{\Gamma(a+b)}{\Gamma(a) \Gamma(b)}}{\frac{\Gamma\left(a^{\prime}+b^{\prime}\right)}{\Gamma\left(a^{\prime}\right) \Gamma\left(b^{\prime}\right)}}\left(\frac{a-a^{\prime}}{a-a^{\prime}+b-b^{\prime}}\right)^{a-a^{\prime}}\left(\frac{b-b^{\prime}}{a-a^{\prime}+b-b^{\prime}}\right)^{b-b^{\prime}} .
$$

We need to minimize $M$ in $a^{\prime}$ and $b^{\prime}$. First consider $\left(\frac{a-a^{\prime}}{a-a^{\prime}+b-b^{\prime}}\right)^{a-a^{\prime}}\left(\frac{b-b^{\prime}}{a-a^{\prime}+b-b^{\prime}}\right)^{b-b^{\prime}}$. Let $c=\alpha+\beta$, then this term becomes $\left(\frac{\alpha}{c}\right)^{\alpha}\left(\frac{c-\alpha}{c}\right)^{c-\alpha}$. This term is maximize at $\frac{\alpha}{c}=\frac{1}{2}$, this is at $\alpha=\frac{1}{2} c$. Then $M=\left(\frac{1}{2}\right)^{\left(a-a^{\prime}+b-b^{\prime}\right)} \frac{\frac{\Gamma(a+b)}{\Gamma(a) \Gamma(b)}}{\frac{\Gamma\left(a^{\prime}+b^{\prime}\right)}{\Gamma\left(a^{\prime}\right) \Gamma\left(b^{\prime}\right)}}$. Note that the minimum that $M$ could be is one, which it is attain when $a=a^{\prime}$ and $b=b^{\prime}$. Otherwise the minimum will occur when $a-a^{\prime}$ and $b-b^{\prime}$ are minimum but greater or equal than zero, this is when $a^{\prime}=[a]$ and $b^{\prime}=[b]$ or $a^{\prime}=a$ and $b^{\prime}=[b]$ or $a^{\prime}=[a]$ and $b^{\prime}=b$.
$5.63 M=\sup _{y} \frac{\frac{1}{\sqrt{2 \pi}} e^{\frac{-y^{2}}{2}}}{\frac{1}{2 \lambda} e^{\frac{-|y|}{\lambda}}}$. Let $f(y)=\frac{-y^{2}}{2}+\frac{|y|}{\lambda}$. Then $f(y)$ is maximize at $y=\frac{1}{\lambda}$ when $y \geq 0$ and at $y=\frac{-1}{\lambda}$ when $y<0$. Therefore in both cases $M=\frac{\frac{1}{\sqrt{2 \pi}} e^{\frac{-1}{2 \lambda^{2}}}}{\frac{1}{2 \lambda} e^{\frac{-1}{\lambda^{2}}}}$. To minimize $M$ let $M^{\prime}=\lambda e^{\frac{1}{2 \lambda^{2}}}$. Then $\frac{d \log M^{\prime}}{d \lambda}=\frac{1}{\lambda}-\frac{1}{\lambda^{3}}$, therefore $M$ is minimize at $\lambda=1$ or $\lambda=-1$. Thus the value of $\lambda$ that will optimize the algorithm is $\lambda=1$.
5.65

$$
\begin{aligned}
& P\left(X^{*} \leq x\right)=\sum_{i=1}^{m} P\left(X^{*} \leq x \mid q_{i}\right) q_{i}=\sum_{i=1}^{m} I\left(Y_{i} \leq x\right) q_{i}=\frac{\frac{1}{m} \sum_{i=1}^{m} \frac{f\left(Y_{i}\right)}{g\left(Y_{i}\right)} I\left(Y_{i} \leq x\right)}{\frac{1}{m} \sum_{i=1}^{m} \frac{f\left(Y_{i}\right)}{g\left(Y_{i}\right)}} \\
& \underset{m \rightarrow \infty}{\longrightarrow} \frac{E_{g} \frac{f(Y)}{g(Y)} I(Y \leq x)}{E_{g} \frac{f(Y)}{g(Y)}}=\frac{\int_{-\infty}^{x} \frac{f(y)}{g(y)} g(y) d y}{\int_{-\infty}^{\infty} \frac{f(y)}{g(y)} g(y) d y}=\int_{-\infty}^{x} f(y) d y .
\end{aligned}
$$

5.67 An R code to generate the sample of size 100 from the specified distribution is shown for part c). The Metropolis Algorithm is used to generate 2000 variables. Among other options one can choose the 100 variables in positions 1001 to 1100 or the ones in positions $1010,1020, \ldots, 2000$.
a. We want to generate $X=\sigma Z+\mu$ where $Z \sim$ Student's $t$ with $\nu$ degrees of freedom. Therefore we first can generate a sample of size 100 from a Student's $t$ distribution with $\nu$ degrees of freedom and then make the transformation to obtain the X's. Thus $f_{Z}(z)=$ $\frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu \pi}} \frac{1}{\left(1+\left(\frac{z^{2}}{\nu}\right)\right)^{(v+1) / 2}}$. Let $V \sim \mathrm{n}\left(0, \frac{\nu}{\nu-2}\right)$ since given $\nu$ we can set

$$
\mathrm{E} V=\mathrm{E} Z=0, \quad \text { and } \quad \operatorname{Var}(V)=\operatorname{Var}(Z)=\frac{\nu}{\nu-2}
$$

Now, follow the algorithm on page 254 and generate the sample $Z_{1}, Z_{2} \ldots, Z_{100}$ and then calculate $X_{i}=\sigma Z_{i}+\mu$.
b. $f_{X}(x)=\frac{1}{\sqrt{2 \pi} \sigma} \frac{e^{-(\log x-\mu)^{2} / 2 \sigma^{2}}}{x}$. Let $V \sim \operatorname{gamma}(\alpha, \beta)$ where

$$
\alpha=\frac{\left(e^{\mu+\left(\sigma^{2} / 2\right)}\right)^{2}}{e^{2\left(\mu+\sigma^{2}\right)}-e^{2 \mu+\sigma^{2}}}, \quad \text { and } \quad \beta=\frac{e^{2\left(\mu+\sigma^{2}\right)}-e^{2 \mu+\sigma^{2}}}{e^{\mu+\left(\sigma^{2} / 2\right)}}
$$

since given $\mu$ and $\sigma^{2}$ we can set

$$
\mathrm{E} V=\alpha \beta=e^{\mu+\left(\sigma^{2} / 2\right)}=\mathrm{E} X
$$

and

$$
\operatorname{Var}(V)=\alpha \beta^{2}=e^{2\left(\mu+\sigma^{2}\right)}-e^{2 \mu+\sigma^{2}}=\operatorname{Var}(X)
$$

Now, follow the algorithm on page 254 .
c. $f_{X}(x)=\frac{\alpha}{\beta} e^{\frac{-x^{\alpha}}{\beta}} x^{\alpha-1}$. Let $V \sim \operatorname{exponential}(\beta)$. Now, follow the algorithm on page 254 where

$$
\rho_{i}=\min \left\{\frac{V_{i}^{\alpha-1}}{Z_{i-1}^{\alpha-1}} e^{\frac{-v_{i}^{\alpha}+V_{i}-z_{i-1}+z_{i-1}^{\alpha}}{\beta}}, 1\right\}
$$

An $R$ code to generate a sample size of 100 from a $\operatorname{Weibull}(3,2)$ is:

```
#initialize a and b
b <- 2
a <- 3
Z <- rexp(1,1/b)
ranvars <- matrix(c(Z),byrow=T,ncol=1)
for( i in seq(2000))
{
U <- runif(1,min=0,max=1)
V <- rexp(1,1/b)
p <- pmin((V/Z) ^ (a-1)*exp((-V^a+V-Z+Z^a)/b),1)
if (U <= p)
    Z <- V
ranvars <- cbind(ranvars,Z)
}
#One option: choose elements in position 1001,1002,...,1100
to be the sample
vector.1 <- ranvars[1001:1100]
mean(vector.1)
var(vector.1)
#Another option: choose elements in position 1010,1020,...,2000
to be the sample
vector.2 <- ranvars[seq(1010,2000,10)]
mean(vector.2)
var(vector.2)
Output:
[1] 1.048035
[1] 0.1758335
[1] 1.130649
[1] 0.1778724
```

5.69 Let $w(v, z)=\frac{f_{Y}(v) f_{V}(z)}{f_{V}(v) f_{Y}(z)}$, and then $\rho(v, z)=\min \{w(v, z), 1\}$. We will show that

$$
Z_{i} \sim f_{Y} \Rightarrow P\left(Z_{i+1} \leq a\right)=P(Y \leq a)
$$

Write

$$
P\left(Z_{i+1} \leq a\right)=P\left(V_{i+1} \leq a \text { and } U_{i+1} \leq \rho_{i+1}\right)+P\left(Z_{i} \leq a \text { and } U_{i+1}>\rho_{i+1}\right)
$$

Since $Z_{i} \sim f_{Y}$, suppressing the unnecessary subscripts we can write

$$
P\left(Z_{i+1} \leq a\right)=P(V \leq a \text { and } U \leq \rho(V, Y))+P(Y \leq a \text { and } U>\rho(V, Y))
$$

Add and subtract $P(Y \leq a$ and $U \leq \rho(V, Y))$ to get

$$
\begin{aligned}
P\left(Z_{i+1} \leq a\right)= & P(Y \leq a)+P(V \leq a \text { and } U \leq \rho(V, Y)) \\
& -P(Y \leq a \text { and } U \leq \rho(V, Y))
\end{aligned}
$$

Thus we need to show that

$$
P(V \leq a \text { and } U \leq \rho(V, Y))=P(Y \leq a \text { and } U \leq \rho(V, Y))
$$

Write out the probability as

$$
\begin{aligned}
& P(V \leq a \text { and } U \leq \rho(V, Y)) \\
&= \int_{-\infty}^{a} \int_{-\infty}^{\infty} \rho(v, y) f_{Y}(y) f_{V}(v) d y d v \\
&= \int_{-\infty}^{a} \int_{-\infty}^{\infty} I(w(v, y) \leq 1)\left(\frac{f_{Y}(v) f_{V}(y)}{f_{V}(v) f_{Y}(y)}\right) f_{Y}(y) f_{V}(v) d y d v \\
&+\int_{-\infty}^{a} \int_{-\infty}^{\infty} I(w(v, y) \geq 1) f_{Y}(y) f_{V}(v) d y d v \\
&= \int_{-\infty}^{a} \int_{-\infty}^{\infty} I(w(v, y) \leq 1) f_{Y}(v) f_{V}(y) d y d v \\
&+\int_{-\infty}^{a} \int_{-\infty}^{\infty} I(w(v, y) \geq 1) f_{Y}(y) f_{V}(v) d y d v
\end{aligned}
$$

Now, notice that $w(v, y)=1 / w(y, v)$, and thus first term above can be written

$$
\begin{aligned}
& \int_{-\infty}^{a} \int_{-\infty}^{\infty} I(w(v, y) \leq 1) f_{Y}(v) f_{V}(y) d y d v \\
& \quad=\int_{-\infty}^{a} \int_{-\infty}^{\infty} I(w(y, v)>1) f_{Y}(v) f_{V}(y) d y d v \\
& \quad=P(Y \leq a, \rho(V, Y)=1, U \leq \rho(V, Y))
\end{aligned}
$$

The second term is

$$
\begin{aligned}
& \int_{-\infty}^{a} \int_{-\infty}^{\infty} I(w(v, y) \geq 1) f_{Y}(y) f_{V}(v) d y d v \\
& \quad=\int_{-\infty}^{a} \int_{-\infty}^{\infty} I(w(y, v) \leq 1) f_{Y}(y) f_{V}(v) d y d v \\
& \quad=\int_{-\infty}^{a} \int_{-\infty}^{\infty} I(w(y, v) \leq 1)\left(\frac{f_{V}(y) f_{Y}(v)}{f_{V}(y) f_{Y}(v)}\right) f_{Y}(y) f_{V}(v) d y d v \\
& =\int_{-\infty}^{a} \int_{-\infty}^{\infty} I(w(y, v) \leq 1)\left(\frac{f_{Y}(y) f_{V}(v)}{f_{V}(y) f_{Y}(v)}\right) f_{V}(y) f_{Y}(v) d y d v \\
& =\int_{-\infty}^{a} \int_{-\infty}^{\infty} I(w(y, v) \leq 1) w(y, v) f_{V}(y) f_{Y}(v) d y d v \\
& =P(Y \leq a, U \leq \rho(V, Y), \rho(V, Y) \leq 1)
\end{aligned}
$$

Putting it all together we have

$$
\begin{aligned}
P(V \leq a \text { and } U \leq \rho(V, Y))= & P(Y \leq a, \rho(V, Y)=1, U \leq \rho(V, Y)) \\
& +P(Y \leq a, U \leq \rho(V, Y), \rho(V, Y) \leq 1) \\
= & P(Y \leq a \text { and } U \leq \rho(V, Y))
\end{aligned}
$$

and hence

$$
P\left(Z_{i+1} \leq a\right)=P(Y \leq a)
$$

so $f_{Y}$ is the stationary density.

## Chapter 6

## Principles of Data Reduction

6.1 By the Factorization Theorem, $|X|$ is sufficient because the pdf of $X$ is

$$
f\left(x \mid \sigma^{2}\right)=\frac{1}{\sqrt{2 \pi} \sigma} e^{-x^{2} / 2 \sigma^{2}}=\frac{1}{\sqrt{2 \pi} \sigma} e^{-|x|^{2} / 2 \sigma^{2}}=g\left(|x| \mid \sigma^{2}\right) \cdot \underbrace{1}_{h(x)} .
$$

6.2 By the Factorization Theorem, $T(X)=\min _{i}\left(X_{i} / i\right)$ is sufficient because the joint pdf is

$$
f\left(x_{1}, \ldots, x_{n} \mid \theta\right)=\prod_{i=1}^{n} e^{i \theta-x_{i}} I_{(i \theta,+\infty)}\left(x_{i}\right)=\underbrace{e^{i n \theta} I_{(\theta,+\infty)}(T(\mathbf{x}))}_{g(T(\mathbf{x}) \mid \theta)} \cdot \underbrace{e^{-\Sigma_{i} x_{i}}}_{h(\mathbf{x})} .
$$

Notice, we use the fact that $i>0$, and the fact that all $x_{i} \mathrm{~s}>i \theta$ if and only if $\min _{i}\left(x_{i} / i\right)>\theta$. 6.3 Let $x_{(1)}=\min _{i} x_{i}$. Then the joint pdf is

$$
f\left(x_{1}, \ldots, x_{n} \mid \mu, \sigma\right)=\prod_{i=1}^{n} \frac{1}{\sigma} e^{-\left(x_{i}-\mu\right) / \sigma} I_{(\mu, \infty)}\left(x_{i}\right)=\underbrace{\left(\frac{e^{\mu / \sigma}}{\sigma}\right)^{n} e^{-\Sigma_{i} x_{i} / \sigma} I_{(\mu, \infty)}\left(x_{(1)}\right)}_{g\left(x_{(1)}, \Sigma_{i} x_{i} \mid \mu, \sigma\right)} \cdot \underbrace{1}_{h(\mathbf{x})}
$$

Thus, by the Factorization Theorem, $\left(X_{(1)}, \sum_{i} X_{i}\right)$ is a sufficient statistic for $(\mu, \sigma)$.
6.4 The joint pdf is

$$
\prod_{j=1}^{n}\left\{h\left(x_{j}\right) c(\boldsymbol{\theta}) \exp \left(\sum_{i=1}^{k} w_{i}(\boldsymbol{\theta}) t_{i}\left(x_{j}\right)\right)\right\}=\underbrace{c(\boldsymbol{\theta})^{n} \exp \left(\sum_{i=1}^{k} w_{i}(\boldsymbol{\theta}) \sum_{j=1}^{n} t_{i}\left(x_{j}\right)\right)}_{g(T(\mathbf{x}) \mid \theta)} \cdot \prod_{h(\mathbf{x})}^{\prod_{j=1}^{n} h\left(x_{j}\right)}
$$

By the Factorization Theorem, $\left(\sum_{j=1}^{n} t_{1}\left(X_{j}\right), \ldots, \sum_{j=1}^{n} t_{k}\left(X_{j}\right)\right)$ is a sufficient statistic for $\boldsymbol{\theta}$. 6.5 The sample density is given by

$$
\begin{aligned}
\prod_{i=1}^{n} f\left(x_{i} \mid \theta\right) & =\prod_{i=1}^{n} \frac{1}{2 i \theta} I\left(-i(\theta-1) \leq x_{i} \leq i(\theta+1)\right) \\
& =\left(\frac{1}{2 \theta}\right)^{n}\left(\prod_{i=1}^{n} \frac{1}{i}\right) I\left(\min \frac{x_{i}}{i} \geq-(\theta-1)\right) I\left(\max \frac{x_{i}}{i} \leq \theta+1\right)
\end{aligned}
$$

Thus $\left(\min X_{i} / i, \max X_{i} / i\right)$ is sufficient for $\theta$.
6.6 The joint pdf is given by

$$
f\left(x_{1}, \ldots, x_{n} \mid \alpha, \beta\right)=\prod_{i=1}^{n} \frac{1}{\Gamma(\alpha) \beta^{\alpha}} x_{i}^{\alpha-1} e^{-x_{i} / \beta}=\left(\frac{1}{\Gamma(\alpha) \beta^{\alpha}}\right)^{n}\left(\prod_{i=1}^{n} x_{i}\right)^{\alpha-1} e^{-\Sigma_{i} x_{i} / \beta}
$$

By the Factorization Theorem, $\left(\prod_{i=1}^{n} X_{i}, \sum_{i=1}^{n} X_{i}\right)$ is sufficient for $(\alpha, \beta)$.
6.7 Let $x_{(1)}=\min _{i}\left\{x_{1}, \ldots, x_{n}\right\}, x_{(n)}=\max _{i}\left\{x_{1}, \ldots, x_{n}\right\}, y_{(1)}=\min _{i}\left\{y_{1}, \ldots, y_{n}\right\}$ and $y_{(n)}=$ $\max _{i}\left\{y_{1}, \ldots, y_{n}\right\}$. Then the joint pdf is

$$
\begin{aligned}
& f(\mathbf{x}, \mathbf{y} \mid \boldsymbol{\theta}) \\
& \quad=\prod_{i=1}^{n} \frac{1}{\left(\theta_{3}-\theta_{1}\right)\left(\theta_{4}-\theta_{2}\right)} I_{\left(\theta_{1}, \theta_{3}\right)}\left(x_{i}\right) I_{\left(\theta_{2}, \theta_{4}\right)}\left(y_{i}\right) \\
& \quad=\underbrace{\left(\frac{1}{\left(\theta_{3}-\theta_{1}\right)\left(\theta_{4}-\theta_{2}\right)}\right)^{n} I_{\left(\theta_{1}, \infty\right)}\left(x_{(1)}\right) I_{\left(-\infty, \theta_{3}\right)}\left(x_{(n)}\right) I_{\left(\theta_{2}, \infty\right)}\left(y_{(1)}\right) I_{\left(-\infty, \theta_{4}\right)}\left(y_{(n)}\right)}_{g(T(\mathbf{x}) \mid \theta)} \cdot \underbrace{1}_{h(\mathbf{x})} .
\end{aligned}
$$

By the Factorization Theorem, $\left(X_{(1)}, X_{(n)}, Y_{(1)}, Y_{(n)}\right)$ is sufficient for $\left(\theta_{1}, \theta_{2}, \theta_{3}, \theta_{4}\right)$.
6.9 Use Theorem 6.2.13.
a.

$$
\frac{f(\mathbf{x} \mid \theta)}{f(\mathbf{y} \mid \theta)}=\frac{(2 \pi)^{-n / 2} e^{-\Sigma_{i}\left(x_{i}-\theta\right)^{2} / 2}}{(2 \pi)^{-n / 2} e^{-\Sigma_{i}\left(y_{i}-\theta\right)^{2} / 2}}=\exp \left\{-\frac{1}{2}\left[\left(\sum_{i=1}^{n} x_{i}^{2}-\sum_{i=1}^{n} y_{i}^{2}\right)+2 \theta n(\bar{y}-\bar{x})\right]\right\} .
$$

This is constant as a function of $\theta$ if and only if $\bar{y}=\bar{x}$; therefore $\bar{X}$ is a minimal sufficient statistic for $\theta$.
b. Note, for $X \sim$ location exponential $(\theta)$, the range depends on the parameter. Now

$$
\begin{aligned}
\frac{f(\mathbf{x} \mid \theta)}{f(\mathbf{y} \mid \theta)} & =\frac{\prod_{i=1}^{n}\left(e^{-\left(x_{i}-\theta\right)} I_{(\theta, \infty)}\left(x_{i}\right)\right)}{\prod_{i=1}^{n}\left(e^{-\left(y_{i}-\theta\right)} I_{(\theta, \infty)}\left(y_{i}\right)\right)} \\
& =\frac{e^{n \theta} e^{-\Sigma_{i} x_{i}} \prod_{i=1}^{n} I_{(\theta, \infty)}\left(x_{i}\right)}{e^{n \theta} e^{-\Sigma_{i} y_{i}} \prod_{i=1}^{n} I_{(\theta, \infty)}\left(y_{i}\right)}=\frac{e^{-\Sigma_{i} x_{i}} I_{(\theta, \infty)}\left(\min x_{i}\right)}{e^{-\Sigma_{i} y_{i}} I_{(\theta, \infty)}\left(\min y_{i}\right)}
\end{aligned}
$$

To make the ratio independent of $\theta$ we need the ratio of indicator functions independent of $\theta$. This will be the case if and only if $\min \left\{x_{1}, \ldots, x_{n}\right\}=\min \left\{y_{1}, \ldots, y_{n}\right\}$. So $T(\mathbf{X})=$ $\min \left\{X_{1}, \ldots, X_{n}\right\}$ is a minimal sufficient statistic.
c.

$$
\begin{aligned}
\frac{f(\mathbf{x} \mid \theta)}{f(\mathbf{y} \mid \theta)} & =\frac{e^{-\Sigma_{i}\left(x_{i}-\theta\right)}}{\prod_{i=1}^{n}\left(1+e^{-\left(x_{i}-\theta\right)}\right)^{2}} \frac{\prod_{i=1}^{n}\left(1+e^{-\left(y_{i}-\theta\right)}\right)^{2}}{e^{-\Sigma_{i}\left(y_{i}-\theta\right)}} \\
& =e^{-\Sigma_{i}\left(y_{i}-x_{i}\right)}\left(\frac{\prod_{i=1}^{n}\left(1+e^{-\left(y_{i}-\theta\right)}\right)}{\prod_{i=1}^{n}\left(1+e^{-\left(x_{i}-\theta\right)}\right)}\right)^{2}
\end{aligned}
$$

This is constant as a function of $\theta$ if and only if $\mathbf{x}$ and $\mathbf{y}$ have the same order statistics. Therefore, the order statistics are minimal sufficient for $\theta$.
d. This is a difficult problem. The order statistics are a minimal sufficient statistic.
e. Fix sample points $\mathbf{x}$ and $\mathbf{y}$. Define $A(\theta)=\left\{i: x_{i} \leq \theta\right\}, B(\theta)=\left\{i: y_{i} \leq \theta\right\}, a(\theta)=$ the number of elements in $A(\theta)$ and $b(\theta)=$ the number of elements in $B(\theta)$. Then the function $f(\mathbf{x} \mid \theta) / f(\mathbf{y} \mid \theta)$ depends on $\theta$ only through the function

$$
\begin{aligned}
\sum_{i=1}^{n} & \left|x_{i}-\theta\right|-\sum_{i=1}^{n}\left|y_{i}-\theta\right| \\
= & \sum_{i \in A(\theta)}\left(\theta-x_{i}\right)+\sum_{i \in A(\theta)^{c}}\left(x_{i}-\theta\right)-\sum_{i \in B(\theta)}\left(\theta-y_{i}\right)-\sum_{i \in B(\theta)^{c}}\left(y_{i}-\theta\right) \\
= & (a(\theta)-[n-a(\theta)]-b(\theta)+[n-b(\theta)]) \theta \\
& +\left(-\sum_{i \in A(\theta)} x_{i}+\sum_{i \in A(\theta)^{c}} x_{i}+\sum_{i \in B(\theta)} y_{i}-\sum_{i \in B(\theta)^{c}} y_{i}\right) \\
= & 2(a(\theta)-b(\theta)) \theta+\left(-\sum_{i \in A(\theta)} x_{i}+\sum_{i \in A(\theta)^{c}} x_{i}+\sum_{i \in B(\theta)} y_{i}-\sum_{i \in B(\theta)^{c}} y_{i}\right) .
\end{aligned}
$$

Consider an interval of $\theta \mathrm{s}$ that does not contain any $x_{i} \mathrm{~s}$ or $y_{i} \mathrm{~s}$. The second term is constant on such an interval. The first term will be constant, on the interval if and only if $a(\theta)=b(\theta)$. This will be true for all such intervals if and only if the order statistics for $\mathbf{x}$ are the same as the order statistics for $\mathbf{y}$. Therefore, the order statistics are a minimal sufficient statistic.
6.10 To prove $T(\mathbf{X})=\left(X_{(1)}, X_{(n)}\right)$ is not complete, we want to find $g[T(\mathbf{X})]$ such that $\mathrm{E} g[T(\mathbf{X})]=0$ for all $\theta$, but $g[T(\mathbf{X})] \not \equiv 0$. A natural candidate is $R=X_{(n)}-X_{(1)}$, the range of $\mathbf{X}$, because by Example 6.2.17 its distribution does not depend on $\theta$. From Example 6.2.17, $R \sim \operatorname{beta}(n-1,2)$. Thus $\mathrm{E} R=(n-1) /(n+1)$ does not depend on $\theta$, and $\mathrm{E}(R-\mathrm{E} R)=0$ for all $\theta$. Thus $g\left[X_{(n)}, X_{(1)}\right]=X_{(n)}-X_{(1)}-(n-1) /(n+1)=R-\mathrm{E} R$ is a nonzero function whose expected value is always 0 . So, $\left(X_{(1)}, X_{(n)}\right)$ is not complete. This problem can be generalized to show that if a function of a sufficient statistic is ancillary, then the sufficient statistic is not complete, because the expectation of that function does not depend on $\theta$. That provides the opportunity to construct an unbiased, nonzero estimator of zero.
6.11 a. These are all location families. Let $Z_{(1)}, \ldots, Z_{(n)}$ be the order statistics from a random sample of size $n$ from the standard pdf $f(z \mid 0)$. Then $\left(Z_{(1)}+\theta, \ldots, Z_{(n)}+\theta\right)$ has the same joint distribution as $\left(X_{(1)}, \ldots, X_{(n)}\right)$, and $\left(Y_{(1)}, \ldots, Y_{(n-1)}\right)$ has the same joint distribution as $\left(Z_{(n)}+\theta-\left(Z_{(1)}+\theta\right), \ldots, Z_{(n)}+\theta-\left(Z_{(n-1)}+\theta\right)\right)=\left(Z_{(n)}-Z_{(1)}, \ldots, Z_{(n)}-Z_{(n-1)}\right)$. The last vector depends only on $\left(Z_{1}, \ldots, Z_{n}\right)$ whose distribution does not depend on $\theta$. So, $\left(Y_{(1)}, \ldots, Y_{(n-1)}\right)$ is ancillary.
b. For a), Basu's lemma shows that $\left(Y_{1}, \ldots, Y_{n-1}\right)$ is independent of the complete sufficient statistic. For c), d), and e) the order statistics are sufficient, so ( $Y_{1}, \ldots, Y_{n-1}$ ) is not independent of the sufficient statistic. For b), $X_{(1)}$ is sufficient. Define $Y_{n}=X_{(1)}$. Then the joint pdf of $\left(Y_{1}, \ldots, Y_{n}\right)$ is

$$
f\left(y_{1}, \ldots, y_{n}\right)=n!e^{-n\left(y_{1}-\theta\right)} e^{-(n-1) y_{n}} \prod_{i=2}^{n-1} e^{y_{i}}, \quad \begin{gathered}
0<y_{n-1}<y_{n-2}<\cdots<y_{1} \\
0<y_{n}<\infty
\end{gathered}
$$

Thus, $Y_{n}=X_{(1)}$ is independent of $\left(Y_{1}, \ldots, Y_{n-1}\right)$.
6.12 a. Use Theorem 6.2.13 and write

$$
\begin{aligned}
\frac{f(x, n \mid \theta)}{f\left(y, n^{\prime} \mid \theta\right)} & =\frac{f(x \mid \theta, N=n) P(N=n)}{f\left(y \mid \theta, N=n^{\prime}\right) P\left(N=n^{\prime}\right)} \\
& =\frac{\binom{n}{x} \theta^{x}(1-\theta)^{n-x} p_{n}}{\binom{n^{\prime}}{y} \theta^{y}(1-\theta)^{n^{\prime}-y} p_{n^{\prime}}}=\theta^{x-y}(1-\theta)^{n-n^{\prime}-x+y} \frac{\binom{n}{x} p_{n}}{\binom{n^{\prime}}{y} p_{n^{\prime}}}
\end{aligned}
$$

The last ratio does not depend on $\theta$. The other terms are constant as a function of $\theta$ if and only if $n=n^{\prime}$ and $x=y$. So $(X, N)$ is minimal sufficient for $\theta$. Because $P(N=n)=p_{n}$ does not depend on $\theta, N$ is ancillary for $\theta$. The point is that although $N$ is independent of $\theta$, the minimal sufficient statistic contains $N$ in this case. A minimal sufficient statistic may contain an ancillary statistic.
b.

$$
\begin{aligned}
\mathrm{E}\left(\frac{X}{N}\right) & =\mathrm{E}\left(\mathrm{E}\left(\left.\frac{X}{N} \right\rvert\, N\right)\right)=\mathrm{E}\left(\frac{1}{N} \mathrm{E}(X \mid N)\right)=\mathrm{E}\left(\frac{1}{N} N \theta\right)=\mathrm{E}(\theta)=\theta \\
\operatorname{Var}\left(\frac{X}{N}\right) & =\operatorname{Var}\left(\mathrm{E}\left(\left.\frac{X}{N} \right\rvert\, N\right)\right)+\mathrm{E}\left(\operatorname{Var}\left(\left.\frac{X}{N} \right\rvert\, N\right)\right)=\operatorname{Var}(\theta)+\mathrm{E}\left(\frac{1}{N^{2}} \operatorname{Var}(X \mid N)\right) \\
& =0+\mathrm{E}\left(\frac{N \theta(1-\theta)}{N^{2}}\right)=\theta(1-\theta) \mathrm{E}\left(\frac{1}{N}\right)
\end{aligned}
$$

We used the fact that $X \mid N \sim \operatorname{binomial}(N, \theta)$.
6.13 Let $Y_{1}=\log X_{1}$ and $Y_{2}=\log X_{2}$. Then $Y_{1}$ and $Y_{2}$ are iid and, by Theorem 2.1.5, the pdf of each is

$$
f(y \mid \alpha)=\alpha \exp \left\{\alpha y-e^{\alpha y}\right\}=\frac{1}{1 / \alpha} \exp \left\{\frac{y}{1 / \alpha}-e^{y /(1 / \alpha)}\right\}, \quad-\infty<y<\infty
$$

We see that the family of distributions of $Y_{i}$ is a scale family with scale parameter $1 / \alpha$. Thus, by Theorem 3.5.6, we can write $Y_{i}=\frac{1}{\alpha} Z_{i}$, where $Z_{1}$ and $Z_{2}$ are a random sample from $f(z \mid 1)$. Then

$$
\frac{\log X_{1}}{\log X_{2}}=\frac{Y_{1}}{Y_{2}}=\frac{(1 / \alpha) Z_{1}}{(1 / \alpha) Z_{2}}=\frac{Z_{1}}{Z_{2}}
$$

Because the distribution of $Z_{1} / Z_{2}$ does not depend on $\alpha$, $\left(\log X_{1}\right) /\left(\log X_{2}\right)$ is an ancillary statistic.
6.14 Because $X_{1}, \ldots, X_{n}$ is from a location family, by Theorem 3.5.6, we can write $X_{i}=Z_{i}+\mu$, where $Z_{1}, \ldots, Z_{n}$ is a random sample from the standard pdf, $f(z)$, and $\mu$ is the location parameter. Let $M(\mathbf{X})$ denote the median calculated from $X_{1}, \ldots, X_{n}$. Then $M(\mathbf{X})=M(\mathbf{Z})+\mu$ and $\bar{X}=\bar{Z}+\mu$. Thus, $M(\mathbf{X})-\bar{X}=(M(\mathbf{Z})+\mu)-(\bar{Z}+\mu)=M(\mathbf{Z})-\bar{Z}$. Because $M(\mathbf{X})-\bar{X}$ is a function of only $Z_{1}, \ldots, Z_{n}$, the distribution of $M(\mathbf{X})-\bar{X}$ does not depend on $\mu$; that is, $M(\mathbf{X})-\bar{X}$ is an ancillary statistic.
6.15 a. The parameter space consists only of the points $(\theta, \nu)$ on the graph of the function $\nu=a \theta^{2}$. This quadratic graph is a line and does not contain a two-dimensional open set.
b. Use the same factorization as in Example 6.2 .9 to show $\left(\bar{X}, S^{2}\right)$ is sufficient. $\mathrm{E}\left(S^{2}\right)=a \theta^{2}$ and $\mathrm{E}\left(\bar{X}^{2}\right)=\operatorname{Var} \bar{X}+(\mathrm{E} \bar{X})^{2}=a \theta^{2} / n+\theta^{2}=(a+n) \theta^{2} / n$. Therefore,

$$
\mathrm{E}\left(\frac{n}{a+n} \bar{X}^{2}-\frac{S^{2}}{a}\right)=\left(\frac{n}{a+n}\right)\left(\frac{a+n}{n} \theta^{2}\right)-\frac{1}{a} a \theta^{2}=0, \text { for all } \theta .
$$

Thus $g\left(\bar{X}, S^{2}\right)=\frac{n}{a+n} \bar{X}^{2}-\frac{S^{2}}{a}$ has zero expectation so $\left(\bar{X}, S^{2}\right)$ not complete.
6.17 The population pmf is $f(x \mid \theta)=\theta(1-\theta)^{x-1}=\frac{\theta}{1-\theta} e^{\log (1-\theta) x}$, an exponential family with $t(x)=$ $x$. Thus, $\sum_{i} X_{i}$ is a complete, sufficient statistic by Theorems 6.2.10 and 6.2.25. $\sum_{i} X_{i}-n \sim$ negative $\operatorname{binomial}(n, \theta)$.
6.18 The distribution of $Y=\sum_{i} X_{i}$ is $\operatorname{Poisson}(n \lambda)$. Now

$$
\mathrm{E} g(Y)=\sum_{y=0}^{\infty} g(y) \frac{(n \lambda)^{y} e^{-n \lambda}}{y!}
$$

If the expectation exists, this is an analytic function which cannot be identically zero.
6.19 To check if the family of distributions of $X$ is complete, we check if $\mathrm{E}_{p} g(X)=0$ for all $p$, implies that $g(X) \equiv 0$. For Distribution 1,

$$
\mathrm{E}_{p} g(X)=\sum_{x=0}^{2} g(x) P(X=x)=p g(0)+3 p g(1)+(1-4 p) g(2)
$$

Note that if $g(0)=-3 g(1)$ and $g(2)=0$, then the expectation is zero for all $p$, but $g(x)$ need not be identically zero. Hence the family is not complete. For Distribution 2 calculate

$$
\mathrm{E}_{p} g(X)=g(0) p+g(1) p^{2}+g(2)\left(1-p-p^{2}\right)=[g(1)-g(2)] p^{2}+[g(0)-g(2)] p+g(2)
$$

This is a polynomial of degree 2 in $p$. To make it zero for all $p$ each coefficient must be zero. Thus, $g(0)=g(1)=g(2)=0$, so the family of distributions is complete.
6.20 The pdfs in b), c), and e) are exponential families, so they have complete sufficient statistics from Theorem 6.2.25. For a), $Y=\max \left\{X_{i}\right\}$ is sufficient and

$$
f(y)=\frac{2 n}{\theta^{2 n}} y^{2 n-1}, \quad 0<y<\theta
$$

For a function $g(y)$,

$$
\mathrm{E} g(Y)=\int_{0}^{\theta} g(y) \frac{2 n}{\theta^{2 n}} y^{2 n-1} d y=0 \text { for all } \theta \text { implies } g(\theta) \frac{2 n \theta^{2 n-1}}{\theta^{2 n}}=0 \text { for all } \theta
$$

by taking derivatives. This can only be zero if $g(\theta)=0$ for all $\theta$, so $Y=\max \left\{X_{i}\right\}$ is complete. For d), the order statistics are minimal sufficient. This is a location family. Thus, by Example 6.2.18 the range $R=X_{(n)}-X_{(1)}$ is ancillary, and its expectation does not depend on $\theta$. So this sufficient statistic is not complete.
6.21 a. $X$ is sufficient because it is the data. To check completeness, calculate

$$
\mathrm{E} g(X)=\frac{\theta}{2} g(-1)+(1-\theta) g(0)+\frac{\theta}{2} g(1)
$$

If $g(-1)=g(1)$ and $g(0)=0$, then $\mathrm{E} g(X)=0$ for all $\theta$, but $g(x)$ need not be identically 0 . So the family is not complete.
b. $|X|$ is sufficient by Theorem 6.2.6, because $f(x \mid \theta)$ depends on $x$ only through the value of $|x|$. The distribution of $|X|$ is Bernoulli, because $P(|X|=0)=1-\theta$ and $P(|X|=1)=\theta$. By Example 6.2.22, a binomial family (Bernoulli is a special case) is complete.
c. Yes, $f(x \mid \theta)=(1-\theta)\left(\theta /(2(1-\theta))^{|x|}=(1-\theta) e^{|x| \log [\theta /(2(1-\theta)]}\right.$, the form of an exponential family.
6.22 a. The sample density is $\prod_{i} \theta x_{i}^{\theta-1}=\theta^{n}\left(\prod_{i} x_{i}\right)^{\theta-1}$, so $\prod_{i} X_{i}$ is sufficient for $\theta$, not $\sum_{i} X_{i}$.
b. Because $\prod_{i} f\left(x_{i} \mid \theta\right)=\theta^{n} e^{(\theta-1) \log \left(\Pi_{i} x_{i}\right)}, \log \left(\prod_{i} X_{i}\right)$ is complete and sufficient by Theorem 6.2.25. Because $\prod_{i} X_{i}$ is a one-to-one function of $\log \left(\prod_{i} X_{i}\right), \prod_{i} X_{i}$ is also a complete sufficient statistic.
6.23 Use Theorem 6.2.13. The ratio

$$
\frac{f(\mathbf{x} \mid \theta)}{f(\mathbf{y} \mid \theta)}=\frac{\theta^{-n} I_{\left(x_{(n)} / 2, x_{(1)}\right)}(\theta)}{\theta^{-n} I_{\left(y_{(n)} / 2, y_{(1)}\right)}(\theta)}
$$

is constant (in fact, one) if and only if $x_{(1)}=y_{(1)}$ and $x_{(n)}=y_{(n)}$. So ( $X_{(1)}, X_{(n)}$ ) is a minimal sufficient statistic for $\theta$. From Exercise 6.10 , we know that if a function of the sufficient statistics is ancillary, then the sufficient statistic is not complete. The uniform $(\theta, 2 \theta)$ family is a scale family, with standard pdf $f(z) \sim \operatorname{uniform}(1,2)$. So if $Z_{1}, \ldots, Z_{n}$ is a random sample
from a uniform $(1,2)$ population, then $X_{1}=\theta Z_{1}, \ldots, X_{n}=\theta Z_{n}$ is a random sample from a uniform $(\theta, 2 \theta)$ population, and $X_{(1)}=\theta Z_{(1)}$ and $X_{(n)}=\theta Z_{(n)}$. So $X_{(1)} / X_{(n)}=Z_{(1)} / Z_{(n)}$, a statistic whose distribution does not depend on $\theta$. Thus, as in Exercise $6.10,\left(X_{(1)}, X_{(n)}\right)$ is not complete.
6.24 If $\lambda=0, \mathrm{E} h(X)=h(0)$. If $\lambda=1$,

$$
\mathrm{E} h(X)=e^{-1} h(0)+e^{-1} \sum_{x=1}^{\infty} \frac{h(x)}{x!} .
$$

Let $h(0)=0$ and $\sum_{x=1}^{\infty} \frac{h(x)}{x!}=0$, so $\mathrm{E} h(X)=0$ but $h(x) \not \equiv 0$. (For example, take $h(0)=0$, $h(1)=1, h(2)=-2, h(x)=0$ for $x \geq 3$.
6.25 Using the fact that $(n-1) s_{\mathbf{x}}^{2}=\sum_{i} x_{i}^{2}-n \bar{x}^{2}$, for any $\left(\mu, \sigma^{2}\right)$ the ratio in Example 6.2.14 can be written as

$$
\frac{f\left(\mathbf{x} \mid \mu, \sigma^{2}\right)}{f\left(\mathbf{y} \mid \mu, \sigma^{2}\right)}=\exp \left[\frac{\mu}{\sigma^{2}}\left(\sum_{i} x_{i}-\sum_{i} y_{i}\right)-\frac{1}{2 \sigma^{2}}\left(\sum_{i} x_{i}^{2}-\sum_{i} y_{i}^{2}\right)\right] .
$$

a. Do part b) first showing that $\sum_{i} X_{i}^{2}$ is a minimal sufficient statistic. Because $\left(\sum_{i} X_{i}, \sum_{i} X_{i}^{2}\right)$ is not a function of $\sum_{i} X_{i}^{2}$, by Definition 6.2.11 $\left(\sum_{i} X_{i}, \sum_{i} X_{i}^{2}\right)$ is not minimal.
b. Substituting $\sigma^{2}=\mu$ in the above expression yields

$$
\frac{f(\mathbf{x} \mid \mu, \mu)}{f(\mathbf{y} \mid \mu, \mu)}=\exp \left[\sum_{i} x_{i}-\sum_{i} y_{i}\right] \exp \left[-\frac{1}{2 \mu}\left(\sum_{i} x_{i}^{2}-\sum_{i} y_{i}^{2}\right)\right]
$$

This is constant as a function of $\mu$ if and only if $\sum_{i} x_{i}^{2}=\sum_{i} y_{i}^{2}$. Thus, $\sum_{i} X_{i}^{2}$ is a minimal sufficient statistic.
c. Substituting $\sigma^{2}=\mu^{2}$ in the first expression yields

$$
\frac{f\left(\mathbf{x} \mid \mu, \mu^{2}\right)}{f\left(\mathbf{y} \mid \mu, \mu^{2}\right)}=\exp \left[\frac{1}{\mu}\left(\sum_{i} x_{i}-\sum_{i} y_{i}\right)-\frac{1}{2 \mu^{2}}\left(\sum_{i} x_{i}^{2}-\sum_{i} y_{i}^{2}\right)\right]
$$

This is constant as a function of $\mu$ if and only if $\sum_{i} x_{i}=\sum_{i} y_{i}$ and $\sum_{i} x_{i}^{2}=\sum_{i} y_{i}^{2}$. Thus, $\left(\sum_{i} X_{i}, \sum_{i} X_{i}^{2}\right)$ is a minimal sufficient statistic.
d. The first expression for the ratio is constant a function of $\mu$ and $\sigma^{2}$ if and only if $\sum_{i} x_{i}=$ $\sum_{i} y_{i}$ and $\sum_{i} x_{i}^{2}=\sum_{i} y_{i}^{2}$. Thus, $\left(\sum_{i} X_{i}, \sum_{i} X_{i}^{2}\right)$ is a minimal sufficient statistic.
6.27 a. This pdf can be written as

$$
f(x \mid \mu, \lambda)=\left(\frac{\lambda}{2 \pi}\right)^{1 / 2}\left(\frac{1}{x^{3}}\right)^{1 / 2} \exp \left(\frac{\lambda}{\mu}\right) \exp \left(-\frac{\lambda}{2 \mu^{2}} x-\frac{\lambda}{2} \frac{1}{x}\right)
$$

This is an exponential family with $t_{1}(x)=x$ and $t_{2}(x)=1 / x$. By Theorem 6.2 .25 , the statistic $\left(\sum_{i} X_{i}, \sum_{i}\left(1 / X_{i}\right)\right)$ is a complete sufficient statistic. $(\bar{X}, T)$ given in the problem is a one-to-one function of $\left(\sum_{i} X_{i}, \sum_{i}\left(1 / X_{i}\right)\right)$. Thus, $(\bar{X}, T)$ is also a complete sufficient statistic.
b. This can be accomplished using the methods from Section 4.3 by a straightforward but messy two-variable transformation $U=\left(X_{1}+X_{2}\right) / 2$ and $V=2 \lambda / T=\lambda\left[\left(1 / X_{1}\right)+\left(1 / X_{2}\right)-\right.$ $\left.\left(2 /\left[X_{1}+X_{2}\right]\right)\right]$. This is a two-to-one transformation.
6.29 Let $f_{j}=\operatorname{logistic}\left(\alpha_{j}, \beta_{j}\right), j=0,1, \ldots, k$. From Theorem 6.6.5, the statistic

$$
T(\mathbf{x})=\left(\frac{\prod_{i=1}^{n} f_{1}\left(x_{i}\right)}{\prod_{i=1}^{n} f_{0}\left(x_{i}\right)}, \ldots, \frac{\prod_{i=1}^{n} f_{k}\left(x_{i}\right)}{\prod_{i=1}^{n} f_{0}\left(x_{i}\right)}\right)=\left(\frac{\prod_{i=1}^{n} f_{1}\left(x_{(i)}\right)}{\prod_{i=1}^{n} f_{0}\left(x_{(i)}\right)}, \ldots, \frac{\prod_{i=1}^{n} f_{k}\left(x_{(i)}\right)}{\prod_{i=1}^{n} f_{0}\left(x_{(i)}\right)}\right)
$$

is minimal sufficient for the family $\left\{f_{0}, f_{1}, \ldots, f_{k}\right\}$. As $T$ is a $1-1$ function of the order statistics, the order statistics are also minimal sufficient for the family $\left\{f_{0}, f_{1}, \ldots, f_{k}\right\}$. If $\mathcal{F}$ is a nonparametric family, $f_{j} \in \mathcal{F}$, so part (b) of Theorem 6.6 .5 can now be directly applied to show that the order statistics are minimal sufficient for $\mathcal{F}$.
6.30 a. From Exercise 6.9 b , we have that $X_{(1)}$ is a minimal sufficient statistic. To check completeness compute $f_{Y_{1}}(y)$, where $Y_{1}=X_{(1)}$. From Theorem 5.4.4 we have

$$
f_{Y_{1}}(y)=f_{X}(y)\left(1-F_{X}(y)\right)^{n-1} n=e^{-(y-\mu)}\left[e^{-(y-\mu)}\right]^{n-1} n=n e^{-n(y-\mu)}, \quad y>\mu
$$

Now, write $\mathrm{E}_{\mu} g\left(Y_{1}\right)=\int_{\mu}^{\infty} g(y) n e^{-n(y-\mu)} d y$. If this is zero for all $\mu$, then $\int_{\mu}^{\infty} g(y) e^{-n y} d y=0$ for all $\mu$ (because $n e^{n \mu}>0$ for all $\mu$ and does not depend on $y$ ). Moreover,

$$
0=\frac{d}{d \mu}\left[\int_{\mu}^{\infty} g(y) e^{-n y} d y\right]=-g(\mu) e^{-n \mu}
$$

for all $\mu$. This implies $g(\mu)=0$ for all $\mu$, so $X_{(1)}$ is complete.
b. Basu's Theorem says that if $X_{(1)}$ is a complete sufficient statistic for $\mu$, then $X_{(1)}$ is independent of any ancillary statistic. Therefore, we need to show only that $S^{2}$ has distribution independent of $\mu$; that is, $S^{2}$ is ancillary. Recognize that $f(x \mid \mu)$ is a location family. So we can write $X_{i}=Z_{i}+\mu$, where $Z_{1}, \ldots, Z_{n}$ is a random sample from $f(x \mid 0)$. Then

$$
S^{2}=\frac{1}{n-1} \sum\left(X_{i}-\bar{X}\right)^{2}=\frac{1}{n-1} \sum\left(\left(Z_{i}+\mu\right)-(\bar{Z}+\mu)\right)^{2}=\frac{1}{n-1} \sum\left(Z_{i}-\bar{Z}\right)^{2} .
$$

Because $S^{2}$ is a function of only $Z_{1}, \ldots, Z_{n}$, the distribution of $S^{2}$ does not depend on $\mu$; that is, $S^{2}$ is ancillary. Therefore, by Basu's theorem, $S^{2}$ is independent of $X_{(1)}$.
6.31 a. (i) By Exercise 3.28 this is a one-dimensional exponential family with $t(x)=x$. By Theorem $6.2 .25, \sum_{i} X_{i}$ is a complete sufficient statistic. $\bar{X}$ is a one-to-one function of $\sum_{i} X_{i}$, so $\bar{X}$ is also a complete sufficient statistic. From Theorem 5.3 .1 we know that $(n-$ 1) $S^{2} / \sigma^{2} \sim \chi_{n-1}^{2}=\operatorname{gamma}((n-1) / 2,2) . S^{2}=\left[\sigma^{2} /(n-1)\right]\left[(n-1) S^{2} / \sigma^{2}\right]$, a simple scale transformation, has a gamma $\left((n-1) / 2,2 \sigma^{2} /(n-1)\right)$ distribution, which does not depend on $\mu$; that is, $S^{2}$ is ancillary. By Basu's Theorem, $\bar{X}$ and $S^{2}$ are independent.
(ii) The independence of $\bar{X}$ and $S^{2}$ is determined by the joint distribution of ( $\bar{X}, S^{2}$ ) for each value of ( $\mu, \sigma^{2}$ ). By part (i), for each value of $\left(\mu, \sigma^{2}\right), \bar{X}$ and $S^{2}$ are independent.
b. (i) $\mu$ is a location parameter. By Exercise $6.14, M-\bar{X}$ is ancillary. As in part (a) $\bar{X}$ is a complete sufficient statistic. By Basu's Theorem, $\bar{X}$ and $M-\bar{X}$ are independent. Because they are independent, by Theorem 4.5.6 Var $M=\operatorname{Var}(M-\bar{X}+\bar{X})=\operatorname{Var}(M-\bar{X})+\operatorname{Var} \bar{X}$.
(ii) If $S^{2}$ is a sample variance calculated from a normal sample of size $N,(N-1) S^{2} / \sigma^{2} \sim$ $\chi_{N-1}^{2}$. Hence, $(N-1)^{2} \operatorname{Var} S^{2} /\left(\sigma^{2}\right)^{2}=2(N-1)$ and $\operatorname{Var} S^{2}=2\left(\sigma^{2}\right)^{2} /(N-1)$. Both $M$ and $M-\bar{X}$ are asymptotically normal, so, $M_{1}, \ldots, M_{N}$ and $M_{1}-\bar{X}_{1}, \ldots, M_{N}-\bar{X}_{N}$ are each approximately normal samples if $n$ is reasonable large. Thus, using the above expression we get the two given expressions where in the straightforward case $\sigma^{2}$ refers to $\operatorname{Var} M$, and in the swindle case $\sigma^{2}$ refers to $\operatorname{Var}(M-\bar{X})$.
c. (i)

$$
\mathrm{E}\left(X^{k}\right)=\mathrm{E}\left(\frac{X}{Y} Y\right)^{k}=\mathrm{E}\left[\left(\frac{X}{Y}\right)^{k}\left(Y^{k}\right)\right] \stackrel{\text { indep. }}{=} \mathrm{E}\left(\frac{X}{Y}\right)^{k} \mathrm{E}\left(Y^{k}\right) .
$$

Divide both sides by $\mathrm{E}\left(Y^{k}\right)$ to obtain the desired equality.
(ii) If $\alpha$ is fixed, $T=\sum_{i} X_{i}$ is a complete sufficient statistic for $\beta$ by Theorem 6.2.25. Because $\beta$ is a scale parameter, if $Z_{1}, \ldots, Z_{n}$ is a random sample from a gamma $(\alpha, 1)$ distribution, then $X_{(i)} / T$ has the same distribution as $\left(\beta Z_{(i)}\right) /\left(\beta \sum_{i} Z_{i}\right)=Z_{(i)} /\left(\sum_{i} Z_{i}\right)$, and this distribution does not depend on $\beta$. Thus, $X_{(i)} / T$ is ancillary, and by Basu's Theorem, it is independent of $T$. We have

$$
\mathrm{E}\left(X_{(i)} \mid T\right)=\mathrm{E}\left(\left.\frac{X_{(i)}}{T} T \right\rvert\, T\right)=T \mathrm{E}\left(\left.\frac{X_{(i)}}{T} \right\rvert\, T\right) \stackrel{\text { indep. }}{=} T \mathrm{E}\left(\frac{X_{(i)}}{T}\right) \stackrel{\text { part }{ }^{(\mathrm{i})}}{=} T \frac{\mathrm{E}\left(X_{(i)}\right)}{\mathrm{E} T} .
$$

Note, this expression is correct for each fixed value of $(\alpha, \beta)$, regardless whether $\alpha$ is "known" or not.
6.32 In the Formal Likelihood Principle, take $E_{1}=E_{2}=E$. Then the conclusion is $\operatorname{Ev}\left(E, x_{1}\right)=$ $\operatorname{Ev}\left(E, x_{2}\right)$ if $L\left(\theta \mid x_{1}\right) / L\left(\theta \mid x_{2}\right)=c$. Thus evidence is equal whenever the likelihood functions are equal, and this follows from Formal Sufficiency and Conditionality.
6.33 a. For all sample points except $\left(2, \mathbf{x}_{2}^{*}\right)$ (but including $\left.\left(1, \mathbf{x}_{1}^{*}\right)\right), T\left(j, \mathbf{x}_{j}\right)=\left(j, \mathbf{x}_{j}\right)$. Hence,

$$
g\left(T\left(j, \mathbf{x}_{j}\right) \mid \theta\right) h\left(j, \mathbf{x}_{j}\right)=g\left(\left(j, \mathbf{x}_{j}\right) \mid \theta\right) 1=f^{*}\left(\left(j, \mathbf{x}_{j}\right) \mid \theta\right) .
$$

For $\left(2, \mathbf{x}_{2}^{*}\right)$ we also have

$$
\begin{aligned}
g\left(T\left(2, \mathbf{x}_{2}^{*}\right) \mid \theta\right) h\left(2, \mathbf{x}_{2}^{*}\right) & =g\left(\left(1, \mathbf{x}_{1}^{*}\right) \mid \theta\right) C=f^{*}\left(\left(1, \mathbf{x}_{1}^{*}\right) \mid \theta\right) C=C \frac{1}{2} f_{1}\left(\mathbf{x}_{1}^{*} \mid \theta\right) \\
& =C \frac{1}{2} L\left(\theta \mid \mathbf{x}_{1}^{*}\right)=\frac{1}{2} L\left(\theta \mid \mathbf{x}_{2}^{*}\right)=\frac{1}{2} f_{2}\left(\mathbf{x}_{2}^{*} \mid \theta\right)=f^{*}\left(\left(2, \mathbf{x}_{2}^{*}\right) \mid \theta\right)
\end{aligned}
$$

By the Factorization Theorem, $T\left(J, \mathbf{X}_{J}\right)$ is sufficient.
b. Equations 6.3.4 and 6.3.5 follow immediately from the two Principles. Combining them we have $\operatorname{Ev}\left(E_{1}, \mathbf{x}_{1}^{*}\right)=\operatorname{Ev}\left(E_{2}, \mathbf{x}_{2}^{*}\right)$, the conclusion of the Formal Likelihood Principle.
c. To prove the Conditionality Principle. Let one experiment be the $E^{*}$ experiment and the other $E_{j}$. Then

$$
L\left(\theta \mid\left(j, \mathbf{x}_{j}\right)\right)=f^{*}\left(\left(j, \mathbf{x}_{j}\right) \mid \theta\right)=\frac{1}{2} f_{j}\left(\mathbf{x}_{j} \mid \theta\right)=\frac{1}{2} L\left(\theta \mid \mathbf{x}_{j}\right)
$$

Letting $\left(j, \mathbf{x}_{j}\right)$ and $\mathbf{x}_{j}$ play the roles of $\mathbf{x}_{1}^{*}$ and $\mathbf{x}_{2}^{*}$ in the Formal Likelihood Principle we can conclude $\operatorname{Ev}\left(E^{*},\left(j, \mathbf{x}_{j}\right)\right)=\operatorname{Ev}\left(E_{j}, \mathbf{x}_{j}\right)$, the Conditionality Principle. Now consider the Formal Sufficiency Principle. If $T(\mathbf{X})$ is sufficient and $T(\mathbf{x})=T(\mathbf{y})$, then $L(\theta \mid \mathbf{x})=C L(\theta \mid \mathbf{y})$, where $C=h(\mathbf{x}) / h(\mathbf{y})$ and $h$ is the function from the Factorization Theorem. Hence, by the Formal Likelihood Principle, $\operatorname{Ev}(E, \mathbf{x})=\operatorname{Ev}(E, \mathbf{y})$, the Formal Sufficiency Principle.
6.35 Let $1=$ success and $0=$ failure. The four sample points are $\{0,10,110,111\}$. From the likelihood principle, inference about $p$ is only through $L(p \mid \mathbf{x})$. The values of the likelihood are $1, p, p^{2}$, and $p^{3}$, and the sample size does not directly influence the inference.
6.37 a. For one observation $(X, Y)$ we have

$$
I(\theta)=-\mathrm{E}\left(\frac{\partial^{2}}{\partial \theta^{2}} \log f(X, Y \mid \theta)\right)=-\mathrm{E}\left(-\frac{2 Y}{\theta^{3}}\right)=\frac{2 \mathrm{E} Y}{\theta^{3}}
$$

But, $Y \sim$ exponential $(\theta)$, and $\mathrm{E} Y=\theta$. Hence, $I(\theta)=2 / \theta^{2}$ for a sample of size one, and $I(\theta)=2 n / \theta^{2}$ for a sample of size $n$.
b. (i) The cdf of $T$ is

$$
P(T \leq t)=P\left(\frac{\sum_{i} Y_{i}}{\sum_{i} X_{i}} \leq t^{2}\right)=P\left(\frac{2 \sum_{i} Y_{i} / \theta}{2 \sum_{i} X_{i} \theta} \leq t^{2} / \theta^{2}\right)=P\left(F_{2 n, 2 n} \leq t^{2} / \theta^{2}\right)
$$

where $F_{2 n, 2 n}$ is an $F$ random variable with $2 n$ degrees of freedom in the numerator and denominator. This follows since $2 Y_{i} / \theta$ and $2 X_{i} \theta$ are all independent exponential(1), or $\chi_{2}^{2}$. Differentiating (in $t$ ) and simplifying gives the density of $T$ as

$$
f_{T}(t)=\frac{\Gamma(2 n)}{\Gamma(n)^{2}} \frac{2}{t}\left(\frac{t^{2}}{t^{2}+\theta^{2}}\right)^{n}\left(\frac{\theta^{2}}{t^{2}+\theta^{2}}\right)^{n}
$$

and the second derivative (in $\theta$ ) of the $\log$ density is

$$
2 n \frac{t^{4}+2 t^{2} \theta^{2}-\theta^{4}}{\theta^{2}\left(t^{2}+\theta^{2}\right)^{2}}=\frac{2 n}{\theta^{2}}\left(1-\frac{2}{\left(t^{2} / \theta^{2}+1\right)^{2}}\right)
$$

and the information in $T$ is

$$
\frac{2 n}{\theta^{2}}\left[1-2 \mathrm{E}\left(\frac{1}{T^{2} / \theta^{2}+1}\right)^{2}\right]=\frac{2 n}{\theta^{2}}\left[1-2 \mathrm{E}\left(\frac{1}{F_{2 n, 2 n}^{2}+1}\right)^{2}\right]
$$

The expected value is

$$
\mathrm{E}\left(\frac{1}{F_{2 n, 2 n}^{2}+1}\right)^{2}=\frac{\Gamma(2 n)}{\Gamma(n)^{2}} \int_{0}^{\infty} \frac{1}{(1+w)^{2}} \frac{w^{n-1}}{(1+w)^{2 n}}=\frac{\Gamma(2 n)}{\Gamma(n)^{2}} \frac{\Gamma(n) \Gamma(n+2)}{\Gamma(2 n+2)}=\frac{n+1}{2(2 n+1)}
$$

Substituting this above gives the information in $T$ as

$$
\frac{2 n}{\theta^{2}}\left[1-2 \frac{n+1}{2(2 n+1)}\right]=I(\theta) \frac{n}{2 n+1},
$$

which is not the answer reported by Joshi and Nabar.
(ii) Let $W=\sum_{i} X_{i}$ and $V=\sum_{i} Y_{i}$. In each pair, $X_{i}$ and $Y_{i}$ are independent, so $W$ and $V$ are independent. $X_{i} \sim \operatorname{exponential}(1 / \theta)$; hence, $W \sim \operatorname{gamma}(n, 1 / \theta) . Y_{i} \sim \operatorname{exponential}(\theta)$; hence, $V \sim \operatorname{gamma}(n, \theta)$. Use this joint distribution of $(W, V)$ to derive the joint pdf of $(T, U)$ as

$$
f(t, u \mid \theta)=\frac{2}{[\Gamma(n)]^{2} t} u^{2 n-1} \exp \left(-\frac{u \theta}{t}-\frac{u t}{\theta}\right), \quad u>0, \quad t>0 .
$$

Now, the information in $(T, U)$ is

$$
-\mathrm{E}\left(\frac{\partial^{2}}{\partial \theta^{2}} \log f(T, U \mid \theta)\right)=-\mathrm{E}\left(-\frac{2 U T}{\theta^{3}}\right)=\mathrm{E}\left(\frac{2 V}{\theta^{3}}\right)=\frac{2 n \theta}{\theta^{3}}=\frac{2 n}{\theta^{2}}
$$

(iii) The pdf of the sample is $f(\mathbf{x}, \mathbf{y})=\exp \left[-\theta\left(\sum_{i} x_{i}\right)-\left(\sum_{i} y_{i}\right) / \theta\right]$. Hence, $(W, V)$ defined as in part (ii) is sufficient. ( $T, U$ ) is a one-to-one function of $(W, V)$, hence $(T, U)$ is also sufficient. But, $\mathrm{E} U^{2}=\mathrm{E} W V=(n / \theta)(n \theta)=n^{2}$ does not depend on $\theta$. So $\mathrm{E}\left(U^{2}-n^{2}\right)=0$ for all $\theta$, and $(T, U)$ is not complete.
6.39 a. The transformation from Celsius to Fahrenheit is $y=9 x / 5+32$. Hence,

$$
\begin{aligned}
\frac{5}{9}\left(T^{*}(y)-32\right) & =\frac{5}{9}((.5)(y)+(.5)(212)-32) \\
& =\frac{5}{9}((.5)(9 x / 5+32)+(.5)(212)-32)=(.5) x+50=T(x)
\end{aligned}
$$

b. $T(x)=(.5) x+50 \neq(.5) x+106=T^{*}(x)$. Thus, we do not have equivariance.
6.40 a. Because $X_{1}, \ldots, X_{n}$ is from a location scale family, by Theorem 3.5.6, we can write $X_{i}=$ $\sigma Z_{i}+\mu$, where $Z_{1}, \ldots, Z_{n}$ is a random sample from the standard pdf $f(z)$. Then

$$
\frac{T_{1}\left(X_{1}, \ldots, X_{n}\right)}{T_{2}\left(X_{1}, \ldots, X_{n}\right)}=\frac{T_{1}\left(\sigma Z_{1}+\mu, \ldots, \sigma Z_{n}+\mu\right)}{T_{2}\left(\sigma Z_{1}+\mu, \ldots, \sigma Z_{n}+\mu\right)}=\frac{\sigma T_{1}\left(Z_{1}, \ldots, Z_{n}\right)}{\sigma T_{2}\left(Z_{1}, \ldots, Z_{n}\right)}=\frac{T_{1}\left(Z_{1}, \ldots, Z_{n}\right)}{T_{2}\left(Z_{1}, \ldots, Z_{n}\right)}
$$

Because $T_{1} / T_{2}$ is a function of only $Z_{1}, \ldots, Z_{n}$, the distribution of $T_{1} / T_{2}$ does not depend on $\mu$ or $\sigma$; that is, $T_{1} / T_{2}$ is an ancillary statistic.
b. $R\left(x_{1}, \ldots, x_{n}\right)=x_{(n)}-x_{(1)}$. Because $a>0, \max \left\{a x_{1}+b, \ldots, a x_{n}+b\right\}=a x_{(n)}+b$ and $\min \left\{a x_{1}+b, \ldots, a x_{n}+b\right\}=a x_{(1)}+b$. Thus, $R\left(a x_{1}+b, \ldots, a x_{n}+b\right)=\left(a x_{(n)}+b\right)-\left(a x_{(1)}+b\right)=$ $a\left(x_{(n)}-x_{(1)}\right)=a R\left(x_{1}, \ldots, x_{n}\right)$. For the sample variance we have

$$
\begin{aligned}
S^{2}\left(a x_{1}+b, \ldots, a x_{n}+b\right) & =\frac{1}{n-1} \sum\left(\left(a x_{i}+b\right)-(a \bar{x}+b)\right)^{2} \\
& =a^{2} \frac{1}{n-1} \sum\left(x_{i}-\bar{x}\right)^{2}=a^{2} S^{2}\left(x_{1}, \ldots, x_{n}\right)
\end{aligned}
$$

Thus, $S\left(a x_{1}+b, \ldots, a x_{n}+b\right)=a S\left(x_{1}, \ldots, x_{n}\right)$. Therefore, $R$ and $S$ both satisfy the above condition, and $R / S$ is ancillary by a).
6.41 a. Measurement equivariance requires that the estimate of $\mu$ based on $\mathbf{y}$ be the same as the estimate of $\mu$ based on $\mathbf{x}$; that is, $T^{*}\left(x_{1}+a, \ldots, x_{n}+a\right)-a=T^{*}(\mathbf{y})-a=T(\mathbf{x})$.
b. The formal structures for the problem involving $\mathbf{X}$ and the problem involving $\mathbf{Y}$ are the same. They both concern a random sample of size $n$ from a normal population and estimation of the mean of the population. Thus, formal invariance requires that $T(\mathbf{x})=T^{*}(\mathbf{x})$ for all $\mathbf{x}$. Combining this with part (a), the Equivariance Principle requires that $T\left(x_{1}+a, \ldots, x_{n}+a\right)-$ $a=T^{*}\left(x_{1}+a, \ldots, x_{n}+a\right)-a=T\left(x_{1}, \ldots, x_{n}\right)$, i.e., $T\left(x_{1}+a, \ldots, x_{n}+a\right)=T\left(x_{1}, \ldots, x_{n}\right)+a$.
c. $W\left(x_{1}+a, \ldots, x_{n}+a\right)=\sum_{i}\left(x_{i}+a\right) / n=\left(\sum_{i} x_{i}\right) / n+a=W\left(x_{1}, \ldots, x_{n}\right)+a$, so $W(\mathbf{x})$ is equivariant. The distribution of $\left(X_{1}, \ldots, X_{n}\right)$ is the same as the distribution of $\left(Z_{1}+\right.$ $\theta, \ldots, Z_{n}+\theta$, where $Z_{1}, \ldots, Z_{n}$ are a random sample from $f(x-0)$ and $\mathrm{E} Z_{i}=0$. Thus, $\mathrm{E}_{\theta} W=\mathrm{E} \sum_{i}\left(Z_{i}+\theta\right) / n=\theta$, for all $\theta$.
6.43 a. For a location-scale family, if $X \sim f\left(x \mid \theta, \sigma^{2}\right)$, then $Y=g_{a, c}(X) \sim f\left(y \mid c \theta+a, c^{2} \sigma^{2}\right)$. So for estimating $\sigma^{2}, \bar{g}_{a, c}\left(\sigma^{2}\right)=c^{2} \sigma^{2}$. An estimator of $\sigma^{2}$ is invariant with respect to $\mathcal{G}_{1}$ if $W\left(c x_{1}+a, \ldots, c x_{n}+a\right)=c^{2} W\left(x_{1}, \ldots, x_{n}\right)$. An estimator of the form $k S^{2}$ is invariant because

$$
\begin{aligned}
k S^{2}\left(c x_{1}+a, \ldots, c x_{n}+a\right) & =\frac{k}{n-1} \sum_{i=1}^{n}\left(\left(c x_{i}+a\right)-\sum_{i=1}^{n}\left(c x_{i}+a\right) / n\right)^{2} \\
& =\frac{k}{n-1} \sum_{i=1}^{n}\left(\left(c x_{i}+a\right)-(c \bar{x}+a)\right)^{2} \\
& =c^{2} \frac{k}{n-1} \sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2}=c^{2} k S^{2}\left(x_{1}, \ldots, x_{n}\right)
\end{aligned}
$$

To show invariance with respect to $\mathcal{G}_{2}$, use the above argument with $c=1$. To show invariance with respect to $\mathcal{G}_{3}$, use the above argument with $a=0$. ( $\mathcal{G}_{2}$ and $\mathcal{G}_{3}$ are both subgroups of $\mathcal{G}_{1}$. So invariance with respect to $\mathcal{G}_{1}$ implies invariance with respect to $\mathcal{G}_{2}$ and $\mathcal{G}_{3}$.)
b. The transformations in $\mathcal{G}_{2}$ leave the scale parameter unchanged. Thus, $\bar{g}_{a}\left(\sigma^{2}\right)=\sigma^{2}$. An estimator of $\sigma^{2}$ is invariant with respect to this group if

$$
W\left(x_{1}+a, \ldots, x_{n}+a\right)=W\left(g_{a}(\mathbf{x})\right)=\bar{g}_{a}(W(\mathbf{x}))=W\left(x_{1}, \ldots, x_{n}\right)
$$

An estimator of the given form is invariant if, for all $a$ and $\left(x_{1}, \ldots, x_{n}\right)$,

$$
W\left(x_{1}+a, \ldots, x_{n}+a\right)=\phi\left(\frac{\bar{x}+a}{s}\right) s^{2}=\phi\left(\frac{\bar{x}}{s}\right) s^{2}=W\left(x_{1}, \ldots, x_{n}\right) .
$$

In particular, for a sample point with $s=1$ and $\bar{x}=0$, this implies we must have $\phi(a)=\phi(0)$, for all $a$; that is, $\phi$ must be constant. On the other hand, if $\phi$ is constant, then the estimators are invariant by part a). So we have invariance if and only if $\phi$ is constant. Invariance with respect to $\mathcal{G}_{1}$ also requires $\phi$ to be constant because $\mathcal{G}_{2}$ is a subgroup of $\mathcal{G}_{1}$. Finally, an estimator of $\sigma^{2}$ is invariant with respect to $\mathcal{G}_{3}$ if $W\left(c x_{1}, \ldots, c x_{n}\right)=c^{2} W\left(x_{1}, \ldots, x_{n}\right)$. Estimators of the given form are invariant because

$$
W\left(c x_{1}, \ldots, c x_{n}\right)=\phi\left(\frac{c \bar{x}}{c s}\right) c^{2} s^{2}=c^{2} \phi\left(\frac{\bar{x}}{s}\right) s^{2}=c^{2} W\left(x_{1}, \ldots, x_{n}\right)
$$

## Chapter 7

## Point Estimation

7.1 For each value of $x$, the MLE $\hat{\theta}$ is the value of $\theta$ that maximizes $f(x \mid \theta)$. These values are in the following table.

$$
\begin{array}{cccccc}
x & 0 & 1 & 2 & 3 & 4 \\
\hat{\theta} & 1 & 1 & 2 \text { or } 3 & 3 & 3
\end{array}
$$

At $x=2, f(x \mid 2)=f(x \mid 3)=1 / 4$ are both maxima, so both $\hat{\theta}=2$ or $\hat{\theta}=3$ are MLEs.
7.2 a.

$$
\begin{aligned}
L(\beta \mid x) & =\prod_{i=1}^{n} \frac{1}{\Gamma(\alpha) \beta^{\alpha}} x_{i}^{\alpha-1} e^{-x_{i} / \beta}=\frac{1}{\Gamma(\alpha)^{n} \beta^{n \alpha}}\left[\prod_{i=1}^{n} x_{i}\right]^{\alpha-1} e^{-\Sigma_{i} x_{i} / \beta} \\
\log L(\beta \mid x) & =-\log \Gamma(\alpha)^{n}-n \alpha \log \beta+(\alpha-1) \log \left[\prod_{i=1}^{n} x_{i}\right]-\frac{\sum_{i} x_{i}}{\beta} \\
\frac{\partial \log L}{\partial \beta} & =-\frac{n \alpha}{\beta}+\frac{\sum_{i} x_{i}}{\beta^{2}}
\end{aligned}
$$

Set the partial derivative equal to 0 and solve for $\beta$ to obtain $\hat{\beta}=\sum_{i} x_{i} /(n \alpha)$. To check that this is a maximum, calculate

$$
\left.\frac{\partial^{2} \log L}{\partial \beta^{2}}\right|_{\beta=\hat{\beta}}=\frac{n \alpha}{\beta^{2}}-\left.\frac{2 \sum_{i} x_{i}}{\beta^{3}}\right|_{\beta=\hat{\beta}}=\frac{(n \alpha)^{3}}{\left(\sum_{i} x_{i}\right)^{2}}-\frac{2(n \alpha)^{3}}{\left(\sum_{i} x_{i}\right)^{2}}=-\frac{(n \alpha)^{3}}{\left(\sum_{i} x_{i}\right)^{2}}<0
$$

Because $\hat{\beta}$ is the unique point where the derivative is 0 and it is a local maximum, it is a global maximum. That is, $\hat{\beta}$ is the MLE.
b. Now the likelihood function is

$$
L(\alpha, \beta \mid x)=\frac{1}{\Gamma(\alpha)^{n} \beta^{n \alpha}}\left[\prod_{i=1}^{n} x_{i}\right]^{\alpha-1} e^{-\Sigma_{i} x_{i} / \beta}
$$

the same as in part (a) except $\alpha$ and $\beta$ are both variables. There is no analytic form for the MLEs, The values $\hat{\alpha}$ and $\hat{\beta}$ that maximize $L$. One approach to finding $\hat{\alpha}$ and $\hat{\beta}$ would be to numerically maximize the function of two arguments. But it is usually best to do as much as possible analytically, first, and perhaps reduce the complexity of the numerical problem. From part (a), for each fixed value of $\alpha$, the value of $\beta$ that maximizes $L$ is $\sum_{i} x_{i} /(n \alpha)$. Substitute this into $L$. Then we just need to maximize the function of the one variable $\alpha$ given by

$$
\begin{aligned}
& \frac{1}{\Gamma(\alpha)^{n}\left(\sum_{i} x_{i} /(n \alpha)\right)^{n \alpha}}\left[\prod_{i=1}^{n} x_{i}\right]^{\alpha-1} e^{-\sum_{i} x_{i} /\left(\sum_{i} x_{i} /(n \alpha)\right)} \\
& =\frac{1}{\Gamma(\alpha)^{n}\left(\sum_{i} x_{i} /(n \alpha)\right)^{n \alpha}}\left[\prod_{i=1}^{n} x_{i}\right]^{\alpha-1} e^{-n \alpha}
\end{aligned}
$$

For the given data, $n=14$ and $\sum_{i} x_{i}=323.6$. Many computer programs can be used to maximize this function. From PROC NLIN in SAS we obtain $\hat{\alpha}=514.219$ and, hence, $\hat{\beta}=\frac{323.6}{14(514.219)}=.0450$.
7.3 The $\log$ function is a strictly monotone increasing function. Therefore, $L(\theta \mid \mathbf{x})>L\left(\theta^{\prime} \mid \mathbf{x}\right)$ if and only if $\log L(\theta \mid \mathbf{x})>\log L\left(\theta^{\prime} \mid \mathbf{x}\right)$. So the value $\hat{\theta}$ that maximizes $\log L(\theta \mid \mathbf{x})$ is the same as the value that maximizes $L(\theta \mid \mathbf{x})$.
7.5 a. The value $\hat{z}$ solves the equation

$$
(1-p)^{n}=\prod_{i}\left(1-x_{i} z\right)
$$

where $0 \leq z \leq\left(\max _{i} x_{i}\right)^{-1}$. Let $\hat{k}=$ greatest integer less than or equal to $1 / \hat{z}$. Then from Example 7.2.9, $\hat{k}$ must satisfy

$$
[k(1-p)]^{n} \geq \prod_{i}\left(k-x_{i}\right) \quad \text { and } \quad[(k+1)(1-p)]^{n}<\prod_{i}\left(k+1-x_{i}\right)
$$

Because the right-hand side of the first equation is decreasing in $\hat{z}$, and because $\hat{k} \leq 1 / \hat{z}$ (so $\hat{z} \leq 1 / \hat{k})$ and $\hat{k}+1>1 / \hat{z}, \hat{k}$ must satisfy the two inequalities. Thus $\hat{k}$ is the MLE.
b. For $p=1 / 2$, we must solve $\left(\frac{1}{2}\right)^{4}=(1-20 z)(1-z)(1-19 z)$, which can be reduced to the cubic equation $-380 z^{3}+419 z^{2}-40 z+15 / 16=0$. The roots are $.9998, .0646$, and .0381 , leading to candidates of 1,15 , and 26 for $\hat{k}$. The first two are less than $\max _{i} x_{i}$. Thus $\hat{k}=26$.
7.6 a. $f(\mathbf{x} \mid \theta)=\prod_{i} \theta x_{i}^{-2} I_{[\theta, \infty)}\left(x_{i}\right)=\left(\prod_{i} x_{i}^{-2}\right) \theta^{n} I_{[\theta, \infty)}\left(x_{(1)}\right)$. Thus, $X_{(1)}$ is a sufficient statistic for $\theta$ by the Factorization Theorem.
b. $L(\theta \mid \mathbf{x})=\theta^{n}\left(\prod_{i} x_{i}^{-2}\right) I_{[\theta, \infty)}\left(x_{(1)}\right)$. $\theta^{n}$ is increasing in $\theta$. The second term does not involve $\theta$. So to maximize $L(\theta \mid \mathbf{x})$, we want to make $\theta$ as large as possible. But because of the indicator function, $L(\theta \mid \mathbf{x})=0$ if $\theta>x_{(1)}$. Thus, $\hat{\theta}=x_{(1)}$.
c. $\mathrm{E} X=\int_{\theta}^{\infty} \theta x^{-1} d x=\left.\theta \log x\right|_{\theta} ^{\infty}=\infty$. Thus the method of moments estimator of $\theta$ does not exist. (This is the Pareto distribution with $\alpha=\theta, \beta=1$.)
7.7 $L(0 \mid \mathbf{x})=1,0<x_{i}<1$, and $L(1 \mid \mathbf{x})=\prod_{i} 1 /\left(2 \sqrt{x_{i}}\right), 0<x_{i}<1$. Thus, the MLE is 0 if $1 \geq \prod_{i} 1 /\left(2 \sqrt{x_{i}}\right)$, and the MLE is 1 if $1<\prod_{i} 1 /\left(2 \sqrt{x_{i}}\right)$.
7.8 a. $\mathrm{E} X^{2}=\operatorname{Var} X+\mu^{2}=\sigma^{2}$. Therefore $X^{2}$ is an unbiased estimator of $\sigma^{2}$.
b.

$$
\begin{aligned}
L(\sigma \mid \mathbf{x}) & =\frac{1}{\sqrt{2 \pi \sigma}} e^{-x^{2} /\left(2 \sigma^{2}\right)} \cdot \log L(\sigma \mid \mathbf{x})=\log (2 \pi)^{-1 / 2}-\log \sigma-x^{2} /\left(2 \sigma^{2}\right) \\
\frac{\partial \log L}{\partial \sigma} & =-\frac{1}{\sigma}+\frac{x^{2}}{\sigma^{3}} \stackrel{\text { set }}{=} 0 \Rightarrow \hat{\sigma} X^{2}=\hat{\sigma}^{3} \Rightarrow \hat{\sigma}=\sqrt{X^{2}}=|X| \\
\frac{\partial^{2} \log L}{\partial \sigma^{2}} & =\frac{-3 x^{2} \sigma^{2}}{\sigma^{6}}+\frac{1}{\sigma^{2}}, \text { which is negative at } \hat{\sigma}=|x|
\end{aligned}
$$

Thus, $\hat{\sigma}=|x|$ is a local maximum. Because it is the only place where the first derivative is zero, it is also a global maximum.
c. Because $\mathrm{E} X=0$ is known, just equate $\mathrm{E} X^{2}=\sigma^{2}=\frac{1}{n} \sum_{i=1}^{1} X_{i}^{2}=X^{2} \Rightarrow \hat{\sigma}=|X|$.
7.9 This is a uniform $(0, \theta)$ model. So $\mathrm{E} X=(0+\theta) / 2=\theta / 2$. The method of moments estimator is the solution to the equation $\tilde{\theta} / 2=\bar{X}$, that is, $\tilde{\theta}=2 \bar{X}$. Because $\tilde{\theta}$ is a simple function of the sample mean, its mean and variance are easy to calculate. We have

$$
\mathrm{E} \tilde{\theta}=2 \mathrm{E} \bar{X}=2 \mathrm{E} X=2 \frac{\theta}{2}=\theta, \quad \text { and } \quad \operatorname{Var} \tilde{\theta}=4 \operatorname{Var} \bar{X}=4 \frac{\theta^{2} / 12}{n}=\frac{\theta^{2}}{3 n}
$$

The likelihood function is

$$
L(\theta \mid \mathbf{x})=\prod_{i=1}^{n} \frac{1}{\theta} I_{[0, \theta]}\left(x_{i}\right)=\frac{1}{\theta^{n}} I_{[0, \theta]}\left(x_{(n)}\right) I_{[0, \infty)}\left(x_{(1)}\right),
$$

where $x_{(1)}$ and $x_{(n)}$ are the smallest and largest order statistics. For $\theta \geq x_{(n)}, L=1 / \theta^{n}$, a decreasing function. So for $\theta \geq x_{(n)}, L$ is maximized at $\hat{\theta}=x_{(n)}$. $L=0$ for $\theta<x_{(n)}$. So the overall maximum, the MLE, is $\hat{\theta}=X_{(n)}$. The pdf of $\hat{\theta}=X_{(n)}$ is $n x^{n-1} / \theta^{n}, 0 \leq x \leq \theta$. This can be used to calculate

$$
\mathrm{E} \hat{\theta}=\frac{n}{n+1} \theta, \quad \mathrm{E} \hat{\theta}^{2}=\frac{n}{n+2} \theta^{2} \quad \text { and } \quad \operatorname{Var} \hat{\theta}=\frac{n \theta^{2}}{(n+2)(n+1)^{2}}
$$

$\tilde{\theta}$ is an unbiased estimator of $\theta ; \hat{\theta}$ is a biased estimator. If $n$ is large, the bias is not large because $n /(n+1)$ is close to one. But if $n$ is small, the bias is quite large. On the other hand, $\operatorname{Var} \hat{\theta}<\operatorname{Var} \tilde{\theta}$ for all $\theta$. So, if $n$ is large, $\hat{\theta}$ is probably preferable to $\tilde{\theta}$.
7.10 a. $f(\mathbf{x} \mid \theta)=\prod_{i} \frac{\alpha}{\beta^{\alpha}} x_{i}^{\alpha-1} I_{[0, \beta]}\left(x_{i}\right)=\left(\frac{\alpha}{\beta^{\alpha}}\right)^{n}\left(\prod_{i} x_{i}\right)^{\alpha-1} I_{(-\infty, \beta]}\left(x_{(n)}\right) I_{[0, \infty)}\left(x_{(1)}\right)=L(\alpha, \beta \mid \mathbf{x})$. By the Factorization Theorem, $\left(\prod_{i} X_{i}, X_{(n)}\right)$ are sufficient.
b. For any fixed $\alpha, L(\alpha, \beta \mid \mathbf{x})=0$ if $\beta<x_{(n)}$, and $L(\alpha, \beta \mid \mathbf{x})$ a decreasing function of $\beta$ if $\beta \geq x_{(n)}$. Thus, $X_{(n)}$ is the MLE of $\beta$. For the MLE of $\alpha$ calculate

$$
\frac{\partial}{\partial \alpha} \log L=\frac{\partial}{\partial \alpha}\left[n \log \alpha-n \alpha \log \beta+(\alpha-1) \log \prod_{i} x_{i}\right]=\frac{n}{\alpha}-n \log \beta+\log \prod_{i} x_{i}
$$

Set the derivative equal to zero and use $\hat{\beta}=X_{(n)}$ to obtain

$$
\hat{\alpha}=\frac{n}{n \log X_{(n)}-\log \prod_{i} X_{i}}=\left[\frac{1}{n} \sum_{i}\left(\log X_{(n)}-\log X_{i}\right)\right]^{-1} .
$$

The second derivative is $-n / \alpha^{2}<0$, so this is the MLE.
c. $X_{(n)}=25.0, \log \prod_{i} X_{i}=\sum_{i} \log X_{i}=43.95 \Rightarrow \hat{\beta}=25.0, \hat{\alpha}=12.59$.
7.11 a.

$$
\begin{aligned}
f(\mathbf{x} \mid \theta) & =\prod_{i} \theta x_{i}^{\theta-1}=\theta^{n}\left(\prod_{i} x_{i}\right)^{\theta-1}=L(\theta \mid \mathbf{x}) \\
\frac{d}{d \theta} \log L & =\frac{d}{d \theta}\left[n \log \theta+(\theta-1) \log \prod_{i} x_{i}\right]=\frac{n}{\theta}+\sum_{i} \log x_{i} .
\end{aligned}
$$

Set the derivative equal to zero and solve for $\theta$ to obtain $\hat{\theta}=\left(-\frac{1}{n} \sum_{i} \log x_{i}\right)^{-1}$. The second derivative is $-n / \theta^{2}<0$, so this is the MLE. To calculate the variance of $\hat{\theta}$, note that $Y_{i}=-\log X_{i} \sim \operatorname{exponential}(1 / \theta)$, so $-\sum_{i} \log X_{i} \sim \operatorname{gamma}(n, 1 / \theta)$. Thus $\hat{\theta}=n / T$, where $T \sim \operatorname{gamma}(n, 1 / \theta)$. We can either calculate the first and second moments directly, or use the fact that $\hat{\theta}$ is inverted gamma (page 51 ). We have

$$
\begin{aligned}
\mathrm{E} \frac{1}{T} & =\frac{\theta^{n}}{\Gamma(n)} \int_{0}^{\infty} \frac{1}{t} t^{n-1} e^{-\theta t} d t=\frac{\theta^{n}}{\Gamma(n)} \frac{\Gamma(n-1)}{\theta^{n-1}}=\frac{\theta}{n-1} \\
\mathrm{E} \frac{1}{T^{2}} & =\frac{\theta^{n}}{\Gamma(n)} \int_{0}^{\infty} \frac{1}{t^{2}} t^{n-1} e^{-\theta t} d t=\frac{\theta^{n}}{\Gamma(n)} \frac{\Gamma(n-2)}{\theta^{n-2}}=\frac{\theta^{2}}{(n-1)(n-2)}
\end{aligned}
$$

and thus

$$
\mathrm{E} \hat{\theta}=\frac{n}{n-1} \theta \quad \text { and } \quad \operatorname{Var} \hat{\theta}=\frac{n^{2}}{(n-1)^{2}(n-2)} \theta^{2} \rightarrow 0 \text { as } n \rightarrow \infty
$$

b. Because $X \sim \operatorname{beta}(\theta, 1), \mathrm{E} X=\theta /(\theta+1)$ and the method of moments estimator is the solution to

$$
\frac{1}{n} \sum_{i} X_{i}=\frac{\theta}{\theta+1} \Rightarrow \tilde{\theta}=\frac{\sum_{i} X_{i}}{n-\sum_{i} X_{i}}
$$

$7.12 X_{i} \sim \operatorname{iid} \operatorname{Bernoulli}(\theta), 0 \leq \theta \leq 1 / 2$.
a. method of moments:

$$
\mathrm{E} X=\theta=\frac{1}{n} \sum_{i} X_{i}=\bar{X} \quad \Rightarrow \quad \tilde{\theta}=\bar{X}
$$

MLE: In Example 7.2.7, we showed that $L(\theta \mid \mathbf{x})$ is increasing for $\theta \leq \bar{x}$ and is decreasing for $\theta \geq \bar{x}$. Remember that $0 \leq \theta \leq 1 / 2$ in this exercise. Therefore, when $\bar{X} \leq 1 / 2, \bar{X}$ is the MLE of $\theta$, because $\bar{X}$ is the overall maximum of $L(\theta \mid \mathbf{x})$. When $\bar{X}>1 / 2, L(\theta \mid \mathbf{x})$ is an increasing function of $\theta$ on $[0,1 / 2]$ and obtains its maximum at the upper bound of $\theta$ which is $1 / 2$. So the MLE is $\hat{\theta}=\min \{\bar{X}, 1 / 2\}$.
b. The $\operatorname{MSE}$ of $\tilde{\theta}$ is $\operatorname{MSE}(\tilde{\theta})=\operatorname{Var} \tilde{\theta}+\operatorname{bias}(\tilde{\theta})^{2}=(\theta(1-\theta) / n)+0^{2}=\theta(1-\theta) / n$. There is no simple formula for $\operatorname{MSE}(\hat{\theta})$, but an expression is

$$
\begin{aligned}
\operatorname{MSE}(\hat{\theta}) & =\mathrm{E}(\hat{\theta}-\theta)^{2}=\sum_{y=0}^{n}(\hat{\theta}-\theta)^{2}\binom{n}{y} \theta^{y}(1-\theta)^{n-y} \\
& =\sum_{y=0}^{[n / 2]}\left(\frac{y}{n}-\theta\right)^{2}\binom{n}{y} \theta^{y}(1-\theta)^{n-y}+\sum_{y=[n / 2]+1}^{n}\left(\frac{1}{2}-\theta\right)^{2}\binom{n}{y} \theta^{y}(1-\theta)^{n-y}
\end{aligned}
$$

where $Y=\sum_{i} X_{i} \sim \operatorname{binomial}(n, \theta)$ and $[n / 2]=n / 2$, if $n$ is even, and $[n / 2]=(n-1) / 2$, if $n$ is odd.
c. Using the notation used in (b), we have

$$
\operatorname{MSE}(\tilde{\theta})=\mathrm{E}(\bar{X}-\theta)^{2}=\sum_{y=0}^{n}\left(\frac{y}{n}-\theta\right)^{2}\binom{n}{y} \theta^{y}(1-\theta)^{n-y}
$$

Therefore,

$$
\begin{aligned}
\operatorname{MSE}(\tilde{\theta})-\operatorname{MSE}(\hat{\theta}) & =\sum_{y=[n / 2]+1}^{n}\left[\left(\frac{y}{n}-\theta\right)^{2}-\left(\frac{1}{2}-\theta\right)^{2}\right]\binom{n}{y} \theta^{y}(1-\theta)^{n-y} \\
& =\sum_{y=[n / 2]+1}^{n}\left(\frac{y}{n}+\frac{1}{2}-2 \theta\right)\left(\frac{y}{n}-\frac{1}{2}\right)\binom{n}{y} \theta^{y}(1-\theta)^{n-y}
\end{aligned}
$$

The facts that $y / n>1 / 2$ in the sum and $\theta \leq 1 / 2$ imply that every term in the sum is positive. Therefore $\operatorname{MSE}(\hat{\theta})<\operatorname{MSE}(\tilde{\theta})$ for every $\theta$ in $0<\theta \leq 1 / 2$. (Note: $\operatorname{MSE}(\hat{\theta})=\operatorname{MSE}(\tilde{\theta})=0$ at $\theta=0$.)
7.13 $L(\theta \mid \mathbf{x})=\prod_{i} \frac{1}{2} e^{-\frac{1}{2}\left|x_{i}-\theta\right|}=\frac{1}{2^{n}} e^{-\frac{1}{2} \Sigma_{i}\left|x_{i}-\theta\right|}$, so the MLE minimizes $\sum_{i}\left|x_{i}-\theta\right|=\sum_{i}\left|x_{(i)}-\theta\right|$, where $x_{(1)}, \ldots, x_{(n)}$ are the order statistics. For $x_{(j)} \leq \theta \leq x_{(j+1)}$,

$$
\sum_{i=1}^{n}\left|x_{(i)}-\theta\right|=\sum_{i=1}^{j}\left(\theta-x_{(i)}\right)+\sum_{i=j+1}^{n}\left(x_{(i)}-\theta\right)=(2 j-n) \theta-\sum_{i=1}^{j} x_{(i)}+\sum_{i=j+1}^{n} x_{(i)} .
$$

This is a linear function of $\theta$ that decreases for $j<n / 2$ and increases for $j>n / 2$. If $n$ is even, $2 j-n=0$ if $j=n / 2$. So the likelihood is constant between $x_{(n / 2)}$ and $x_{((n / 2)+1)}$, and any value in this interval is the MLE. Usually the midpoint of this interval is taken as the MLE. If $n$ is odd, the likelihood is minimized at $\hat{\theta}=x_{((n+1) / 2)}$.
7.15 a . The likelihood is

$$
L(\mu, \lambda \mid \mathbf{x})=\frac{\lambda^{n / 2}}{(2 \pi)^{n} \prod_{i} x_{i}} \exp \left\{-\frac{\lambda}{2} \sum_{i} \frac{\left(x_{i}-\mu\right)^{2}}{\mu^{2} x_{i}}\right\}
$$

For fixed $\lambda$, maximizing with respect to $\mu$ is equivalent to minimizing the sum in the exponential.

$$
\frac{d}{d \mu} \sum_{i} \frac{\left(x_{i}-\mu\right)^{2}}{\mu^{2} x_{i}}=\frac{d}{d \mu} \sum_{i} \frac{\left(\left(x_{i} / \mu\right)-1\right)^{2}}{x_{i}}=-\sum_{i} \frac{2\left(\left(x_{i} / \mu\right)-1\right)}{x_{i}} \frac{x_{i}}{\mu^{2}}
$$

Setting this equal to zero is equivalent to setting

$$
\sum_{i}\left(\frac{x_{i}}{\mu}-1\right)=0
$$

and solving for $\mu$ yields $\hat{\mu}_{n}=\bar{x}$. Plugging in this $\hat{\mu}_{n}$ and maximizing with respect to $\lambda$ amounts to maximizing an expression of the form $\lambda^{n / 2} e^{-\lambda b}$. Simple calculus yields

$$
\hat{\lambda}_{n}=\frac{n}{2 b} \quad \text { where } \quad b=\sum_{i} \frac{\left(x_{i}-\bar{x}\right)^{2}}{2 \bar{x}^{2} x_{i}} .
$$

Finally,

$$
2 b=\sum_{i} \frac{x_{i}}{\bar{x}^{2}}-2 \sum_{i} \frac{1}{\bar{x}}+\sum_{i} \frac{1}{x_{i}}=-\frac{n}{\bar{x}}+\sum_{i} \frac{1}{x_{i}}=\sum_{i}\left(\frac{1}{x_{i}}-\frac{1}{\bar{x}}\right) .
$$

b. This is the same as Exercise 6.27b.
c. This involved algebra can be found in Schwarz and Samanta (1991).
7.17 a. This is a special case of the computation in Exercise 7.2a.
b. Make the transformation

$$
z=\left(x_{2}-1\right) / x_{1}, w=x_{1} \quad \Rightarrow \quad x_{1}=w, x_{2}=w z+1
$$

The Jacobean is $|w|$, and

$$
f_{Z}(z)=\int f_{X_{1}}(w) f_{X_{2}}(w z+1) w d w=\frac{1}{\theta^{2}} e^{-1 / \theta} \int w e^{-w(1+z) / \theta} d w
$$

where the range of integration is $0<w<-1 / z$ if $z<0,0<w<\infty$ if $z>0$. Thus,

$$
f_{Z}(z)=\frac{1}{\theta^{2}} e^{-1 / \theta} \begin{cases}\int_{0}^{-1 / z} w e^{-w(1+z) / \theta} d w & \text { if } z<0 \\ \int_{0}^{\infty} w e^{-w(1+z) / \theta} d w & \text { if } z \geq 0\end{cases}
$$

Using the fact that $\int w e^{-w / a} d w=-e^{-w / a}\left(a w+a^{2}\right)$, we have

$$
f_{Z}(z)=e^{-1 / \theta} \begin{cases}\frac{z \theta+e^{(1+z) / z \theta}(1+z-z \theta)}{\theta z(1+z)^{2}} & \text { if } z<0 \\ \frac{1}{(1+z)^{2}} & \text { if } z \geq 0\end{cases}
$$

c. From part ( $a$ ) we get $\hat{\theta}=1$. From part (b), $X_{2}=1$ implies $Z=0$ which, if we use the second density, gives us $\hat{\theta}=\infty$.
d. The posterior distributions are just the normalized likelihood times prior, so of course they are different.
7.18 a. The usual first two moment equations for $X$ and $Y$ are

$$
\begin{aligned}
& \bar{x}=\mathrm{E} X=\mu_{X}, \quad \frac{1}{n} \sum_{i} x_{i}^{2}=\mathrm{E} X^{2}=\sigma_{X}^{2}+\mu_{X}^{2} \\
& \bar{y}=\mathrm{E} Y=\mu_{Y}, \quad \frac{1}{n} \sum_{i} y_{i}^{2}=\mathrm{E} Y^{2}=\sigma_{Y}^{2}+\mu_{Y}^{2}
\end{aligned}
$$

We also need an equation involving $\rho$.

$$
\frac{1}{n} \sum_{i} x_{i} y_{i}=\mathrm{E} X Y=\operatorname{Cov}(X, Y)+(\mathrm{E} X)(\mathrm{E} Y)=\rho \sigma_{X} \sigma_{Y}+\mu_{X} \mu_{Y}
$$

Solving these five equations yields the estimators given. Facts such as

$$
\frac{1}{n} \sum_{i} x_{i}^{2}-\bar{x}^{2}=\frac{\sum_{i} x_{i}^{2}-\left(\sum_{i} x_{i}\right)^{2} / n}{n}=\frac{\sum_{i}\left(x_{i}-\bar{x}\right)^{2}}{n}
$$

are used.
b. Two answers are provided. First, use the Miscellanea: For

$$
L(\boldsymbol{\theta} \mid \mathbf{x})=h(\mathbf{x}) c(\boldsymbol{\theta}) \exp \left(\sum_{i=1}^{k} w_{i}(\boldsymbol{\theta}) t_{i}(\mathbf{x})\right)
$$

the solutions to the $k$ equations $\sum_{j=1}^{n} t_{i}\left(x_{j}\right)=\mathrm{E}_{\theta}\left(\sum_{j=1}^{n} t_{i}\left(X_{j}\right)\right)=n \mathrm{E}_{\theta} t_{i}\left(X_{1}\right), i=1, \ldots, k$, provide the unique MLE for $\boldsymbol{\theta}$. Multiplying out the exponent in the bivariate normal pdf shows it has this exponential family form with $k=5$ and $t_{1}(x, y)=x, t_{2}(x, y)=y, t_{3}(x, y)=$ $x^{2}, t_{4}(x, y)=y^{2}$ and $t_{5}(x, y)=x y$. Setting up the method of moment equations, we have

$$
\begin{aligned}
\sum_{i} x_{i} & =n \mu_{X}, \quad \sum_{i} x_{i}^{2}=n\left(\mu_{X}^{2}+\sigma_{X}^{2}\right) \\
\sum_{i} y_{i} & =n \mu_{Y}, \quad \sum_{i} y_{i}^{2}=n\left(\mu_{Y}^{2}+\sigma_{Y}^{2}\right) \\
\sum_{i} x_{i} y_{i} & =\sum_{i}\left[\operatorname{Cov}(X, Y)+\mu_{X} \mu_{Y}\right]=n\left(\rho \sigma_{X} \sigma_{Y}+\mu_{X} \mu_{Y}\right)
\end{aligned}
$$

These are the same equations as in part (a) if you divide each one by $n$. So the MLEs are the same as the method of moment estimators in part (a).
For the second answer, use the hint in the book to write

$$
\begin{aligned}
L(\theta \mid \mathbf{x}, \mathbf{y})= & L(\theta \mid \mathbf{x}) L(\theta, \mathbf{x} \mid \mathbf{y}) \\
= & \underbrace{\left(2 \pi \sigma_{X}^{2}\right)^{-\frac{n}{2}} \exp \left\{-\frac{1}{2 \sigma_{X}^{2}} \sum_{i}\left(x_{i}-\mu_{X}\right)^{2}\right\}}_{A} \\
& \times \underbrace{\left(2 \pi \sigma_{Y}^{2}\left(1-\rho^{2}\right)\right)^{-\frac{n}{2}} \exp \left[\frac{-1}{2 \sigma_{Y}^{2}\left(1-\rho^{2}\right)} \sum_{i}\left\{y_{i}-\left(\mu_{Y}+\rho \frac{\sigma_{Y}}{\sigma_{X}}\left(x_{i}-\mu_{X}\right)\right)\right\}^{2}\right]}_{B}
\end{aligned}
$$

We know that $\bar{x}$ and $\hat{\sigma}_{X}^{2}=\sum_{i}\left(x_{i}-\bar{x}\right)^{2} / n$ maximizes $A$; the question is whether given $\sigma_{Y}$, $\mu_{Y}$, and $\rho$, does $\bar{x}, \hat{\sigma}_{X}^{2}$ maximize $B$ ? Let us first fix $\sigma_{X}^{2}$ and look for $\hat{\mu}_{X}$, that maximizes $B$. We have

$$
\begin{aligned}
\frac{\partial \log B}{\partial \mu_{X}} & \propto-2\left(\sum_{i}\left[\left(y_{i}-\mu_{Y}\right)-\frac{\rho \sigma_{Y}}{\sigma_{X}}\left(x_{i}-\mu_{X}\right)\right]\right) \frac{\rho \sigma_{Y}}{\sigma_{X}} \stackrel{\text { set }}{=} 0 \\
& \Rightarrow \sum_{i}\left(y_{i}-\mu_{Y}\right)=\frac{\rho \sigma_{Y}}{\sigma_{X}} \Sigma\left(x_{i}-\hat{\mu}_{X}\right)
\end{aligned}
$$

Similarly do the same procedure for $L(\theta \mid \mathbf{y}) L(\theta, \mathbf{y} \mid \mathbf{x})$ This implies $\sum_{i}\left(x_{i}-\mu_{X}\right)=\frac{\rho \sigma_{X}}{\sigma_{Y}} \sum_{i}\left(y_{i}-\right.$ $\left.\hat{\mu}_{Y}\right)$. The solutions $\hat{\mu}_{X}$ and $\hat{\mu}_{Y}$ therefore must satisfy both equations. If $\sum_{i}\left(y_{i}-\hat{\mu}_{Y}\right) \neq 0$ or $\sum_{i}\left(x_{i}-\hat{\mu}_{X}\right) \neq 0$, we will get $\rho=1 / \rho$, so we need $\sum_{i}\left(y_{i}-\hat{\mu}_{Y}\right)=0$ and $\sum_{i}\left(x_{i}-\hat{\mu}_{X}\right)=0$. This implies $\hat{\mu}_{X}=\bar{x}$ and $\hat{\mu}_{Y}=\bar{y} .\left(\frac{\partial^{2} \log B}{\partial \mu_{X}^{2}}<0\right.$. Therefore it is maximum $)$. To get $\hat{\sigma}_{X}^{2}$ take

$$
\begin{aligned}
\frac{\partial \log B}{\partial \sigma_{X}^{2}} & \propto \sum_{i} \frac{\rho \sigma_{Y}}{\sigma_{X}^{2}}\left(x_{i}-\hat{\mu}_{X}\right)\left[\left(y_{i}-\mu_{Y}\right)-\frac{\rho \sigma_{Y}}{\sigma_{X}}\left(x_{i}-\mu_{X}\right)\right] \stackrel{\text { set }}{=} 0 \\
& \Rightarrow \sum_{i}\left(x_{i}-\hat{\mu}_{X}\right)\left(y_{i}-\hat{\mu}_{Y}\right)=\frac{\rho \sigma_{Y}}{\hat{\sigma}_{X}} \sum\left(x_{i}-\hat{\mu}_{X}\right)^{2}
\end{aligned}
$$

Similarly, $\sum_{i}\left(x_{i}-\hat{\mu}_{X}\right)\left(y_{i}-\hat{\mu}_{Y}\right)=\frac{\rho \sigma_{X}}{\hat{\sigma}_{Y}} \sum_{i}\left(y_{i}-\hat{\mu}_{Y}\right)^{2}$. Thus $\hat{\sigma}_{X}^{2}$ and $\hat{\sigma}_{Y}^{2}$ must satisfy the above two equations with $\hat{\mu}_{X}=\bar{X}, \hat{\mu}_{Y}=\bar{Y}$. This implies

$$
\frac{\hat{\sigma}_{Y}}{\hat{\sigma}_{X}} \sum_{i}\left(x_{i}-\bar{x}\right)^{2}=\frac{\hat{\sigma}_{X}}{\hat{\sigma}_{Y}} \sum_{i}\left(y_{i}-\bar{y}\right)^{2} \Rightarrow \frac{\sum_{i}\left(x_{i}-\bar{x}\right)^{2}}{\hat{\sigma}_{X}^{2}}=\frac{\sum_{i}\left(y_{i}-\bar{y}\right)^{2}}{\hat{\sigma}_{Y}^{2}}
$$

Therefore, $\hat{\sigma}_{X}^{2}=a \sum_{i}\left(x_{i}-\bar{x}\right)^{2}, \hat{\sigma}_{Y}^{2}=a \sum_{i}\left(y_{i}-\bar{y}\right)^{2}$ where $a$ is a constant. Combining the knowledge that $\left(\bar{x}, \frac{1}{n} \sum_{i}\left(x_{i}-\bar{x}\right)^{2}\right)=\left(\hat{\mu}_{X}, \hat{\sigma}_{X}^{2}\right)$ maximizes $A$, we conclude that $a=1 / n$. Lastly, we find $\hat{\rho}$, the MLE of $\rho$. Write

$$
\begin{aligned}
& \log L\left(\bar{x}, \bar{y}, \hat{\sigma}_{X}^{2}, \hat{\sigma}_{Y}^{2}, \rho \mid \mathbf{x}, \mathbf{y}\right) \\
& \quad=-\frac{n}{2} \log \left(1-\rho^{2}\right)-\frac{1}{2\left(1-\rho^{2}\right)} \sum_{i}\left[\frac{\left(x_{i}-\bar{x}\right)^{2}}{\hat{\sigma}_{X}^{2}}-\frac{2 \rho\left(x_{i}-\bar{x}\right)\left(y_{i}-\bar{y}\right)}{\hat{\sigma}_{X}, \hat{\sigma}_{Y}}+\frac{\left(y_{i}-\bar{y}\right)^{2}}{\hat{\sigma}_{Y}^{2}}\right] \\
& \quad=-\frac{n}{2} \log \left(1-\rho^{2}\right)-\frac{1}{2\left(1-\rho^{2}\right)}[2 n-2 \rho \underbrace{\sum_{i} \frac{\left(x_{i}-\bar{x}\right)\left(y_{i}-\bar{y}\right)}{\hat{\sigma}_{X} \hat{\sigma}_{Y}}}_{A}]
\end{aligned}
$$

because $\hat{\sigma}_{X}^{2}=\frac{1}{n} \sum_{i}\left(x_{i}-\bar{x}\right)^{2}$ and $\hat{\sigma}_{Y}^{2}=\frac{1}{n} \sum_{i}\left(y_{i}-\bar{y}\right)^{2}$. Now

$$
\log L=-\frac{n}{2} \log \left(1-\rho^{2}\right)-\frac{n}{1-\rho^{2}}+\frac{\rho}{1-\rho^{2}} A
$$

and

$$
\frac{\partial \log L}{\partial \rho}=\frac{n}{1-\rho^{2}}-\frac{n \rho}{\left(1-\rho^{2}\right)^{2}}+\frac{A\left(1-\rho^{2}\right)+2 A \rho^{2}}{\left(1-\rho^{2}\right)^{2}} \stackrel{\text { set }}{=} 0
$$

This implies

$$
\begin{aligned}
\frac{A+A \rho^{2}-n \hat{\rho}-n \hat{\rho}^{3}}{\left(1-\rho^{2}\right)^{2}}=0 & \Rightarrow A\left(1+\hat{\rho}^{2}\right)=n \hat{\rho}\left(1+\hat{\rho}^{2}\right) \\
& \Rightarrow \hat{\rho}=\frac{A}{n}=\frac{1}{n} \sum_{i} \frac{\left(x_{i}-\bar{x}\right)\left(y_{i}-\bar{y}\right)}{\hat{\sigma}_{X} \hat{\sigma}_{Y}}
\end{aligned}
$$

7.19 a.

$$
\begin{aligned}
L(\theta \mid \mathbf{y}) & =\prod_{i} \frac{1}{\sqrt{2 \pi \sigma^{2}}} \exp \left(-\frac{1}{2 \sigma^{2}}\left(y_{i}-\beta x_{i}\right)^{2}\right) \\
& =\left(2 \pi \sigma^{2}\right)^{-n / 2} \exp \left(-\frac{1}{2 \sigma^{2}} \sum_{i}\left(y_{i}^{2}-2 \beta x_{i} y_{i}+\beta^{2} x_{i}^{2}\right)\right) \\
& =\left(2 \pi \sigma^{2}\right)^{-n / 2} \exp \left(-\frac{\beta^{2} \sum_{i} x_{i}^{2}}{2 \sigma^{2}}\right) \exp \left(-\frac{1}{2 \sigma^{2}} \sum_{i} y_{i}^{2}+\frac{\beta}{\sigma^{2}} \sum_{i} x_{i} y_{i}\right)
\end{aligned}
$$

By Theorem 6.1.2, $\left(\sum_{i} Y_{i}^{2}, \sum_{i} x_{i} Y_{i}\right)$ is a sufficient statistic for $\left(\beta, \sigma^{2}\right)$.
b.

$$
\log L\left(\beta, \sigma^{2} \mid \mathbf{y}\right)=-\frac{n}{2} \log (2 \pi)-\frac{n}{2} \log \sigma^{2}-\frac{1}{2 \sigma^{2}} \sum y_{i}^{2}+\frac{\beta}{\sigma^{2}} \sum_{i} x_{i} y_{i}-\frac{\beta^{2}}{2 \sigma^{2}} \sum_{i} x_{i}^{2}
$$

For a fixed value of $\sigma^{2}$,

$$
\frac{\partial \log L}{\partial \beta}=\frac{1}{\sigma^{2}} \sum_{i} x_{i} y_{i}-\frac{\beta}{\sigma^{2}} \sum_{i} x_{i}^{2} \stackrel{\text { set }}{=} 0 \Rightarrow \hat{\beta}=\frac{\sum_{i} x_{i} y_{i}}{\sum_{i} x_{i}^{2}}
$$

Also,

$$
\frac{\partial^{2} \log L}{\partial \beta^{2}}=\frac{1}{\sigma^{2}} \sum_{i} x_{i}^{2}<0
$$

so it is a maximum. Because $\hat{\beta}$ does not depend on $\sigma^{2}$, it is the MLE. And $\hat{\beta}$ is unbiased because

$$
\mathrm{E} \hat{\beta}=\frac{\sum_{i} x_{i} \mathrm{E} Y_{i}}{\sum_{i} x_{i}^{2}}=\frac{\sum_{i} x_{i} \cdot \beta x_{i}}{\sum_{i} x_{i}^{2}}=\beta
$$

c. $\hat{\beta}=\sum_{i} a_{i} Y_{i}$, where $a_{i}=x_{i} / \sum_{j} x_{j}^{2}$ are constants. By Corollary 4.6.10, $\hat{\beta}$ is normally distributed with mean $\beta$, and

$$
\operatorname{Var} \hat{\beta}=\sum_{i} a_{i}^{2} \operatorname{Var} Y_{i}=\sum_{i}\left(\frac{x_{i}}{\sum_{j} x_{j}^{2}}\right)^{2} \sigma^{2}=\frac{\sum_{i} x_{i}^{2}}{\left(\sum_{j} x_{j}^{2}\right)^{2}} \sigma^{2}=\frac{\sigma^{2}}{\sum_{i} x_{i}^{2}}
$$

7.20 a.

$$
\mathrm{E} \frac{\sum_{i} Y_{i}}{\sum_{i} x_{i}}=\frac{1}{\sum_{i} x_{i}} \sum_{i} \mathrm{E} Y_{i}=\frac{1}{\sum_{i} x_{i}} \sum_{i} \beta x_{i}=\beta
$$

b.

$$
\operatorname{Var}\left(\frac{\sum_{i} Y_{i}}{\sum_{i} x_{i}}\right)=\frac{1}{\left(\sum_{i} x_{i}\right)^{2}} \sum_{i} \operatorname{Var} Y_{i}=\frac{\sum_{i} \sigma^{2}}{\left(\sum_{i} x_{i}\right)^{2}}=\frac{n \sigma^{2}}{n^{2} \bar{x}^{2}}=\frac{\sigma^{2}}{n \bar{x}^{2}}
$$

Because $\sum_{i} x_{i}^{2}-n \bar{x}^{2}=\sum_{i}\left(x_{i}-\bar{x}\right)^{2} \geq 0, \sum_{i} x_{i}^{2} \geq n \bar{x}^{2}$. Hence,

$$
\operatorname{Var} \hat{\beta}=\frac{\sigma^{2}}{\sum_{i} x_{i}^{2}} \leq \frac{\sigma^{2}}{n \bar{x}^{2}}=\operatorname{Var}\left(\frac{\sum_{i} Y_{i}}{\sum_{i} x_{i}}\right)
$$

(In fact, $\hat{\beta}$ is BLUE (Best Linear Unbiased Estimator of $\beta$ ), as discussed in Section 11.3.2.)
7.21 a.

$$
\mathrm{E} \frac{1}{n} \sum_{i} \frac{Y_{i}}{x_{i}}=\frac{1}{n} \sum_{i} \frac{\mathrm{E} Y_{i}}{x_{i}}=\frac{1}{n} \sum_{i} \frac{\beta x_{i}}{x_{i}}=\beta
$$

b.

$$
\operatorname{Var} \frac{1}{n} \sum_{i} \frac{Y_{i}}{x_{i}}=\frac{1}{n^{2}} \sum_{i} \frac{\operatorname{Var} Y_{i}}{x_{i}^{2}}=\frac{\sigma^{2}}{n^{2}} \sum_{i} \frac{1}{x_{i}^{2}}
$$

Using Example 4.7.8 with $a_{i}=1 / x_{i}^{2}$ we obtain

$$
\frac{1}{n} \sum_{i} \frac{1}{x_{i}^{2}} \geq \frac{n}{\sum_{i} x_{i}^{2}}
$$

Thus,

$$
\operatorname{Var} \hat{\beta}=\frac{\sigma^{2}}{\sum_{i} x_{i}^{2}} \leq \frac{\sigma^{2}}{n^{2}} \sum_{i} \frac{1}{x_{i}^{2}}=\operatorname{Var} \frac{1}{n} \sum_{i} \frac{Y_{i}}{x_{i}}
$$

Because $g(u)=1 / u^{2}$ is convex, using Jensen's Inequality we have

$$
\frac{1}{\bar{x}^{2}} \leq \frac{1}{n} \sum_{i} \frac{1}{x_{i}^{2}}
$$

Thus,

$$
\operatorname{Var}\left(\frac{\sum_{i} Y_{i}}{\sum_{i} x_{i}}\right)=\frac{\sigma^{2}}{n \bar{x}^{2}} \leq \frac{\sigma^{2}}{n^{2}} \sum_{i} \frac{1}{x_{i}^{2}}=\operatorname{Var} \frac{1}{n} \sum_{i} \frac{Y_{i}}{x_{i}}
$$

7.22 а.

$$
f(\bar{x}, \theta)=f(\bar{x} \mid \theta) \pi(\theta)=\frac{\sqrt{n}}{\sqrt{2 \pi} \sigma} e^{-n(\bar{x}-\theta)^{2} /\left(2 \sigma^{2}\right)} \frac{1}{\sqrt{2 \pi} \tau} e^{-(\theta-\mu)^{2} / 2 \tau^{2}}
$$

b. Factor the exponent in part (a) as

$$
\frac{-n}{2 \sigma^{2}}(\bar{x}-\theta)^{2}-\frac{1}{2 \tau^{2}}(\theta-\mu)^{2}=-\frac{1}{2 v^{2}}(\theta-\delta(\mathbf{x}))^{2}-\frac{1}{\tau^{2}+\sigma^{2} / n}(\bar{x}-\mu)^{2}
$$

where $\delta(\mathbf{x})=\left(\tau^{2} \bar{x}+\left(\sigma^{2} / n\right) \mu\right) /\left(\tau^{2}+\sigma^{2} / n\right)$ and $v=\left(\sigma^{2} \tau^{2} / n\right) /\left(\tau+\sigma^{2} / n\right)$. Let $\mathrm{n}(a, b)$ denote the pdf of a normal distribution with mean $a$ and variance $b$. The above factorization shows that

$$
f(\mathrm{x}, \theta)=\mathrm{n}\left(\theta, \sigma^{2} / n\right) \times \mathrm{n}\left(\mu, \tau^{2}\right)=\mathrm{n}\left(\delta(\mathbf{x}), v^{2}\right) \times \mathrm{n}\left(\mu, \tau^{2}+\sigma^{2} / n\right)
$$

where the marginal distribution of $\bar{X}$ is $\mathrm{n}\left(\mu, \tau^{2}+\sigma^{2} / n\right)$ and the posterior distribution of $\theta \mid \mathbf{x}$ is $\mathrm{n}\left(\delta(\mathbf{x}), v^{2}\right)$. This also completes part (c).
7.23 Let $t=s^{2}$ and $\theta=\sigma^{2}$. Because $(n-1) S^{2} / \sigma^{2} \sim \chi_{n-1}^{2}$, we have

$$
f(t \mid \theta)=\frac{1}{\Gamma((n-1) / 2) 2^{(n-1) / 2}}\left(\frac{n-1}{\theta} t\right)^{[(n-1) / 2]-1} e^{-(n-1) t / 2 \theta} \frac{n-1}{\theta}
$$

With $\pi(\theta)$ as given, we have (ignoring terms that do not depend on $\theta$ )

$$
\begin{aligned}
\pi(\theta \mid t) & \propto\left[\left(\frac{1}{\theta}\right)^{((n-1) / 2)-1} e^{-(n-1) t / 2 \theta} \frac{1}{\theta}\right]\left[\frac{1}{\theta^{\alpha+1}} e^{-1 / \beta \theta}\right] \\
& \propto\left(\frac{1}{\theta}\right)^{((n-1) / 2)+\alpha+1} \exp \left\{-\frac{1}{\theta}\left[\frac{(n-1) t}{2}+\frac{1}{\beta}\right]\right\},
\end{aligned}
$$

which we recognize as the kernel of an inverted gamma pdf, $\operatorname{IG}(a, b)$, with

$$
a=\frac{n-1}{2}+\alpha \quad \text { and } \quad b=\left[\frac{(n-1) t}{2}+\frac{1}{\beta}\right]^{-1} .
$$

Direct calculation shows that the mean of an $\operatorname{IG}(a, b)$ is $1 /((a-1) b)$, so

$$
\mathrm{E}(\theta \mid t)=\frac{\frac{n-1}{2} t+\frac{1}{\beta}}{\frac{n-1}{2}+\alpha-1}=\frac{\frac{n-1}{2} s^{2}+\frac{1}{\beta}}{\frac{n-1}{2}+\alpha-1} .
$$

This is a Bayes estimator of $\sigma^{2}$.
7.24 For $n$ observations, $Y=\sum_{i} X_{i} \sim \operatorname{Poisson}(n \lambda)$.
a. The marginal pmf of $Y$ is

$$
\begin{aligned}
m(y) & =\int_{0}^{\infty} \frac{(n \lambda)^{y} e^{-n \lambda}}{y!} \frac{1}{\Gamma(\alpha) \beta^{\alpha}} \lambda^{\alpha-1} e^{-\lambda / \beta} d \lambda \\
& =\frac{n^{y}}{y!\Gamma(\alpha) \beta^{\alpha}} \int_{0}^{\infty} \lambda^{(y+\alpha)-1} e^{-\frac{\lambda}{\beta /(n \beta+1)}} d \lambda=\frac{n^{y}}{y!\Gamma(\alpha) \beta^{\alpha}} \Gamma(y+\alpha)\left(\frac{\beta}{n \beta+1}\right)^{y+\alpha}
\end{aligned}
$$

Thus,

$$
\pi(\lambda \mid y)=\frac{f(y \mid \lambda) \pi(\lambda)}{m(y)}=\frac{\lambda^{(y+\alpha)-1} e^{-\frac{\lambda}{\beta /(n \beta+1)}}}{\Gamma(y+\alpha)\left(\frac{\beta}{n \beta+1}\right)^{y+\alpha}} \sim \operatorname{gamma}\left(y+\alpha, \frac{\beta}{n \beta+1}\right)
$$

b.

$$
\begin{aligned}
\mathrm{E}(\lambda \mid y) & =(y+\alpha) \frac{\beta}{n \beta+1}=\frac{\beta}{n \beta+1} y+\frac{1}{n \beta+1}(\alpha \beta) \\
\operatorname{Var}(\lambda \mid y) & =(y+\alpha) \frac{\beta^{2}}{(n \beta+1)^{2}}
\end{aligned}
$$

7.25 a. We will use the results and notation from part (b) to do this special case. From part (b), the $X_{i}$ s are independent and each $X_{i}$ has marginal pdf

$$
m\left(x \mid \mu, \sigma^{2}, \tau^{2}\right)=\int_{-\infty}^{\infty} f\left(x \mid \theta, \sigma^{2}\right) \pi\left(\theta \mid \mu, \tau^{2}\right) d \theta=\int_{-\infty}^{\infty} \frac{1}{2 \pi \sigma \tau} e^{-(x-\theta)^{2} / 2 \sigma^{2}} e^{-(\theta-\mu)^{2} / 2 \tau^{2}} d \theta
$$

Complete the square in $\theta$ to write the sum of the two exponents as

$$
-\frac{\left(\theta-\left[\frac{x \tau^{2}}{\sigma^{2}+\tau^{2}}+\frac{\mu \sigma^{2}}{\sigma^{2}+\tau^{2}}\right]\right)^{2}}{2 \frac{\sigma^{2} \tau^{2}}{\sigma^{2}+\tau^{2}}}-\frac{(x-\mu)^{2}}{2\left(\sigma^{2}+\tau^{2}\right)}
$$

Only the first term involves $\theta$; call it $-A(\theta)$. Also, $e^{-A(\theta)}$ is the kernel of a normal pdf. Thus,

$$
\int_{-\infty}^{\infty} e^{-A(\theta)} d \theta=\sqrt{2 \pi} \frac{\sigma \tau}{\sqrt{\sigma^{2}+\tau^{2}}}
$$

and the marginal pdf is

$$
\begin{aligned}
m\left(x \mid \mu, \sigma^{2}, \tau^{2}\right) & =\frac{1}{2 \pi \sigma \tau} \sqrt{2 \pi} \frac{\sigma \tau}{\sqrt{\sigma^{2}+\tau^{2}}} \exp \left\{-\frac{(x-\mu)^{2}}{2\left(\sigma^{2}+\tau^{2}\right)}\right\} \\
& =\frac{1}{\sqrt{2 \pi} \sqrt{\sigma^{2}+\tau^{2}}} \exp \left\{-\frac{(x-\mu)^{2}}{2\left(\sigma^{2}+\tau^{2}\right)}\right\}
\end{aligned}
$$

a $\mathrm{n}\left(\mu, \sigma^{2}+\tau^{2}\right)$ pdf.
b. For one observation of $X$ and $\theta$ the joint pdf is

$$
h(x, \theta \mid \tau)=f(x \mid \theta) \pi(\theta \mid \tau)
$$

and the marginal pdf of $X$ is

$$
m(x \mid \tau)=\int_{-\infty}^{\infty} h(x, \theta \mid \tau) d \theta
$$

Thus, the joint pdf of $\mathbf{X}=\left(X_{1}, \ldots, X_{n}\right)$ and $\boldsymbol{\theta}=\left(\theta_{1}, \ldots, \theta_{n}\right)$ is

$$
h(\mathbf{x}, \boldsymbol{\theta} \mid \tau)=\prod_{i} h\left(x_{i}, \theta_{i} \mid \tau\right)
$$

and the marginal pdf of $\mathbf{X}$ is

$$
\begin{aligned}
m(\mathbf{x} \mid \tau) & =\int_{-\infty}^{\infty} \ldots \int_{-\infty}^{\infty} \prod_{i} h\left(x_{i}, \theta_{i} \mid \tau\right) d \theta_{1} \ldots d \theta_{n} \\
& =\int_{-\infty}^{\infty} \ldots\left\{\int_{-\infty}^{\infty} h\left(x_{1}, \theta_{1} \mid \tau\right) d \theta_{1}\right\} \prod_{i=2}^{n} h\left(x_{i}, \theta_{i} \mid \tau\right) d \theta_{2} \ldots d \theta_{n}
\end{aligned}
$$

The $d \theta_{1}$ integral is just $m\left(x_{1} \mid \tau\right)$, and this is not a function of $\theta_{2}, \ldots, \theta_{n}$. So, $m\left(x_{1} \mid \tau\right)$ can be pulled out of the integrals. Doing each integral in turn yields the marginal pdf

$$
m(\mathbf{x} \mid \tau)=\prod_{i} m\left(x_{i} \mid \tau\right)
$$

Because this marginal pdf factors, this shows that marginally $X_{1}, \ldots, X_{n}$ are independent, and they each have the same marginal distribution, $m(x \mid \tau)$.
7.26 First write

$$
f\left(x_{1}, \ldots, x_{n} \mid \theta\right) \pi(\theta) \propto e^{-\frac{n}{2 \sigma^{2}}(\bar{x}-\theta)^{2}-|\theta| / a}
$$

where the exponent can be written

$$
\frac{n}{2 \sigma^{2}}(\bar{x}-\theta)^{2}-\frac{|\theta|}{a}=\frac{n}{2 \sigma^{2}}\left(\theta-\delta_{ \pm}(\mathbf{x})\right)+\frac{n}{2 \sigma^{2}}\left(\bar{x}^{2}-\delta_{ \pm}^{2}(\mathbf{x})\right)
$$

with $\delta_{ \pm}(\mathbf{x})=\bar{x} \pm \frac{\sigma^{2}}{n a}$, where we use the " + " if $\theta>0$ and the "-" if $\theta<0$. Thus, the posterior mean is

$$
\mathrm{E}(\theta \mid \mathbf{x})=\frac{\int_{-\infty}^{\infty} \theta e^{-\frac{n}{2 \sigma^{2}}\left(\theta-\delta_{ \pm}(\mathbf{x})\right)^{2}} d \theta}{\int_{-\infty}^{\infty} e^{-\frac{n}{2 \sigma^{2}}\left(\theta-\delta_{ \pm}(\mathbf{x})\right)^{2}} d \theta}
$$

Now use the facts that for constants $a$ and $b$,

$$
\begin{aligned}
\int_{0}^{\infty} e^{-\frac{a}{2}(t-b)^{2}} d t & =\int_{-\infty}^{0} e^{-\frac{a}{2}(t-b)^{2}} d t=\sqrt{\frac{\pi}{2 a}} \\
\int_{0}^{\infty} t e^{-\frac{a}{2}(t-b)^{2}} d t & =\int_{0}^{\infty}(t-b) e^{-\frac{a}{2}(t-b)^{2}} d t+\int_{0}^{\infty} b e^{-\frac{a}{2}(t-b)^{2}} d t=\frac{1}{a} e^{-\frac{a}{2} b^{2}}+b \sqrt{\frac{\pi}{2 a}}, \\
\int_{-\infty}^{0} t e^{-\frac{a}{2}(t-b)^{2}} d t & =-\frac{1}{a} e^{-\frac{a}{2} b^{2}}+b \sqrt{\frac{\pi}{2 a}}
\end{aligned}
$$

to get

$$
\mathrm{E}(\theta \mid \mathbf{x})=\frac{\sqrt{\frac{\pi \sigma^{2}}{2 n}}\left(\delta_{-}(\mathbf{x})+\delta_{+}(\mathbf{x})\right)+\frac{\sigma^{2}}{n}\left(e^{-\frac{n}{2 \sigma^{2}} \delta_{+}^{2}(\mathbf{x})}-e^{-\frac{n}{2 \sigma^{2}} \delta_{-}^{2}(\mathbf{x})}\right)}{2 \sqrt{\frac{\pi \sigma^{2}}{2 n}}}
$$

7.27 a. The log likelihood is

$$
\log L=\sum_{i=1}^{n}-\beta \tau_{i}+y_{i} \log \left(\beta \tau_{i}\right)-\tau_{i}+x_{i} \log \left(\tau_{i}\right)-\log y_{i}!-\log x_{i}!
$$

and differentiation gives

$$
\begin{aligned}
\frac{\partial}{\partial \beta} \log L & =\sum_{i=1}^{n}-\tau_{i}+\frac{y_{i} \tau_{i}}{\beta \tau_{i}} \Rightarrow \beta=\frac{\sum_{i=1}^{n} y_{i}}{\sum_{i=1}^{n} \tau_{i}} \\
\frac{\partial}{\partial \tau_{j}} \log L & =-\beta+\frac{y_{j} \beta}{\beta \tau_{j}}-i+\frac{x_{j}}{\tau_{j}} \Rightarrow \tau_{j}=\frac{x_{j}+y_{j}}{1+\beta} \\
& \Rightarrow \sum_{j=1}^{n} \tau_{j}=\frac{\sum_{j=1}^{n} x_{j}+\sum_{j=1}^{n} y_{j}}{1+\beta}
\end{aligned}
$$

Combining these expressions yields $\hat{\beta}=\sum_{j=1}^{n} y_{j} / \sum_{j=1}^{n} x_{j}$ and $\hat{\tau}_{j}=\frac{x_{j}+y_{j}}{1+\hat{\beta}}$.
b. The stationary point of the EM algorithm will satisfy

$$
\begin{aligned}
\hat{\beta} & =\frac{\sum_{i=1}^{n} y_{i}}{\hat{\tau}_{1}+\sum_{i=2}^{n} x_{i}} \\
\hat{\tau}_{1} & =\frac{\hat{\tau}_{1}+y_{1}}{\hat{\beta}+1} \\
\hat{\tau}_{j} & =\frac{x_{j}+y_{j}}{\hat{\beta}+1}
\end{aligned}
$$

The second equation yields $\tau_{1}=y_{1} / \beta$, and substituting this into the first equation yields $\beta=\sum_{j=2}^{n} y_{j} / \sum_{j=2}^{n} x_{j}$. Summing over $j$ in the third equation, and substituting $\beta=$ $\sum_{j=2}^{n} y_{j} / \sum_{j=2}^{n} x_{j}$ shows us that $\sum_{j=2}^{n} \hat{\tau}_{j}=\sum_{j=2}^{n} x_{j}$, and plugging this into the first equation gives the desired expression for $\hat{\beta}$. The other two equations in (7.2.16) are obviously satisfied.
c. The expression for $\hat{\beta}$ was derived in part (b), as were the expressions for $\hat{\tau}_{i}$.
7.29 a. The joint density is the product of the individual densities.
b. The log likelihood is

$$
\log L=\sum_{i=1}^{n}-m \beta \tau_{i}+y_{i} \log \left(m \beta \tau_{i}\right)+x_{i} \log \left(\tau_{i}\right)+\log m!-\log y_{i}!-\log x_{i}!
$$

and

$$
\begin{aligned}
\frac{\partial}{\partial \beta} \log L & =0 \quad \Rightarrow \quad \beta=\frac{\sum_{i=1}^{n} y_{i}}{\sum_{i=1}^{n} m \tau_{i}} \\
\frac{\partial}{\partial \tau_{j}} \log L & =0 \Rightarrow \tau_{j}=\frac{x_{j}+y_{j}}{m \beta}
\end{aligned}
$$

Since $\sum \tau_{j}=1, \hat{\beta}=\sum_{i=1}^{n} y_{i} / m=\sum_{i=1}^{n} y_{i} / \sum_{i=1}^{n} x_{i}$. Also, $\sum_{j} \tau_{j}=\sum_{j}\left(y_{j}+x_{j}\right)=1$, which implies that $m \beta=\sum_{j}\left(y_{j}+x_{j}\right)$ and $\hat{\tau}_{j}=\left(x_{j}+y_{j}\right) / \sum_{i}\left(y_{i}+x_{i}\right)$.
c. In the likelihood function we can ignore the factorial terms, and the expected complete-data likelihood is obtained by on the $r^{t h}$ iteration by replacing $x_{1}$ with $\mathrm{E}\left(X_{1} \mid \hat{\tau}_{1}^{(r)}\right)=m \hat{\tau}_{1}^{(r)}$. Substituting this into the MLEs of part (b) gives the EM sequence.

The MLEs from the full data set are $\hat{\beta}=0.0008413892$ and

$$
\begin{aligned}
\hat{\tau}= & (0.06337310,0.06374873,0.06689681,0.04981487,0.04604075,0.04883109 \\
& 0.07072460,0.01776164,0.03416388,0.01695673,0.02098127,0.01878119 \\
& 0.05621836,0.09818091,0.09945087,0.05267677,0.08896918,0.08642925)
\end{aligned}
$$

The MLEs for the incomplete data were computed using $R$, where we take $m=\sum x_{i}$. The $R$ code is

```
#mles on the incomplete data#
xdatam<-c(3560,3739,2784,2571,2729,3952,993,1908,948,1172,
    1047,3138,5485,5554,2943,4969,4828)
ydata<-c(3,4,1,1,3,1,2,0,2,0,1,3,5,4,6,2,5,4)
xdata<-c(mean(xdatam),xdatam); for (j in 1:500) {
xdata<-c(sum(xdata)*tau[1],xdatam) beta<-sum(ydata)/sum(xdata)
tau<-c((xdata+ydata)/(sum(xdata)+sum(ydata))) } beta tau
```

The MLEs from the incomplete data set are $\hat{\beta}=0.0008415534$ and

$$
\begin{aligned}
\hat{\tau}= & (0.06319044,0.06376116,0.06690986,0.04982459,0.04604973,0.04884062, \\
& 0.07073839,0.01776510,0.03417054,0.01696004,0.02098536,0.01878485, \\
& 0.05622933,0.09820005,0.09947027,0.05268704,0.08898653,0.08644610)
\end{aligned}
$$

7.31 a. By direct substitution we can write

$$
\log L(\theta \mid \mathbf{y})=\mathrm{E}\left[\log L(\theta \mid \mathbf{y}, \mathbf{X}) \mid \hat{\theta}^{(r)}, \mathbf{y}\right]-\mathrm{E}\left[\log k(\mathbf{X} \mid \theta, \mathbf{y}) \mid \hat{\theta}^{(r)}, \mathbf{y}\right]
$$

The next iterate, $\hat{\theta}^{(r+1)}$ is obtained by maximizing the expected complete-data log likelihood, so for any $\theta, \mathrm{E}\left[\log L\left(\hat{\theta}^{(r+1)} \mathbf{y}, \mathbf{X}\right) \mid \hat{\theta}^{(r)}, \mathbf{y}\right] \geq \mathrm{E}\left[\log L(\theta \mid \mathbf{y}, \mathbf{X}) \mid \hat{\theta}^{(r)}, \mathbf{y}\right]$
b. Write

$$
\mathrm{E}\left[\log k(\mathbf{X} \mid \theta, \mathbf{y}) \mid \theta^{\prime}, \mathbf{y}\right]=\int \log k(\mathbf{x} \mid \theta, \mathbf{y}) \log k\left(\mathbf{x} \mid \theta^{\prime}, \mathbf{y}\right) d \mathbf{x} \leq \int \log k\left(\mathbf{x} \mid \theta^{\prime}, \mathbf{y}\right) \log k\left(\mathbf{x} \mid \theta^{\prime}, \mathbf{y}\right) d \mathbf{x}
$$

from the hint. Hence $\mathrm{E}\left[\log k\left(\mathbf{X} \mid \hat{\theta}^{(r+1)}, \mathbf{y}\right) \mid \hat{\theta}^{(r)}, \mathbf{y}\right] \leq \mathrm{E}\left[\log k\left(\mathbf{X} \mid \hat{\theta}^{(r)}, \mathbf{y}\right) \mid \hat{\theta}^{(r)}, \mathbf{y}\right]$, and so the entire right hand side in part $(a)$ is decreasing.
7.33 Substitute $\alpha=\beta=\sqrt{n / 4}$ into $\operatorname{MSE}\left(\hat{p}_{B}\right)=\frac{n p(1-p)}{(\alpha+\beta+n)^{2}}+\left(\frac{n p+\alpha}{\alpha+\beta+n}-p\right)^{2}$ and simplify to obtain

$$
\operatorname{MSE}\left(\hat{p}_{B}\right)=\frac{n}{4(\sqrt{n}+n)^{2}}
$$

independent of $p$, as desired.
7.35 a.

$$
\begin{aligned}
\delta_{p}(g(\mathbf{x})) & =\delta_{p}\left(x_{1}+a, \ldots, x_{n}+a\right) \\
& =\frac{\int_{-\infty}^{\infty} t \prod_{i} f\left(x_{i}+a-t\right) d t}{\int_{-\infty}^{\infty} \prod_{i} f\left(x_{i}+a-t\right) d t}=\frac{\int_{-\infty}^{\infty}(y+a) \prod_{i} f\left(x_{i}-y\right) d y}{\int_{-\infty}^{\infty} \prod_{i} f\left(x_{i}-y\right) d y} \quad(y=t-a) \\
& =a+\delta_{p}(\mathbf{x})=\bar{g}\left(\delta_{p}(\mathbf{x})\right)
\end{aligned}
$$

b.

$$
\prod_{i} f\left(x_{i}-t\right)=\frac{1}{(2 \pi)^{n / 2}} e^{-\frac{1}{2} \sum_{i}\left(x_{i}-t\right)^{2}}=\frac{1}{(2 \pi)^{n / 2}} e^{-\frac{1}{2} n(\bar{x}-t)^{2}} e^{-\frac{1}{2}(n-1) s^{2}}
$$

so

$$
\delta_{p}(\mathbf{x})=\frac{(\sqrt{n} / \sqrt{2 \pi}) \int_{-\infty}^{\infty} t e^{-\frac{1}{2} n(\bar{x}-t)^{2}} d t}{(\sqrt{n} / \sqrt{2 \pi}) \int_{-\infty}^{\infty} e^{-\frac{1}{2} n(\bar{x}-t)^{2}} d t}=\frac{\bar{x}}{1}=\bar{x}
$$

c.

$$
\prod_{i} f\left(x_{i}-t\right)=\prod_{i} I\left(t-\frac{1}{2} \leq x_{i} \leq t+\frac{1}{2}\right)=I\left(x_{(n)}-\frac{1}{2} \leq t \leq x_{(1)}+\frac{1}{2}\right)
$$

so

$$
\delta_{p}(\mathbf{x})=\frac{\int_{x_{(n)}+1 / 2}^{x_{(1)}+1 / 2} t d t}{\int_{x_{(n)}+1 / 2}^{x_{(1)}+1 / 2} 1 d t}=\frac{x_{(1)}+x_{(n)}}{2}
$$

7.37 To find a best unbiased estimator of $\theta$, first find a complete sufficient statistic. The joint pdf is

$$
f(\mathbf{x} \mid \theta)=\left(\frac{1}{2 \theta}\right)^{n} \prod_{i} I_{(-\theta, \theta)}\left(x_{i}\right)=\left(\frac{1}{2 \theta}\right)^{n} I_{[0, \theta)}\left(\max _{i}\left|x_{i}\right|\right)
$$

By the Factorization Theorem, $\max _{i}\left|X_{i}\right|$ is a sufficient statistic. To check that it is a complete sufficient statistic, let $Y=\max _{i}\left|X_{i}\right|$. Note that the pdf of $Y$ is $f_{Y}(y)=n y^{n-1} / \theta^{n}, 0<y<\theta$. Suppose $g(y)$ is a function such that

$$
\mathrm{E} g(Y)=\int_{0}^{\theta} \frac{n y^{n-1}}{\theta^{n}} g(y) d y=0, \text { for all } \theta
$$

Taking derivatives shows that $\theta^{n-1} g(\theta)=0$, for all $\theta$. So $g(\theta)=0$, for all $\theta$, and $Y=\max _{i}\left|X_{i}\right|$ is a complete sufficient statistic. Now

$$
\mathrm{E} Y=\int_{0}^{\theta} y \frac{n y^{n-1}}{\theta^{n}} d y=\frac{n}{n+1} \theta \quad \Rightarrow \quad \mathrm{E}\left(\frac{n+1}{n} Y\right)=\theta
$$

Therefore $\frac{n+1}{n} \max _{i}\left|X_{i}\right|$ is a best unbiased estimator for $\theta$ because it is a function of a complete sufficient statistic. (Note that $\left(X_{(1)}, X_{(n)}\right)$ is not a minimal sufficient statistic (recall Exercise 5.36). It is for $\theta<X_{i}<2 \theta,-2 \theta<X_{i}<\theta, 4 \theta<X_{i}<6 \theta$, etc., but not when the range is symmetric about zero. Then $\max _{i}\left|X_{i}\right|$ is minimal sufficient.)
7.38 Use Corollary 7.3.15.
a.

$$
\begin{aligned}
\frac{\partial}{\partial \theta} \log L(\theta \mid \mathbf{x}) & =\frac{\partial}{\partial \theta} \log \prod_{i} \theta x_{i}^{\theta-1}=\frac{\partial}{\partial \theta} \sum_{i}\left[\log \theta+(\theta-1) \log x_{i}\right] \\
& =\sum_{i}\left[\frac{1}{\theta}+\log x_{i}\right]=-n\left[-\sum_{i} \frac{\log x_{i}}{n}-\frac{1}{\theta}\right]
\end{aligned}
$$

Thus, $-\sum_{i} \log X_{i} / n$ is the UMVUE of $1 / \theta$ and attains the Cramér-Rao bound.
b.

$$
\begin{aligned}
\frac{\partial}{\partial \theta} \log L(\theta \mid \mathbf{x}) & =\frac{\partial}{\partial \theta} \log \prod_{i} \frac{\log \theta}{\theta-1} \theta^{x_{i}}=\frac{\partial}{\partial \theta} \sum_{i}\left[\log \log \theta-\log (\theta-1)+x_{i} \log \theta\right] \\
& =\sum_{i}\left(\frac{1}{\theta \log \theta}-\frac{1}{\theta-1}\right)+\frac{1}{\theta} \sum_{i} x_{i}=\frac{n}{\theta \log \theta}-\frac{n}{\theta-1}+\frac{n \bar{x}}{\theta} \\
& =\frac{n}{\theta}\left[\bar{x}-\left(\frac{\theta}{\theta-1}-\frac{1}{\log \theta}\right)\right] .
\end{aligned}
$$

Thus, $\bar{X}$ is the UMVUE of $\frac{\theta}{\theta-1}-\frac{1}{\log \theta}$ and attains the Cramér-Rao lower bound.
Note: We claim that if $\frac{\partial}{\partial \theta} \log L(\theta \mid \mathbf{X})=a(\theta)[W(\mathbf{X})-\tau(\theta)]$, then $\mathrm{E} W(\mathbf{X})=\tau(\theta)$, because under the condition of the Cramér-Rao Theorem, $\mathrm{E} \frac{\partial}{\partial \theta} \log L(\theta \mid \mathbf{x})=0$. To be rigorous, we need to check the "interchange differentiation and integration" condition. Both (a) and (b) are exponential families, and this condition is satisfied for all exponential families.

$$
\begin{aligned}
\mathrm{E}_{\theta}\left[\frac{\partial^{2}}{\partial \theta^{2}} \log f(\mathbf{X} \mid \theta)\right] & =E_{\theta}\left[\frac{\partial}{\partial \theta}\left(\frac{\partial}{\partial \theta} \log f(\mathbf{X} \mid \theta)\right)\right] \\
& =\mathrm{E}_{\theta}\left[\frac{\partial}{\partial \theta}\left(\frac{\frac{\partial}{\partial \theta} f(\mathbf{X} \mid \theta)}{f(\mathbf{X} \mid \theta)}\right)\right]=\mathrm{E}_{\theta}\left[\frac{\frac{\partial^{2}}{\partial \theta^{2}} f(\mathbf{X} \mid \theta)}{f(\mathbf{X} \mid \theta)}-\left(\frac{\frac{\partial}{\partial \theta} f(\mathbf{X} \mid \theta)}{f(\mathbf{X} \mid \theta)}\right)^{2}\right]
\end{aligned}
$$

Now consider the first term:

$$
\begin{align*}
\mathrm{E}_{\theta}\left[\frac{\frac{\partial^{2}}{\partial \theta^{2}} f(\mathbf{X} \mid \theta)}{f(\mathbf{X} \mid \theta)}\right] & =\int\left[\frac{\partial^{2}}{\partial \theta^{2}} f(\mathbf{x} \mid \theta)\right] d \mathbf{x}=\frac{d}{d \theta} \int \frac{\partial}{\partial \theta} f(\mathbf{x} \mid \theta) d \mathbf{x} \quad \text { (assumption) } \\
& =\frac{d}{d \theta} \mathrm{E}_{\theta}\left[\frac{\partial}{\partial \theta} \log f(\mathbf{X} \mid \theta)\right]=0 \tag{7.3.8}
\end{align*}
$$

and the identity is proved.
7.40

$$
\begin{aligned}
\frac{\partial}{\partial \theta} \log L(\theta \mid \mathbf{x}) & =\frac{\partial}{\partial p} \log \prod_{i} p^{x_{i}}(1-p)^{1-x_{i}}=\frac{\partial}{\partial p} \sum_{i} x_{i} \log p+\left(1-x_{i}\right) \log (1-p) \\
& =\sum_{i}\left[\frac{x_{i}}{p}-\frac{\left(1-x_{i}\right)}{1-p}\right]=\frac{n \bar{x}}{p}-\frac{n-n \bar{x}}{1-p}=\frac{n}{p(1-p)}[\bar{x}-p] .
\end{aligned}
$$

By Corollary 7.3.15, $\bar{X}$ is the UMVUE of $p$ and attains the Cramér-Rao lower bound. Alternatively, we could calculate

$$
\begin{aligned}
& -n \mathrm{E}_{\theta}\left(\frac{\partial^{2}}{\partial \theta^{2}} \log f(X \mid \theta)\right) \\
& =-n \mathrm{E}\left(\frac{\partial^{2}}{\partial p^{2}} \log \left[p^{X}(1-p)^{1-X}\right]\right)=-n \mathrm{E}\left(\frac{\partial^{2}}{\partial p^{2}}[X \log p+(1-X) \log (1-p)]\right) \\
& \quad=-n \mathrm{E}\left(\frac{\partial}{\partial p}\left[\frac{X}{p}-\frac{(1-X)}{1-p}\right]\right)=-n \mathrm{E}\left(\frac{-X}{p^{2}}-\frac{1-X}{(1-p)^{2}}\right) \\
& \quad=-n\left(-\frac{1}{p}-\frac{1}{1-p}\right)=\frac{n}{p(1-p)} .
\end{aligned}
$$

Then using $\tau(\theta)=p$ and $\tau^{\prime}(\theta)=1$,

$$
\frac{\tau^{\prime}(\theta)}{-n \mathrm{E}_{\theta}\left(\frac{\partial^{2}}{\partial \theta^{2}} \log f(X \mid \theta)\right)}=\frac{1}{n / p(1-p)}=\frac{p(1-p)}{n}=\operatorname{Var} \bar{X}
$$

We know that $\mathrm{E} \bar{X}=p$. Thus, $\bar{X}$ attains the Cramér-Rao bound.
7.41 a. $\mathrm{E}\left(\sum_{i} a_{i} X_{i}\right)=\sum_{i} a_{i} \mathrm{E} X_{i}=\sum_{i} a_{i} \mu=\mu \sum_{i} a_{i}=\mu$. Hence the estimator is unbiased.
b. $\operatorname{Var}\left(\sum_{i} a_{i} X_{i}\right)=\sum_{i} a_{i}^{2} \operatorname{Var} X_{i}=\sum_{i} a_{i}^{2} \sigma^{2}=\sigma^{2} \sum_{i} a_{i}^{2}$. Therefore, we need to minimize $\sum_{i} a_{i}^{2}$, subject to the constraint $\sum_{i} a_{i}=1$. Add and subtract the mean of the $a_{i}, 1 / n$, to get

$$
\sum_{i} a_{i}^{2}=\sum_{i}\left[\left(a_{i}-\frac{1}{n}\right)+\frac{1}{n}\right]^{2}=\sum_{i}\left(a_{i}-\frac{1}{n}\right)^{2}+\frac{1}{n}
$$

because the cross-term is zero. Hence, $\sum_{i} a_{i}^{2}$ is minimized by choosing $a_{i}=1 / n$ for all $i$. Thus, $\sum_{i}(1 / n) X_{i}=\bar{X}$ has the minimum variance among all linear unbiased estimators.
7.43 a. This one is real hard - it was taken from an American Statistician article, but the proof is not there. A cryptic version of the proof is in Tukey (Approximate Weights, Ann. Math. Statist. 1948, 91-92); here is a more detailed version.
Let $q_{i}=q_{i}^{*}\left(1+\lambda t_{i}\right)$ with $0 \leq \lambda \leq 1$ and $\left|t_{i}\right| \leq 1$. Recall that $q_{i}^{*}=\left(1 / \sigma_{i}^{2}\right) / \sum_{j}\left(1 / \sigma_{j}^{2}\right)$ and $\operatorname{Var} W^{*}=1 / \sum_{j}\left(1 / \sigma_{j}^{2}\right)$. Then

$$
\begin{aligned}
\operatorname{Var}\left(\frac{q_{i} W_{i}}{\sum_{j} q_{j}}\right) & =\frac{1}{\left(\sum_{j} q_{j}\right)^{2}} \sum_{i} q_{i} \sigma_{i}^{2} \\
& =\frac{1}{\left[\sum_{j} q_{j}^{*}\left(1+\lambda t_{j}\right)\right]^{2}} \sum_{i} q_{i}^{* 2}\left(1+\lambda t_{i}\right)^{2} \sigma_{i}^{2} \\
& =\frac{1}{\left[\sum_{j} q_{j}^{*}\left(1+\lambda t_{j}\right)\right]^{2} \sum_{j}\left(1 / \sigma_{j}^{2}\right)} \sum_{i} q_{i}^{*}\left(1+\lambda t_{i}\right)^{2}
\end{aligned}
$$

using the definition of $q_{i}^{*}$. Now write
$\sum_{i} q_{i}^{*}\left(1+\lambda t_{i}\right)^{2}=1+2 \lambda \sum_{j} q_{j} t_{j}+\lambda^{2} \sum_{j} q_{j} t_{j}^{2}=\left[1+\lambda \sum_{j} q_{j} t_{j}\right]^{2}+\lambda^{2}\left[\sum_{j} q_{j} t_{j}^{2}-\left(\sum_{j} q_{j} t_{j}\right)^{2}\right]$,
where we used the fact that $\sum_{j} q_{j}^{*}=1$. Now since

$$
\begin{gathered}
{\left[\sum_{j} q_{j}^{*}\left(1+\lambda t_{j}\right)\right]^{2}=\left[1+\lambda \sum_{j} q_{j} t_{j}\right]^{2}} \\
\operatorname{Var}\left(\frac{q_{i} W_{i}}{\sum_{j} q_{j}}\right)=\frac{1}{\sum_{j}\left(1 / \sigma_{j}^{2}\right)}\left[1+\frac{\lambda^{2}\left[\sum_{j} q_{j} t_{j}^{2}-\left(\sum_{j} q_{j} t_{j}\right)^{2}\right]}{\left[1+\lambda \sum_{j} q_{j} t_{j}\right]^{2}}\right] \\
\leq \frac{1}{\sum_{j}\left(1 / \sigma_{j}^{2}\right)}\left[1+\frac{\lambda^{2}\left[1-\left(\sum_{j} q_{j} t_{j}\right)^{2}\right]}{\left[1+\lambda \sum_{j} q_{j} t_{j}\right]^{2}}\right]
\end{gathered}
$$

since $\sum_{j} q_{j} t_{j}^{2} \leq 1$. Now let $T=\sum_{j} q_{j} t_{j}$, and

$$
\operatorname{Var}\left(\frac{q_{i} W_{i}}{\sum_{j} q_{j}}\right) \leq \frac{1}{\sum_{j}\left(1 / \sigma_{j}^{2}\right)}\left[1+\frac{\lambda^{2}\left[1-T^{2}\right]}{[1+\lambda T]^{2}}\right]
$$

and the right hand side is maximized at $T=-\lambda$, with maximizing value

$$
\operatorname{Var}\left(\frac{q_{i} W_{i}}{\sum_{j} q_{j}}\right) \leq \frac{1}{\sum_{j}\left(1 / \sigma_{j}^{2}\right)}\left[1+\frac{\lambda^{2}\left[1-\lambda^{2}\right]}{\left[1-\lambda^{2}\right]^{2}}\right]=\operatorname{Var} W^{*} \frac{1}{1-\lambda^{2}}
$$

Bloch and Moses (1988) define $\lambda$ as the solution to

$$
b_{\max } / b_{\min }=\frac{1+\lambda}{1-\lambda}
$$

where $b_{i} / b_{j}$ are the ratio of the normalized weights which, in the present notation, is

$$
b_{i} / b_{j}=\left(1+\lambda t_{i}\right) /\left(1+\lambda t_{j}\right)
$$

The right hand side is maximized by taking $t_{i}$ as large as possible and $t_{j}$ as small as possible, and setting $t_{i}=1$ and $t_{j}=-1$ (the extremes) yields the Bloch and Moses (1988) solution. b.

$$
b_{i}=\frac{1 / k}{\left(1 / \sigma_{i}^{2}\right) /\left(\sum_{j} 1 / \sigma_{j}^{2}\right)}=\frac{\sigma_{i}^{2}}{k} \sum_{j} 1 / \sigma_{j}^{2}
$$

Thus,

$$
b_{\max }=\frac{\sigma_{\max }^{2}}{k} \sum_{j} 1 / \sigma_{j}^{2} \quad \text { and } \quad b_{\min }=\frac{\sigma_{\min }^{2}}{k} \sum_{j} 1 / \sigma_{j}^{2}
$$

and $B=b_{\max } / b_{\min }=\sigma_{\max }^{2} / \sigma_{\min }^{2}$. Solving $B=(1+\lambda) /(1-\lambda)$ yields $\lambda=(B-1) /(B+1)$. Substituting this into Tukey's inequality yields

$$
\frac{\operatorname{Var} W}{\operatorname{Var} W^{*}} \leq \frac{(B+1)^{2}}{4 B}=\frac{\left(\left(\sigma_{\max }^{2} / \sigma_{\min }^{2}\right)+1\right)^{2}}{4\left(\sigma_{\max }^{2} / \sigma_{\min }^{2}\right)}
$$

$7.44 \sum_{i} X_{i}$ is a complete sufficient statistic for $\theta$ when $X_{i} \sim \mathrm{n}(\theta, 1) . \bar{X}^{2}-1 / n$ is a function of $\sum_{i} X_{i}$. Therefore, by Theorem 7.3.23, $\bar{X}^{2}-1 / n$ is the unique best unbiased estimator of its expectation.

$$
\mathrm{E}\left(\bar{X}^{2}-\frac{1}{n}\right)=\operatorname{Var} \bar{X}+(\mathrm{E} \bar{X})^{2}-\frac{1}{n}=\frac{1}{n}+\theta^{2}-\frac{1}{n}=\theta^{2}
$$

Therefore, $\bar{X}^{2}-1 / n$ is the UMVUE of $\theta^{2}$. We will calculate

$$
\operatorname{Var}\left(\bar{X}^{2}-1 / n\right)=\operatorname{Var}\left(\bar{X}^{2}\right)=\mathrm{E}\left(\bar{X}^{4}\right)-\left[\mathrm{E}\left(\bar{X}^{2}\right)\right]^{2}, \quad \text { where } \bar{X} \sim \mathrm{n}(\theta, 1 / n)
$$

but first we derive some general formulas that will also be useful in later exercises. Let $Y \sim$ $\mathrm{n}\left(\theta, \sigma^{2}\right)$. Then here are formulas for $\mathrm{E} Y^{4}$ and $\operatorname{Var} Y^{2}$.

$$
\begin{array}{rlc}
\mathrm{E} Y^{4} & =\mathrm{E}\left[Y^{3}(Y-\theta+\theta)\right]=\mathrm{E} Y^{3}(Y-\theta)+\mathrm{E} Y^{3} \theta=E Y^{3}(Y-\theta)+\theta \mathrm{E} Y^{3} . \\
\mathrm{E} Y^{3}(Y-\theta) & =\sigma^{2} \mathrm{E}\left(3 Y^{2}\right)=\sigma^{2} 3\left(\sigma^{2}+\theta^{2}\right)=3 \sigma^{4}+3 \theta^{2} \sigma^{2} . & \text { (Stein's Lemma) } \\
\theta \mathrm{E} Y^{3} & =\theta\left(3 \theta \sigma^{2}+\theta^{3}\right)=3 \theta^{2} \sigma^{2}+\theta^{4} . & \text { (Example 3.6.6) } \\
\operatorname{Var} Y^{2} & =3 \sigma^{4}+6 \theta^{2} \sigma^{2}+\theta^{4}-\left(\sigma^{2}+\theta^{2}\right)^{2}=2 \sigma^{4}+4 \theta^{2} \sigma^{2} . &
\end{array}
$$

Thus,

$$
\operatorname{Var}\left(\bar{X}^{2}-\frac{1}{n}\right)=\operatorname{Var} \bar{X}^{2}=2 \frac{1}{n^{2}}+4 \theta^{2} \frac{1}{n}>\frac{4 \theta^{2}}{n}
$$

To calculate the Cramér-Rao lower bound, we have

$$
\begin{aligned}
\mathrm{E}_{\theta}\left(\frac{\partial^{2} \log f(X \mid \theta)}{\partial \theta^{2}}\right) & =\mathrm{E}_{\theta}\left(\frac{\partial^{2}}{\partial \theta^{2}} \log \frac{1}{\sqrt{2 \pi}} e^{-(X-\theta)^{2} / 2}\right) \\
& =\mathrm{E}_{\theta}\left(\frac{\partial^{2}}{\partial \theta^{2}}\left[\log (2 \pi)^{-1 / 2}-\frac{1}{2}(X-\theta)^{2}\right]\right)=\mathrm{E}_{\theta}\left(\frac{\partial}{\partial \theta}(X-\theta)\right)=-1
\end{aligned}
$$

and $\tau(\theta)=\theta^{2},\left[\tau^{\prime}(\theta)\right]^{2}=(2 \theta)^{2}=4 \theta^{2}$ so the Cramér-Rao Lower Bound for estimating $\theta^{2}$ is

$$
\frac{\left[\tau^{\prime}(\theta)\right]^{2}}{-n \mathrm{E}_{\theta}\left(\frac{\partial^{2}}{\partial \theta^{2}} \log f(X \mid \theta)\right)}=\frac{4 \theta^{2}}{n}
$$

Thus, the UMVUE of $\theta^{2}$ does not attain the Cramér-Rao bound. (However, the ratio of the variance and the lower bound $\rightarrow 1$ as $n \rightarrow \infty$.)
7.45 a. Because $\mathrm{E} S^{2}=\sigma^{2}, \operatorname{bias}\left(a S^{2}\right)=\mathrm{E}\left(a S^{2}\right)-\sigma^{2}=(a-1) \sigma^{2}$. Hence,

$$
\operatorname{MSE}\left(a S^{2}\right)=\operatorname{Var}\left(a S^{2}\right)+\operatorname{bias}\left(a S^{2}\right)^{2}=a^{2} \operatorname{Var}\left(S^{2}\right)+(a-1)^{2} \sigma^{4}
$$

b. There were two typos in early printings; $\kappa=\mathrm{E}[X-\mu]^{4} / \sigma^{4}$ and

$$
\operatorname{Var}\left(S^{2}\right)=\frac{1}{n}\left(\kappa-\frac{n-3}{n-1}\right) \sigma^{4}
$$

See Exercise 5.8b for the proof.
c. There was a typo in early printings; under normality $\kappa=3$. Under normality we have

$$
\kappa=\frac{\mathrm{E}[X-\mu]^{4}}{\sigma^{4}}=\mathrm{E}\left[\frac{X-\mu}{\sigma}\right]^{4}=\mathrm{E} Z^{4}
$$

where $Z \sim \mathrm{n}(0,1)$. Now, using Lemma 3.6.5 with $g(z)=z^{3}$ we have

$$
\kappa=\mathrm{E} Z^{4}=\mathrm{E} g(Z) Z=1 \mathrm{E}\left(3 Z^{2}\right)=3 \mathrm{E} Z^{2}=3 .
$$

To minimize $\operatorname{MSE}\left(S^{2}\right)$ in general, write $\operatorname{Var}\left(S^{2}\right)=B \sigma^{4}$. Then minimizing $\operatorname{MSE}\left(S^{2}\right)$ is equivalent to minimizing $a^{2} B+(a-1)^{2}$. Set the derivative of this equal to 0 ( $B$ is not a function of $a$ ) to obtain the minimizing value of $a$ is $1 /(B+1)$. Using the expression in part (b), under normality the minimizing value of $a$ is

$$
\frac{1}{B+1}=\frac{1}{\frac{1}{n}\left(3-\frac{n-3}{n-1}\right)+1}=\frac{n-1}{n+1}
$$

d. There was a typo in early printings; the minimizing $a$ is

$$
a=\frac{n-1}{(n+1)+\frac{(\kappa-3)(n-1)}{n}} .
$$

To obtain this simply calculate $1 /(B+1)$ with (from part (b))

$$
B=\frac{1}{n}\left(\kappa-\frac{n-3}{n-1}\right)
$$

e. Using the expression for $a$ in part (d), if $\kappa=3$ the second term in the denominator is zero and $a=(n-1) /(n+1)$, the normal result from part (c). If $\kappa<3$, the second term in the denominator is negative. Because we are dividing by a smaller value, we have $a>$ $(n-1) /(n+1)$. Because $\operatorname{Var}\left(S^{2}\right)=B \sigma^{4}, B>0$, and, hence, $a=1 /(B+1)<1$. Similarly, if $\kappa>3$, the second term in the denominator is positive. Because we are dividing by a larger value, we have $a<(n-1) /(n+1)$.
7.46 a. For the uniform $(\theta, 2 \theta)$ distribution we have $\mathrm{E} X=(2 \theta+\theta) / 2=3 \theta / 2$. So we solve $3 \theta / 2=\bar{X}$ for $\theta$ to obtain the method of moments estimator $\tilde{\theta}=2 \bar{X} / 3$.
b. Let $x_{(1)}, \ldots, x_{(n)}$ denote the observed order statistics. Then, the likelihood function is

$$
L(\theta \mid \mathbf{x})=\frac{1}{\theta^{n}} I_{\left[x_{(n)} / 2, x_{(1)}\right]}(\theta) .
$$

Because $1 / \theta^{n}$ is decreasing, this is maximized at $\hat{\theta}=x_{(n)} / 2$. So $\hat{\theta}=X_{(n)} / 2$ is the MLE. Use the pdf of $X_{(n)}$ to calculate $\mathrm{E} X_{(n)}=\frac{2 n+1}{n+1} \theta$. So $\mathrm{E} \hat{\theta}=\frac{2 n+1}{2 n+2} \theta$, and if $k=(2 n+2) /(2 n+1)$, $\mathrm{E} k \hat{\theta}=\theta$.
c. From Exercise 6.23 , a minimal sufficient statistic for $\theta$ is $\left(X_{(1)}, X_{(n)}\right)$. $\tilde{\theta}$ is not a function of this minimal sufficient statistic. So by the Rao-Blackwell Theorem, $\mathrm{E}\left(\tilde{\theta} \mid X_{(1)}, X_{(n)}\right)$ is an unbiased estimator of $\theta$ ( $\tilde{\theta}$ is unbiased) with smaller variance than $\tilde{\theta}$. The MLE is a function of $\left(X_{(1)}, X_{(n)}\right)$, so it can not be improved with the Rao-Blackwell Theorem.
d. $\tilde{\theta}=2(1.16) / 3=.7733$ and $\hat{\theta}=1.33 / 2=.6650$.
$7.47 X_{i} \sim \mathrm{n}\left(r, \sigma^{2}\right)$, so $\bar{X} \sim \mathrm{n}\left(r, \sigma^{2} / n\right)$ and $\mathrm{E} \bar{X}^{2}=r^{2}+\sigma^{2} / n$. Thus $\mathrm{E}\left[\left(\pi \bar{X}^{2}-\pi \sigma^{2} / n\right)\right]=\pi r^{2}$ is best unbiased because $\bar{X}$ is a complete sufficient statistic. If $\sigma^{2}$ is unknown replace it with $s^{2}$ and the conclusion still holds.
7.48 a. The Cramér-Rao Lower Bound for unbiased estimates of $p$ is

$$
\frac{\left[\frac{d}{d p} p\right]^{2}}{-n \mathrm{E} \frac{d^{2}}{d p^{2}} \log L(p \mid X)}=\frac{1}{-n \mathrm{E}\left\{\frac{d^{2}}{d p^{2}} \log \left[p^{X}(1-p)^{1-X}\right]\right\}}=\frac{1}{-n \mathrm{E}\left\{-\frac{X}{p^{2}}-\frac{(1-X)}{(1-p)^{2}}\right\}}=\frac{p(1-p)}{n}
$$

because $\mathrm{E} X=p$. The MLE of $p$ is $\hat{p}=\sum_{i} X_{i} / n$, with $\mathrm{E} \hat{p}=p$ and $\operatorname{Var} \hat{p}=p(1-p) / n$. Thus $\hat{p}$ attains the CRLB and is the best unbiased estimator of $p$.
b. By independence, $\mathrm{E}\left(X_{1} X_{2} X_{3} X_{4}\right)=\prod_{i} \mathrm{E} X_{i}=p^{4}$, so the estimator is unbiased. Because $\sum_{i} X_{i}$ is a complete sufficient statistic, Theorems 7.3.17 and 7.3.23 imply that $\mathrm{E}\left(X_{1} X_{2} X_{3} X_{4}\right)$ $\sum_{i}\left(X_{i}\right)$ is the best unbiased estimator of $p^{4}$. Evaluating this yields

$$
\begin{aligned}
\mathrm{E}\left(X_{1} X_{2} X_{3} X_{4} \mid \sum_{i} X_{i}=t\right) & =\frac{P\left(X_{1}=X_{2}=X_{3}=X_{4}=1, \sum_{i=5}^{n} X_{i}=t-4\right)}{P\left(\sum_{i} X_{i}=t\right)} \\
& =\frac{p^{4}\binom{n-4}{t-4} p^{t-4}(1-p)^{n-t}}{\binom{n}{t} p^{t}(1-p)^{n-t}}=\binom{n-4}{t-4} /\binom{n}{t}
\end{aligned}
$$

for $t \geq 4$. For $t<4$ one of the $X_{i} \mathrm{~s}$ must be zero, so the estimator is $\mathrm{E}\left(X_{1} X_{2} X_{3} X_{4} \mid \sum_{i} X_{i}=\right.$ $t)=0$.
7.49 a. From Theorem 5.5.9, $Y=X_{(1)}$ has pdf

$$
f_{Y}(y)=\frac{n!}{(n-1)!} \frac{1}{\lambda} e^{-y / \lambda}\left[1-\left(1-e^{-y / \lambda}\right)\right]^{n-1}=\frac{n}{\lambda} e^{-n y / \lambda} .
$$

Thus $Y \sim \operatorname{exponential}(\lambda / n)$ so $\mathrm{E} Y=\lambda / n$ and $n Y$ is an unbiased estimator of $\lambda$.
b. Because $f_{X}(x)$ is in the exponential family, $\sum_{i} X_{i}$ is a complete sufficient statistic and $\mathrm{E}\left(n X_{(1)} \mid \sum_{i} X_{i}\right)$ is the best unbiased estimator of $\lambda$. Because $\mathrm{E}\left(\sum_{i} X_{i}\right)=n \lambda$, we must have $\mathrm{E}\left(n X_{(1)} \mid \sum_{i} X_{i}\right)=\sum_{i} X_{i} / n$ by completeness. Of course, any function of $\sum_{i} X_{i}$ that is an unbiased estimator of $\lambda$ is the best unbiased estimator of $\lambda$. Thus, we know directly that because $\mathrm{E}\left(\sum_{i} X_{i}\right)=n \lambda, \sum_{i} X_{i} / n$ is the best unbiased estimator of $\lambda$.
c. From part (a), $\hat{\lambda}=601.2$ and from part (b) $\hat{\lambda}=128.8$. Maybe the exponential model is not a good assumption.
7.50 a. $\mathrm{E}(a \bar{X}+(1-a) c S)=a \mathrm{E} \bar{X}+(1-a) \mathrm{E}(c S)=a \theta+(1-a) \theta=\theta$. So $a \bar{X}+(1-a) c S$ is an unbiased estimator of $\theta$.
b. Because $\bar{X}$ and $S^{2}$ are independent for this normal model, $\operatorname{Var}(a \bar{X}+(1-a) c S)=a^{2} V_{1}+(1-$ $a)^{2} V_{2}$, where $V_{1}=\operatorname{Var} \bar{X}=\theta^{2} / n$ and $V_{2}=\operatorname{Var}(c S)=c^{2} \mathrm{E} S^{2}-\theta^{2}=c^{2} \theta^{2}-\theta^{2}=\left(c^{2}-1\right) \theta^{2}$. Use calculus to show that this quadratic function of $a$ is minimized at

$$
a=\frac{V_{2}}{V_{1}+V_{2}}=\frac{\left(c^{2}-1\right) \theta^{2}}{\left((1 / n)+c^{2}-1\right) \theta^{2}}=\frac{\left(c^{2}-1\right)}{\left((1 / n)+c^{2}-1\right)} .
$$

c. Use the factorization in Example 6.2.9, with the special values $\mu=\theta$ and $\sigma^{2}=\theta^{2}$, to show that $\left(\bar{X}, S^{2}\right)$ is sufficient. $\mathrm{E}(\bar{X}-c S)=\theta-\theta=0$, for all $\theta$. So $\bar{X}-c S$ is a nonzero function of ( $\bar{X}, S^{2}$ ) whose expected value is always zero. Thus $\left(\bar{X}, S^{2}\right)$ is not complete.
7.51 a. Straightforward calculation gives:

$$
\mathrm{E}\left[\theta-\left(a_{1} \bar{X}+a_{2} c S\right)\right]^{2}=a_{1}^{2} \operatorname{Var} \bar{X}+a_{2}^{2} c^{2} \operatorname{Var} S+\theta^{2}\left(a_{1}+a_{2}-1\right)^{2} .
$$

Because $\operatorname{Var} \bar{X}=\theta^{2} / n$ and $\operatorname{Var} S=\mathrm{E} S^{2}-(\mathrm{E} S)^{2}=\theta^{2}\left(\frac{c^{2}-1}{c^{2}}\right)$, we have

$$
\mathrm{E}\left[\theta-\left(a_{1} \bar{X}+a_{2} c S\right)\right]^{2}=\theta^{2}\left[a_{1}^{2} / n+a_{2}^{2}\left(c^{2}-1\right)+\left(a_{1}+a_{2}-1\right)^{2}\right]
$$

and we only need minimize the expression in square brackets, which is independent of $\theta$. Differentiating yields $a_{2}=\left[(n+1) c^{2}-n\right]^{-1}$ and $a_{1}=1-\left[(n+1) c^{2}-n\right]^{-1}$.
b. The estimator $T^{*}$ has minimum MSE over a class of estimators that contain those in Exercise 7.50 .
c. Because $\theta>0$, restricting $T^{*} \geq 0$ will improve the MSE.
d. No. It does not fit the definition of either one.
7.52 a. Because the Poisson family is an exponential family with $t(x)=x, \sum_{i} X_{i}$ is a complete sufficient statistic. Any function of $\sum_{i} X_{i}$ that is an unbiased estimator of $\lambda$ is the unique best unbiased estimator of $\lambda$. Because $\bar{X}$ is a function of $\sum_{i} X_{i}$ and $\mathrm{E} \bar{X}=\lambda, \bar{X}$ is the best unbiased estimator of $\lambda$.
b. $S^{2}$ is an unbiased estimator of the population variance, that is, $\mathrm{E} S^{2}=\lambda . \bar{X}$ is a one-to-one function of $\sum_{i} X_{i}$. So $\bar{X}$ is also a complete sufficient statistic. Thus, $\mathrm{E}\left(S^{2} \mid \bar{X}\right)$ is an unbiased estimator of $\lambda$ and, by Theorem 7.3.23, it is also the unique best unbiased estimator of $\lambda$. Therefore $\mathrm{E}\left(S^{2} \mid \bar{X}\right)=\bar{X}$. Then we have

$$
\operatorname{Var} S^{2}=\operatorname{Var}\left(\mathrm{E}\left(S^{2} \mid \bar{X}\right)\right)+\mathrm{E} \operatorname{Var}\left(S^{2} \mid \bar{X}\right)=\operatorname{Var} \bar{X}+\mathrm{E} \operatorname{Var}\left(S^{2} \mid \bar{X}\right)
$$

so Var $S^{2}>\operatorname{Var} \bar{X}$.
c. We formulate a general theorem. Let $T(X)$ be a complete sufficient statistic, and let $T^{\prime}(X)$ be any statistic other than $T(X)$ such that $\mathrm{E} T(X)=\mathrm{E} T^{\prime}(X)$. Then $\mathrm{E}\left[T^{\prime}(X) \mid T(X)\right]=T(X)$ and $\operatorname{Var} T^{\prime}(X)>\operatorname{Var} T(X)$.
7.53 Let $a$ be a constant and suppose $\operatorname{Cov}_{\theta_{0}}(W, U)>0$. Then

$$
\operatorname{Var}_{\theta_{0}}(W+a U)=\operatorname{Var}_{\theta_{0}} W+a^{2} \operatorname{Var}_{\theta_{0}} U+2 a \operatorname{Cov}_{\theta_{0}}(W, U)
$$

Choose $a \in\left(-2 \operatorname{Cov}_{\theta_{0}}(W, U) / \operatorname{Var}_{\theta_{0}} U, 0\right)$. Then $\operatorname{Var}_{\theta_{0}}(W+a U)<\operatorname{Var}_{\theta_{0}} W$, so $W$ cannot be best unbiased.
7.55 All three parts can be solved by this general method. Suppose $X \sim f(x \mid \theta)=c(\theta) m(x), a<x<$ $\theta$. Then $1 / c(\theta)=\int_{a}^{\theta} m(x) d x$, and the cdf of $X$ is $F(x)=c(\theta) / c(x), a<x<\theta$. Let $Y=X_{(n)}$ be the largest order statistic. Arguing as in Example 6.2.23 we see that $Y$ is a complete sufficient statistic. Thus, any function $T(Y)$ that is an unbiased estimator of $h(\theta)$ is the best unbiased estimator of $h(\theta)$. By Theorem 5.4.4 the pdf of $Y$ is $g(y \mid \theta)=n m(y) c(\theta)^{n} / c(y)^{n-1}, a<y<\theta$. Consider the equations

$$
\int_{a}^{\theta} f(x \mid \theta) d x=1 \quad \text { and } \quad \int_{a}^{\theta} T(y) g(y \mid \theta) d y=h(\theta)
$$

which are equivalent to

$$
\int_{a}^{\theta} m(x) d x=\frac{1}{c(\theta)} \quad \text { and } \quad \int_{a}^{\theta} \frac{T(y) n m(y)}{c(y)^{n-1}} d y=\frac{h(\theta)}{c(\theta)^{n}}
$$

Differentiating both sides of these two equations with respect to $\theta$ and using the Fundamental Theorem of Calculus yields

$$
m(\theta)=-\frac{c^{\prime}(\theta)}{c(\theta)^{2}} \quad \text { and } \quad \frac{T(\theta) n m(\theta)}{c(\theta)^{n-1}}=\frac{c(\theta)^{n} h^{\prime}(\theta)-h(\theta) n c(\theta)^{n-1} c^{\prime}(\theta)}{c(\theta)^{2 n}}
$$

Change $\theta \mathrm{s}$ to $y$ s and solve these two equations for $T(y)$ to get the best unbiased estimator of $h(\theta)$ is

$$
T(y)=h(y)+\frac{h^{\prime}(y)}{n m(y) c(y)} .
$$

For $h(\theta)=\theta^{r}, h^{\prime}(\theta)=r \theta^{r-1}$.
a. For this pdf, $m(x)=1$ and $c(\theta)=1 / \theta$. Hence

$$
T(y)=y^{r}+\frac{r y^{r-1}}{n(1 / y)}=\frac{n+r}{n} y^{r}
$$

b. If $\theta$ is the lower endpoint of the support, the smallest order statistic $Y=X_{(1)}$ is a complete sufficient statistic. Arguing as above yields the best unbiased estimator of $h(\theta)$ is

$$
T(y)=h(y)-\frac{h^{\prime}(y)}{n m(y) c(y)} .
$$

For this pdf, $m(x)=e^{-x}$ and $c(\theta)=e^{\theta}$. Hence

$$
T(y)=y^{r}-\frac{r y^{r-1}}{n e^{-y} e^{y}}=y^{r}-\frac{r y^{r-1}}{n} .
$$

c. For this pdf, $m(x)=e^{-x}$ and $c(\theta)=1 /\left(e^{-\theta}-e^{-b}\right)$. Hence

$$
T(y)=y^{r}-\frac{r y^{r-1}}{n e^{-y}}\left(e^{-y}-e^{-b}\right)=y^{r}-\frac{r y^{r-1}\left(1-e^{-(b-y)}\right)}{n} .
$$

7.56 Because $T$ is sufficient, $\phi(T)=\mathrm{E}\left[h\left(X_{1}, \ldots, X_{n}\right) \mid T\right]$ is a function only of $T$. That is, $\phi(T)$ is an estimator. If $\mathrm{E} h\left(X_{1}, \ldots, X_{n}\right)=\tau(\theta)$, then

$$
\mathrm{E} h\left(X_{1}, \cdots, X_{n}\right)=\mathrm{E}\left[\mathrm{E}\left(h\left(X_{1}, \ldots, X_{n}\right) \mid T\right)\right]=\tau(\theta)
$$

so $\phi(T)$ is an unbiased estimator of $\tau(\theta)$. By Theorem 7.3.23, $\phi(T)$ is the best unbiased estimator of $\tau(\theta)$.
7.57 a. $T$ is a Bernoulli random variable. Hence,

$$
\mathrm{E}_{p} T=P_{p}(T=1)=P_{p}\left(\sum_{i=1}^{n} X_{i}>X_{n+1}\right)=h(p)
$$

b. $\sum_{i=1}^{n+1} X_{i}$ is a complete sufficient statistic for $\theta$, so $\mathrm{E}\left(T \mid \sum_{i=1}^{n+1} X_{i}\right)$ is the best unbiased estimator of $h(p)$. We have

$$
\begin{aligned}
\mathrm{E}\left(T \mid \sum_{i=1}^{n+1} X_{i}=y\right) & =P\left(\sum_{i=1}^{n} X_{i}>X_{n+1} \mid \sum_{i=1}^{n+1} X_{i}=y\right) \\
& =P\left(\sum_{i=1}^{n} X_{i}>X_{n+1}, \sum_{i=1}^{n+1} X_{i}=y\right) / P\left(\sum_{i=1}^{n+1} X_{i}=y\right)
\end{aligned}
$$

The denominator equals $\binom{c+1}{y} p^{y}(1-p)^{n+1-y}$. If $y=0$ the numerator is

$$
P\left(\sum_{i=1}^{n} X_{i}>X_{n+1}, \sum_{i=1}^{n+1} X_{i}=0\right)=0
$$

If $y>0$ the numerator is

$$
P\left(\sum_{i=1}^{n} X_{i}>X_{n+1}, \sum_{i=1}^{n+1} X_{i}=y, X_{n+1}=0\right)+P\left(\sum_{i=1}^{n} X_{i}>X_{n+1}, \sum_{i=1}^{n+1} X_{i}=y, X_{n+1}=1\right)
$$

which equals

$$
P\left(\sum_{i=1}^{n} X_{i}>0, \sum_{i=1}^{n} X_{i}=y\right) P\left(X_{n+1}=0\right)+P\left(\sum_{i=1}^{n} X_{i}>1, \sum_{i=1}^{n} X_{i}=y-1\right) P\left(X_{n+1}=1\right) .
$$

For all $y>0$,

$$
P\left(\sum_{i=1}^{n} X_{i}>0, \sum_{i=1}^{n} X_{i}=y\right)=P\left(\sum_{i=1}^{n} X_{i}=y\right)=\binom{n}{y} p^{y}(1-p)^{n-y}
$$

If $y=1$ or 2 , then

$$
P\left(\sum_{i=1}^{n} X_{i}>1, \sum_{i=1}^{n} X_{i}=y-1\right)=0 .
$$

And if $y>2$, then

$$
P\left(\sum_{i=1}^{n} X_{i}>1, \sum_{i=1}^{n} X_{i}=y-1\right)=P\left(\sum_{i=1}^{n} X_{i}=y-1\right)=\binom{n}{y-1} p^{y-1}(1-p)^{n-y+1} .
$$

Therefore, the UMVUE is

$$
\mathrm{E}\left(T \mid \sum_{i=1}^{n+1} X_{i}=y\right)= \begin{cases}0 & \text { if } y=0 \\
\left.\frac{\binom{n}{y} p^{y}(1-p)^{n-y}(1-p)}{\binom{n+1}{y} p^{y}(1-p)^{n-y+1}}=\frac{\binom{n}{y}}{(n+1} \begin{array}{l}
n \\
y
\end{array}\right) \frac{1}{(n+1)(n+1-y)} & \text { if } y=1 \text { or } 2 \\
\frac{\left(\left(\begin{array}{l}
n \\
y \\
y
\end{array}\right)+\binom{n}{y-1}\right) p^{y}(1-p)^{n-y+1}}{\binom{n+1}{y} p^{y}(1-p)^{n-y+1}}=\frac{\binom{n}{y}+\binom{n}{y-1}}{\binom{n+1}{y}}=1 & \text { if } y>2 .\end{cases}
$$

7.59 We know $T=(n-1) S^{2} / \sigma^{2} \sim \chi_{n-1}^{2}$. Then

$$
\mathrm{E} T^{p / 2}=\frac{1}{\Gamma\left(\frac{n-1}{2}\right) 2^{\frac{n-1}{2}}} \int_{0}^{\infty} t^{\frac{p+n-1}{2}-1} e^{-\frac{t}{2}} d t=\frac{2^{\frac{p}{2}} \Gamma\left(\frac{p+n-1}{2}\right)}{\Gamma\left(\frac{n-1}{2}\right)}=C_{p, n}
$$

Thus

$$
\mathrm{E}\left(\frac{(n-1) S^{2}}{\sigma^{2}}\right)^{p / 2}=C_{p, n}
$$

so $(n-1)^{p / 2} S^{p} / C_{p, n}$ is an unbiased estimator of $\sigma^{p}$. From Theorem 6.2.25, $\left(\bar{X}, S^{2}\right)$ is a complete, sufficient statistic. The unbiased estimator $(n-1)^{p / 2} S^{p} / C_{p, n}$ is a function of $\left(\bar{X}, S^{2}\right)$. Hence, it is the best unbiased estimator.
7.61 The pdf for $Y \sim \chi_{\nu}^{2}$ is

$$
f(y)=\frac{1}{\Gamma(\nu / 2) 2^{\nu / 2}} y^{\nu / 2-1} e^{-y / 2}
$$

Thus the pdf for $S^{2}=\sigma^{2} Y / \nu$ is

$$
g\left(s^{2}\right)=\frac{\nu}{\sigma^{2}} \frac{1}{\Gamma(\nu / 2) 2^{\nu / 2}}\left(\frac{s^{2} \nu}{\sigma^{2}}\right)^{\nu / 2-1} e^{-s^{2} \nu /\left(2 \sigma^{2}\right)}
$$

Thus, the log-likelihood has the form (gathering together constants that do not depend on $s^{2}$ or $\sigma^{2}$ )

$$
\log L\left(\sigma^{2} \mid s^{2}\right)=\log \left(\frac{1}{\sigma^{2}}\right)+K \log \left(\frac{s^{2}}{\sigma^{2}}\right)-K^{\prime} \frac{s^{2}}{\sigma^{2}}+K^{\prime \prime}
$$

where $K>0$ and $K^{\prime}>0$.
The loss function in Example 7.3.27 is

$$
L\left(\sigma^{2}, a\right)=\frac{a}{\sigma^{2}}-\log \left(\frac{a}{\sigma^{2}}\right)-1
$$

so the loss of an estimator is the negative of its likelihood.
7.63 Let $a=\tau^{2} /\left(\tau^{2}+1\right)$, so the Bayes estimator is $\delta^{\pi}(x)=a x$. Then $R\left(\mu, \delta^{\pi}\right)=(a-1)^{2} \mu^{2}+a^{2}$. As $\tau^{2}$ increases, $R\left(\mu, \delta^{\pi}\right)$ becomes flatter.
7.65 a. Figure omitted.
b. The posterior expected loss is $\mathrm{E}(L(\theta, a) \mid x)=e^{c a} \mathrm{E} e^{-c \theta}-c \mathrm{E}(a-\theta)-1$, where the expectation is with respect to $\pi(\theta \mid x)$. Then

$$
\frac{d}{d a} \mathrm{E}(L(\theta, a) \mid x)=c e^{c a} \mathrm{E} e^{-c \theta}-c \stackrel{\text { set }}{=} 0
$$

and $a=-\frac{1}{c} \log \mathrm{E} e^{-c \theta}$ is the solution. The second derivative is positive, so this is the minimum.
c. $\pi(\theta \mid x)=\mathrm{n}\left(\bar{x}, \sigma^{2} / n\right)$. So, substituting into the formula for a normal mgf, we find $\mathrm{E} e^{-c \theta}=$ $e^{-c \bar{x}+\sigma^{2} c^{2} / 2 n}$, and the LINEX posterior loss is

$$
\mathrm{E}(L(\theta, a) \mid x)=e^{c(a-\bar{x})+\sigma^{2} c^{2} / 2 n}-c(a-\bar{x})-1
$$

Substitute $\mathrm{E} e^{-c \theta}=e^{-c \bar{x}+\sigma^{2} c^{2} / 2 n}$ into the formula in part (b) to find the Bayes rule is $\bar{x}-c \sigma^{2} / 2 n$.
d. For an estimator $\bar{X}+b$, the LINEX posterior loss (from part (c)) is

$$
\mathrm{E}(L(\theta, \bar{x}+b) \mid x)=e^{c b} e^{c^{2} \sigma^{2} / 2 n}-c b-1
$$

For $\bar{X}$ the expected loss is $e^{c^{2} \sigma^{2} / 2 n}-1$, and for the Bayes estimator $\left(b=-c \sigma^{2} / 2 n\right)$ the expected loss is $c^{2} \sigma^{2} / 2 n$. The marginal distribution of $\bar{X}$ is $m(\bar{x})=1$, so the Bayes risk is infinite for any estimator of the form $\bar{X}+b$.
e. For $\bar{X}+b$, the squared error risk is $\mathrm{E}[(\bar{X}+b)-\theta]^{2}=\sigma^{2} / n+b^{2}$, so $\bar{X}$ is better than the Bayes estimator. The Bayes risk is infinite for both estimators.
7.66 Let $S=\sum_{i} X_{i} \sim \operatorname{binomial}(n, \theta)$.
a. $\mathrm{E} \hat{\theta}^{2}=\mathrm{E} \frac{S^{2}}{n^{2}}=\frac{1}{n^{2}} \mathrm{E} S^{2}=\frac{1}{n^{2}}\left(n \theta(1-\theta)+(n \theta)^{2}\right)=\frac{\theta}{n}+\frac{n-1}{n} \theta^{2}$.
b. $T_{n}^{(i)}=\left(\sum_{j \neq i} X_{j}\right)^{2} /(n-1)^{2}$. For $S$ values of $i, T_{n}^{(i)}=(S-1)^{2} /(n-1)^{2}$ because the $X_{i}$ that is dropped out equals 1 . For the other $n-S$ values of $i, T_{n}^{(i)}=S^{2} /(n-1)^{2}$ because the $X_{i}$ that is dropped out equals 0 . Thus we can write the estimator as

$$
\mathrm{JK}\left(T_{n}\right)=n \frac{S^{2}}{n^{2}}-\frac{n-1}{n}\left(S \frac{(S-1)^{2}}{(n-1)^{2}}+(n-S) \frac{S^{2}}{(n-1)^{2}}\right)=\frac{S^{2}-S}{n(n-1)}
$$

c. $\operatorname{EJK}\left(T_{n}\right)=\frac{1}{n(n-1)}\left(n \theta(1-\theta)+(n \theta)^{2}-n \theta\right)=\frac{n^{2} \theta^{2}-n \theta^{2}}{n(n-1)}=\theta^{2}$.
d. For this binomial model, $S$ is a complete sufficient statistic. Because $\operatorname{JK}\left(T_{n}\right)$ is a function of $S$ that is an unbiased estimator of $\theta^{2}$, it is the best unbiased estimator of $\theta^{2}$.

## Chapter 8

## Hypothesis Testing

8.1 Let $X=\#$ of heads out of 1000 . If the coin is fair, then $X \sim \operatorname{binomial}(1000,1 / 2)$. So

$$
P(X \geq 560)=\sum_{x=560}^{1000}\binom{1000}{x}\left(\frac{1}{2}\right)^{x}\left(\frac{1}{2}\right)^{n-x} \approx .0000825
$$

where a computer was used to do the calculation. For this binomial, E $X=1000 p=500$ and $\operatorname{Var} X=1000 p(1-p)=250$. A normal approximation is also very good for this calculation.

$$
P\{X \geq 560\}=P\left\{\frac{X-500}{\sqrt{250}} \geq \frac{559.5-500}{\sqrt{250}}\right\} \approx P\{Z \geq 3.763\} \approx .0000839
$$

Thus, if the coin is fair, the probability of observing 560 or more heads out of 1000 is very small. We might tend to believe that the coin is not fair, and $p>1 / 2$.
8.2 Let $X \sim \operatorname{Poisson}(\lambda)$, and we observed $X=10$. To assess if the accident rate has dropped, we could calculate

$$
P(X \leq 10 \mid \lambda=15)=\sum_{i=0}^{10} \frac{e^{-15} 15^{i}}{i!}=e^{-15}\left[1+15+\frac{15^{2}}{2!}+\cdots+\frac{15^{10}}{10!}\right] \approx .11846
$$

This is a fairly large value, not overwhelming evidence that the accident rate has dropped. (A normal approximation with continuity correction gives a value of .12264.)
8.3 The LRT statistic is

$$
\lambda(y)=\frac{\sup _{\theta \leq \theta_{0}} L\left(\theta \mid y_{1}, \ldots, y_{m}\right)}{\sup _{\Theta} L\left(\theta \mid y_{1}, \ldots, y_{m}\right)}
$$

Let $y=\sum_{i=1}^{m} y_{i}$, and note that the MLE in the numerator is $\min \left\{y / m, \theta_{0}\right\}$ (see Exercise 7.12) while the denominator has $y / m$ as the MLE (see Example 7.2.7). Thus

$$
\lambda(y)= \begin{cases}1 & \text { if } y / m \leq \theta_{0} \\ \frac{\left(\theta_{0}\right)^{y}\left(1-\theta_{0}\right)^{m-y}}{(y / m)^{y}(1-y / m)^{m-y}} & \text { if } y / m>\theta_{0}\end{cases}
$$

and we reject $H_{0}$ if

$$
\frac{\left(\theta_{0}\right)^{y}\left(1-\theta_{0}\right)^{m-y}}{(y / m)^{y}(1-y / m)^{m-y}}<c .
$$

To show that this is equivalent to rejecting if $y>b$, we could show $\lambda(y)$ is decreasing in $y$ so that $\lambda(y)<c$ occurs for $y>b>m \theta_{0}$. It is easier to work with $\log \lambda(y)$, and we have

$$
\log \lambda(y)=y \log \theta_{0}+(m-y) \log \left(1-\theta_{0}\right)-y \log \left(\frac{y}{m}\right)-(m-y) \log \left(\frac{m-y}{m}\right)
$$

and

$$
\begin{aligned}
\frac{d}{d y} \log \lambda(y) & =\log \theta_{0}-\log \left(1-\theta_{0}\right)-\log \left(\frac{y}{m}\right)-y \frac{1}{y}+\log \left(\frac{m-y}{m}\right)+(m-y) \frac{1}{m-y} \\
& =\log \left(\frac{\theta_{0}}{y / m} \frac{\left(\frac{m-y}{m}\right)}{1-\theta_{0}}\right)
\end{aligned}
$$

For $y / m>\theta_{0}, 1-y / m=(m-y) / m<1-\theta_{0}$, so each fraction above is less than 1 , and the $\log$ is less than 0 . Thus $\frac{d}{d y} \log \lambda<0$ which shows that $\lambda$ is decreasing in $y$ and $\lambda(y)<c$ if and only if $y>b$.
8.4 For discrete random variables, $L(\theta \mid \mathbf{x})=f(\mathbf{x} \mid \theta)=P(\mathbf{X}=\mathbf{x} \mid \theta)$. So the numerator and denominator of $\lambda(\mathbf{x})$ are the supremum of this probability over the indicated sets.
8.5 a. The log-likelihood is

$$
\log L(\theta, \nu \mid \mathbf{x})=n \log \theta+n \theta \log \nu-(\theta+1) \log \left(\prod_{i} x_{i}\right), \quad \nu \leq x_{(1)}
$$

where $x_{(1)}=\min _{i} x_{i}$. For any value of $\theta$, this is an increasing function of $\nu$ for $\nu \leq x_{(1)}$. So both the restricted and unrestricted MLEs of $\nu$ are $\hat{\nu}=x_{(1)}$. To find the MLE of $\theta$, set

$$
\frac{\partial}{\partial \theta} \log L\left(\theta, x_{(1)} \mid \mathbf{x}\right)=\frac{n}{\theta}+n \log x_{(1)}-\log \left(\prod_{i} x_{i}\right)=0
$$

and solve for $\theta$ yielding

$$
\hat{\theta}=\frac{n}{\log \left(\prod_{i} x_{i} / x_{(1)}^{n}\right)}=\frac{n}{T} .
$$

$\left(\partial^{2} / \partial \theta^{2}\right) \log L\left(\theta, x_{(1)} \mid \mathbf{x}\right)=-n / \theta^{2}<0$, for all $\theta$. So $\hat{\theta}$ is a maximum.
b. Under $H_{0}$, the MLE of $\theta$ is $\hat{\theta}_{0}=1$, and the MLE of $\nu$ is still $\hat{\nu}=x_{(1)}$. So the likelihood ratio statistic is

$$
\lambda(\mathbf{x})=\frac{x_{(1)}^{n} /\left(\prod_{i} x_{i}\right)^{2}}{(n / T)^{n} x_{(1)}^{n^{2} / T} /\left(\prod_{i} x_{i}\right)^{n / T+1}}=\left(\frac{T}{n}\right)^{n} \frac{e^{-T}}{\left(e^{-T}\right)^{n / T}}=\left(\frac{T}{n}\right)^{n} e^{-T+n}
$$

$(\partial / \partial T) \log \lambda(\mathbf{x})=(n / T)-1$. Hence, $\lambda(\mathbf{x})$ is increasing if $T \leq n$ and decreasing if $T \geq n$. Thus, $T \leq c$ is equivalent to $T \leq c_{1}$ or $T \geq c_{2}$, for appropriately chosen constants $c_{1}$ and $c_{2}$.
c. We will not use the hint, although the problem can be solved that way. Instead, make the following three transformations. First, let $Y_{i}=\log X_{i}, i=1, \ldots, n$. Next, make the $n$-to-1 transformation that sets $Z_{1}=\min _{i} Y_{i}$ and sets $Z_{2}, \ldots, Z_{n}$ equal to the remaining $Y_{i} \mathrm{~s}$, with their order unchanged. Finally, let $W_{1}=Z_{1}$ and $W_{i}=Z_{i}-Z_{1}, i=2, \ldots, n$. Then you find that the $W_{i}$ s are independent with $W_{1} \sim f_{W_{1}}(w)=n \nu^{n} e^{-n w}, w>\log \nu$, and $W_{i} \sim \operatorname{exponential}(1), i=2, \ldots, n$. Now $T=\sum_{i=2}^{n} W_{i} \sim \operatorname{gamma}(n-1,1)$, and, hence, $2 T \sim \operatorname{gamma}(n-1,2)=\chi_{2(n-1)}^{2}$.
8.6 a.

$$
\begin{aligned}
\lambda(\mathbf{x}, \mathbf{y})=\frac{\sup _{\Theta_{0}} L(\theta \mid \mathbf{x}, \mathbf{y})}{\sup _{\Theta} L(\theta \mid \mathbf{x}, \mathbf{y})} & =\frac{\sup _{\theta} \prod_{i=1}^{n} \frac{1}{\theta} e^{-x_{i} / \theta} \prod_{j=1}^{m} \frac{1}{\theta} e^{-y_{j} / \theta}}{\sup _{\theta, \mu} \prod_{i=1}^{n} \frac{1}{\theta} e^{-x_{i} / \theta} \prod_{j=1}^{m} \frac{1}{\mu} e^{-y_{j} / \mu}} \\
& =\frac{\sup _{\theta \frac{1}{\theta^{m+n}} \exp \left\{-\left(\sum_{i=1}^{n} x_{i}+\sum_{j=1}^{m} y_{j}\right) / \theta\right\}}^{\sup _{\theta, \mu} \frac{1}{\theta^{n}} \exp \left\{-\sum_{i=1}^{n} x_{i} / \theta\right\} \frac{1}{\mu^{m}} \exp \left\{-\sum_{j=1}^{m} y_{j} / \mu\right\}}}{} .
\end{aligned}
$$

Differentiation will show that in the numerator $\hat{\theta}_{0}=\left(\sum_{i} x_{i}+\sum_{j} y_{j}\right) /(n+m)$, while in the denominator $\hat{\theta}=\bar{x}$ and $\hat{\mu}=\bar{y}$. Therefore,

$$
\begin{aligned}
\lambda(\mathbf{x}, \mathbf{y}) & =\frac{\left(\frac{n+m}{\sum_{i} x_{i}+\sum_{j} y_{j}}\right)^{n+m} \exp \left\{-\left(\frac{n+m}{\sum_{i} x_{i}+\sum_{j} y_{j}}\right)\left(\sum_{i} x_{i}+\sum_{j} y_{j}\right)\right\}}{\left(\frac{n}{\sum_{i}^{n} x_{i}}\right)^{n} \exp \left\{-\left(\frac{n}{\sum_{i} x_{i}}\right) \sum_{i} x_{i}\right\}\left(\frac{m}{\sum_{j} y_{j}}\right)^{m} \exp \left\{-\left(\frac{m}{\sum_{j} y_{j}}\right) \sum_{j} y_{j}\right\}} \\
& =\frac{(n+m)^{n+m}}{n^{n} m^{m}} \frac{\left(\sum_{i} x_{i}\right)^{n}\left(\sum_{j} y_{j}\right)^{m}}{\left(\sum_{i} x_{i}+\sum_{j} y_{j}\right)^{n+m}}
\end{aligned}
$$

And the LRT is to reject $H_{0}$ if $\lambda(\mathbf{x}, \mathbf{y}) \leq c$.
b.

$$
\lambda=\frac{(n+m)^{n+m}}{n^{n} m^{m}}\left(\frac{\sum_{i} x_{i}}{\sum_{i} x_{i}+\sum_{j} y_{j}}\right)^{n}\left(\frac{\sum_{j} y_{j}}{\sum_{i} x_{i}+\sum_{j} y_{j}}\right)^{m}=\frac{(n+m)^{n+m}}{n^{n} m^{m}} T^{n}(1-T)^{m}
$$

Therefore $\lambda$ is a function of $T . \lambda$ is a unimodal function of $T$ which is maximized when $T=\frac{n}{m+n}$. Rejection for $\lambda \leq c$ is equivalent to rejection for $T \leq a$ or $T \geq b$, where $a$ and $b$ are constants that satisfy $a^{n}(1-a)^{m}=b^{n}(1-b)^{m}$.
c. When $H_{0}$ is true, $\sum_{i} X_{i} \sim \operatorname{gamma}(n, \theta)$ and $\sum_{j} Y_{j} \sim \operatorname{gamma}(m, \theta)$ and they are independent. So by an extension of Exercise 4.19b, $T \sim \operatorname{beta}(n, m)$.
8.7 a.

$$
L(\theta, \lambda \mid \mathbf{x})=\prod_{i=1}^{n} \frac{1}{\lambda} e^{-\left(x_{i}-\theta\right) / \lambda} I_{[\theta, \infty)}\left(x_{i}\right)=\left(\frac{1}{\lambda}\right)^{n} e^{-\left(\Sigma_{i} x_{i}-n \theta\right) / \lambda} I_{[\theta, \infty)}\left(x_{(1)}\right),
$$

which is increasing in $\theta$ if $x_{(1)} \geq \theta$ (regardless of $\lambda$ ). So the MLE of $\theta$ is $\hat{\theta}=x_{(1)}$. Then

$$
\frac{\partial \log L}{\partial \lambda}=-\frac{n}{\lambda}+\frac{\sum_{i} x_{i}-n \hat{\theta}}{\lambda^{2}} \stackrel{\text { set }}{=} 0 \quad \Rightarrow \quad n \hat{\lambda}=\sum_{i} x_{i}-n \hat{\theta} \quad \Rightarrow \quad \hat{\lambda}=\bar{x}-x_{(1)}
$$

Because

$$
\frac{\partial^{2} \log L}{\partial \lambda^{2}}=\frac{n}{\lambda^{2}}-\left.2 \frac{\sum_{i} x_{i}-n \hat{\theta}}{\lambda^{3}}\right|_{\bar{x}-x_{(1)}}=\frac{n}{\left(\bar{x}-x_{(1)}\right)^{2}}-\frac{2 n\left(\bar{x}-x_{(1)}\right)}{\left(\bar{x}-x_{(1)}\right)^{3}}=\frac{-n}{\left(\bar{x}-x_{(1)}\right)^{2}}<0
$$

we have $\hat{\theta}=x_{(1)}$ and $\hat{\lambda}=\bar{x}-x_{(1)}$ as the unrestricted MLEs of $\theta$ and $\lambda$. Under the restriction $\theta \leq 0$, the MLE of $\theta$ (regardless of $\lambda$ ) is

$$
\hat{\theta}_{0}= \begin{cases}0 & \text { if } x_{(1)}>0 \\ x_{(1)} & \text { if } x_{(1)} \leq 0\end{cases}
$$

For $x_{(1)}>0$, substituting $\hat{\theta}_{0}=0$ and maximizing with respect to $\lambda$, as above, yields $\hat{\lambda}_{0}=\bar{x}$. Therefore,

$$
\lambda(\mathbf{x})=\frac{\sup _{\Theta_{0}} L(\theta, \lambda \mid \mathbf{x})}{\sup _{\Theta} L(\theta, \lambda \mid \mathbf{x})}=\frac{\sup _{\{(\lambda, \theta): \theta \leq 0\}} L(\lambda, \theta \mid \mathbf{x})}{L(\hat{\theta}, \hat{\lambda} \mid \mathbf{x})}= \begin{cases}1 & \text { if } x_{(1)} \leq 0 \\ \frac{L(\bar{x}, 0 \mid \mathbf{x})}{L(\hat{\lambda}, \hat{\theta} \mid \mathbf{x})} & \text { if } x_{(1)}>0\end{cases}
$$

where

$$
\frac{L(\bar{x}, 0 \mid \mathbf{x})}{L(\hat{\lambda}, \hat{\theta} \mid \mathbf{x})}=\frac{(1 / \bar{x})^{n} e^{-n \bar{x} / \bar{x}}}{(1 / \hat{\lambda})^{n} e^{-n\left(\bar{x}-x_{(1)}\right) /\left(\bar{x}-x_{(1)}\right)}}=\left(\frac{\hat{\lambda}}{\bar{x}}\right)^{n}=\left(\frac{\bar{x}-x_{(1)}}{\bar{x}}\right)^{n}=\left(1-\frac{x_{(1)}}{\bar{x}}\right)^{n}
$$

So rejecting if $\lambda(\mathbf{x}) \leq c$ is equivalent to rejecting if $x_{(1)} / \bar{x} \geq c^{*}$, where $c^{*}$ is some constant.
b. The LRT statistic is

$$
\lambda(\mathbf{x})=\frac{\sup _{\beta}\left(1 / \beta^{n}\right) e^{-\Sigma_{i} x_{i} / \beta}}{\sup _{\beta, \gamma}\left(\gamma^{n} / \beta^{n}\right)\left(\prod_{i} x_{i}\right)^{\gamma-1} e^{-\Sigma_{i} x_{i}^{\gamma} / \beta}}
$$

The numerator is maximized at $\hat{\beta}_{0}=\bar{x}$. For fixed $\gamma$, the denominator is maximized at $\hat{\beta}_{\gamma}=\sum_{i} x_{i}^{\gamma} / n$. Thus

$$
\lambda(\mathbf{x})=\frac{\bar{x}^{-n} e^{-n}}{\sup _{\gamma}\left(\gamma^{n} / \hat{\beta}_{\gamma}^{n}\right)\left(\prod_{i} x_{i}\right)^{\gamma-1} e^{-\Sigma_{i} x_{i}^{\gamma} / \hat{\beta}_{\gamma}}}=\frac{\bar{x}^{-n}}{\sup _{\gamma}\left(\gamma^{n} / \hat{\beta}_{\gamma}^{n}\right)\left(\prod_{i} x_{i}\right)^{\gamma-1}} .
$$

The denominator cannot be maximized in closed form. Numeric maximization could be used to compute the statistic for observed data $\mathbf{x}$.
8.8 a. We will first find the MLEs of $a$ and $\theta$. We have

$$
\begin{aligned}
L(a, \theta \mid \mathbf{x}) & =\prod_{i=1}^{n} \frac{1}{\sqrt{2 \pi a \theta}} e^{-\left(x_{i}-\theta\right)^{2} /(2 a \theta)} \\
\log L(a, \theta \mid \mathbf{x}) & =\sum_{i=1}^{n}-\frac{1}{2} \log (2 \pi a \theta)-\frac{1}{2 a \theta}\left(x_{i}-\theta\right)^{2}
\end{aligned}
$$

Thus

$$
\begin{aligned}
\frac{\partial \log L}{\partial a} & =\sum_{i=1}^{n}\left(-\frac{1}{2 a}+\frac{1}{2 \theta a^{2}}\left(x_{i}-\theta\right)^{2}\right)=-\frac{n}{2 a}+\frac{1}{2 \theta a^{2}} \sum_{i=1}^{n}\left(x_{i}-\theta\right)^{2} \stackrel{\text { set }}{=} 0 \\
\frac{\partial \log L}{\partial \theta} & =\sum_{i=1}^{n}\left[-\frac{1}{2 \theta}+\frac{1}{2 a \theta^{2}}\left(x_{i}-\theta\right)^{2}+\frac{1}{a \theta}\left(x_{i}-\theta\right)\right] \\
& =-\frac{n}{2 \theta}+\frac{1}{2 a \theta^{2}} \sum_{i=1}^{n}\left(x_{i}-\theta\right)^{2}+\frac{n \bar{x}-n \theta}{a \theta} \stackrel{\text { set }}{=} 0 .
\end{aligned}
$$

We have to solve these two equations simultaneously to get MLEs of $a$ and $\theta$, say $\hat{a}$ and $\hat{\theta}$. Solve the first equation for $a$ in terms of $\theta$ to get

$$
a=\frac{1}{n \theta} \sum_{i=1}^{n}\left(x_{i}-\theta\right)^{2} .
$$

Substitute this into the second equation to get

$$
-\frac{n}{2 \theta}+\frac{n}{2 \theta}+\frac{n(\bar{x}-\theta)}{a \theta}=0 .
$$

So we get $\hat{\theta}=\bar{x}$, and

$$
\hat{a}=\frac{1}{n \bar{x}} \sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2}=\frac{\hat{\sigma}^{2}}{\bar{x}},
$$

the ratio of the usual MLEs of the mean and variance. (Verification that this is a maximum is lengthy. We omit it.) For $a=1$, we just solve the second equation, which gives a quadratic in $\theta$ that leads to the restricted MLE

$$
\hat{\theta}_{R}=\frac{-1+\sqrt{1+4\left(\hat{\sigma}^{2}+\bar{x}^{2}\right)}}{2}
$$

Noting that $\hat{a} \hat{\theta}=\hat{\sigma}^{2}$, we obtain

$$
\begin{aligned}
\lambda(\mathbf{x}) & =\frac{L\left(\hat{\theta}_{R} \mid \mathbf{x}\right)}{L(\hat{a}, \hat{\theta} \mid \mathbf{x})}=\frac{\prod_{i=1}^{n} \frac{1}{\sqrt{2 \pi \hat{\theta}_{R}}} e^{-\left(x_{i}-\hat{\theta}_{R}\right)^{2} /\left(2 \hat{\theta}_{R}\right)}}{\prod_{i=1}^{n} \frac{1}{\sqrt{2 \pi \hat{a} \hat{\theta}}} e^{-\left(x_{i}-\hat{\theta}\right)^{2} /(2 \hat{\theta} \hat{\theta})}} \\
& =\frac{\left(1 /\left(2 \pi \hat{\theta}_{R}\right)\right)^{n / 2} e^{-\Sigma_{i}\left(x_{i}-\hat{\theta}_{R}\right)^{2} /\left(2 \hat{\theta}_{R}\right)}}{\left(1 /\left(2 \pi \hat{\sigma}^{2}\right)\right)^{n / 2} e^{-\Sigma_{i}\left(x_{i}-\bar{x}\right)^{2} /\left(2 \hat{\sigma}^{2}\right)}} \\
& =\left(\hat{\sigma}^{2} / \hat{\theta}_{R}\right)^{n / 2} e^{(n / 2)-\Sigma_{i}\left(x_{i}-\hat{\theta}_{R}\right)^{2} /\left(2 \hat{\theta}_{R}\right)}
\end{aligned}
$$

b. In this case we have

$$
\log L(a, \theta \mid \mathbf{x})=\sum_{i=1}^{n}\left[-\frac{1}{2} \log \left(2 \pi a \theta^{2}\right)-\frac{1}{2 a \theta^{2}}\left(x_{i}-\theta\right)^{2}\right]
$$

Thus

$$
\begin{aligned}
\frac{\partial \log L}{\partial a} & =\sum_{i=1}^{n}\left(-\frac{1}{2 a}+\frac{1}{2 a^{2} \theta^{2}}\left(x_{i}-\theta\right)^{2}\right)=-\frac{n}{2 a}+\frac{1}{2 a^{2} \theta^{2}} \sum_{i=1}^{n}\left(x_{i}-\theta\right)^{2} \stackrel{\text { set }}{=} 0 . \\
\frac{\partial \log L}{\partial \theta} & =\sum_{i=1}^{n}\left[-\frac{1}{\theta}+\frac{1}{a \theta^{3}}\left(x_{i}-\theta\right)^{2}+\frac{1}{a \theta^{2}}\left(x_{i}-\theta\right)\right] \\
& =-\frac{n}{\theta}+\frac{1}{a \theta^{3}} \sum_{i=1}^{n}\left(x_{i}-\theta\right)^{2}+\frac{1}{a \theta^{2}} \sum_{i=1}^{n}\left(x_{i}-\theta\right) \stackrel{\text { set }}{=} 0
\end{aligned}
$$

Solving the first equation for $a$ in terms of $\theta$ yields

$$
a=\frac{1}{n \theta^{2}} \sum_{i=1}^{n}\left(x_{i}-\theta\right)^{2}
$$

Substituting this into the second equation, we get

$$
-\frac{n}{\theta}+\frac{n}{\theta}+n \frac{\sum_{i}\left(x_{i}-\theta\right)}{\sum_{i}\left(x_{i}-\theta\right)^{2}}=0
$$

So again, $\hat{\theta}=\bar{x}$ and

$$
\hat{a}=\frac{1}{n \bar{x}^{2}} \sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2}=\frac{\hat{\sigma}^{2}}{\bar{x}^{2}}
$$

in the unrestricted case. In the restricted case, set $a=1$ in the second equation to obtain

$$
\frac{\partial \log L}{\partial \theta}=-\frac{n}{\theta}+\frac{1}{\theta^{3}} \sum_{i=1}^{n}\left(x_{i}-\theta\right)^{2}+\frac{1}{\theta^{2}} \sum_{i=1}^{n}\left(x_{i}-\theta\right) \stackrel{\text { set }}{=} 0 .
$$

Multiply through by $\theta^{3} / n$ to get

$$
-\theta^{2}+\frac{1}{n} \sum_{i=1}^{n}\left(x_{i}-\theta\right)^{2}-\frac{\theta}{n} \sum_{i=1}^{n}\left(x_{i}-\theta\right)=0
$$

Add $\pm \bar{x}$ inside the square and complete all sums to get the equation

$$
-\theta^{2}+\hat{\sigma}^{2}+(\bar{x}-\theta)^{2}+\theta(\bar{x}-\theta)=0
$$

This is a quadratic in $\theta$ with solution for the MLE

$$
\hat{\theta}_{R}=\bar{x}+\sqrt{\bar{x}+4\left(\hat{\sigma}^{2}+\bar{x}^{2}\right)} / 2
$$

which yields the LRT statistic

$$
\lambda(\mathbf{x})=\frac{L\left(\hat{\theta}_{R} \mid \mathbf{x}\right)}{L(\hat{a}, \hat{\theta} \mid \mathbf{x})}=\frac{\prod_{i=1}^{n} \frac{1}{\sqrt{2 \pi \hat{\theta}_{R}^{2}}} e^{-\left(x_{i}-\hat{\theta}_{R}\right)^{2} /\left(2 \hat{\theta}_{R}^{2}\right)}}{\prod_{i=1}^{n} \frac{1}{\sqrt{2 \pi \hat{a} \hat{\theta}^{2}}} e^{-\left(x_{i}-\hat{\theta}\right)^{2} /\left(2 \hat{a} \hat{\theta}^{2}\right)}}=\left(\frac{\hat{\sigma}}{\hat{\theta}_{R}}\right)^{n} e^{(n / 2)-\Sigma_{i}\left(x_{i}-\hat{\theta}_{R}\right)^{2} /\left(2 \hat{\theta}_{R}\right)}
$$

8.9 a. The MLE of $\lambda$ under $H_{0}$ is $\hat{\lambda}_{0}=(\bar{Y})^{-1}$, and the MLE of $\lambda_{i}$ under $H_{1}$ is $\hat{\lambda}_{i}=Y_{i}^{-1}$. The LRT statistic is bounded above by 1 and is given by

$$
1 \geq \frac{(\bar{Y})^{-n} e^{-n}}{\left(\prod_{i} Y_{i}\right)^{-1} e^{-n}}
$$

Rearrangement of this inequality yields $\bar{Y} \geq\left(\prod_{i} Y_{i}\right)^{1 / n}$, the arithmetic-geometric mean inequality.
b. The pdf of $X_{i}$ is $f\left(x_{i} \mid \lambda_{i}\right)=\left(\lambda_{i} / x_{i}^{2}\right) e^{-\lambda_{i} / x_{i}}, x_{i}>0$. The MLE of $\lambda$ under $H_{0}$ is $\hat{\lambda}_{0}=$ $n /\left[\sum_{i}\left(1 / X_{i}\right)\right]$, and the MLE of $\lambda_{i}$ under $H_{1}$ is $\hat{\lambda}_{i}=X_{i}$. Now, the argument proceeds as in part (a).
8.10 Let $Y=\sum_{i} X_{i}$. The posterior distribution of $\lambda \mid y$ is gamma $(y+\alpha, \beta /(\beta+1))$.
a.

$$
P\left(\lambda \leq \lambda_{0} \mid y\right)=\frac{(\beta+1)^{y+\alpha}}{\Gamma(y+\alpha) \beta^{y+\alpha}} \int_{0}^{\lambda_{0}} t^{y+\alpha-1} e^{-t(\beta+1) / \beta} d t
$$

$P\left(\lambda>\lambda_{0} \mid y\right)=1-P\left(\lambda \leq \lambda_{0} \mid y\right)$.
b. Because $\beta /(\beta+1)$ is a scale parameter in the posterior distribution, $(2(\beta+1) \lambda / \beta) \mid y$ has a gamma $(y+\alpha, 2)$ distribution. If $2 \alpha$ is an integer, this is a $\chi_{2 y+2 \alpha}^{2}$ distribution. So, for $\alpha=5 / 2$ and $\beta=2$,

$$
P\left(\lambda \leq \lambda_{0} \mid y\right)=P\left(\left.\frac{2(\beta+1) \lambda}{\beta} \leq \frac{2(\beta+1) \lambda_{0}}{\beta} \right\rvert\, y\right)=P\left(\chi_{2 y+5}^{2} \leq 3 \lambda_{0}\right)
$$

8.11 a. From Exercise 7.23 , the posterior distribution of $\sigma^{2}$ given $S^{2}$ is $\operatorname{IG}(\gamma, \delta)$, where $\gamma=\alpha+(n-$ 1) $/ 2$ and $\delta=\left[(n-1) S^{2} / 2+1 / \beta\right]^{-1}$. Let $Y=2 /\left(\sigma^{2} \delta\right)$. Then $Y \mid S^{2} \sim \operatorname{gamma}(\gamma, 2)$. (Note: If $2 \alpha$ is an integer, this is a $\chi_{2 \gamma}^{2}$ distribution.) Let $M$ denote the median of a gamma $(\gamma, 2)$ distribution. Note that $M$ depends on only $\alpha$ and $n$, not on $S^{2}$ or $\beta$. Then we have $P(Y \geq$ $\left.2 / \delta \mid S^{2}\right)=P\left(\sigma^{2} \leq 1 \mid S^{2}\right)>1 / 2$ if and only if

$$
M>\frac{2}{\delta}=(n-1) S^{2}+\frac{2}{\beta}, \quad \text { that is }, \quad S^{2}<\frac{M-2 / \beta}{n-1}
$$

b. From Example 7.2.11, the unrestricted MLEs are $\hat{\mu}=\bar{X}$ and $\hat{\sigma}^{2}=(n-1) S^{2} / n$. Under $H_{0}$, $\hat{\mu}$ is still $\bar{X}$, because this was the maximizing value of $\mu$, regardless of $\sigma^{2}$. Then because $L\left(\bar{x}, \sigma^{2} \mid \mathbf{x}\right)$ is a unimodal function of $\sigma^{2}$, the restricted MLE of $\sigma^{2}$ is $\hat{\sigma}^{2}$, if $\hat{\sigma}^{2} \leq 1$, and is 1 , if $\hat{\sigma}^{2}>1$. So the LRT statistic is

$$
\lambda(\mathbf{x})= \begin{cases}1 & \text { if } \hat{\sigma}^{2} \leq 1 \\ \left(\hat{\sigma}^{2}\right)^{n / 2} e^{-n\left(\hat{\sigma}^{2}-1\right) / 2} & \text { if } \hat{\sigma}^{2}>1\end{cases}
$$

We have that, for $\hat{\sigma}^{2}>1$,

$$
\frac{\partial}{\partial\left(\hat{\sigma}^{2}\right)} \log \lambda(\mathbf{x})=\frac{n}{2}\left(\frac{1}{\hat{\sigma}^{2}}-1\right)<0
$$

So $\lambda(\mathbf{x})$ is decreasing in $\hat{\sigma}^{2}$, and rejecting $H_{0}$ for small values of $\lambda(\mathbf{x})$ is equivalent to rejecting for large values of $\hat{\sigma}^{2}$, that is, large values of $S^{2}$. The LRT accepts $H_{0}$ if and only if $S^{2}<k$, where $k$ is a constant. We can pick the prior parameters so that the acceptance regions match in this way. First, pick $\alpha$ large enough that $M /(n-1)>k$. Then, as $\beta$ varies between 0 and $\infty,(M-2 / \beta) /(n-1)$ varies between $-\infty$ and $M /(n-1)$. So, for some choice of $\beta$, $(M-2 / \beta) /(n-1)=k$ and the acceptance regions match.
8.12 a. For $H_{0}: \mu \leq 0$ vs. $H_{1}: \mu>0$ the LRT is to reject $H_{0}$ if $\bar{x}>c \sigma / \sqrt{n}$ (Example 8.3.3). For $\alpha=.05$ take $c=1.645$. The power function is

$$
\beta(\mu)=P\left(\frac{\bar{X}-\mu}{\sigma / \sqrt{n}}>1.645-\frac{\mu}{\sigma / \sqrt{n}}\right)=P\left(Z>1.645-\frac{\sqrt{n} \mu}{\sigma}\right)
$$

Note that the power will equal .5 when $\mu=1.645 \sigma / \sqrt{n}$.
b. For $H_{0}: \mu=0$ vs. $H_{A}: \mu \neq 0$ the LRT is to reject $H_{0}$ if $|\bar{x}|>c \sigma / \sqrt{n}$ (Example 8.2.2). For $\alpha=.05$ take $c=1.96$. The power function is

$$
\beta(\mu)=P(-1.96-\sqrt{n} \mu / \sigma \leq Z \leq 1.96+\sqrt{n} \mu / \sigma) .
$$

In this case, $\mu= \pm 1.96 \sigma / \sqrt{n}$ gives power of approximately .5.
8.13 a. The size of $\phi_{1}$ is $\alpha_{1}=P\left(X_{1}>.95 \mid \theta=0\right)=.05$. The size of $\phi_{2}$ is $\alpha_{2}=P\left(X_{1}+X_{2}>C \mid \theta=0\right)$. If $1 \leq C \leq 2$, this is

$$
\alpha_{2}=P\left(X_{1}+X_{2}>C \mid \theta=0\right)=\int_{1-C}^{1} \int_{C-x_{1}}^{1} 1 d x_{2} d x_{1}=\frac{(2-C)^{2}}{2}
$$

Setting this equal to $\alpha$ and solving for $C$ gives $C=2-\sqrt{2 \alpha}$, and for $\alpha=.05$, we get $C=2-\sqrt{.1} \approx 1.68$.
b. For the first test we have the power function

$$
\beta_{1}(\theta)=P_{\theta}\left(X_{1}>.95\right)= \begin{cases}0 & \text { if } \theta \leq-.05 \\ \theta+.05 & \text { if }-.05<\theta \leq .95 \\ 1 & \text { if } .95<\theta\end{cases}
$$

Using the distribution of $Y=X_{1}+X_{2}$, given by

$$
f_{Y}(y \mid \theta)= \begin{cases}y-2 \theta & \text { if } 2 \theta \leq y<2 \theta+1 \\ 2 \theta+2-y & \text { if } 2 \theta+1 \leq y<2 \theta+2 \\ 0 & \text { otherwise }\end{cases}
$$

we obtain the power function for the second test as

$$
\beta_{2}(\theta)=P_{\theta}(Y>C)= \begin{cases}0 & \text { if } \theta \leq(C / 2)-1 \\ (2 \theta+2-C)^{2} / 2 & \text { if }(C / 2)-1<\theta \leq(C-1) / 2 \\ 1-(C-2 \theta)^{2} / 2 & \text { if }(C-1) / 2<\theta \leq C / 2 \\ 1 & \text { if } C / 2<\theta\end{cases}
$$

c. From the graph it is clear that $\phi_{1}$ is more powerful for $\theta$ near 0 , but $\phi_{2}$ is more powerful for larger $\theta \mathrm{s}$. $\phi_{2}$ is not uniformly more powerful than $\phi_{1}$.
d. If either $X_{1} \geq 1$ or $X_{2} \geq 1$, we should reject $H_{0}$, because if $\theta=0, P\left(X_{i}<1\right)=1$. Thus, consider the rejection region given by

$$
\left\{\left(x_{1}, x_{2}\right): x_{1}+x_{2}>C\right\} \bigcup\left\{\left(x_{1}, x_{2}\right): x_{1}>1\right\} \bigcup\left\{\left(x_{1}, x_{2}\right): x_{2}>1\right\}
$$

The first set is the rejection region for $\phi_{2}$. The test with this rejection region has the same size as $\phi_{2}$ because the last two sets both have probability 0 if $\theta=0$. But for $0<\theta<C-1$, The power function of this test is strictly larger than $\beta_{2}(\theta)$. If $C-1 \leq \theta$, this test and $\phi_{2}$ have the same power.
8.14 The CLT tells us that $Z=\left(\sum_{i} X_{i}-n p\right) / \sqrt{n p(1-p)}$ is approximately $\mathrm{n}(0,1)$. For a test that rejects $H_{0}$ when $\sum_{i} X_{i}>c$, we need to find $c$ and $n$ to satisfy

$$
P\left(Z>\frac{c-n(.49)}{\sqrt{n(.49)(.51)}}\right)=.01 \quad \text { and } \quad P\left(Z>\frac{c-n(.51)}{\sqrt{n(.51)(.49)}}\right)=.99
$$

We thus want

$$
\frac{c-n(.49)}{\sqrt{n(.49)(.51)}}=2.33 \quad \text { and } \quad \frac{c-n(.51)}{\sqrt{n(.51)(.49)}}=-2.33 .
$$

Solving these equations gives $n=13,567$ and $c=6,783.5$.
8.15 From the Neyman-Pearson lemma the UMP test rejects $H_{0}$ if

$$
\frac{f\left(x \mid \sigma_{1}\right)}{f\left(x \mid \sigma_{0}\right)}=\frac{\left(2 \pi \sigma_{1}^{2}\right)^{-n / 2} e^{-\Sigma_{i} x_{i}^{2} /\left(2 \sigma_{1}^{2}\right)}}{\left(2 \pi \sigma_{0}^{2}\right)^{-n / 2} e^{-\Sigma_{i} x_{i}^{2} /\left(2 \sigma_{0}^{2}\right)}}=\left(\frac{\sigma_{0}}{\sigma_{1}}\right)^{n} \exp \left\{\frac{1}{2} \sum_{i} x_{i}^{2}\left(\frac{1}{\sigma_{0}^{2}}-\frac{1}{\sigma_{1}^{2}}\right)\right\}>k
$$

for some $k \geq 0$. After some algebra, this is equivalent to rejecting if

$$
\sum_{i} x_{i}^{2}>\frac{2 \log \left(k\left(\sigma_{1} / \sigma_{0}\right)^{n}\right)}{\left(\frac{1}{\sigma_{0}^{2}}-\frac{1}{\sigma_{1}^{2}}\right)}=c \quad\left(\text { because } \frac{1}{\sigma_{0}^{2}}-\frac{1}{\sigma_{1}^{2}}>0\right)
$$

This is the UMP test of size $\alpha$, where $\alpha=P_{\sigma_{0}}\left(\sum_{i} X_{i}^{2}>c\right)$. To determine $c$ to obtain a specified $\alpha$, use the fact that $\sum_{i} X_{i}^{2} / \sigma_{0}^{2} \sim \chi_{n}^{2}$. Thus

$$
\alpha=P_{\sigma_{0}}\left(\sum_{i} X_{i}^{2} / \sigma_{0}^{2}>c / \sigma_{0}^{2}\right)=P\left(\chi_{n}^{2}>c / \sigma_{0}^{2}\right),
$$

so we must have $c / \sigma_{0}^{2}=\chi_{n, \alpha}^{2}$, which means $c=\sigma_{0}^{2} \chi_{n, \alpha}^{2}$.
8.16 a.

$$
\begin{aligned}
\text { Size } & =P\left(\text { reject } H_{0} \mid H_{0} \text { is true }\right)=1 \Rightarrow \text { Type I error }=1 \\
\text { Power } & =P\left(\text { reject } H_{0} \mid H_{A} \text { is true }\right)=1 \Rightarrow \text { Type II error }=0 .
\end{aligned}
$$

b.

$$
\begin{aligned}
\text { Size } & =P\left(\text { reject } H_{0} \mid H_{0} \text { is true }\right)=0 \Rightarrow \text { Type I error }=0 . \\
\text { Power } & =P\left(\text { reject } H_{0} \mid H_{A} \text { is true }\right)=0 \Rightarrow \text { Type II error }=1 .
\end{aligned}
$$

8.17 a. The likelihood function is

$$
L(\mu, \theta \mid \mathbf{x}, \mathbf{y})=\mu^{n}\left(\prod_{i} x_{i}\right)^{\mu-1} \theta^{n}\left(\prod_{j} y_{j}\right)^{\theta-1}
$$

Maximizing, by differentiating the log-likelihood, yields the MLEs

$$
\hat{\mu}=-\frac{n}{\sum_{i} \log x_{i}} \quad \text { and } \quad \hat{\theta}=-\frac{m}{\sum_{j} \log y_{j}} .
$$

Under $H_{0}$, the likelihood is

$$
L(\theta \mid \mathbf{x}, \mathbf{y})=\theta^{n+m}\left(\prod_{i} x_{i} \prod_{j} y_{j}\right)^{\theta-1}
$$

and maximizing as above yields the restricted MLE,

$$
\hat{\theta}_{0}=-\frac{n+m}{\sum_{i} \log x_{i}+\sum_{j} \log y_{j}}
$$

The LRT statistic is

$$
\lambda(\mathbf{x}, \mathbf{y})=\frac{\hat{\theta}_{0}^{m+n}}{\hat{\mu}^{n} \hat{\theta}^{m}}\left(\prod_{i} x_{i}\right)^{\hat{\theta}_{0}-\hat{\mu}}\left(\prod_{j} y_{j}\right)^{\hat{\theta}_{0}-\hat{\theta}}
$$

b. Substituting in the formulas for $\hat{\theta}, \hat{\mu}$ and $\hat{\theta}_{0}$ yields $\left(\prod_{i} x_{i}\right)^{\hat{\theta}_{0}-\hat{\mu}}\left(\prod_{j} y_{j}\right)^{\hat{\theta}_{0}-\hat{\theta}}=1$ and

$$
\lambda(\mathbf{x}, \mathbf{y})=\frac{\hat{\theta}_{0}^{m+n}}{\hat{\mu}^{n} \hat{\theta}^{m}}=\frac{\hat{\theta}_{0}^{n}}{\hat{\mu}^{n}} \frac{\hat{\theta}_{0}^{m}}{\hat{\theta}^{m}}=\left(\frac{m+n}{m}\right)^{m}\left(\frac{m+n}{n}\right)^{n}(1-T)^{m} T^{n}
$$

This is a unimodal function of $T$. So rejecting if $\lambda(\mathbf{x}, \mathbf{y}) \leq c$ is equivalent to rejecting if $T \leq c_{1}$ or $T \geq c_{2}$, where $c_{1}$ and $c_{2}$ are appropriately chosen constants.
c. Simple transformations yield $-\log X_{i} \sim \operatorname{exponential}(1 / \mu)$ and $-\log Y_{i} \sim \operatorname{exponential}(1 / \theta)$. Therefore, $T=W /(W+V)$ where $W$ and $V$ are independent, $W \sim \operatorname{gamma}(n, 1 / \mu)$ and $V \sim \operatorname{gamma}(m, 1 / \theta)$. Under $H_{0}$, the scale parameters of $W$ and $V$ are equal. Then, a simple generalization of Exercise 4.19 b yields $T \sim \operatorname{beta}(n, m)$. The constants $c_{1}$ and $c_{2}$ are determined by the two equations

$$
P\left(T \leq c_{1}\right)+P\left(T \geq c_{2}\right)=\alpha \quad \text { and } \quad\left(1-c_{1}\right)^{m} c_{1}^{n}=\left(1-c_{2}\right)^{m} c_{2}^{n}
$$

8.18 a.

$$
\begin{aligned}
\beta(\theta) & =P_{\theta}\left(\frac{\left|\bar{X}-\theta_{0}\right|}{\sigma / \sqrt{n}}>c\right)=1-P_{\theta}\left(\frac{\left|\bar{X}-\theta_{0}\right|}{\sigma / \sqrt{n}} \leq c\right) \\
& =1-P_{\theta}\left(-\frac{c \sigma}{\sqrt{n}} \leq \bar{X}-\theta_{0} \leq \frac{c \sigma}{\sqrt{n}}\right) \\
& =1-P_{\theta}\left(\frac{-c \sigma / \sqrt{n}+\theta_{0}-\theta}{\sigma / \sqrt{n}} \leq \frac{\bar{X}-\theta}{\sigma / \sqrt{n}} \leq \frac{c \sigma / \sqrt{n}+\theta_{0}-\theta}{\sigma / \sqrt{n}}\right) \\
& =1-P\left(-c+\frac{\theta_{0}-\theta}{\sigma / \sqrt{n}} \leq Z \leq c+\frac{\theta_{0}-\theta}{\sigma / \sqrt{n}}\right) \\
& =1+\Phi\left(-c+\frac{\theta_{0}-\theta}{\sigma / \sqrt{n}}\right)-\Phi\left(c+\frac{\theta_{0}-\theta}{\sigma / \sqrt{n}}\right)
\end{aligned}
$$

where $Z \sim \mathrm{n}(0,1)$ and $\Phi$ is the standard normal cdf.
b. The size is $.05=\beta\left(\theta_{0}\right)=1+\Phi(-c)-\Phi(c)$ which implies $c=1.96$. The power $(1-$ type II error) is

$$
.75 \leq \beta\left(\theta_{0}+\sigma\right)=1+\Phi(-c-\sqrt{n})-\Phi(c-\sqrt{n})=1+\underbrace{\Phi(-1.96-\sqrt{n})}_{\approx 0}-\Phi(1.96-\sqrt{n})
$$

$\Phi(-.675) \approx .25$ implies $1.96-\sqrt{n}=-.675$ implies $n=6.943 \approx 7$.
8.19 The pdf of $Y$ is

$$
f(y \mid \theta)=\frac{1}{\theta} y^{(1 / \theta)-1} e^{-y^{1 / \theta}}, \quad y>0
$$

By the Neyman-Pearson Lemma, the UMP test will reject if

$$
\frac{1}{2} y^{-1 / 2} e^{y-y^{1 / 2}}=\frac{f(y \mid 2)}{f(y \mid 1)}>k
$$

To see the form of this rejection region, we compute

$$
\frac{d}{d y}\left(\frac{1}{2} y^{-1 / 2} e^{y-y^{1 / 2}}\right)=\frac{1}{2} y^{-3 / 2} e^{y-y^{1 / 2}}\left(y-\frac{y^{1 / 2}}{2}-\frac{1}{2}\right)
$$

which is negative for $y<1$ and positive for $y>1$. Thus $f(y \mid 2) / f(y \mid 1)$ is decreasing for $y \leq 1$ and increasing for $y \geq 1$. Hence, rejecting for $f(y \mid 2) / f(y \mid 1)>k$ is equivalent to rejecting for $y \leq c_{0}$ or $y \geq c_{1}$. To obtain a size $\alpha$ test, the constants $c_{0}$ and $c_{1}$ must satisfy

$$
\alpha=P\left(Y \leq c_{0} \mid \theta=1\right)+P\left(Y \geq c_{1} \mid \theta=1\right)=1-e^{-c_{0}}+e^{-c_{1}} \quad \text { and } \quad \frac{f\left(c_{0} \mid 2\right)}{f\left(c_{0} \mid 1\right)}=\frac{f\left(c_{1} \mid 2\right)}{f\left(c_{1} \mid 1\right)}
$$

Solving these two equations numerically, for $\alpha=.10$, yields $c_{0}=.076546$ and $c_{1}=3.637798$. The Type II error probability is

$$
P\left(c_{0}<Y<c_{1} \mid \theta=2\right)=\int_{c_{0}}^{c_{1}} \frac{1}{2} y^{-1 / 2} e^{-y^{1 / 2}} d y=-\left.e^{-y^{1 / 2}}\right|_{c_{0}} ^{c_{1}}=.609824
$$

8.20 By the Neyman-Pearson Lemma, the UMP test rejects for large values of $f\left(x \mid H_{1}\right) / f\left(x \mid H_{0}\right)$. Computing this ratio we obtain

$$
\begin{array}{cccccccc}
x & 1 & 2 & 3 & 4 & 5 & 6 & 7 \\
\hline \frac{f\left(x \mid H_{1}\right)}{f\left(x \mid H_{0}\right)} & 6 & 5 & 4 & 3 & 2 & 1 & .84
\end{array}
$$

The ratio is decreasing in $x$. So rejecting for large values of $f\left(x \mid H_{1}\right) / f\left(x \mid H_{0}\right)$ corresponds to rejecting for small values of $x$. To get a size $\alpha$ test, we need to choose $c$ so that $P(X \leq$ $\left.c \mid H_{0}\right)=\alpha$. The value $c=4$ gives the UMP size $\alpha=.04$ test. The Type II error probability is $P\left(X=5,6,7 \mid H_{1}\right)=.82$.
8.21 The proof is the same with integrals replaced by sums.
8.22 a. From Corollary 8.3 .13 we can base the test on $\sum_{i} X_{i}$, the sufficient statistic. Let $Y=$ $\sum_{i} X_{i} \sim \operatorname{binomial}(10, p)$ and let $f(y \mid p)$ denote the pmf of $Y$. By Corollary 8.3.13, a test that rejects if $f(y \mid 1 / 4) / f(y \mid 1 / 2)>k$ is UMP of its size. By Exercise 8.25 c, the ratio $f(y \mid 1 / 2) / f(y \mid 1 / 4)$ is increasing in $y$. So the ratio $f(y \mid 1 / 4) / f(y \mid 1 / 2)$ is decreasing in $y$, and rejecting for large value of the ratio is equivalent to rejecting for small values of $y$. To get $\alpha=.0547$, we must find $c$ such that $P(Y \leq c \mid p=1 / 2)=.0547$. Trying values $c=0,1, \ldots$, we find that for $c=2, P(Y \leq 2 \mid p=1 / 2)=.0547$. So the test that rejects if $Y \leq 2$ is the UMP size $\alpha=.0547$ test. The power of the test is $P(Y \leq 2 \mid p=1 / 4) \approx .526$.
b. The size of the test is $P(Y \geq 6 \mid p=1 / 2)=\sum_{k=6}^{10}\binom{10}{k}\left(\frac{1}{2}\right)^{k}\left(\frac{1}{2}\right)^{10-k} \approx .377$. The power function is $\beta(\theta)=\sum_{k=6}^{10}\binom{10}{k} \theta^{k}(1-\theta)^{10-k}$
c. There is a nonrandomized UMP test for all $\alpha$ levels corresponding to the probabilities $P(Y \leq i \mid p=1 / 2)$, where $i$ is an integer. For $n=10, \alpha$ can have any of the values 0 , $\frac{1}{1024}, \frac{11}{1024}, \frac{56}{1024}, \frac{176}{1024}, \frac{386}{1024}, \frac{638}{1024}, \frac{848}{1024}, \frac{968}{1024}, \frac{1013}{1024}, \frac{1023}{1024}$, and 1.
8.23 a . The test is Reject $H_{0}$ if $X>1 / 2$. So the power function is

$$
\beta(\theta)=P_{\theta}(X>1 / 2)=\int_{1 / 2}^{1} \frac{\Gamma(\theta+1)}{\Gamma(\theta) \Gamma(1)} x^{\theta-1}(1-x)^{1-1} d x=\left.\theta \frac{1}{\theta} x^{\theta}\right|_{1 / 2} ^{1}=1-\frac{1}{2^{\theta}}
$$

The size is $\sup _{\theta \in H_{0}} \beta(\theta)=\sup _{\theta \leq 1}\left(1-1 / 2^{\theta}\right)=1-1 / 2=1 / 2$.
b. By the Neyman-Pearson Lemma, the most powerful test of $H_{0}: \theta=1$ vs. $H_{1}: \theta=2$ is given by Reject $H_{0}$ if $f(x \mid 2) / f(x \mid 1)>k$ for some $k \geq 0$. Substituting the beta pdf gives

$$
\frac{f(x \mid 2)}{f(x \mid 1)}=\frac{\frac{1}{\beta(2,1)} x^{2-1}(1-x)^{1-1}}{\frac{1}{\beta(1,1)} x^{1-1}(1-x)^{1-1}}=\frac{\Gamma(3)}{\Gamma(2) \Gamma(1)} x=2 x .
$$

Thus, the MP test is Reject $H_{0}$ if $X>k / 2$. We now use the $\alpha$ level to determine $k$. We have

$$
\alpha=\sup _{\theta \in \Theta_{0}} \beta(\theta)=\beta(1)=\int_{k / 2}^{1} f_{X}(x \mid 1) d x=\int_{k / 2}^{1} \frac{1}{\beta(1,1)} x^{1-1}(1-x)^{1-1} d x=1-\frac{k}{2}
$$

Thus $1-k / 2=\alpha$, so the most powerful $\alpha$ level test is reject $H_{0}$ if $X>1-\alpha$.
c. For $\theta_{2}>\theta_{1}, f\left(x \mid \theta_{2}\right) / f\left(x \mid \theta_{1}\right)=\left(\theta_{2} / \theta_{1}\right) x^{\theta_{2}-\theta_{1}}$, an increasing function of $x$ because $\theta_{2}>\theta_{1}$. So this family has MLR. By the Karlin-Rubin Theorem, the test that rejects $H_{0}$ if $X>t$ is the UMP test of its size. By the argument in part (b), use $t=1-\alpha$ to get size $\alpha$.
8.24 For $H_{0}: \theta=\theta_{0}$ vs. $H_{1}: \theta=\theta_{1}$, the LRT statistic is

$$
\lambda(\mathbf{x})=\frac{L\left(\theta_{0} \mid \mathbf{x}\right)}{\max \left\{L\left(\theta_{0} \mid \mathbf{x}\right), L\left(\theta_{1} \mid \mathbf{x}\right)\right\}}= \begin{cases}1 & \text { if } L\left(\theta_{0} \mid \mathbf{x}\right) \geq L\left(\theta_{1} \mid \mathbf{x}\right) \\ L\left(\theta_{0} \mid \mathbf{x}\right) / L\left(\theta_{1} \mid \mathbf{x}\right) & \text { if } L\left(\theta_{0} \mid \mathbf{x}\right)<L\left(\theta_{1} \mid \mathbf{x}\right)\end{cases}
$$

The LRT rejects $H_{0}$ if $\lambda(\mathbf{x})<c$. The Neyman-Pearson test rejects $H_{0}$ if $f\left(\mathbf{x} \mid \theta_{1}\right) / f\left(\mathbf{x} \mid \theta_{0}\right)=$ $L\left(\theta_{1} \mid \mathbf{x}\right) / L\left(\theta_{0} \mid \mathbf{x}\right)>k$. If $k=1 / c>1$, this is equivalent to $L\left(\theta_{0} \mid \mathbf{x}\right) / L\left(\theta_{1} \mid \mathbf{x}\right)<c$, the LRT. But if $c \geq 1$ or $k \leq 1$, the tests will not be the same. Because $c$ is usually chosen to be small $(k$ large) to get a small size $\alpha$, in practice the two tests are often the same.
8.25 a. For $\theta_{2}>\theta_{1}$,

$$
\frac{g\left(x \mid \theta_{2}\right)}{g\left(x \mid \theta_{1}\right)}=\frac{e^{-\left(x-\theta_{2}\right)^{2} / 2 \sigma^{2}}}{e^{-\left(x-\theta_{1}\right)^{2} / 2 \sigma^{2}}}=e^{x\left(\theta_{2}-\theta_{1}\right) / \sigma^{2}} e^{\left(\theta_{1}^{2}-\theta_{2}^{2}\right) / 2 \sigma^{2}}
$$

Because $\theta_{2}-\theta_{1}>0$, the ratio is increasing in $x$. So the families of $n\left(\theta, \sigma^{2}\right)$ have MLR.
b. For $\theta_{2}>\theta_{1}$,

$$
\frac{g\left(x \mid \theta_{2}\right)}{g\left(x \mid \theta_{1}\right)}=\frac{e^{-\theta_{2}} \theta_{2}^{x} / x!}{e^{-\theta_{1}} \theta_{1}^{x} / x!}=\left(\frac{\theta_{2}}{\theta_{1}}\right)^{x} e^{\theta_{1}-\theta_{2}}
$$

which is increasing in $x$ because $\theta_{2} / \theta_{1}>1$. Thus the $\operatorname{Poisson}(\theta)$ family has an MLR.
c. For $\theta_{2}>\theta_{1}$,

$$
\frac{g\left(x \mid \theta_{2}\right)}{g\left(x \mid \theta_{1}\right)}=\frac{\binom{n}{x} \theta_{2}^{x}\left(1-\theta_{2}\right)^{n-x}}{\binom{n}{x} \theta_{1}^{x}\left(1-\theta_{1}\right)^{n-x}}=\left(\frac{\theta_{2}\left(1-\theta_{1}\right)}{\theta_{1}\left(1-\theta_{2}\right)}\right)^{x}\left(\frac{1-\theta_{2}}{1-\theta_{1}}\right)^{n}
$$

Both $\theta_{2} / \theta_{1}>1$ and $\left(1-\theta_{1}\right) /\left(1-\theta_{2}\right)>1$. Thus the ratio is increasing in $x$, and the family has MLR.
(Note: You can also use the fact that an exponential family $h(x) c(\theta) \exp (w(\theta) x)$ has MLR if $w(\theta)$ is increasing in $\theta$ (Exercise 8.27). For example, the Poisson $(\theta)$ pmf is $e^{-\theta} \exp (x \log \theta) / x!$, and the family has MLR because $\log \theta$ is increasing in $\theta$.)
8.26 a. We will prove the result for continuous distributions. But it is also true for discrete MLR families. For $\theta_{1}>\theta_{2}$, we must show $F\left(x \mid \theta_{1}\right) \leq F\left(x \mid \theta_{2}\right)$. Now

$$
\frac{d}{d x}\left[F\left(x \mid \theta_{1}\right)-F\left(x \mid \theta_{2}\right)\right]=f\left(x \mid \theta_{1}\right)-f\left(x \mid \theta_{2}\right)=f\left(x \mid \theta_{2}\right)\left(\frac{f\left(x \mid \theta_{1}\right)}{f\left(x \mid \theta_{2}\right)}-1\right)
$$

Because $f$ has MLR, the ratio on the right-hand side is increasing, so the derivative can only change sign from negative to positive showing that any interior extremum is a minimum. Thus the function in square brackets is maximized by its value at $\infty$ or $-\infty$, which is zero.
b. From Exercise 3.42, location families are stochastically increasing in their location parameter, so the location Cauchy family with pdf $f(x \mid \theta)=\left(\pi\left[1+(x-\theta)^{2}\right]\right)^{-1}$ is stochastically increasing. The family does not have MLR.
8.27 For $\theta_{2}>\theta_{1}$,

$$
\frac{g\left(t \mid \theta_{2}\right)}{g\left(t \mid \theta_{1}\right)}=\frac{c\left(\theta_{2}\right)}{c\left(\theta_{1}\right)} e^{\left[w\left(\theta_{2}\right)-w\left(\theta_{1}\right)\right] t}
$$

which is increasing in $t$ because $w\left(\theta_{2}\right)-w\left(\theta_{1}\right)>0$. Examples include $\mathrm{n}(\theta, 1), \operatorname{beta}(\theta, 1)$, and Bernoulli $(\theta)$.
8.28 a . For $\theta_{2}>\theta_{1}$, the likelihood ratio is

$$
\frac{f\left(x \mid \theta_{2}\right)}{f\left(x \mid \theta_{1}\right)}=e^{\theta_{1}-\theta_{2}}\left[\frac{1+e^{x-\theta_{1}}}{1+e^{x-\theta_{2}}}\right]^{2}
$$

The derivative of the quantity in brackets is

$$
\frac{d}{d x} \frac{1+e^{x-\theta_{1}}}{1+e^{x-\theta_{2}}}=\frac{e^{x-\theta_{1}}-e^{x-\theta_{2}}}{\left(1+e^{x-\theta_{2}}\right)^{2}}
$$

Because $\theta_{2}>\theta_{1}, e^{x-\theta_{1}}>e^{x-\theta_{2}}$, and, hence, the ratio is increasing. This family has MLR.
b. The best test is to reject $H_{0}$ if $f(x \mid 1) / f(x \mid 0)>k$. From part (a), this ratio is increasing in $x$. Thus this inequality is equivalent to rejecting if $x>k^{\prime}$. The cdf of this logistic is $F(x \mid \theta)=e^{x-\theta} /\left(1+e^{x-\theta}\right)$. Thus

$$
\alpha=1-F\left(k^{\prime} \mid 0\right)=\frac{1}{1+e^{k^{\prime}}} \quad \text { and } \quad \beta=F\left(k^{\prime} \mid 1\right)=\frac{e^{k^{\prime}-1}}{1+e^{k^{\prime}-1}}
$$

For a specified $\alpha, k^{\prime}=\log (1-\alpha) / \alpha$. So for $\alpha=.2, k^{\prime} \approx 1.386$ and $\beta \approx .595$.
c. The Karlin-Rubin Theorem is satisfied, so the test is UMP of its size.
8.29 a. Let $\theta_{2}>\theta_{1}$. Then

$$
\frac{f\left(x \mid \theta_{2}\right)}{f\left(x \mid \theta_{1}\right)}=\frac{1+\left(x-\theta_{1}\right)^{2}}{1+\left(x-\theta_{2}\right)^{2}}=\frac{1+\left(1+\theta_{1}\right)^{2} / x^{2}-2 \theta_{1} / x}{1+\left(1+\theta_{2}\right)^{2} / x^{2}-2 \theta_{2} / x}
$$

The limit of this ratio as $x \rightarrow \infty$ or as $x \rightarrow-\infty$ is 1 . So the ratio cannot be monotone increasing (or decreasing) between $-\infty$ and $\infty$. Thus, the family does not have MLR.
b. By the Neyman-Pearson Lemma, a test will be UMP if it rejects when $f(x \mid 1) / f(x \mid 0)>k$, for some constant $k$. Examination of the derivative shows that $f(x \mid 1) / f(x \mid 0)$ is decreasing for $x \leq(1-\sqrt{5}) / 2=-.618$, is increasing for $(1-\sqrt{5}) / 2 \leq x \leq(1+\sqrt{5}) / 2=1.618$, and is decreasing for $(1+\sqrt{5}) / 2 \leq x$. Furthermore, $f(1 \mid 1) / f(1 \mid 0)=f(3 \mid 1) / f(3 \mid 0)=2$. So rejecting if $f(x \mid 1) / f(x \mid 0)>2$ is equivalent to rejecting if $1<x<3$. Thus, the given test is UMP of its size. The size of the test is

$$
P(1<X<3 \mid \theta=0)=\int_{1}^{3} \frac{1}{\pi} \frac{1}{1+x^{2}} d x=\left.\frac{1}{\pi} \arctan x\right|_{1} ^{3} \approx .1476
$$

The Type II error probability is

$$
1-P(1<X<3 \mid \theta=1)=1-\int_{1}^{3} \frac{1}{\pi} \frac{1}{1+(x-1)^{2}} d x=1-\left.\frac{1}{\pi} \arctan (x-1)\right|_{1} ^{3} \approx .6476
$$

c. We will not have $f(1 \mid \theta) / f(1 \mid 0)=f(3 \mid \theta) / f(3 \mid 0)$ for any other value of $\theta \neq 1$. Try $\theta=2$, for example. So the rejection region $1<x<3$ will not be most powerful at any other value of $\theta$. The test is not UMP for testing $H_{0}: \theta \leq 0$ versus $H_{1}: \theta>0$.
8.30 a. For $\theta_{2}>\theta_{1}>0$, the likelihood ratio and its derivative are

$$
\frac{f\left(x \mid \theta_{2}\right)}{f\left(x \mid \theta_{1}\right)}=\frac{\theta_{2}}{\theta_{1}} \frac{\theta_{1}^{2}+x^{2}}{\theta_{2}^{2}+x^{2}} \quad \text { and } \quad \frac{d}{d x} \frac{f\left(x \mid \theta_{2}\right)}{f\left(x \mid \theta_{1}\right)}=\frac{\theta_{2}}{\theta_{1}} \frac{\theta_{2}^{2}-\theta_{1}^{2}}{\left(\theta_{2}^{2}+x^{2}\right)^{2}} x .
$$

The sign of the derivative is the same as the sign of $x$ (recall, $\theta_{2}^{2}-\theta_{1}^{2}>0$ ), which changes sign. Hence the ratio is not monotone.
b. Because $f(x \mid \theta)=(\theta / \pi)\left(\theta^{2}+|x|^{2}\right)^{-1}, Y=|X|$ is sufficient. Its pdf is

$$
f(y \mid \theta)=\frac{2 \theta}{\pi} \frac{1}{\theta^{2}+y^{2}}, \quad y>0
$$

Differentiating as above, the sign of the derivative is the same as the sign of $y$, which is positive. Hence the family has MLR.
8.31 a. By the Karlin-Rubin Theorem, the UMP test is to reject $H_{0}$ if $\sum_{i} X_{i}>k$, because $\sum_{i} X_{i}$ is sufficient and $\sum_{i} X_{i} \sim \operatorname{Poisson}(n \lambda)$ which has MLR. Choose the constant $k$ to satisfy $P\left(\sum_{i} X_{i}>k \mid \lambda=\lambda_{0}\right)=\alpha$.
b.

$$
\begin{aligned}
P\left(\sum_{i} X_{i}>k \mid \lambda=1\right) & \approx P(Z>(k-n) / \sqrt{n}) \stackrel{\text { set }}{=} .05 \\
P\left(\sum_{i} X_{i}>k \mid \lambda=2\right) & \approx P(Z>(k-2 n) / \sqrt{2 n}) \stackrel{\text { set }}{=} .90 .
\end{aligned}
$$

Thus, solve for $k$ and $n$ in

$$
\frac{k-n}{\sqrt{n}}=1.645 \quad \text { and } \quad \frac{k-2 n}{\sqrt{2 n}}=-1.28
$$

yielding $n=12$ and $k=17.70$.
8.32 a. This is Example 8.3.15.
b. This is Example 8.3.19.
8.33 a. From Theorems 5.4.4 and 5.4.6, the marginal pdf of $Y_{1}$ and the joint pdf of $\left(Y_{1}, Y_{n}\right)$ are

$$
\begin{aligned}
f\left(y_{1} \mid \theta\right) & =n\left(1-\left(y_{1}-\theta\right)\right)^{n-1}, \quad \theta<y_{1}<\theta+1 \\
f\left(y_{1}, y_{n} \mid \theta\right) & =n(n-1)\left(y_{n}-y_{1}\right)^{n-2}, \quad \theta<y_{1}<y_{n}<\theta+1 .
\end{aligned}
$$

Under $H_{0}, P\left(Y_{n} \geq 1\right)=0$. So

$$
\alpha=P\left(Y_{1} \geq k \mid 0\right)=\int_{k}^{1} n\left(1-y_{1}\right)^{n-1} d y_{1}=(1-k)^{n}
$$

Thus, use $k=1-\alpha^{1 / n}$ to have a size $\alpha$ test.
b. For $\theta \leq k-1, \beta(\theta)=0$. For $k-1<\theta \leq 0$,

$$
\beta(\theta)=\int_{k}^{\theta+1} n\left(1-\left(y_{1}-\theta\right)\right)^{n-1} d y_{1}=(1-k+\theta)^{n}
$$

For $0<\theta \leq k$,

$$
\begin{aligned}
\beta(\theta) & =\int_{k}^{\theta+1} n\left(1-\left(y_{1}-\theta\right)\right)^{n-1} d y_{1}+\int_{\theta}^{k} \int_{1}^{\theta+1} n(n-1)\left(y_{n}-y_{1}\right)^{n-2} d y_{n} d y_{1} \\
& =\alpha+1-(1-\theta)^{n} .
\end{aligned}
$$

And for $k<\theta, \beta(\theta)=1$.
c. $\left(Y_{1}, Y_{n}\right)$ are sufficient statistics. So we can attempt to find a UMP test using Corollary 8.3.13 and the joint pdf $f\left(y_{1}, y_{n} \mid \theta\right)$ in part (a). For $0<\theta<1$, the ratio of pdfs is

$$
\frac{f\left(y_{1}, y_{n} \mid \theta\right)}{f\left(y_{1}, y_{n} \mid 0\right)}= \begin{cases}0 & \text { if } 0<y_{1} \leq \theta, y_{1}<y_{n}<1 \\ 1 & \text { if } \theta<y_{1}<y_{n}<1 \\ \infty & \text { if } 1 \leq y_{n}<\theta+1, \theta<y_{1}<y_{n}\end{cases}
$$

For $1 \leq \theta$, the ratio of pdfs is

$$
\frac{f\left(y_{1}, y_{n} \mid \theta\right)}{f\left(y_{1}, y_{n} \mid 0\right)}= \begin{cases}0 & \text { if } y_{1}<y_{n}<1 \\ \infty & \text { if } \theta<y_{1}<y_{n}<\theta+1\end{cases}
$$

For $0<\theta<k$, use $k^{\prime}=1$. The given test always rejects if $f\left(y_{1}, y_{n} \mid \theta\right) / f\left(y_{1}, y_{n} \mid 0\right)>1$ and always accepts if $f\left(y_{1}, y_{n} \mid \theta\right) / f\left(y_{1}, y_{n} \mid 0\right)<1$. For $\theta \geq k$, use $k^{\prime}=0$. The given test always rejects if $f\left(y_{1}, y_{n} \mid \theta\right) / f\left(y_{1}, y_{n} \mid 0\right)>0$ and always accepts if $f\left(y_{1}, y_{n} \mid \theta\right) / f\left(y_{1}, y_{n} \mid 0\right)<0$. Thus the given test is UMP by Corollary 8.3.13.
d. According to the power function in part (b), $\beta(\theta)=1$ for all $\theta \geq k=1-\alpha^{1 / n}$. So these conditions are satisfied for any $n$.
8.34 a. This is Exercise 3.42a.
b. This is Exercise 8.26a.
8.35 a. We will use the equality in Exercise 3.17 which remains true so long as $\nu>-\alpha$. Recall that $Y \sim \chi_{\nu}^{2}=\operatorname{gamma}(\nu / 2,2)$. Thus, using the independence of $X$ and $Y$ we have

$$
\mathrm{E} T^{\prime}=\mathrm{E} \frac{X}{\sqrt{Y / \nu}}=(\mathrm{E} X) \sqrt{\nu} \mathrm{E} Y^{-1 / 2}=\mu \sqrt{\nu} \frac{\Gamma((\nu-1) / 2)}{\Gamma(\nu / 2) \sqrt{2}}
$$

if $\nu>1$. To calculate the variance, compute

$$
\mathrm{E}\left(T^{\prime}\right)^{2}=\mathrm{E} \frac{X^{2}}{Y / \nu}=\left(\mathrm{E} X^{2}\right) \nu \mathrm{E} Y^{-1}=\left(\mu^{2}+1\right) \nu \frac{\Gamma((\nu-2) / 2)}{\Gamma(\nu / 2) 2}=\frac{\left(\mu^{2}+1\right) \nu}{\nu-2}
$$

if $\nu>2$. Thus, if $\nu>2$,

$$
\operatorname{Var} T^{\prime}=\frac{\left(\mu^{2}+1\right) \nu}{\nu-2}-\left(\mu \sqrt{\nu} \frac{\Gamma((\nu-1) / 2)}{\Gamma(\nu / 2) \sqrt{2}}\right)^{2}
$$

b. If $\delta=0$, all the terms in the sum for $k=1,2, \ldots$ are zero because of the $\delta^{k}$ term. The expression with just the $k=0$ term and $\delta=0$ simplifies to the central $t$ pdf.
c. The argument that the noncentral $t$ has an MLR is fairly involved. It may be found in Lehmann (1986, p. 295).
8.37 a. $P\left(\bar{X}>\theta_{0}+z_{\alpha} \sigma / \sqrt{n} \mid \theta_{0}\right)=P\left(\left(\bar{X}-\theta_{0}\right) /(\sigma / \sqrt{n})>z_{\alpha} \mid \theta_{0}\right)=P\left(Z>z_{\alpha}\right)=\alpha$, where $Z \sim$ $\mathrm{n}(0,1)$. Because $\bar{x}$ is the unrestricted MLE, and the restricted MLE is $\theta_{0}$ if $\bar{x}>\theta_{0}$, the LRT statistic is, for $\bar{x} \geq \theta_{0}$

$$
\lambda(\mathbf{x})=\frac{\left(2 \pi \sigma^{2}\right)^{-n / 2} e^{-\Sigma_{i}\left(x_{i}-\theta_{0}\right)^{2} / 2 \sigma^{2}}}{\left(2 \pi \sigma^{2}\right)^{-n / 2} e^{-\Sigma_{i}\left(x_{i}-\bar{x}\right)^{2} / 2 \sigma^{2}}}=\frac{e^{\left.-\left[n\left(\bar{x}-\theta_{0}\right)^{2}+(n-1) s^{2}\right]\right] / 2 \sigma^{2}}}{e^{-(n-1) s^{2} / 2 \sigma^{2}}}=e^{-n\left(\bar{x}-\theta_{0}\right)^{2} / 2 \sigma^{2}}
$$

and the LRT statistic is 1 for $\bar{x}<\theta_{0}$. Thus, rejecting if $\lambda<c$ is equivalent to rejecting if $\left(\bar{x}-\theta_{0}\right) /(\sigma / \sqrt{n})>c^{\prime}$ (as long as $c<1$ - see Exercise 8.24).
b. The test is UMP by the Karlin-Rubin Theorem.
c. $P\left(\bar{X}>\theta_{0}+t_{n-1, \alpha} S / \sqrt{n} \mid \theta=\theta_{0}\right)=P\left(T_{n-1}>t_{n-1, \alpha}\right)=\alpha$, when $T_{n-1}$ is a Student's $t$ random variable with $n-1$ degrees of freedom. If we define $\hat{\sigma}^{2}=\frac{1}{n} \sum\left(x_{i}-\bar{x}\right)^{2}$ and $\hat{\sigma}_{0}^{2}=\frac{1}{n} \sum\left(x_{i}-\theta_{0}\right)^{2}$, then for $\bar{x} \geq \theta_{0}$ the LRT statistic is $\lambda=\left(\hat{\sigma}^{2} / \hat{\sigma}_{0}^{2}\right)^{n / 2}$, and for $\bar{x}<\theta_{0}$ the LRT statistic is $\lambda=1$. Writing $\hat{\sigma}^{2}=\frac{n-1}{n} s^{2}$ and $\hat{\sigma}_{0}^{2}=\left(\bar{x}-\theta_{0}\right)^{2}+\frac{n-1}{n} s^{2}$, it is clear that the LRT is equivalent to the $t$-test because $\lambda<c$ when

$$
\frac{\frac{n-1}{n} s^{2}}{\left(\bar{x}-\theta_{0}\right)^{2}+\frac{n-1}{n} s^{2}}=\frac{(n-1) / n}{\left(\bar{x}-\theta_{0}\right)^{2} / s^{2}+(n-1) / n}<c^{\prime} \quad \text { and } \quad \bar{x} \geq \theta_{0}
$$

which is the same as rejecting when $\left(\bar{x}-\theta_{0}\right) /(s / \sqrt{n})$ is large.
d. The proof that the one-sided $t$ test is UMP unbiased is rather involved, using the bounded completeness of the normal distribution and other facts. See Chapter 5 of Lehmann (1986) for a complete treatment.
8.38 a.

$$
\begin{aligned}
\text { Size } & =P_{\theta_{0}}\left\{\left|\bar{X}-\theta_{0}\right|>t_{n-1, \alpha / 2} \sqrt{S^{2} / n}\right\} \\
& =1-P_{\theta_{0}}\left\{-t_{n-1, \alpha / 2} \sqrt{S^{2} / n} \leq \bar{X}-\theta_{0} \leq t_{n-1, \alpha / 2} \sqrt{S^{2} / n}\right\} \\
& =1-P_{\theta_{0}}\left\{-t_{n-1, \alpha / 2} \leq \frac{\bar{X}-\theta_{0}}{\sqrt{S^{2} / n}} \leq t_{n-1, \alpha / 2}\right\} \quad\left(\frac{\bar{X}-\theta_{0}}{\sqrt{S^{2} / n}} \sim t_{n-1} \text { under } H_{0}\right) \\
& =1-(1-\alpha)=\alpha
\end{aligned}
$$

b. The unrestricted MLEs are $\hat{\theta}=\bar{X}$ and $\hat{\sigma}^{2}=\sum_{i}\left(X_{i}-\bar{X}\right)^{2} / n$. The restricted MLEs are $\hat{\theta}_{0}=\theta_{0}$ and $\hat{\sigma}_{0}^{2}=\sum_{i}\left(X_{i}-\theta_{0}\right)^{2} / n$. So the LRT statistic is

$$
\begin{aligned}
\lambda(\mathbf{x}) & =\frac{\left(2 \pi \hat{\sigma}_{0}\right)^{-n / 2} \exp \left\{-n \hat{\sigma}_{0}^{2} /\left(2 \hat{\sigma}_{0}^{2}\right)\right\}}{(2 \pi \hat{\sigma})^{-n / 2} \exp \left\{-n \hat{\sigma}^{2} /\left(2 \hat{\sigma}^{2}\right)\right\}} \\
& =\left[\frac{\sum_{i}\left(x_{i}-\bar{x}\right)^{2}}{\sum_{i}\left(x_{i}-\theta_{0}\right)^{2}}\right]^{n / 2}=\left[\frac{\sum_{i}\left(x_{i}-\bar{x}\right)^{2}}{\sum_{i}\left(x_{i}-\bar{x}\right)^{2}+n\left(\bar{x}-\theta_{0}\right)^{2}}\right]^{n / 2}
\end{aligned}
$$

For a constant $c$, the LRT is

$$
\text { reject } H_{0} \text { if }\left[\frac{\sum_{i}\left(x_{i}-\bar{x}\right)^{2}}{\sum_{i}\left(x_{i}-\bar{x}\right)^{2}+n\left(\bar{x}-\theta_{0}\right)^{2}}\right]=\frac{1}{1+n\left(\bar{x}-\theta_{0}\right)^{2} / \sum_{i}\left(x_{i}-\bar{x}\right)^{2}}<c^{2 / n}
$$

After some algebra we can write the test as

$$
\text { reject } H_{0} \text { if }\left|\bar{x}-\theta_{0}\right|>\left[\left(c^{-2 / n}-1\right)(n-1) \frac{s^{2}}{n}\right]^{1 / 2} .
$$

We now choose the constant $c$ to achieve size $\alpha$, and we

$$
\text { reject if }\left|\bar{x}-\theta_{0}\right|>t_{n-1, \alpha / 2} \sqrt{s^{2} / n}
$$

c. Again, see Chapter 5 of Lehmann (1986).
8.39 a. From Exercise $4.45 \mathrm{c}, W_{i}=X_{i}-Y_{i} \sim \mathrm{n}\left(\mu_{W}, \sigma_{W}^{2}\right)$, where $\mu_{X}-\mu_{Y}=\mu_{W}$ and $\sigma_{X}^{2}+\sigma_{Y}^{2}-$ $\rho \sigma_{X} \sigma_{Y}=\sigma_{W}^{2}$. The $W_{i}$ s are independent because the pairs $\left(X_{i}, Y_{i}\right)$ are.
b. The hypotheses are equivalent to $H_{0}: \mu_{W}=0$ vs $H_{1}: \mu_{W} \neq 0$, and, from Exercise 8.38, if we reject $H_{0}$ when $|\bar{W}|>t_{n-1, \alpha / 2} \sqrt{S_{W}^{2} / n}$, this is the LRT (based on $W_{1}, \ldots, W_{n}$ ) of size $\alpha$. (Note that if $\rho>0, \operatorname{Var} W_{i}$ can be small and the test will have good power.)
8.41 a.

$$
\lambda(\mathbf{x}, \mathbf{y})=\frac{\sup _{H_{0}} L\left(\mu_{X}, \mu_{Y}, \sigma^{2} \mid \mathbf{x}, \mathbf{y}\right)}{\sup L\left(\mu_{X}, \mu_{Y}, \sigma^{2} \mid \mathbf{x}, \mathbf{y}\right)}=\frac{L\left(\hat{\mu}, \hat{\sigma}_{0}^{2} \mid \mathbf{x}, \mathbf{y}\right)}{L\left(\hat{\mu}_{X}, \hat{\mu}_{Y}, \hat{\sigma}_{1}^{2} \mid \mathbf{x}, \mathbf{y}\right)}
$$

Under $H_{0}$, the $X_{i} \mathrm{~s}$ and $Y_{i} \mathrm{~s}$ are one sample of size $m+n$ from a $\mathrm{n}\left(\mu, \sigma^{2}\right)$ population, where $\mu=\mu_{X}=\mu_{Y}$. So the restricted MLEs are

$$
\hat{\mu}=\frac{\sum_{i} X_{i}+\sum_{i} Y_{i}}{n+m}=\frac{n \bar{x}+n \bar{y}}{n+m} \quad \text { and } \quad \hat{\sigma}_{0}^{2}=\frac{\sum_{i}\left(X_{i}-\hat{\mu}\right)^{2}+\sum_{i}\left(Y_{i}-\hat{\mu}\right)^{2}}{n+m}
$$

To obtain the unrestricted MLEs, $\hat{\mu}_{x}, \hat{\mu}_{y}, \hat{\sigma}^{2}$, use

$$
L\left(\mu_{X}, \mu_{Y}, \sigma^{2} \mid x, y\right)=\left(2 \pi \sigma^{2}\right)^{-(n+m) / 2} e^{-\left[\Sigma_{i}\left(x_{i}-\mu_{X}\right)^{2}+\Sigma_{i}\left(y_{i}-\mu_{Y}\right)^{2}\right] / 2 \sigma^{2}}
$$

Firstly, note that $\hat{\mu}_{X}=\bar{x}$ and $\hat{\mu}_{Y}=\bar{y}$, because maximizing over $\mu_{X}$ does not involve $\mu_{Y}$ and vice versa. Then

$$
\frac{\partial \log L}{\partial \sigma^{2}}=-\frac{n+m}{2} \frac{1}{\sigma^{2}}+\frac{1}{2}\left[\sum_{i}\left(x_{i}-\hat{\mu}_{X}\right)^{2}+\sum_{i}\left(y_{i}-\hat{\mu}_{Y}\right)^{2}\right] \frac{1}{\left(\sigma^{2}\right)^{2}} \stackrel{\text { set }}{=} 0
$$

implies

$$
\hat{\sigma}^{2}=\left[\sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2}+\sum_{i=1}^{m}\left(y_{i}-\bar{y}\right)^{2}\right] \frac{1}{n+m}
$$

To check that this is a maximum,

$$
\begin{aligned}
\left.\frac{\partial^{2} \log L}{\partial\left(\sigma^{2}\right)^{2}}\right|_{\hat{\sigma}^{2}} & =\frac{n+m}{2} \frac{1}{\left(\sigma^{2}\right)^{2}}-\left.\left[\sum_{i}\left(x_{i}-\hat{\mu}_{X}\right)^{2}+\sum_{i}\left(y_{i}-\hat{\mu}_{Y}\right)^{2}\right] \frac{1}{\left(\sigma^{2}\right)^{3}}\right|_{\hat{\sigma}^{2}} \\
& =\frac{n+m}{2} \frac{1}{\left(\hat{\sigma}^{2}\right)^{2}}-(n+m) \frac{1}{\left(\hat{\sigma}^{2}\right)^{2}}=-\frac{n+m}{2} \frac{1}{\left(\hat{\sigma}^{2}\right)^{2}}<0
\end{aligned}
$$

Thus, it is a maximum. We then have

$$
\lambda(\mathbf{x}, \mathbf{y})=\frac{\left(2 \pi \hat{\sigma}_{0}^{2}\right)^{-\frac{n+m}{2}} \exp \left\{-\frac{1}{2 \hat{\sigma}_{0}^{2}}\left[\sum_{i=1}^{n}\left(x_{i}-\hat{\mu}\right)^{2}+\sum_{i=1}^{m}\left(y_{i}-\hat{\mu}\right)^{2}\right]\right\}}{\left(2 \pi \hat{\sigma}^{2}\right)^{-\frac{n+m}{2}} \exp \left\{-\frac{1}{2 \hat{\sigma}^{2}}\left[\sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2}+\sum_{i=1}^{m}\left(y_{i}-\bar{y}\right)^{2}\right]\right\}}=\left(\frac{\hat{\sigma}_{0}^{2}}{\hat{\sigma}_{1}^{2}}\right)^{-\frac{n+m}{2}}
$$

and the LRT is rejects $H_{0}$ if $\hat{\sigma}_{0}^{2} / \hat{\sigma}^{2}>k$. In the numerator, first substitute $\hat{\mu}=(n \bar{x}+$ $m \bar{y}) /(n+m)$ and write
$\sum_{i=1}^{n}\left(x_{i}-\frac{n \bar{x}+m \bar{y}}{n+m}\right)^{2}=\sum_{i=1}^{n}\left(\left(x_{i}-\bar{x}\right)+\left(\bar{x}-\frac{n \bar{x}+m \bar{y}}{n+m}\right)\right)^{2}=\sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2}+\frac{n m^{2}}{(n+m)^{2}}(\bar{x}-\bar{y})^{2}$,
because the cross term is zero. Performing a similar operation on the $Y$ sum yields

$$
\frac{\hat{\sigma}_{0}^{2}}{\hat{\sigma}^{2}}=\frac{\sum\left(x_{i}-\bar{x}\right)^{2}+\sum\left(y_{i}-\bar{y}\right)^{2}+\frac{n m}{n+m}(\bar{x}-\bar{y})^{2}}{\hat{\sigma}^{2}}=n+m+\frac{n m}{n+m} \frac{(\bar{x}-\bar{y})^{2}}{\hat{\sigma}^{2}}
$$

Because $\hat{\sigma}^{2}=\frac{n+m-2}{n+m} S_{p}^{2}$, large values of $\hat{\sigma}_{0}^{2} / \hat{\sigma}^{2}$ are equivalent to large values of $(\bar{x}-\bar{y})^{2} / S_{p}^{2}$ and large values of $|T|$. Hence, the LRT is the two-sample $t$-test.
b.

$$
T=\frac{\bar{X}-\bar{Y}}{\sqrt{S_{p}^{2}(1 / n+1 / m)}}=\frac{(\bar{X}-\bar{Y}) / \sqrt{\sigma^{2}(1 / n+1 / m)}}{\sqrt{\left[(n+m-2) S_{p}^{2} / \sigma^{2}\right] /(n+m-2)}}
$$

Under $H_{0},(\bar{X}-\bar{Y}) \sim \mathrm{n}\left(0, \sigma^{2}(1 / n+1 / m)\right)$. Under the model, $(n-1) S_{X}^{2} / \sigma^{2}$ and $(m-1) S_{Y}^{2} / \sigma^{2}$ are independent $\chi^{2}$ random variables with $(n-1)$ and $(m-1)$ degrees of freedom. Thus, $(n+m-2) S_{p}^{2} / \sigma^{2}=(n-1) S_{X}^{2} / \sigma^{2}+(m-1) S_{Y}^{2} / \sigma^{2} \sim \chi_{n+m-2}^{2}$. Furthermore, $\bar{X}-\bar{Y}$ is independent of $S_{X}^{2}$ and $S_{Y}^{2}$, and, hence, $S_{p}^{2}$. So $T \sim t_{n+m-2}$.
c. The two-sample $t$ test is UMP unbiased, but the proof is rather involved. See Chapter 5 of Lehmann (1986).
d. For these data we have $n=14, \bar{X}=1249.86, S_{X}^{2}=591.36, m=9, \bar{Y}=1261.33, S_{Y}^{2}=176.00$ and $S_{p}^{2}=433.13$. Therefore, $T=-1.29$ and comparing this to a $t_{21}$ distribution gives a p-value of .21 . So there is no evidence that the mean age differs between the core and periphery.
8.42 a. The Satterthwaite approximation states that if $Y_{i} \sim \chi_{r_{i}}^{2}$, where the $Y_{i}$ 's are independent, then

$$
\sum_{i} a_{i} Y_{i} \stackrel{\text { approx }}{\sim} \frac{\chi_{\hat{\hat{\nu}}}^{2}}{\hat{\nu}} \quad \text { where } \quad \hat{\nu}=\frac{\left(\sum_{i} a_{i} Y_{i}\right)^{2}}{\sum_{i} a_{i}^{2} Y_{i}^{2} / r_{i}} .
$$

We have $Y_{1}=(n-1) S_{X}^{2} / \sigma_{X}^{2} \sim \chi_{n-1}^{2}$ and $Y_{2}=(m-1) S_{Y}^{2} / \sigma_{Y}^{2} \sim \chi_{m-1}^{2}$. Now define

$$
a_{1}=\frac{\sigma_{X}^{2}}{n(n-1)\left[\left(\sigma_{X}^{2} / n\right)+\left(\sigma_{Y}^{2} / m\right)\right]} \quad \text { and } \quad a_{2}=\frac{\sigma_{Y}^{2}}{m(m-1)\left[\left(\sigma_{X}^{2} / n\right)+\left(\sigma_{Y}^{2} / m\right)\right]}
$$

Then,

$$
\begin{aligned}
\sum a_{i} Y_{i}= & \frac{\sigma_{X}^{2}}{n(n-1)\left[\left(\sigma_{X}^{2} / n\right)+\left(\sigma_{Y}^{2} / m\right)\right]} \frac{(n-1) S_{X}^{2}}{\sigma_{X}^{2}} \\
& +\frac{\sigma_{Y}^{2}}{m(m-1)\left[\left(\sigma_{X}^{2} / n\right)+\left(\sigma_{Y}^{2} / m\right)\right]} \frac{(m-1) S_{Y}^{2}}{\sigma_{Y}^{2}} \\
= & \frac{S_{X}^{2} / n+S_{Y}^{2} / m}{\sigma_{X}^{2} / n+\sigma_{Y}^{2} / m} \sim \frac{\chi_{\hat{\hat{N}}}^{2}}{\hat{\nu}}
\end{aligned}
$$

where

$$
\hat{\nu}=\frac{\left(\frac{S_{X}^{2} / n+S_{Y}^{2} / m}{\sigma_{X}^{2} / n+\sigma_{Y}^{2} / m}\right)^{2}}{\frac{1}{(n-1)} \frac{S_{X}^{4}}{n^{2}\left(\sigma_{X}^{2} / n+\sigma_{Y}^{2} / m\right)^{2}}+\frac{1}{(m-1)} \frac{S_{Y}^{4}}{m^{2}\left(\sigma_{X}^{2} / n+\sigma_{Y}^{2} / m\right)^{2}}}=\frac{\left(S_{X}^{2} / n+S_{Y}^{2} / m\right)^{2}}{\frac{S_{X}^{4}}{n^{2}(n-1)}+\frac{S_{Y}^{4}}{m^{2}(m-1)}} .
$$

b. Because $\bar{X}-\bar{Y} \sim \mathrm{n}\left(\mu_{X}-\mu_{Y}, \sigma_{X}^{2} / n+\sigma_{Y}^{2} / m\right)$ and $\frac{S_{X}^{2} / n+S_{Y}^{2} / m}{\sigma_{X}^{2} / n+\sigma_{Y}^{2} / m} \stackrel{\text { approx }}{\sim} \chi_{\hat{\nu}}^{2} / \hat{\nu}$, under $H_{0}$ : $\mu_{X}-\mu_{Y}=0$ we have

$$
T^{\prime}=\frac{\bar{X}-\bar{Y}}{\sqrt{S_{X}^{2} / n+S_{Y}^{2} / m}}=\frac{(\bar{X}-\bar{Y}) / \sqrt{\sigma_{X}^{2} / n+\sigma_{Y}^{2} / m}}{\sqrt{\frac{\left(S_{X}^{2} / n+S_{Y}^{2} / m\right)}{\left(\sigma_{X}^{2} / n+\sigma_{Y}^{2} / m\right)}}} \stackrel{\text { approx }}{\sim} t_{\hat{\nu}}
$$

c. Using the values in Exercise 8.41d, we obtain $T^{\prime}=-1.46$ and $\hat{\nu}=20.64$. So the p-value is .16. There is no evidence that the mean age differs between the core and periphery.
d. $F=S_{X}^{2} / S_{Y}^{2}=3.36$. Comparing this with an $F_{13,8}$ distribution yields a p-value of $2 P(F \geq$ $3.36)=.09$. So there is some slight evidence that the variance differs between the core and periphery.
8.43 There were typos in early printings. The $t$ statistic should be

$$
\frac{(\bar{X}-\bar{Y})-\left(\mu_{1}-\mu_{2}\right)}{\sqrt{\frac{1}{n_{1}}+\frac{\rho^{2}}{n_{2}}} \sqrt{\frac{\left(n_{1}-1\right) s_{X}^{2}+\left(n_{2}-1\right) s_{Y}^{2} / \rho^{2}}{n_{1}+n_{2}-2}}},
$$

and the $F$ statistic should be $s_{Y}^{2} /\left(\rho^{2} s_{X}^{2}\right)$. Multiply and divide the denominator of the $t$ statistic by $\sigma$ to express it as

$$
\frac{(\bar{X}-\bar{Y})-\left(\mu_{1}-\mu_{2}\right)}{\sqrt{\frac{\sigma^{2}}{n_{1}}+\frac{\rho^{2} \sigma^{2}}{n_{2}}}}
$$

divided by

$$
\sqrt{\frac{\left(n_{1}-1\right) s_{X}^{2} / \sigma^{2}+\left(n_{2}-1\right) s_{Y}^{2} /\left(\rho^{2} \sigma^{2}\right)}{n_{1}+n_{2}-2}}
$$

The numerator has a $\mathrm{n}(0,1)$ distribution. In the denominator, $\left(n_{1}-1\right) s_{X}^{2} / \sigma^{2} \sim \chi_{n_{1}-1}^{2}$ and $\left(n_{2}-1\right) s_{Y}^{2} /\left(\rho^{2} \sigma^{2}\right) \sim \chi_{n_{2}-1}^{2}$ and they are independent, so their sum has a $\chi_{n_{1}+n_{2}-2}^{2}$ distribution. Thus, the statistic has the form of $\mathrm{n}(0,1) / \sqrt{\chi_{\nu}^{2} / \nu}$ where $\nu=n_{1}+n_{2}-2$, and the numerator and denominator are independent because of the independence of sample means and variances in normal sampling. Thus the statistic has a $t_{n_{1}+n_{2}-2}$ distribution. The $F$ statistic can be written as

$$
\frac{s_{Y}^{2}}{\rho^{2} s_{X}^{2}}=\frac{s_{Y}^{2} /\left(\rho^{2} \sigma^{2}\right)}{s_{X}^{2} / \sigma^{2}}=\frac{\left[\left(n_{2}-1\right) s_{Y}^{2} /\left(\rho^{2} \sigma^{2}\right)\right] /\left(n_{2}-1\right)}{\left[\left(n_{1}-1\right) s_{X}^{2} /\left(\sigma^{2}\right)\right] /\left(n_{1}-1\right)}
$$

which has the form $\left[\chi_{n_{2}-1}^{2} /\left(n_{2}-1\right)\right] /\left[\chi_{n_{1}-1}^{2} /\left(n_{1}-1\right)\right]$ which has an $F_{n_{2}-1, n_{1}-1}$ distribution. (Note, early printings had a typo with the numerator and denominator degrees of freedom switched.)
8.44 Test 3 rejects $H_{0}: \theta=\theta_{0}$ in favor of $H_{1}: \theta \neq \theta_{0}$ if $\bar{X}>\theta_{0}+z_{\alpha / 2} \sigma / \sqrt{n}$ or $\bar{X}<\theta_{0}-z_{\alpha / 2} \sigma / \sqrt{n}$. Let $\Phi$ and $\phi$ denote the standard normal cdf and pdf, respectively. Because $\bar{X} \sim \mathrm{n}\left(\theta, \sigma^{2} / n\right)$, the power function of Test 3 is

$$
\begin{aligned}
\beta(\theta) & =P_{\theta}\left(\bar{X}<\theta_{0}-z_{\alpha / 2} \sigma / \sqrt{n}\right)+P_{\theta}\left(\bar{X}>\theta_{0}+z_{\alpha / 2} \sigma / \sqrt{n}\right) \\
& =\Phi\left(\frac{\theta_{0}-\theta}{\sigma / \sqrt{n}}-z_{\alpha / 2}\right)+1-\Phi\left(\frac{\theta_{0}-\theta}{\sigma / \sqrt{n}}+z_{\alpha / 2}\right)
\end{aligned}
$$

and its derivative is

$$
\frac{d \beta(\theta)}{d \theta}=-\frac{\sqrt{n}}{\sigma} \phi\left(\frac{\theta_{0}-\theta}{\sigma / \sqrt{n}}-z_{\alpha / 2}\right)+\frac{\sqrt{n}}{\sigma} \phi\left(\frac{\theta_{0}-\theta}{\sigma / \sqrt{n}}+z_{\alpha / 2}\right)
$$

Because $\phi$ is symmetric and unimodal about zero, this derivative will be zero only if

$$
-\left(\frac{\theta_{0}-\theta}{\sigma / \sqrt{n}}-z_{\alpha / 2}\right)=\frac{\theta_{0}-\theta}{\sigma / \sqrt{n}}+z_{\alpha / 2}
$$

that is, only if $\theta=\theta_{0}$. So, $\theta=\theta_{0}$ is the only possible local maximum or minimum of the power function. $\beta\left(\theta_{0}\right)=\alpha$ and $\lim _{\theta \rightarrow \pm \infty} \beta(\theta)=1$. Thus, $\theta=\theta_{0}$ is the global minimum of $\beta(\theta)$, and, for any $\theta^{\prime} \neq \theta_{0}, \beta\left(\theta^{\prime}\right)>\beta\left(\theta_{0}\right)$. That is, Test 3 is unbiased.
8.45 The verification of size $\alpha$ is the same computation as in Exercise 8.37a. Example 8.3.3 shows that the power function $\beta_{m}(\theta)$ for each of these tests is an increasing function. So for $\theta>\theta_{0}$, $\beta_{m}(\theta)>\beta_{m}\left(\theta_{0}\right)=\alpha$. Hence, the tests are all unbiased.
8.47 a. This is very similar to the argument for Exercise 8.41.
b. By an argument similar to part (a), this LRT rejects $H_{0}^{+}$if

$$
T^{+}=\frac{\bar{X}-\bar{Y}-\delta}{\sqrt{S_{p}^{2}\left(\frac{1}{n}+\frac{1}{m}\right)}} \leq-t_{n+m-2, \alpha}
$$

c. Because $H_{0}$ is the union of $H_{0}^{+}$and $H_{0}^{-}$, by the IUT method of Theorem 8.3.23 the test that rejects $H_{0}$ if the tests in parts (a) and (b) both reject is a level $\alpha$ test of $H_{0}$. That is, the test rejects $H_{0}$ if $T^{+} \leq-t_{n+m-2, \alpha}$ and $T^{-} \geq t_{n+m-2, \alpha}$.
d. Use Theorem 8.3.24. Consider parameter points with $\mu_{X}-\mu_{Y}=\delta$ and $\sigma \rightarrow 0$. For any $\sigma, P\left(T^{+} \leq-t_{n+m-2, \alpha}\right)=\alpha$. The power of the $T^{-}$test is computed from the noncentral $t$ distribution with noncentrality parameter $\left|\mu_{x}-\mu_{Y}-(-\delta)\right| /[\sigma(1 / n+1 / m)]=2 \delta /[\sigma(1 / n+$ $1 / m)$ ] which converges to $\infty$ as $\sigma \rightarrow 0$. Thus, $P\left(T^{-} \geq t_{n+m-2, \alpha}\right) \rightarrow 1$ as $\sigma \rightarrow 0$. By Theorem 8.3.24, this IUT is a size $\alpha$ test of $H_{0}$.
8.49 a . The p-value is

$$
\begin{aligned}
P & \left\{\left.\binom{7 \text { or more successes }}{\text { out of } 10 \text { Bernoulli trials }} \right\rvert\, \theta=\frac{1}{2}\right\} \\
& =\binom{10}{7}\left(\frac{1}{2}\right)^{7}\left(\frac{1}{2}\right)^{3}+\binom{10}{8}\left(\frac{1}{2}\right)^{8}\left(\frac{1}{2}\right)^{2}+\binom{10}{9}\left(\frac{1}{2}\right)^{9}\left(\frac{1}{2}\right)^{1}+\binom{10}{10}\left(\frac{1}{2}\right)^{10}\left(\frac{1}{2}\right)^{0} \\
& =.171875 .
\end{aligned}
$$

b.

$$
\begin{aligned}
\text { P-value } & =P\{X \geq 3 \mid \lambda=1\}=1-P(X<3 \mid \lambda=1) \\
& =1-\left[\frac{e^{-1} 1^{2}}{2!}+\frac{e^{-1} 1^{1}}{1!}+\frac{e^{-1} 1^{0}}{0!}\right] \approx .0803 .
\end{aligned}
$$

c.

$$
\begin{aligned}
\text { P-value } & =P\left\{\sum_{i} X_{i} \geq 9 \mid 3 \lambda=3\right\}=1-P(Y<9 \mid 3 \lambda=3) \\
& =1-e^{-3}\left[\frac{3^{8}}{8!}+\frac{3^{7}}{7!}+\frac{3^{6}}{6!}+\frac{3^{5}}{5!}+\cdots+\frac{3^{1}}{1!}+\frac{3^{0}}{0!}\right] \approx .0038,
\end{aligned}
$$

where $Y=\sum_{i=1}^{3} X_{i} \sim \operatorname{Poisson}(3 \lambda)$.
8.50 From Exercise 7.26,

$$
\pi(\theta \mid \mathbf{x})=\sqrt{\frac{n}{2 \pi \sigma^{2}}} e^{-n\left(\theta-\delta_{ \pm}(\mathbf{x})\right)^{2} /\left(2 \sigma^{2}\right)}
$$

where $\delta_{ \pm}(\mathbf{x})=\bar{x} \pm \frac{\sigma^{2}}{n a}$ and we use the " + " if $\theta>0$ and the " - " if $\theta<0$.
a. For $K>0$,

$$
P(\theta>K \mid \mathbf{x}, a)=\sqrt{\frac{n}{2 \pi \sigma^{2}}} \int_{K}^{\infty} e^{-n\left(\theta-\delta_{+}(\mathbf{x})\right)^{2} /\left(2 \sigma^{2}\right)} d \theta=P\left(Z>\frac{\sqrt{n}}{\sigma}\left[K-\delta_{+}(\mathbf{x})\right]\right)
$$

where $Z \sim \mathrm{n}(0,1)$.
b. As $a \rightarrow \infty, \delta_{+}(\mathbf{x}) \rightarrow \bar{x}$ so $P(\theta>K) \rightarrow P\left(Z>\frac{\sqrt{n}}{\sigma}(K-\bar{x})\right)$.
c. For $K=0$, the answer in part (b) is $1-\left(\mathrm{p}\right.$-value) for $H_{0}: \theta \leq 0$.
8.51 If $\alpha<p(\mathbf{x})$,

$$
\sup _{\theta \in \Theta_{0}} P\left(W(\mathbf{X}) \geq c_{\alpha}\right)=\alpha<p(\mathbf{x})=\sup _{\theta \in \Theta_{0}} P(W(\mathbf{X}) \geq W(\mathbf{x})) .
$$

Thus $W(\mathbf{x})<c_{\alpha}$ and we could not reject $H_{0}$ at level $\alpha$ having observed $\mathbf{x}$. On the other hand, if $\alpha \geq p(\mathbf{x})$,

$$
\sup _{\theta \in \Theta_{0}} P\left(W(\mathbf{X}) \geq c_{\alpha}\right)=\alpha \geq p(\mathbf{x})=\sup _{\theta \in \Theta_{0}} P(W(\mathbf{X}) \geq W(\mathbf{x})) .
$$

Either $W(\mathbf{x}) \geq c_{\alpha}$ in which case we could reject $H_{0}$ at level $\alpha$ having observed $\mathbf{x}$ or $W(\mathbf{x})<c_{\alpha}$. But, in the latter case we could use $c_{\alpha}^{\prime}=W(\mathbf{x})$ and have $\left\{\mathbf{x}^{\prime}: W\left(\mathbf{x}^{\prime}\right) \geq c_{\alpha}^{\prime}\right\}$ define a size $\alpha$ rejection region. Then we could reject $H_{0}$ at level $\alpha$ having observed $\mathbf{x}$.
8.53 a.

$$
P(-\infty<\theta<\infty)=\frac{1}{2}+\frac{1}{2} \frac{1}{\sqrt{2 \pi \tau^{2}}} \int_{-\infty}^{\infty} e^{-\theta^{2} /\left(2 \tau^{2}\right)} d \theta=\frac{1}{2}+\frac{1}{2}=1
$$

b. First calculate the posterior density. Because

$$
f(\bar{x} \mid \theta)=\frac{\sqrt{n}}{\sqrt{2 \pi} \sigma} e^{-n(\bar{x}-\theta)^{2} /\left(2 \sigma^{2}\right)}
$$

we can calculate the marginal density as

$$
\begin{aligned}
m_{\pi}(\bar{x}) & =\frac{1}{2} f(\bar{x} \mid 0)+\frac{1}{2} \int_{-\infty}^{\infty} f(\bar{x} \mid \theta) \frac{1}{\sqrt{2 \pi} \tau} e^{-\theta^{2} /\left(2 \tau^{2}\right)} d \theta \\
& =\frac{1}{2} \frac{\sqrt{n}}{\sqrt{2 \pi} \sigma} e^{-n \bar{x}^{2} /\left(2 \sigma^{2}\right)}+\frac{1}{2} \frac{1}{\sqrt{2 \pi} \sqrt{\left(\sigma^{2} / n\right)+\tau^{2}}} e^{-\bar{x}^{2} /\left[2\left(\left(\sigma^{2} / n\right)+\tau^{2}\right)\right]}
\end{aligned}
$$

(see Exercise 7.22). Then $P(\theta=0 \mid \bar{x})=\frac{1}{2} f(\bar{x} \mid 0) / m_{\pi}(\bar{x})$.
c.

$$
\begin{aligned}
P(|\bar{X}|>\bar{x} \mid \theta=0) & =1-P(|\bar{X}| \leq \bar{x} \mid \theta=0) \\
& =1-P(-\bar{x} \leq \bar{X} \leq \bar{x} \mid \theta=0) \quad=2[1-\Phi(\bar{x} /(\sigma / \sqrt{n}))]
\end{aligned}
$$

where $\Phi$ is the standard normal cdf.
d. For $\sigma^{2}=\tau^{2}=1$ and $n=9$ we have a p-value of $2(1-\Phi(3 \bar{x}))$ and

$$
P(\theta=0 \mid \bar{x})=\left(1+\sqrt{\frac{1}{10}} e^{81 \bar{x}^{2} / 20}\right)^{-1}
$$

The p-value of $\bar{x}$ is usually smaller than the Bayes posterior probability except when $\bar{x}$ is very close to the $\theta$ value specified by $H_{0}$. The following table illustrates this.

Some p-values and posterior probabilities $(n=9)$

|  | 0 | $\pm .1$ | $\pm .15$ | $\pm .2$ | $\pm .5$ | $\pm .6533$ | $\pm .7$ | $\pm 1$ | $\pm 2$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| p-value of $\bar{x}$ | 1 | .7642 | .6528 | .5486 | .1336 | .05 | .0358 | .0026 | $\approx 0$ |
| posterior |  |  |  |  |  |  |  |  |  |
| $P(\theta=0 \mid \bar{x})$ | .7597 | .7523 | .7427 | .7290 | .5347 | .3595 | .3030 | .0522 | $\approx 0$ |

8.54 a. From Exercise 7.22 , the posterior distribution of $\theta \mid \mathbf{x}$ is normal with mean $\left[\tau^{2} /\left(\tau^{2}+\sigma^{2} / n\right)\right] \bar{x}$ and variance $\tau^{2} /\left(1+n \tau^{2} / \sigma^{2}\right)$. So

$$
\begin{aligned}
P(\theta \leq 0 \mid \mathbf{x}) & =P\left(Z \leq \frac{0-\left[\tau^{2} /\left(\tau^{2}+\sigma^{2} / n\right)\right] \bar{x}}{\sqrt{\tau^{2} /\left(1+n \tau^{2} / \sigma^{2}\right)}}\right) \\
& =P\left(Z \leq-\frac{\tau}{\sqrt{\left(\sigma^{2} / n\right)\left(\tau^{2}+\sigma^{2} / n\right)}} \bar{x}\right)=P\left(Z \geq \frac{\tau}{\sqrt{\left(\sigma^{2} / n\right)\left(\tau^{2}+\sigma^{2} / n\right)}} \bar{x}\right) .
\end{aligned}
$$

b. Using the fact that if $\theta=0, \bar{X} \sim \mathrm{n}\left(0, \sigma^{2} / n\right)$, the p -value is

$$
P(\bar{X} \geq \bar{x})=P\left(Z \geq \frac{\bar{x}-0}{\sigma / \sqrt{n}}\right)=P\left(Z \geq \frac{1}{\sigma / \sqrt{n}} \bar{x}\right)
$$

c. For $\sigma^{2}=\tau^{2}=1$,

$$
P(\theta \leq 0 \mid x)=P\left(Z \geq \frac{1}{\sqrt{(1 / n)(1+1 / n)}} \bar{x}\right) \quad \text { and } \quad P(\bar{X} \geq \bar{x})=P\left(Z \geq \frac{1}{\sqrt{1 / n}} \bar{x}\right)
$$

Because

$$
\frac{1}{\sqrt{(1 / n)(1+1 / n)}}<\frac{1}{\sqrt{1 / n}}
$$

the Bayes probability is larger than the p-value if $\bar{x} \geq 0$. (Note: The inequality is in the opposite direction for $\bar{x}<0$, but the primary interest would be in large values of $\bar{x}$.)
d. As $\tau^{2} \rightarrow \infty$, the constant in the Bayes probability,

$$
\frac{\tau}{\sqrt{\left(\sigma^{2} / n\right)\left(\tau^{2}+\sigma^{2} / n\right)}}=\frac{1}{\sqrt{\left(\sigma^{2} / n\right)\left(1+\sigma^{2} /\left(\tau^{2} n\right)\right)}} \rightarrow \frac{1}{\sigma / \sqrt{n}}
$$

the constant in the p-value. So the indicated equality is true.
8.55 The formulas for the risk functions are obtained from (8.3.14) using the power function $\beta(\theta)=$ $\Phi\left(-z_{\alpha}+\theta_{0}-\theta\right)$, where $\Phi$ is the standard normal cdf.
8.57 For $0-1$ loss by (8.3.12) the risk function for any test is the power function $\beta(\mu)$ for $\mu \leq 0$ and $1-\beta(\mu)$ for $\mu>0$. Let $\alpha=P(1<Z<2)$, the size of test $\delta$. By the Karlin-Rubin Theorem, the test $\delta_{z_{\alpha}}$ that rejects if $X>z_{\alpha}$ is also size $\alpha$ and is uniformly more powerful than $\delta$, that is, $\beta_{\delta_{z_{\alpha}}}(\mu)>\beta_{\delta}(\mu)$ for all $\mu>0$. Hence,

$$
R\left(\mu, \delta_{z_{\alpha}}\right)=1-\beta_{\delta_{z_{\alpha}}}(\mu)<1-\beta_{\delta}(\mu)=R(\mu, \delta), \quad \text { for all } \mu>0 .
$$

Now reverse the roles of $H_{0}$ and $H_{1}$ and consider testing $H_{0}^{*}: \mu>0$ versus $H_{1}^{*}: \mu \leq 0$. Consider the test $\delta^{*}$ that rejects $H_{0}^{*}$ if $X \leq 1$ or $X \geq 2$, and the test $\delta_{z_{\alpha}}^{*}$ that rejects $H_{0}^{*}$ if $X \leq z_{\alpha}$. It is easily verified that for $0-1$ loss $\delta$ and $\delta^{*}$ have the same risk functions, and $\delta_{z_{\alpha}}^{*}$ and $\delta_{z_{\alpha}}$ have the same risk functions. Furthermore, using the Karlin-Rubin Theorem as before, we can conclude that $\delta_{z_{\alpha}}^{*}$ is uniformly more powerful than $\delta^{*}$. Thus we have

$$
R(\mu, \delta)=R\left(\mu, \delta^{*}\right) \geq R\left(\mu, \delta_{z_{\alpha}}^{*}\right)=R\left(\mu, \delta_{z_{\alpha}}\right), \quad \text { for all } \mu \leq 0
$$

with strict inequality if $\mu<0$. Thus, $\delta_{z_{\alpha}}$ is better than $\delta$.

## Chapter 9

## Interval Estimation

9.1 Denote $A=\{x: L(x) \leq \theta\}$ and $B=\{x: U(x) \geq \theta\}$. Then $A \cap B=\{x: L(x) \leq \theta \leq U(x)\}$ and $1 \geq P\{A \cup B\}=P\{L(X) \leq \theta$ or $\theta \leq U(X)\} \geq P\{L(X) \leq \theta$ or $\theta \leq L(X)\}=1$, since $L(x) \leq U(x)$. Therefore, $P(A \cap B)=P(A)+P(B)-P(A \cup B)=1-\alpha_{1}+1-\alpha_{2}-1=1-\alpha_{1}-\alpha_{2}$.
9.3 a. The MLE of $\beta$ is $X_{(n)}=\max X_{i}$. Since $\beta$ is a scale parameter, $X_{(n)} / \beta$ is a pivot, and

$$
.05=P_{\beta}\left(X_{(n)} / \beta \leq c\right)=P_{\beta}\left(\operatorname{all} X_{i} \leq c \beta\right)=\left(\frac{c \beta}{\beta}\right)^{\alpha_{0} n}=c^{\alpha_{0} n}
$$

implies $c=.05^{1 / \alpha_{0} n}$. Thus, $.95=P_{\beta}\left(X_{(n)} / \beta>c\right)=P_{\beta}\left(X_{(n)} / c>\beta\right)$, and $\{\beta: \beta<$ $\left.X_{(n)} /\left(.05^{1 / \alpha_{0} n}\right)\right\}$ is a $95 \%$ upper confidence limit for $\beta$.
b. From 7.10, $\hat{\alpha}=12.59$ and $X_{(n)}=25$. So the confidence interval is $\left(0,25 /\left[\cdot 05^{1 /(12.59 \cdot 14)}\right]\right)=$ (0, 25.43).
9.4 a.

$$
\lambda(x, y)=\frac{\sup _{\lambda=\lambda_{0}} L\left(\sigma_{X}^{2}, \sigma_{Y}^{2} \mid x, y\right)}{\sup _{\lambda \in(0,+\infty)} L\left(\sigma_{X}^{2}, \sigma_{Y}^{2} \mid x, y\right)}
$$

The unrestricted MLEs of $\sigma_{X}^{2}$ and $\sigma_{Y}^{2}$ are $\hat{\sigma}_{X}^{2}=\frac{\Sigma X_{i}^{2}}{n}$ and $\hat{\sigma}_{Y}^{2}=\frac{\Sigma Y_{i}^{2}}{m}$, as usual. Under the restriction, $\lambda=\lambda_{0}, \sigma_{Y}^{2}=\lambda_{0} \sigma_{X}^{2}$, and

$$
\begin{aligned}
L\left(\sigma_{X}^{2}, \lambda_{0} \sigma_{X}^{2} \mid x, y\right) & =\left(2 \pi \sigma_{X}^{2}\right)^{-n / 2}\left(2 \pi \lambda_{0} \sigma_{X}^{2}\right)^{-m / 2} e^{-\Sigma x_{i}^{2} /\left(2 \sigma_{X}^{2}\right)} \cdot e^{-\Sigma y_{i}^{2} /\left(2 \lambda_{0} \sigma_{X}^{2}\right)} \\
& =\left(2 \pi \sigma_{X}^{2}\right)^{-(m+n) / 2} \lambda_{0}^{-m / 2} e^{-\left(\lambda_{0} \Sigma x_{i}^{2}+\Sigma y_{i}^{2}\right) /\left(2 \lambda_{0} \sigma_{X}^{2}\right)}
\end{aligned}
$$

Differentiating the log likelihood gives

$$
\begin{aligned}
\frac{d \log L}{d\left(\sigma_{X}^{2}\right)^{2}} & =\frac{d}{d \sigma_{X}^{2}}\left[-\frac{m+n}{2} \log \sigma_{X}^{2}-\frac{m+n}{2} \log (2 \pi)-\frac{m}{2} \log \lambda_{0}-\frac{\lambda_{0} \Sigma x_{i}^{2}+\Sigma y_{i}^{2}}{2 \lambda_{0} \sigma_{X}^{2}}\right] \\
& =-\frac{m+n}{2}\left(\sigma_{X}^{2}\right)^{-1}+\frac{\lambda_{0} \Sigma x_{i}^{2}+\Sigma y_{i}^{2}}{2 \lambda_{0}}\left(\sigma_{X}^{2}\right)^{-2} \stackrel{\text { set }}{=} 0
\end{aligned}
$$

which implies

$$
\hat{\sigma}_{0}^{2}=\frac{\lambda_{0} \Sigma x_{i}^{2}+\Sigma y_{i}^{2}}{\lambda_{0}(m+n)} .
$$

To see this is a maximum, check the second derivative:

$$
\begin{aligned}
\frac{d^{2} \log L}{d\left(\sigma_{X}^{2}\right)^{2}} & =\frac{m+n}{2}\left(\sigma_{X}^{2}\right)^{-2}-\left.\frac{1}{\lambda_{0}}\left(\lambda_{0} \Sigma x_{i}^{2}+\Sigma y_{i}^{2}\right)\left(\sigma_{X}^{2}\right)^{-3}\right|_{\sigma_{X}^{2}=\hat{\sigma}_{0}^{2}} \\
& =-\frac{m+n}{2}\left(\hat{\sigma}_{0}^{2}\right)^{-2}<0
\end{aligned}
$$

therefore $\hat{\sigma}_{0}^{2}$ is the MLE. The LRT statistic is

$$
\frac{\left(\hat{\sigma}_{X}^{2}\right)^{n / 2}\left(\hat{\sigma}_{Y}^{2}\right)^{m / 2}}{\lambda_{0}^{m / 2}\left(\hat{\sigma}_{0}^{2}\right)^{(m+n) / 2}}
$$

and the test is: Reject $H_{0}$ if $\lambda(x, y)<k$, where $k$ is chosen to give the test size $\alpha$.
b. Under $H_{0}, \sum Y_{i}^{2} /\left(\lambda_{0} \sigma_{X}^{2}\right) \sim \chi_{m}^{2}$ and $\sum X_{i}^{2} / \sigma_{X}^{2} \sim \chi_{n}^{2}$, independent. Also, we can write

$$
\begin{aligned}
\lambda(X, Y) & =\left(\frac{1}{\frac{n}{m+n}+\frac{\left(\Sigma Y_{i}^{2} / \lambda_{0} \sigma_{X}^{2}\right) / m}{\left(\Sigma X_{i}^{2} / \sigma_{X}^{2}\right) / n} \cdot \frac{m}{m+n}}\right)^{n / 2}\left(\frac{1}{\frac{m}{m+n}+\frac{\left(\Sigma X_{i}^{2} / \sigma_{X}^{2}\right) / n}{\left(\Sigma Y_{i}^{2} / \lambda_{0} \sigma_{X}^{2}\right) / m} \cdot \frac{n}{m+n}}\right)^{m / 2} \\
& =\left[\frac{1}{\frac{n}{n+m}+\frac{m}{m+n} F}\right]^{n / 2}\left[\frac{1}{\frac{m}{m+n}+\frac{n}{m+n} F^{-1}}\right]^{m / 2}
\end{aligned}
$$

where $F=\frac{\Sigma Y_{i}^{2} / \lambda_{0} m}{\Sigma X_{i}^{2} / n} \sim F_{m, n}$ under $H_{0}$. The rejection region is

$$
\left\{(x, y): \frac{1}{\left[\frac{n}{n+m}+\frac{m}{m+n} F\right]^{n / 2}} \cdot \frac{1}{\left[\frac{m}{m+n}+\frac{n}{m+n} F^{-1}\right]^{m / 2}}<c_{\alpha}\right\}
$$

where $c_{\alpha}$ is chosen to satisfy

$$
P\left\{\left[\frac{n}{n+m}+\frac{m}{m+n} F\right]^{-n / 2}\left[\frac{m}{n+m}+\frac{n}{m+n} F^{-1}\right]^{-m / 2}<c_{\alpha}\right\}=\alpha
$$

c. To ease notation, let $a=m /(n+m)$ and $b=a \sum y_{i}^{2} / \sum x_{i}^{2}$. From the duality of hypothesis tests and confidence sets, the set

$$
c(\lambda)=\left\{\lambda:\left(\frac{1}{a+b / \lambda}\right)^{n / 2}\left(\frac{1}{(1-a)+\frac{a(1-a)}{b} \lambda}\right)^{m / 2} \geq c_{\alpha}\right\}
$$

is a $1-\alpha$ confidence set for $\lambda$. We now must establish that this set is indeed an interval. To do this, we establish that the function on the left hand side of the inequality has only an interior maximum. That is, it looks like an upside-down bowl. Furthermore, it is straightforward to establish that the function is zero at both $\lambda=0$ and $\lambda=\infty$. These facts imply that the set of $\lambda$ values for which the function is greater than or equal to $c_{\alpha}$ must be an interval. We make some further simplifications. If we multiply both sides of the inequality by $[(1-a) / b]^{m / 2}$, we need be concerned with only the behavior of the function

$$
h(\lambda)=\left(\frac{1}{a+b / \lambda}\right)^{n / 2}\left(\frac{1}{b+a \lambda}\right)^{m / 2}
$$

Moreover, since we are most interested in the sign of the derivative of $h$, this is the same as the sign of the derivative of $\log h$, which is much easier to work with. We have

$$
\begin{aligned}
\frac{d}{d \lambda} \log h(\lambda) & =\frac{d}{d \lambda}\left[-\frac{n}{2} \log (a+b / \lambda)-\frac{m}{2} \log (b+a \lambda)\right] \\
& =\frac{n}{2} \frac{b / \lambda^{2}}{a+b / \lambda}-\frac{m}{2} \frac{a}{b+a \lambda} \\
& =\frac{1}{2 \lambda^{2}(a+b / \lambda)(b+a \lambda)}\left[-a^{2} m \lambda^{2}+a b(n-m) \lambda+n b^{2}\right]
\end{aligned}
$$

The sign of the derivative is given by the expression in square brackets, a parabola. It is easy to see that for $\lambda \geq 0$, the parabola changes sign from positive to negative. Since this is the sign change of the derivative, the function must increase then decrease. Hence, the function is an upside-down bowl, and the set is an interval.
9.5 a. Analogous to Example 9.2.5, the test here will reject $H_{0}$ if $T<k\left(p_{0}\right)$. Thus the confidence set is $C=\{p: T \geq k(p)\}$. Since $k(p)$ is nondecreasing, this gives an upper bound on $p$.
b. $k(p)$ is the integer that simultaneously satisfies

$$
\sum_{y=k(p)}^{n}\binom{n}{y} p^{y}(1-p)^{n-y} \geq 1-\alpha \quad \text { and } \quad \sum_{y=k(p)+1}^{n}\binom{n}{y} p^{y}(1-p)^{n-y}<1-\alpha
$$

9.6 a. For $Y=\sum X_{i} \sim \operatorname{binomial}(n, p)$, the LRT statistic is

$$
\lambda(y)=\frac{\binom{n}{y} p_{0}^{y}\left(1-p_{0}\right)^{n-y}}{\binom{n}{y} \hat{p}^{y}(1-\hat{p})^{n-y}}=\left(\frac{p_{0}(1-\hat{p})}{\hat{p}\left(1-p_{0}\right)}\right)^{y}\left(\frac{1-p_{0}}{1-\hat{p}}\right)^{n}
$$

where $\hat{p}=y / n$ is the MLE of $p$. The acceptance region is

$$
A\left(p_{0}\right)=\left\{y:\left(\frac{p_{0}}{\hat{p}}\right)^{y}\left(\frac{1-p_{0}}{1-\hat{p}}\right)^{n-y} \geq k^{*}\right\}
$$

where $k^{*}$ is chosen to satisfy $P_{p_{0}}\left(Y \in A\left(p_{0}\right)\right)=1-\alpha$. Inverting the acceptance region to a confidence set, we have

$$
C(y)=\left\{p:\left(\frac{p}{\hat{p}}\right)^{y}\left(\frac{(1-p)}{1-\hat{p}}\right)^{n-y} \geq k^{*}\right\}
$$

b. For given $n$ and observed $y$, write

$$
C(y)=\left\{p:(n / y)^{y}(n /(n-y))^{n-y} p^{y}(1-p)^{n-y} \geq k^{*}\right\}
$$

This is clearly a highest density region. The endpoints of $C(y)$ are roots of the $n^{\text {th }}$ degree polynomial (in $p),(n / y)^{y}(n /(n-y))^{n-y} p^{y}(1-p)^{n-y}-k^{*}$. The interval of (10.4.4) is

$$
\left\{p:\left|\frac{\hat{p}-p}{\sqrt{p(1-p) / n}}\right| \leq z_{\alpha / 2}\right\}
$$

The endpoints of this interval are the roots of the second degree polynomial (in $p$ ), $(\hat{p}-p)^{2}-$ $z_{\alpha / 2}^{2} p(1-p) / n$. Typically, the second degree and $n^{\text {th }}$ degree polynomials will not have the same roots. Therefore, the two intervals are different. (Note that when $n \rightarrow \infty$ and $y \rightarrow \infty$, the density becomes symmetric (CLT). Then the two intervals are the same.)
9.7 These densities have already appeared in Exercise 8.8, where LRT statistics were calculated for testing $H_{0}: a=1$.
a. Using the result of Exercise 8.8(a), the restricted MLE of $\theta$ (when $a=a_{0}$ ) is

$$
\hat{\theta}_{0}=\frac{-a_{0}+\sqrt{a_{0}^{2}+4 \sum x_{i}^{2} / n}}{2}
$$

and the unrestricted MLEs are

$$
\hat{\theta}=\bar{x} \quad \text { and } \quad \hat{a}=\frac{\sum\left(x_{i}-\bar{x}\right)^{2}}{n \bar{x}}
$$

The LRT statistic is

$$
\lambda(x)=\frac{\left(\frac{\hat{a} \hat{\theta}}{a_{0} \hat{\theta}_{0}}\right)^{n / 2} e^{-\frac{1}{2 a_{0} \hat{\theta}_{0}} \Sigma\left(x_{i}-\hat{\theta}_{0}\right)^{2}}}{e^{-\frac{1}{2 \hat{a} \theta} \Sigma\left(x_{i}-\hat{\theta}\right)^{2}}}=\left(\frac{1}{2 \pi a_{0} \hat{\theta}_{0}}\right)^{n / 2} e^{n / 2} e^{-\frac{1}{2 a_{0} \hat{\theta}_{0}} \Sigma\left(x_{i}-\hat{\theta}_{0}\right)^{2}}
$$

The rejection region of a size $\alpha$ test is $\left\{x: \lambda(x) \leq c_{\alpha}\right\}$, and a $1-\alpha$ confidence set is $\left\{a_{0}: \lambda(x) \geq c_{\alpha}\right\}$.
b. Using the results of Exercise 8.8b, the restricted MLE (for $a=a_{0}$ ) is found by solving

$$
-a_{0} \theta^{2}+\left[\hat{\sigma}^{2}+(\bar{x}-\theta)^{2}\right]+\theta(\bar{x}-\theta)=0
$$

yielding the MLE

$$
\hat{\theta}_{R}=\bar{x}+\sqrt{\bar{x}+4 a_{0}\left(\hat{\sigma}^{2}+\bar{x}^{2}\right)} / 2 a_{0} .
$$

The unrestricted MLEs are

$$
\hat{\theta}=\bar{x} \quad \text { and } \quad \hat{a}=\frac{1}{n \bar{x}^{2}} \sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2}=\frac{\hat{\sigma}^{2}}{\bar{x}^{2}}
$$

yielding the LRT statistic

$$
\lambda(x)=\left(\hat{\sigma} / \hat{\theta}_{R}\right)^{n} e^{(n / 2)-\Sigma\left(x_{i}-\hat{\theta}_{R}\right)^{2} /\left(2 \hat{\theta}_{R}\right)}
$$

The rejection region of a size $\alpha$ test is $\left\{x: \lambda(x) \leq c_{\alpha}\right\}$, and a $1-\alpha$ confidence set is $\left\{a_{0}: \lambda(x) \geq c_{\alpha}\right\}$.
9.9 Let $Z_{1}, \ldots, Z_{n}$ be iid with pdf $f(z)$.
a. For $X_{i} \sim f(x-\mu),\left(X_{1}, \ldots, X_{n}\right) \sim\left(Z_{1}+\mu, \ldots, Z_{n}+\mu\right)$, and $\bar{X}-\mu \sim \overline{Z+\mu}-\mu=\bar{Z}$. The distribution of $\bar{Z}$ does not depend on $\mu$.
b. For $X_{i} \sim f(x / \sigma) / \sigma,\left(X_{1}, \ldots, X_{n}\right) \sim\left(\sigma Z_{1}, \ldots, \sigma Z_{n}\right)$, and $\bar{X} / \sigma \sim \overline{\sigma Z} / \sigma=\bar{Z}$. The distribution of $\bar{Z}$ does not depend on $\sigma$.
c. For $X_{i} \sim f((x-\mu) / \sigma) / \sigma,\left(X_{1}, \ldots, X_{n}\right) \sim\left(\sigma Z_{1}+\mu, \ldots, \sigma Z_{n}+\mu\right)$, and $(\bar{X}-\mu) / S_{X} \sim$ $(\overline{\sigma Z+\mu}-\mu) / S_{\sigma Z+\mu}=\sigma \bar{Z} /\left(\sigma S_{Z}\right)=\bar{Z} / S_{Z}$. The distribution of $\bar{Z} / S_{Z}$ does not depend on $\mu$ or $\sigma$.
9.11 Recall that if $\theta$ is the true parameter, then $F_{T}(T \mid \theta) \sim$ uniform $(0,1)$. Thus,

$$
P_{\theta_{0}}\left(\left\{T: \alpha_{1} \leq F_{T}\left(T \mid \theta_{0}\right) \leq 1-\alpha_{2}\right\}\right)=P\left(\alpha_{1} \leq U \leq 1-\alpha_{2}\right)=1-\alpha_{2}-\alpha_{1}
$$

where $U \sim$ uniform $(0,1)$. Since

$$
t \in\left\{t: \alpha_{1} \leq F_{T}(t \mid \theta) \leq 1-\alpha_{2}\right\} \quad \Leftrightarrow \quad \theta \in\left\{\theta: \alpha_{1} \leq F_{T}(t \mid \theta) \leq 1-\alpha_{2}\right\}
$$

the same calculation shows that the interval has confidence $1-\alpha_{2}-\alpha_{1}$.
9.12 If $X_{1}, \ldots, X_{n} \sim \operatorname{iid} \mathrm{n}(\theta, \theta)$, then $\sqrt{n}(\bar{X}-\theta) / \sqrt{\theta} \sim \mathrm{n}(0,1)$ and a $1-\alpha$ confidence interval is $\left\{\theta:|\sqrt{n}(\bar{x}-\theta) / \sqrt{\theta}| \leq z_{\alpha / 2}\right\}$. Solving for $\theta$, we get

$$
\left\{\theta: n \theta^{2}-\theta\left(2 n \bar{x}+z_{\alpha / 2}^{2}\right)+n \bar{x}^{2} \leq 0\right\}=\left\{\theta: \theta \in\left(2 n \bar{x}+z_{\alpha / 2}^{2} \pm \sqrt{4 n \bar{x} z_{\alpha / 2}^{2}+z_{\alpha / 2}^{4}}\right) / 2 n\right\}
$$

Simpler answers can be obtained using the $t$ pivot, $(\bar{X}-\theta) /(S / \sqrt{n})$, or the $\chi^{2}$ pivot, $(n-1) S^{2} / \theta^{2}$. (Tom Werhley of Texas A\&M university notes the following: The largest probability of getting a negative discriminant (hence empty confidence interval) occurs when $\sqrt{n \theta}=\frac{1}{2} z_{\alpha / 2}$, and the probability is equal to $\alpha / 2$. The behavior of the intervals for negative values of $\bar{x}$ is also interesting. When $\bar{x}=0$ the lefthand endpoint is also equal to 0 , but when $\bar{x}<0$, the lefthand endpoint is positive. Thus, the interval based on $\bar{x}=0$ contains smaller values of $\theta$ than that based on $\bar{x}<0$. The intervals get smaller as $\bar{x}$ decreases, finally becoming empty.)
9.13 a. For $Y=-(\log X)^{-1}$, the pdf of $Y$ is $f_{Y}(y)=\frac{\theta}{y^{2}} e^{-\theta / y}, 0<y<\infty$, and

$$
P(Y / 2 \leq \theta \leq Y)=\int_{\theta}^{2 \theta} \frac{\theta}{y^{2}} e^{-\theta / y} d y=\left.e^{-\theta / y}\right|_{\theta} ^{2 \theta}=e^{-1 / 2}-e^{-1}=.239
$$

b. Since $f_{X}(x)=\theta x^{\theta-1}, 0<x<1, T=X^{\theta}$ is a good guess at a pivot, and it is since $f_{T}(t)=1$, $0<t<1$. Thus a pivotal interval is formed from $P\left(a<X^{\theta}<b\right)=b-a$ and is

$$
\left\{\theta: \frac{\log b}{\log x} \leq \theta \leq \frac{\log a}{\log x}\right\}
$$

Since $X^{\theta} \sim$ uniform $(0,1)$, the interval will have confidence .239 as long as $b-a=.239$.
c. The interval in part a) is a special case of the one in part b). To find the best interval, we minimize $\log b-\log a$ subject to $b-a=1-\alpha$, or $b=1-\alpha+a$. Thus we want to minimize $\log (1-\alpha+a)-\log a=\log \left(1+\frac{1-\alpha}{a}\right)$, which is minimized by taking $a$ as big as possible. Thus, take $b=1$ and $a=\alpha$, and the best $1-\alpha$ pivotal interval is $\left\{\theta: 0 \leq \theta \leq \frac{\log \alpha}{\log x}\right\}$. Thus the interval in part a) is nonoptimal. A shorter interval with confidence coefficient .239 is $\{\theta: 0 \leq \theta \leq \log (1-.239) / \log (x)\}$.
9.14 a. Recall the Bonferroni Inequality (1.2.9), $P\left(A_{1} \cap A_{2}\right) \geq P\left(A_{1}\right)+P\left(A_{2}\right)-1$. Let $A_{1}=$ $P($ interval covers $\mu)$ and $A_{2}=P$ (interval covers $\sigma^{2}$ ). Use the interval (9.2.14), with $t_{n-1, \alpha / 4}$ to get a $1-\alpha / 2$ confidence interval for $\mu$. Use the interval after (9.2.14) with $b=\chi_{n-1, \alpha / 4}^{2}$ and $a=\chi_{n-1,1-\alpha / 4}^{2}$ to get a $1-\alpha / 2$ confidence interval for $\sigma$. Then the natural simultaneous set is

$$
\begin{gathered}
C_{a}(x)=\left\{\left(\mu, \sigma^{2}\right): \bar{x}-t_{n-1, \alpha / 4} \frac{s}{\sqrt{n}} \leq \mu \leq \bar{x}+t_{n-1, \alpha / 4} \frac{s}{\sqrt{n}}\right. \\
\text { and } \left.\frac{(n-1) s^{2}}{\chi_{n-1, \alpha / 4}^{2}} \leq \sigma^{2} \leq \frac{(n-1) s^{2}}{\chi_{n-1,1-\alpha / 4}^{2}}\right\}
\end{gathered}
$$

and $P\left(C_{a}(X)\right.$ covers $\left.\left(\mu, \sigma^{2}\right)\right)=P\left(A_{1} \cap A_{2}\right) \geq P\left(A_{1}\right)+P\left(A_{2}\right)-1=2(1-\alpha / 2)-1=1-\alpha$.
b. If we replace the $\mu$ interval in a) by $\left\{\mu: \bar{x}-\frac{k \sigma}{\sqrt{n}} \leq \mu \leq \bar{x}+\frac{k \sigma}{\sqrt{n}}\right\}$ then $\frac{\bar{X}-\mu}{\sigma / \sqrt{n}} \sim \mathrm{n}(0,1)$, so we use $z_{\alpha / 4}$ and

$$
C_{b}(x)=\left\{\left(\mu, \sigma^{2}\right): \bar{x}-z_{\alpha / 4} \frac{\sigma}{\sqrt{n}} \leq \mu \leq \bar{x}+z_{\alpha / 4} \frac{\sigma}{\sqrt{n}} \text { and } \frac{(n-1) s^{2}}{\chi_{n-1, \alpha / 4}^{2}} \leq \sigma^{2} \leq \frac{(n-1) s^{2}}{\chi_{n-1,1-\alpha / 4}^{2}}\right\}
$$

and $P\left(C_{b}(X)\right.$ covers $\left.\left(\mu, \sigma^{2}\right)\right) \geq 2(1-\alpha / 2)-1=1-\alpha$.
c. The sets can be compared graphically in the $(\mu, \sigma)$ plane: $C_{a}$ is a rectangle, since $\mu$ and $\sigma^{2}$ are treated independently, while $C_{b}$ is a trapezoid, with larger $\sigma^{2}$ giving a longer interval. Their areas can also be calculated

$$
\begin{aligned}
\text { Area of } C_{a}= & {\left[2 t_{n-1, \alpha / 4} \frac{s}{\sqrt{n}}\right]\left\{\sqrt{(n-1) s^{2}}\left(\frac{1}{\chi_{n-1,1-\alpha / 4}^{2}}-\frac{1}{\chi_{n-1, \alpha / 4}^{2}}\right)\right\} } \\
\text { Area of } C_{b}= & {\left[z_{\alpha / 4} \frac{s}{\sqrt{n}}\left(\sqrt{\frac{n-1}{\chi_{n-1,1-\alpha / 4}^{2}}}+\sqrt{\left.\frac{n-1}{\chi_{n-1, \alpha / 4}^{2}}\right)}\right]\right.} \\
& \times\left\{\sqrt{(n-1) s^{2}}\left(\frac{1}{\chi_{n-1,1-\alpha / 4}^{2}}-\frac{1}{\chi_{n-1, \alpha / 4}^{2}}\right)\right\}
\end{aligned}
$$

and compared numerically.
9.15 Fieller's Theorem says that a $1-\alpha$ confidence set for $\theta=\mu_{Y} / \mu_{X}$ is

$$
\left\{\theta:\left(\bar{x}^{2}-\frac{t_{n-1, \alpha / 2}^{2}}{n-1} s_{X}^{2}\right) \theta^{2}-2\left(\bar{x} \bar{y}-\frac{t_{n-1, \alpha / 2}^{2}}{n-1} s_{Y X}\right) \theta+\left(\bar{y}^{2}-\frac{t_{n-1, \alpha / 2}^{2}}{n-1} s_{Y}^{2}\right) \leq 0\right\}
$$

a. Define $a=\bar{x}^{2}-t s_{X}^{2}, b=\bar{x} \bar{y}-t s_{Y X}, c=\bar{y}^{2}-t s_{Y}^{2}$, where $t=\frac{t_{n-1, \alpha / 2}^{2}}{n-1}$. Then the parabola opens upward if $a>0$. Furthermore, if $a>0$, then there always exists at least one real root. This follows from the fact that at $\theta=\bar{y} / \bar{x}$, the value of the function is negative. For $\bar{\theta}=\bar{y} / \bar{x}$ we have

$$
\begin{aligned}
& \left(\bar{x}^{2}-t s_{X}^{2}\right)\left(\frac{\bar{y}}{\bar{x}}\right)^{2}-2\left(\bar{x} \bar{y}-t s_{X Y}\right)\left(\frac{\bar{y}}{\bar{x}}\right)+\left(\bar{y}^{2}-a s_{Y}^{2}\right) \\
& \quad=-t\left[\frac{\bar{y}^{2}}{\bar{x}^{2}} s_{X}^{2}-2 \frac{\bar{y}}{\bar{x}} s_{X Y}+s_{Y}^{2}\right] \\
& \quad=-t\left[\sum_{i=1}^{n}\left(\frac{\bar{y}^{2}}{\bar{x}^{2}}\left(x_{i}-\bar{x}\right)^{2}-2 \frac{\bar{y}}{\bar{x}}\left(x_{i}-\bar{x}\right)\left(y_{i}-\bar{y}\right)+\left(y_{i}-\bar{y}\right)^{2}\right)\right] \\
& \quad=-t\left[\sum_{i=1}^{n}\left(\frac{\bar{y}}{\bar{x}}\left(x_{i}-\bar{x}\right)-\left(y_{i}-\bar{y}\right)\right)^{2}\right]
\end{aligned}
$$

which is negative.
b. The parabola opens downward if $a<0$, that is, if $\bar{x}^{2}<t s_{X}^{2}$. This will happen if the test of $H_{0}: \mu_{X}=0$ accepts $H_{0}$ at level $\alpha$.
c. The parabola has no real roots if $b^{2}<a c$. This can only occur if $a<0$.
9.16 a. The LRT (see Example 8.2.1) has rejection region $\left\{x:\left|\bar{x}-\theta_{0}\right|>z_{\alpha / 2} \sigma / \sqrt{n}\right\}$, acceptance region $A\left(\theta_{0}\right)=\left\{x:-z_{\alpha / 2} \sigma / \sqrt{n} \leq \bar{x}-\theta_{0} \leq z_{\alpha / 2} \sigma / \sqrt{n}\right\}$, and $1-\alpha$ confidence interval $C(\theta)=$ $\left\{\theta: \bar{x}-z_{\alpha / 2} \sigma / \sqrt{n} \leq \theta \leq \bar{x}+z_{\alpha / 2} \sigma / \sqrt{n}\right\}$.
b. We have a UMP test with rejection region $\left\{x: \bar{x}-\theta_{0}<-z_{\alpha} \sigma / \sqrt{n}\right\}$, acceptance region $A\left(\theta_{0}\right)=\left\{x: \bar{x}-\theta_{0} \geq-z_{\alpha} \sigma / \sqrt{n}\right\}$, and $1-\alpha$ confidence interval $C(\theta)=\left\{\theta: \bar{x}+z_{\alpha} \sigma / \sqrt{n} \geq \theta\right\}$.
c. Similar to b), the UMP test has rejection region $\left\{x: \bar{x}-\theta_{0}>z_{\alpha} \sigma / \sqrt{n}\right\}$, acceptance region $A\left(\theta_{0}\right)=\left\{x: \bar{x}-\theta_{0} \leq z_{\alpha} \sigma / \sqrt{n}\right\}$, and $1-\alpha$ confidence interval $C(\theta)=\left\{\theta: \bar{x}-z_{\alpha} \sigma / \sqrt{n} \leq \theta\right\}$.
9.17 a. Since $X-\theta \sim \operatorname{uniform}(-1 / 2,1 / 2), P(a \leq X-\theta \leq b)=b-a$. Any $a$ and $b$ satisfying $b=a+1-\alpha$ will do. One choice is $a=-\frac{1}{2}+\frac{\alpha}{2}, b=\frac{1}{2}-\frac{\alpha}{2}$.
b. Since $T=X / \theta$ has pdf $f(t)=2 t, 0 \leq t \leq 1$,

$$
P(a \leq X / \theta \leq b)=\int_{a}^{b} 2 t d t=b^{2}-a^{2}
$$

Any $a$ and $b$ satisfying $b^{2}=a^{2}+1-\alpha$ will do. One choice is $a=\sqrt{\alpha / 2}, b=\sqrt{1-\alpha / 2}$.
9.18 a. $P_{p}(X=1)=\binom{3}{1} p^{1}(1-p)^{3-1}=3 p(1-p)^{2}$, maximum at $p=1 / 3$. $P_{p}(X=2)=\binom{3}{2} p^{2}(1-p)^{3-2}=3 p^{2}(1-p)$, maximum at $p=2 / 3$.
b. $P(X=0)=\binom{3}{0} p^{0}(1-p)^{3-0}=(1-p)^{3}$, and this is greater than $P(X=2)$ if $(1-p)^{2}>3 p^{2}$, or $2 p^{2}+2 p-1<0$. At $p=1 / 3,2 p^{2}+2 p-1=-1 / 9$.
c. To show that this is a $1-\alpha=.442$ interval, compare with the interval in Example 9.2.11. There are only two discrepancies. For example,

$$
P(p \in \text { interval } \mid .362<p<.634)=P(X=1 \text { or } X=2)>.442
$$

by comparison with Sterne's procedure, which is given by

|  | interval |
| :--- | :--- |
| 0 | $[.000, .305)$ |
| 1 | $[.305, .634)$ |
| 2 | $[.362, .762)$ |
| 3 | $[.695,1]$. |

9.19 For $F_{T}(t \mid \theta)$ increasing in $\theta$, there are unique values $\theta_{U}(t)$ and $\theta_{L}(t)$ such that $F_{T}(t \mid \theta)<1-\frac{\alpha}{2}$ if and only if $\theta<\theta_{U}(t)$ and $F_{T}(t \mid \theta)>\frac{\alpha}{2}$ if and only if $\theta>\theta_{L}(t)$. Hence,

$$
\begin{aligned}
P\left(\theta_{L}(T) \leq \theta \leq \theta_{U}(T)\right) & =P\left(\theta \leq \theta_{U}(T)\right)-P\left(\theta \leq \theta_{L}(T)\right) \\
& =P\left(F_{T}(T) \leq 1-\frac{\alpha}{2}\right)-P\left(F_{T}(T) \leq \frac{\alpha}{2}\right) \\
& =1-\alpha .
\end{aligned}
$$

9.21 To construct a $1-\alpha$ confidence interval for $p$ of the form $\{p: \ell \leq p \leq u\}$ with $P(\ell \leq p \leq u)=$ $1-\alpha$, we use the method of Theorem 9.2.12. We must solve for $\ell$ and $u$ in the equations

$$
\text { (1) } \frac{\alpha}{2}=\sum_{k=0}^{x}\binom{n}{k} u^{k}(1-u)^{n-k} \quad \text { and } \quad(2) \frac{\alpha}{2}=\sum_{k=x}^{n}\binom{n}{k} \ell^{k}(1-\ell)^{n-k} \text {. }
$$

In equation (1) $\alpha / 2=P(K \leq x)=P(Y \leq 1-u)$, where $Y \sim \operatorname{beta}(n-x, x+1)$ and $K \sim \operatorname{binomial}(n, u)$. This is Exercise 2.40. Let $Z \sim F_{2(n-x), 2(x+1)}$ and $c=(n-x) /(x+1)$. By Theorem 5.3.8c, $c Z /(1+c Z) \sim \operatorname{beta}(n-x, x+1) \sim Y$. So we want

$$
\alpha / 2=P\left(\frac{c Z}{(1+c Z)} \leq 1-u\right)=P\left(\frac{1}{Z} \geq \frac{c u}{1-u}\right)
$$

From Theorem 5.3.8a, $1 / Z \sim F_{2(x+1), 2(n-x)}$. So we need $c u /(1-u)=F_{2(x+1), 2(n-x), \alpha / 2}$. Solving for $u$ yields

$$
u=\frac{\frac{x+1}{n-x} F_{2(x+1), 2(n-x), \alpha / 2}}{1+\frac{x+1}{n-x} F_{2(x+1), 2(n-x), \alpha / 2}}
$$

A similar manipulation on equation (2) yields the value for $\ell$.
9.23 a. The LRT statistic for $H_{0}: \lambda=\lambda_{0}$ versus $H_{1}: \lambda \neq \lambda_{0}$ is

$$
g(y)=e^{-n \lambda_{0}}\left(n \lambda_{0}\right)^{y} / e^{-n \hat{\lambda}}(n \hat{\lambda})^{y}
$$

where $Y=\sum X_{i} \sim \operatorname{Poisson}(n \lambda)$ and $\hat{\lambda}=y / n$. The acceptance region for this test is $A\left(\lambda_{0}\right)=\left\{y: g(y)>c\left(\lambda_{0}\right)\right)$ where $c\left(\lambda_{0}\right)$ is chosen so that $P\left(Y \in A\left(\lambda_{0}\right)\right) \geq 1-\alpha . g(y)$ is a unimodal function of $y$ so $A\left(\lambda_{0}\right)$ is an interval of $y$ values. Consider constructing $A\left(\lambda_{0}\right)$ for each $\lambda_{0}>0$. Then, for a fixed $y$, there will be a smallest $\lambda_{0}$, call it $a(y)$, and a largest $\lambda_{0}$, call it $b(y)$, such that $y \in A\left(\lambda_{0}\right)$. The confidence interval for $\lambda$ is then $C(y)=(a(y), b(y))$. The values $a(y)$ and $b(y)$ are not expressible in closed form. They can be determined by a numerical search, constructing $A\left(\lambda_{0}\right)$ for different values of $\lambda_{0}$ and determining those values for which $y \in A\left(\lambda_{0}\right)$. (Jay Beder of the University of Wisconsin, Milwaukee, reminds us that since $c$ is a function of $\lambda$, the resulting confidence set need not be a highest density region of a likelihood function. This is an example of the effect of the imposition of one type of inference (frequentist) on another theory (likelihood).)
b. The procedure in part a) was carried out for $y=558$ and the confidence interval was found to be ( $57.78,66.45$ ). For the confidence interval in Example 9.2.15, we need the values $\chi_{1116, .95}^{2}=$ 1039.444 and $\chi_{1118, .05}^{2}=1196.899$. This confidence interval is $(1039.444 / 18,1196.899 / 18)=$ ( $57.75,66.49$ ). The two confidence intervals are virtually the same.
9.25 The confidence interval derived by the method of Section 9.2.3 is

$$
C(y)=\left\{\mu: y+\frac{1}{n} \log \left(\frac{\alpha}{2}\right) \leq \mu \leq y+\frac{1}{n} \log \left(1-\frac{\alpha}{2}\right)\right\}
$$

where $y=\min _{i} x_{i}$. The LRT method derives its interval from the test of $H_{0}: \mu=\mu_{0}$ versus $H_{1}: \mu \neq \mu_{0}$. Since $Y$ is sufficient for $\mu$, we can use $f_{Y}(y \mid \mu)$. We have

$$
\begin{aligned}
\lambda(y) & =\frac{\sup _{\mu=\mu_{0}} L(\mu \mid y)}{\sup _{\mu \in(-\infty, \infty)} L(\mu \mid y)}=\frac{n e^{-n}\left(y-\mu_{0}\right) I_{\left[\mu_{0}, \infty\right)(y)}}{n e^{-(y-y)} I_{[\mu, \infty)(y)}} \\
& =e^{-n\left(y-\mu_{0}\right)} I_{\left[\mu_{0}, \infty\right)}(y)= \begin{cases}0 & \text { if } y<\mu_{0} \\
e^{-n\left(y-\mu_{0}\right)} & \text { if } y \geq \mu_{0}\end{cases}
\end{aligned}
$$

We reject $H_{0}$ if $\lambda(y)=e^{-n\left(y-\mu_{0}\right)}<c_{\alpha}$, where $0 \leq c_{\alpha} \leq 1$ is chosen to give the test level $\alpha$. To determine $c_{\alpha}$, set

$$
\begin{aligned}
\alpha & =P\left\{\text { reject } H_{0} \mid \mu=\mu_{0}\right\}=P\left\{Y>\mu_{0}-\frac{\log c_{\alpha}}{n} \text { or } Y<\mu_{0} \mid \mu=\mu_{0}\right\} \\
& =P\left\{\left.Y>\mu_{0}-\frac{\log c_{\alpha}}{n} \right\rvert\, \mu=\mu_{0}\right\}=\int_{\mu_{0}-\frac{\log c_{\alpha}}{n}}^{\infty} n e^{-n\left(y-\mu_{0}\right)} d y \\
& =-\left.e^{-n\left(y-\mu_{0}\right)}\right|_{\mu_{0}-\frac{\log c_{\alpha}}{n}} ^{\infty}=e^{\log c_{\alpha}}=c_{\alpha} .
\end{aligned}
$$

Therefore, $c_{\alpha}=\alpha$ and the $1-\alpha$ confidence interval is

$$
C(y)=\left\{\mu: \mu \leq y \leq \mu-\frac{\log \alpha}{n}\right\}=\left\{\mu: y+\frac{1}{n} \log \alpha \leq \mu \leq y\right\} .
$$

To use the pivotal method, note that since $\mu$ is a location parameter, a natural pivotal quantity is $Z=Y-\mu$. Then, $f_{Z}(z)=n e^{-n z} I_{(0, \infty)}(z)$. Let $P\{a \leq Z \leq b\}=1-\alpha$, where $a$ and $b$ satisfy

$$
\begin{aligned}
\frac{\alpha}{2}=\int_{0}^{a} n e^{-n z} d z=-\left.e^{-n z}\right|_{0} ^{a}=1-e^{-n a} & \Rightarrow e^{-n a}=1-\frac{\alpha}{2} \\
& \Rightarrow a=\frac{-\log \left(1-\frac{\alpha}{2}\right)}{n} \\
\frac{\alpha}{2}=\int_{b}^{\infty} n e^{-n z} d z=-\left.e^{-n z}\right|_{b} ^{\infty}=e^{-n b} & \Rightarrow-n b=\log \frac{\alpha}{2} \\
& \Rightarrow b=-\frac{1}{n} \log \left(\frac{\alpha}{2}\right)
\end{aligned}
$$

Thus, the pivotal interval is $Y+\log (\alpha / 2) / n \leq \mu \leq Y+\log (1-\alpha / 2)$, the same interval as from Example 9.2.13. To compare the intervals we compare their lengths. We have

Length of LRT interval $=y-\left(y+\frac{1}{n} \log \alpha\right)=-\frac{1}{n} \log \alpha$
Length of Pivotal interval $=\left(y+\frac{1}{n} \log (1-\alpha / 2)\right)-\left(y+\frac{1}{n} \log \alpha / 2\right)=\frac{1}{n} \log \frac{1-\alpha / 2}{\alpha / 2}$
Thus, the LRT interval is shorter if $-\log \alpha<\log [(1-\alpha / 2) /(\alpha / 2)]$, but this is always satisfied. 9.27 a. $Y=\sum X_{i} \sim \operatorname{gamma}(n, \lambda)$, and the posterior distribution of $\lambda$ is

$$
\pi(\lambda \mid y)=\frac{\left(y+\frac{1}{b}\right)^{n+a}}{\Gamma(n+a)} \frac{1}{\lambda^{n+a+1}} e^{-\frac{1}{\lambda}\left(y+\frac{1}{b}\right)},
$$

an IG $\left(n+a,\left(y+\frac{1}{b}\right)^{-1}\right)$. The Bayes HPD region is of the form $\{\lambda: \pi(\lambda \mid y) \geq k\}$, which is an interval since $\pi(\lambda \mid y)$ is unimodal. It thus has the form $\left\{\lambda: a_{1}(y) \leq \lambda \leq a_{2}(y)\right\}$, where $a_{1}$ and $a_{2}$ satisfy

$$
\frac{1}{a_{1} n+a+1} e^{-\frac{1}{a_{1}}\left(y+\frac{1}{b}\right)}=\frac{1}{a_{2}^{n+a+1}} e^{-\frac{1}{a_{2}}\left(y+\frac{1}{b}\right)} .
$$

b. The posterior distribution is $\operatorname{IG}\left(((n-1) / 2)+a,\left(\left((n-1) s^{2} / 2\right)+1 / b\right)^{-1}\right)$. So the Bayes HPD region is as in part a) with these parameters replacing $n+a$ and $y+1 / b$.
c. As $a \rightarrow 0$ and $b \rightarrow \infty$, the condition on $a_{1}$ and $a_{2}$ becomes

$$
\frac{1}{a_{1}((n-1) / 2)+1} e^{-\frac{1}{a_{1}} \frac{(n-1) s^{2}}{2}}=\frac{1}{a_{2}((n-1) / 2)+1} e^{-\frac{1}{a_{2}} \frac{(n-1) s^{2}}{2}} .
$$

9.29 a. We know from Example 7.2 .14 that if $\pi(p) \sim \operatorname{beta}(a, b)$, the posterior is $\pi(p \mid y) \sim \operatorname{beta}(y+$ $a, n-y+b)$ for $y=\sum x_{i}$. So a $1-\alpha$ credible set for $p$ is:

$$
\left\{p: \beta_{y+a, n-y+b, 1-\alpha / 2} \leq p \leq \beta_{y+a, n-y+b, \alpha / 2}\right\}
$$

b. Converting to an $F$ distribution, $\beta_{c, d}=\frac{(c / d) F_{2 c, 2 d}}{1+(c / d) F_{2 c, 2 d}}$, the interval is

$$
\frac{\frac{y+a}{n-y+b} F_{2(y+a), 2(n-y+b), 1-\alpha / 2}}{1+\frac{y+a}{n-y+b} F_{2(y+a), 2(n-y+b), 1-\alpha / 2}} \leq p \leq \frac{\frac{y+a}{n-y+b} F_{2(y+a), 2(n-y+b), \alpha / 2}}{1+\frac{y+a}{n-y+b} F_{2(y+a), 2(n-y+b), \alpha / 2}}
$$

or, using the fact that $F_{m, n}=F_{n, m}^{-1}$,

$$
\frac{1}{1+\frac{n-y+b}{y+a} F_{2(n-y+b), 2(y+a), \alpha / 2}} \leq p \leq \frac{\frac{y+a}{n-y+b} F_{2(y+a), 2(n+b), \alpha / 2}}{1+\frac{y+a}{n-y+b} F_{2(y+a), 2(n-y+b), \alpha / 2}}
$$

For this to match the interval of Exercise 9.21, we need $x=y$ and

$$
\begin{aligned}
\text { Lower limit: } n-y+b=n-x+1 & \Rightarrow b=1 \\
y+a=x & \Rightarrow a=0 \\
\text { Upper limit: } y+a=x+1 & \Rightarrow a=1 \\
n-y+b=n-x & \Rightarrow b=0
\end{aligned}
$$

So no values of $a$ and $b$ will make the intervals match.
9.31 a. We continually use the fact that given $Y=y, \chi_{2 y}^{2}$ is a central $\chi^{2}$ random variable with $2 y$ degrees of freedom. Hence

$$
\begin{aligned}
\mathrm{E} \chi_{2 Y}^{2} & =\mathrm{E}\left[\mathrm{E}\left(\chi_{2 Y}^{2} \mid Y\right)\right]=\mathrm{E} 2 Y=2 \lambda \\
\operatorname{Var} \chi_{2 Y}^{2} & =\mathrm{E}\left[\operatorname{Var}\left(\chi_{2 Y}^{2} \mid Y\right)\right]+\operatorname{Var}\left[\mathrm{E}\left(\chi_{2 Y}^{2} \mid Y\right)\right] \\
& =\mathrm{E}[4 Y]+\operatorname{Var}[2 Y]=4 \lambda+4 \lambda=8 \lambda \\
\mathrm{mgf} & =\mathrm{E} e^{t \chi_{2 Y}^{2}}=\mathrm{E}\left[\mathrm { E } \left(e^{\left.\left.t \chi_{2 Y}^{2} \mid Y\right)\right]=\mathrm{E}\left(\frac{1}{1-2 t}\right)^{Y}}\right.\right. \\
& =\sum_{y=0}^{\infty} \frac{e^{-\lambda}\left(\frac{\lambda}{1-2 t}\right)^{y}}{y!}=e^{-\lambda+\frac{\lambda}{1-2 t}}
\end{aligned}
$$

From Theorem 2.3.15, the mgf of $\left(\chi_{2 Y}^{2}-2 \lambda\right) / \sqrt{8 \lambda}$ is

$$
e^{-t \sqrt{\lambda / 2}}\left[e^{-\lambda+\frac{\lambda}{1-t / \sqrt{2 \lambda}}}\right]
$$

The $\log$ of this is

$$
-\sqrt{\lambda / 2} t-\lambda+\frac{\lambda}{1-t / \sqrt{2 \lambda}}=\frac{t^{2} \sqrt{\lambda}}{-t \sqrt{2}+2 \sqrt{\lambda}}=\frac{t^{2}}{-(t \sqrt{2} / \sqrt{\lambda})+2} \rightarrow t^{2} / 2 \text { as } \lambda \rightarrow \infty
$$

so the mgf converges to $e^{t^{2} / 2}$, the mgf of a standard normal.
b. Since $P\left(\chi_{2 Y}^{2} \leq \chi_{2 Y, \alpha}^{2}\right)=\alpha$ for all $\lambda$,

$$
\frac{\chi_{2 Y, \alpha}^{2}-2 \lambda}{\sqrt{8 \lambda}} \rightarrow z_{\alpha} \text { as } \lambda \rightarrow \infty
$$

In standardizing (9.2.22), the upper bound is

$$
\frac{\frac{n b}{n b+1} \chi_{2(Y+a), \alpha / 2}^{2}-2 \lambda}{\sqrt{8 \lambda}}=\sqrt{\frac{8(\lambda+a)}{8 \lambda}}\left[\frac{\frac{n b}{n b+1}\left[\chi_{2(Y+a), \alpha / 2}^{2}-2(\lambda+a)\right]}{\sqrt{8(\lambda+a)}}+\frac{\frac{n b}{n b+1} 2(\lambda+a)-2 \lambda}{\sqrt{8(\lambda+a)}}\right] .
$$

While the first quantity in square brackets $\rightarrow z_{\alpha / 2}$, the second one has limit

$$
\lim _{\lambda \rightarrow \infty} \frac{-2 \frac{1}{n b+1} \lambda+a \frac{n b}{n b+1}}{\sqrt{8(\lambda+a)}} \rightarrow-\infty
$$

so the coverage probability goes to zero.
9.33 a. Since $0 \in C_{a}(x)$ for every $x, P\left(0 \in C_{a}(X) \mid \mu=0\right)=1$. If $\mu>0$,

$$
\begin{aligned}
P\left(\mu \in C_{a}(X)\right) & =P(\mu \leq \max \{0, X+a\})=P(\mu \leq X+a) & & (\text { since } \mu>0) \\
& =P(Z \geq-a) & & (Z \sim \mathrm{n}(0,1)) \\
& =.95 & & (a=1.645 .)
\end{aligned}
$$

A similar calculation holds for $\mu<0$.
b. The credible probability is

$$
\begin{aligned}
\int_{\min (0, x-a)}^{\max (0, x+a)} \frac{1}{\sqrt{2 \pi}} e^{-\frac{1}{2}(\mu-x)^{2}} d \mu & =\int_{\min (-x,-a)}^{\max (-x, a)} \frac{1}{\sqrt{2 \pi}} e^{-\frac{1}{2} t^{2}} d t \\
& =P(\min (-x,-a) \leq Z \leq \max (-x, a))
\end{aligned}
$$

To evaluate this probability we have two cases:
(i) $\quad|x| \leq a \quad \Rightarrow \quad$ credible probability $=P(|Z| \leq a)$
(ii) $|x|>a \Rightarrow$ credible probability $=P(-a \leq Z \leq|x|)$

Thus we see that for $a=1.645$, the credible probability is equal to .90 if $|x| \leq 1.645$ and increases to .95 as $|x| \rightarrow \infty$.
9.34 a. A $1-\alpha$ confidence interval for $\mu$ is $\{\mu: \bar{x}-1.96 \sigma / \sqrt{n} \leq \mu \leq \bar{x}+1.96 \sigma / \sqrt{n}\}$. We need $2(1.96) \sigma / \sqrt{n} \leq \sigma / 4$ or $\sqrt{n} \geq 4(2)(1.96)$. Thus we need $n \geq 64(1.96)^{2} \approx 245.9$. So $n=246$ suffices.
b. The length of a $95 \%$ confidence interval is $2 t_{n-1, .025} S / \sqrt{n}$. Thus we need

$$
\begin{aligned}
P\left(2 t_{n-1, .025} \frac{S}{\sqrt{n}} \leq \frac{\sigma}{4}\right) \geq .9 & \Rightarrow P\left(4 t_{n-1, .025}^{2} \frac{S^{2}}{n} \leq \frac{\sigma^{2}}{16}\right) \geq .9 \\
& \Rightarrow P(\underbrace{\frac{(n-1) S^{2}}{\sigma^{2}}}_{\sim \chi_{n-1}^{2}} \leq \frac{(n-1) n}{t_{n-1, .025}^{2} \cdot 64}) \geq .9
\end{aligned}
$$

We need to solve this numerically for the smallest $n$ that satisfies the inequality

$$
\frac{(n-1) n}{t_{n-1, .025}^{2} \cdot 64} \geq \chi_{n-1, .1}^{2}
$$

Trying different values of $n$ we find that the smallest such $n$ is $n=276$ for which

$$
\frac{(n-1) n}{t_{n-1, .025}^{2} \cdot 64}=306.0 \geq 305.5=\chi_{n-1, .1}^{2}
$$

As to be expected, this is somewhat larger than the value found in a).
9.35 length $=2 z_{\alpha / 2} \sigma / \sqrt{n}$, and if it is unknown, E (length) $=2 t_{\alpha / 2, n-1} c \sigma / \sqrt{n}$, where

$$
c=\frac{\sqrt{n-1} \Gamma\left(\frac{n-1}{2}\right)}{\sqrt{2} \Gamma(n / 2)}
$$

and $\mathrm{E} c S=\sigma$ (Exercise 7.50). Thus the difference in lengths is $(2 \sigma / \sqrt{n})\left(z_{\alpha / 2}-c t_{\alpha / 2}\right)$. A little work will show that, as $n \rightarrow \infty, c \rightarrow$ constant. (This can be done using Stirling's formula along with Lemma 2.3.14. In fact, some careful algebra will show that $c \rightarrow 1$ as $n \rightarrow \infty$.) Also, we know that, as $n \rightarrow \infty, t_{\alpha / 2, n-1} \rightarrow z_{\alpha / 2}$. Thus, the difference in lengths $(2 \sigma / \sqrt{n})\left(z_{\alpha / 2}-c t_{\alpha / 2}\right) \rightarrow 0$ as $n \rightarrow \infty$.
9.36 The sample pdf is

$$
f\left(x_{1}, \ldots, x_{n} \mid \theta\right)=\prod_{i=1}^{n} e^{i \theta-x_{i}} I_{(i \theta, \infty)}\left(x_{i}\right)=e^{\Sigma\left(i \theta-x_{i}\right)} I_{(\theta, \infty)}\left[\min \left(x_{i} / i\right)\right]
$$

Thus $T=\min \left(X_{i} / i\right)$ is sufficient by the Factorization Theorem, and

$$
P(T>t)=\prod_{i=1}^{n} P\left(X_{i}>i t\right)=\prod_{i=1}^{n} \int_{i t}^{\infty} e^{i \theta-x} d x=\prod_{i=1}^{n} e^{i(\theta-t)}=e^{-\frac{n(n+1)}{2}(t-\theta)}
$$

and

$$
f_{T}(t)=\frac{n(n+1)}{2} e^{-\frac{n(n+1)}{2}(t-\theta)}, \quad t \geq \theta
$$

Clearly, $\theta$ is a location parameter and $Y=T-\theta$ is a pivot. To find the shortest confidence interval of the form $[T+a, T+b]$, we must minimize $b-a$ subject to the constraint $P(-b \leq$ $Y \leq-a)=1-\alpha$. Now the pdf of $Y$ is strictly decreasing, so the interval length is shortest if $-b=0$ and $a$ satisfies

$$
P(0 \leq Y \leq-a)=e^{-\frac{n(n+1)}{2} a}=1-\alpha
$$

So $a=2 \log (1-\alpha) /(n(n+1))$.
9.37 a. The density of $Y=X_{(n)}$ is $f_{Y}(y)=n y^{n-1} / \theta^{n}, 0<y<\theta$. So $\theta$ is a scale parameter, and $T=Y / \theta$ is a pivotal quantity. The pdf of $T$ is $f_{T}(t)=n t^{n-1}, 0 \leq t \leq 1$.
b. A pivotal interval is formed from the set

$$
\{\theta: a \leq t \leq b\}=\left\{\theta: a \leq \frac{y}{\theta} \leq b\right\}=\left\{\theta: \frac{y}{b} \leq \theta \leq \frac{y}{a}\right\}
$$

and has length $Y(1 / a-1 / b)=Y(b-a) / a b$. Since $f_{T}(t)$ is increasing, $b-a$ is minimized and $a b$ is maximized if $b=1$. Thus shortest interval will have $b=1$ and $a$ satisfying $\alpha=\int_{0}^{a} n t^{n-1} d t=a^{n} \Rightarrow a=\alpha^{1 / n}$. So the shortest $1-\alpha$ confidence interval is $\{\theta: y \leq \theta \leq$ $\left.y / \alpha^{1 / n}\right\}$.
9.39 Let $a$ be such that $\int_{-\infty}^{a} f(x) d x=\alpha / 2$. This value is unique for a unimodal pdf if $\alpha>0$. Let $\mu$ be the point of symmetry and let $b=2 \mu-a$. Then $f(b)=f(a)$ and $\int_{b}^{\infty} f(x) d x=\alpha / 2$. $a \leq \mu$ since $\int_{-\infty}^{a} f(x) d x=\alpha / 2 \leq 1 / 2=\int_{-\infty}^{\mu} f(x) d x$. Similarly, $b \geq \mu$. And, $f(b)=f(a)>0$ since $f(a) \geq f(x)$ for all $x \leq a$ and $\int_{-\infty}^{a} f(x) d x=\alpha / 2>0 \Rightarrow f(x)>0$ for some $x<a \Rightarrow f(a)>0$. So the conditions of Theorem 9.3.2 are satisfied.
9.41 a. We show that for any interval $[a, b]$ and $\epsilon>0$, the probability content of $[a-\epsilon, b-\epsilon]$ is greater (as long as $b-\epsilon>a$ ). Write

$$
\begin{aligned}
\int_{b}^{a} f(x) d x-\int_{a-\epsilon}^{b-\epsilon} f(x) d x & =\int_{b-\epsilon}^{b} f(x) d x-\int_{a-\epsilon}^{a} f(x) d x \\
& \leq f(b-\epsilon)[b-(b-\epsilon)]-f(a)[a-(a-\epsilon)] \\
& \leq \epsilon[f(b-\epsilon)-f(a)] \leq 0,
\end{aligned}
$$

where all of the inequalities follow because $f(x)$ is decreasing. So moving the interval toward zero increases the probability, and it is therefore maximized by moving a all the way to zero.
b. $T=Y-\mu$ is a pivot with decreasing pdf $f_{T}(t)=n e^{-n t} I_{[0, \infty]}(t)$. The shortest $1-\alpha$ interval on $T$ is $\left[0,-\frac{1}{n} \log \alpha\right]$, since

$$
\int_{0}^{b} n e^{-n t} d t=1-\alpha \Rightarrow b=-\frac{1}{n} \log \alpha .
$$

Since $a \leq T \leq b$ implies $Y-b \leq \mu \leq Y-a$, the best $1-\alpha$ interval on $\mu$ is $Y+\frac{1}{n} \log \alpha \leq \mu \leq Y$.
9.43 a. Using Theorem 8.3.12, identify $g(t)$ with $f\left(x \mid \theta_{1}\right)$ and $f(t)$ with $f\left(x \mid \theta_{0}\right)$. Define $\phi(t)=1$ if $t \in C$ and 0 otherwise, and let $\phi^{\prime}$ be the indicator of any other set $C^{\prime}$ satisfying $\int_{C^{\prime}} f(t) d t \geq$ $1-\alpha$. Then $\left(\phi(t)-\phi^{\prime}(t)\right)(g(t)-\lambda f(t)) \leq 0$ and

$$
0 \geq \int\left(\phi-\phi^{\prime}\right)(g-\lambda f)=\int_{C} g-\int_{C^{\prime}} g-\lambda\left[\int_{C} f-\int_{C^{\prime}} f\right] \geq \int_{C} g-\int_{C^{\prime}} g
$$

showing that $C$ is the best set.
b. For Exercise 9.37, the pivot $T=Y / \theta$ has density $n t^{n-1}$, and the pivotal interval $a \leq T \leq b$ results in the $\theta$ interval $Y / b \leq \theta \leq Y / a$. The length is proportional to $1 / a-1 / b$, and thus $g(t)=1 / t^{2}$. The best set is $\left\{t: 1 / t^{2} \leq \lambda n t^{n-1}\right\}$, which is a set of the form $\{t: a \leq t \leq 1\}$. This has probability content $1-\alpha$ if $a=\alpha^{1 / n}$. For Exercise 9.24 (or Example 9.3.4), the $g$ function is the same and the density of the pivot is $f_{k}$, the density of a $\operatorname{gamma}(k, 1)$. The set $\left\{t: 1 / t^{2} \leq \lambda f_{k}(t)\right\}=\left\{t: f_{k+2}(t) \geq \lambda^{\prime}\right\}$, so the best $a$ and $b$ satisfy $\int_{a}^{b} f_{k}(t) d t=1-\alpha$ and $f_{k+2}(a)=f_{k+2}(b)$.
9.45 a. Since $Y=\sum X_{i} \sim \operatorname{gamma}(n, \lambda)$ has MLR, the Karlin-Rubin Theorem (Theorem 8.3.2) shows that the UMP test is to reject $H_{0}$ if $Y<k\left(\lambda_{0}\right)$, where $P\left(Y<k\left(\lambda_{0}\right) \mid \lambda=\lambda_{0}\right)=\alpha$.
b. $T=2 Y / \lambda \sim \chi_{2 n}^{2}$ so choose $k\left(\lambda_{0}\right)=\frac{1}{2} \lambda_{0} \chi_{2 n, \alpha}^{2}$ and

$$
\{\lambda: Y \geq k(\lambda)\}=\left\{\lambda: Y \geq \frac{1}{2} \lambda \chi_{2 n, \alpha}^{2}\right\}=\left\{\lambda: 0<\lambda \leq 2 Y / \chi_{2 n, \alpha}^{2}\right\}
$$

is the UMA confidence set.
c. The expected length is $\mathrm{E} \frac{2 Y}{\chi_{2 n, \alpha}^{2}}=\frac{2 n \lambda}{\chi_{2 n, \alpha}^{2}}$.
d. $X_{(1)} \sim \operatorname{exponential}(\lambda / n)$, so $\mathrm{E} X_{(1)}=\lambda / n$. Thus

$$
\begin{aligned}
\mathrm{E}\left(\operatorname{length}\left(C^{*}\right)\right) & =\frac{2 \times 120}{251.046} \lambda=.956 \lambda \\
\mathrm{E}\left(\operatorname{length}\left(C^{m}\right)\right) & =\frac{-\lambda}{120 \times \log (.99)}=.829 \lambda
\end{aligned}
$$

9.46 The proof is similar to that of Theorem 9.3.5:

$$
P_{\theta}\left(\theta^{\prime} \in C^{*}(X)\right)=P_{\theta}\left(X \in A^{*}\left(\theta^{\prime}\right)\right) \leq P_{\theta}\left(X \in A\left(\theta^{\prime}\right)\right)=P_{\theta}\left(\theta^{\prime} \in C(X)\right)
$$

where $A$ and $C$ are any competitors. The inequality follows directly from Definition 8.3.11.
9.47 Referring to (9.3.2), we want to show that for the upper confidence bound, $P_{\theta}\left(\theta^{\prime} \in C\right) \leq 1-\alpha$ if $\theta^{\prime} \geq \theta$. We have

$$
P_{\theta}\left(\theta^{\prime} \in C\right)=P_{\theta}\left(\theta^{\prime} \leq \bar{X}+z_{\alpha} \sigma / \sqrt{n}\right)
$$

Subtract $\theta$ from both sides and rearrange to get

$$
P_{\theta}\left(\theta^{\prime} \in C\right)=P_{\theta}\left(\frac{\theta^{\prime}-\theta}{\sigma / \sqrt{n}} \leq \frac{\bar{X}-\theta}{\sigma / \sqrt{n}}+z_{\alpha}\right)=P\left(Z \geq \frac{\theta^{\prime}-\theta}{\sigma / \sqrt{n}}-z_{\alpha}\right)
$$

which is less than $1-\alpha$ as long as $\theta^{\prime} \geq \theta$. The solution for the lower confidence interval is similar.
9.48 a. Start with the hypothesis test $H_{0}: \theta \geq \theta_{0}$ versus $H_{1}: \theta<\theta_{0}$. Arguing as in Example 8.2.4 and Exercise 8.47, we find that the LRT rejects $H_{0}$ if $\left(\bar{X}-\theta_{0}\right) /(S / \sqrt{n})<-t_{n-1, \alpha}$. So the acceptance region is $\left\{x:\left(\bar{x}-\theta_{0}\right) /(s / \sqrt{n}) \geq-t_{n-1, \alpha}\right\}$ and the corresponding confidence set is $\left\{\theta: \bar{x}+t_{n-1, \alpha} s / \sqrt{n} \geq \theta\right\}$.
b. The test in part a) is the UMP unbiased test so the interval is the UMA unbiased interval.
9.49 a. Clearly, for each $\sigma$, the conditional probability $P_{\theta_{0}}\left(\bar{X}>\theta_{0}+z_{\alpha} \sigma / \sqrt{n} \mid \sigma\right)=\alpha$, hence the test has unconditional size $\alpha$. The confidence set is $\left\{(\theta, \sigma): \theta \geq \bar{x}-z_{\alpha} \sigma / \sqrt{n}\right\}$, which has confidence coefficient $1-\alpha$ conditionally and, hence, unconditionally.
b. From the Karlin-Rubin Theorem, the UMP test is to reject $H_{0}$ if $X>c$. To make this size $\alpha$,

$$
\begin{aligned}
P_{\theta_{0}}(X>c) & =P_{\theta_{0}}(X>c \mid \sigma=10) P(\sigma=10)+P(X>c \mid \sigma=1) P(\sigma=1) \\
& =p P\left(\frac{X-\theta_{0}}{10}>\frac{c-\theta_{0}}{10}\right)+(1-p) P\left(X-\theta_{0}>c-\theta_{0}\right) \\
& =p P\left(Z>\frac{c-\theta_{0}}{10}\right)+(1-p) P\left(Z>c-\theta_{0}\right)
\end{aligned}
$$

where $Z \sim \mathrm{n}(0,1)$. Without loss of generality take $\theta_{0}=0$. For $c=z_{(\alpha-p) /(1-p)}$ we have for the proposed test

$$
\begin{aligned}
P_{\theta_{0}}(\text { reject }) & =p+(1-p) P\left(Z>z_{(\alpha-p) /(1-p)}\right) \\
& =p+(1-p) \frac{(\alpha-p)}{(1-p)}=p+\alpha-p=\alpha .
\end{aligned}
$$

This is not UMP, but more powerful than part a. To get UMP, solve for $c$ in $p P(Z>$ $c / 10)+(1-p) P(Z>c)=\alpha$, and the UMP test is to reject if $X>c$. For $p=1 / 2, \alpha=.05$, we get $c=12.81$. If $\alpha=.1$ and $p=.05, c=1.392$ and $\frac{z_{\frac{.1-.05}{.95}}}{}=.0526=1.62$.

$$
\begin{aligned}
P_{\theta}\left(\theta \in C\left(X_{1}, \ldots, X_{n}\right)\right) & =P_{\theta}\left(\bar{X}-k_{1} \leq \theta \leq \bar{X}+k_{2}\right) \\
& =P_{\theta}\left(-k_{2} \leq \bar{X}-\theta \leq k_{1}\right) \\
& =P_{\theta}\left(-k_{2} \leq \sum Z_{i} / n \leq k_{1}\right)
\end{aligned}
$$

where $Z_{i}=X_{i}-\theta, i=1, \ldots, n$. Since this is a location family, for any $\theta, Z_{1}, \ldots, Z_{n}$ are iid with $\operatorname{pdf} f(z)$, i. e., the $Z_{i}$ s are pivots. So the last probability does not depend on $\theta$.
9.52 a. The LRT of $H_{0}: \sigma=\sigma_{0}$ versus $H_{1}: \sigma \neq \sigma_{0}$ is based on the statistic

$$
\lambda(x)=\frac{\sup _{\mu, \sigma=\sigma_{0}} L\left(\mu, \sigma_{0} \mid x\right)}{\sup _{\mu, \sigma \in(0, \infty)} L\left(\mu, \sigma^{2} \mid x\right)} .
$$

In the denominator, $\hat{\sigma}^{2}=\sum\left(x_{i}-\bar{x}\right)^{2} / n$ and $\hat{\mu}=\bar{x}$ are the MLEs, while in the numerator, $\sigma_{0}^{2}$ and $\hat{\mu}$ are the MLEs. Thus

$$
\lambda(x)=\frac{\left(2 \pi \sigma_{0}^{2}\right)^{-n / 2} e^{-\frac{\Sigma\left(x_{i}-\bar{x}\right)^{2}}{2 \sigma_{0}^{2}}}}{\left(2 \pi \hat{\sigma}^{2}\right)^{-n / 2} e^{-\frac{\Sigma\left(x_{i}-\bar{x}\right)^{2}}{2 \sigma^{2}}}}=\left(\frac{\sigma_{0}^{2}}{\hat{\sigma}^{2}}\right)^{-n / 2} \frac{e^{-\frac{\Sigma\left(x_{i}-\bar{x}\right)^{2}}{2 \sigma_{0}^{2}}}}{e^{-n / 2}}
$$

and, writing $\hat{\sigma}^{2}=[(n-1) / n] s^{2}$, the LRT rejects $H_{0}$ if

$$
\left(\frac{\sigma_{0}^{2}}{\frac{n-1}{n} s^{2}}\right)^{-n / 2} e^{-\frac{(n-1) s^{2}}{2 \sigma_{0}^{2}}}<k_{\alpha}
$$

where $k_{\alpha}$ is chosen to give a size $\alpha$ test. If we denote $t=\frac{(n-1) s^{2}}{\sigma_{0}^{2}}$, then $T \sim \chi_{n-1}^{2}$ under $H_{0}$, and the test can be written: reject $H_{0}$ if $t^{n / 2} e^{-t / 2}<k_{\alpha}^{\prime}$. Thus, a $1-\alpha$ confidence set is

$$
\left\{\sigma^{2}: t^{n / 2} e^{-t / 2} \geq k_{\alpha}^{\prime}\right\}=\left\{\sigma^{2}:\left(\frac{(n-1) s^{2}}{\sigma^{2}}\right)^{n / 2} e^{-\frac{(n-1) s^{2}}{\sigma^{2}} / 2} \geq k_{\alpha}^{\prime}\right\}
$$

Note that the function $t^{n / 2} e^{-t / 2}$ is unimodal (it is the kernel of a gamma density) so it follows that the confidence set is of the form

$$
\begin{aligned}
\left\{\sigma^{2}: t^{n / 2} e^{-t / 2} \geq k_{\alpha}^{\prime}\right\} & =\left\{\sigma^{2}: a \leq t \leq b\right\}=\left\{\sigma^{2}: a \leq \frac{(n-1) s^{2}}{\sigma^{2}} \leq b\right\} \\
& =\left\{\sigma^{2}: \frac{(n-1) s^{2}}{b} \leq \sigma^{2} \leq \frac{(n-1) s^{2}}{b}\right\}
\end{aligned}
$$

where $a$ and $b$ satisfy $a^{n / 2} e^{-a / 2}=b^{n / 2} e^{-b / 2}$ (since they are points on the curve $t^{n / 2} e^{-t / 2}$ ). Since $\frac{n}{2}=\frac{n+2}{2}-1, a$ and $b$ also satisfy

$$
\frac{1}{\Gamma\left(\frac{n+2}{2}\right) 2^{(n+2) / 2}} a^{((n+2) / 2)-1} e^{-a / 2}=\frac{1}{\Gamma\left(\frac{n+2}{2}\right) 2^{(n+2) / 2}} b^{((n+2) / 2)-1} e^{-b / 2},
$$

or, $f_{n+2}(a)=f_{n+2}(b)$.
b. The constants $a$ and $b$ must satisfy $f_{n-1}(b) b^{2}=f_{n-1}(a) a^{2}$. But since $b^{((n-1) / 2)-1} b^{2}=$ $b^{((n+3) / 2)-1}$, after adjusting constants, this is equivalent to $f_{n+3}(b)=f_{n+3}(a)$. Thus, the values of $a$ and $b$ that give the minimum length interval must satisfy this along with the probability constraint. The confidence interval, say $I\left(s^{2}\right)$ will be unbiased if (Definition 9.3.7)
c.

$$
P_{\sigma^{2}}\left(\sigma^{\prime 2} \in I\left(S^{2}\right)\right) \leq P_{\sigma^{2}}\left(\sigma^{2} \in I\left(S^{2}\right)\right)=1-\alpha
$$

Some algebra will establish

$$
\begin{aligned}
P_{\sigma^{2}}\left(\sigma^{\prime 2} \in I\left(S^{2}\right)\right) & =P_{\sigma^{2}}\left(\frac{(n-1) S^{2}}{b \sigma^{2}} \leq \frac{\sigma^{\prime 2}}{\sigma^{2}} \leq \frac{(n-1) S^{2}}{a \sigma^{2}}\right) \\
& =P_{\sigma^{2}}\left(\frac{\chi_{n-1}^{2}}{b} \leq \frac{\sigma^{\prime 2}}{\sigma^{2}} \leq \frac{\chi_{n-1}^{2}}{a}\right)=\int_{a c}^{b c} f_{n-1}(t) d t
\end{aligned}
$$

where $c=\sigma^{2} / \sigma^{2}$. The derivative (with respect to $c$ ) of this last expression is $b f_{n-1}(b c)-$ $a f_{n-1}(a c)$, and hence is equal to zero if both $c=1$ (so the interval is unbiased) and $b f_{n-1}(b)=a f_{n-1}(a)$. From the form of the chi squared pdf, this latter condition is equivalent to $f_{n+1}(b)=f_{n+1}(a)$.
d. By construction, the interval will be $1-\alpha$ equal-tailed.
9.53 a. $\mathrm{E}\left[b \operatorname{length}(C)-I_{C}(\mu)\right]=2 c \sigma b-P(|Z| \leq c)$, where $Z \sim \mathrm{n}(0,1)$.
b. $\frac{d}{d c}[2 c \sigma b-P(|Z| \leq c)]=2 \sigma b-2\left(\frac{1}{\sqrt{2 \pi}} e^{-c^{2} / 2}\right)$.
c. If $b \sigma>1 / \sqrt{2 \pi}$ the derivative is always positive since $e^{-c^{2} / 2}<1$.
9.55

$$
\begin{aligned}
\mathrm{E}[L((\mu, \sigma), C)] & =\mathrm{E}[L((\mu, \sigma), C) \mid S<K] P(S<K)+\mathrm{E}[L((\mu, \sigma), C) \mid S>K] P(S>K) \\
& =\mathrm{E}\left[L\left((\mu, \sigma), C^{\prime}\right) \mid S<K\right] P(S<K)+\mathrm{E}[L((\mu, \sigma), C) \mid S>K] P(S>K) \\
& =R\left[L\left((\mu, \sigma), C^{\prime}\right)\right]+\mathrm{E}[L((\mu, \sigma), C) \mid S>K] P(S>K),
\end{aligned}
$$

where the last equality follows because $C^{\prime}=\emptyset$ if $S>K$. The conditional expectation in the second term is bounded by

$$
\begin{aligned}
\mathrm{E}[L((\mu, \sigma), C) \mid S>K] & =\mathrm{E}\left[b \operatorname{length}(C)-I_{C}(\mu) \mid S>K\right] \\
& =\mathrm{E}\left[2 b c S-I_{C}(\mu) \mid S>K\right] \\
& \left.>\mathrm{E}[2 b c K-1 \mid S>K] \quad \text { (since } S>K \text { and } I_{C} \leq 1\right) \\
& =2 b c K-1,
\end{aligned}
$$

which is positive if $K>1 / 2 b c$. For those values of $K, C^{\prime}$ dominates $C$.
9.57 a. The distribution of $X_{n+1}-\bar{X}$ is $\mathrm{n}\left[0, \sigma^{2}(1+1 / n)\right]$, so

$$
P\left(X_{n+1} \in \bar{X} \pm z_{\alpha / 2} \sigma \sqrt{1+1 / n}\right)=P\left(|Z| \leq z_{\alpha / 2}\right)=1-\alpha
$$

b. $p$ percent of the normal population is in the interval $\mu \pm z_{p / 2} \sigma$, so $\bar{x} \pm k \sigma$ is a $1-\alpha$ tolerance interval if

$$
P\left(\mu \pm z_{p / 2} \subseteq \sigma \bar{X} \pm k \sigma\right)=P\left(\bar{X}-k \sigma \leq \mu-z_{p / 2} \sigma \text { and } \bar{X}+k \sigma \geq \mu+z_{p / 2} \sigma\right) \geq 1-\alpha
$$

This can be attained by requiring

$$
P\left(\bar{X}-k \sigma \geq \mu-z_{p / 2} \sigma\right)=\alpha / 2 \quad \text { and } \quad P\left(\bar{X}+k \sigma \leq \mu+z_{p / 2} \sigma\right)=\alpha / 2
$$

which is attained for $k=z_{p / 2}+z_{\alpha / 2} / \sqrt{n}$.
c. From part (a), $\left(X_{n+1}-\bar{X}\right) /(S \sqrt{1+1 / n}) \sim t_{n-1}$, so a $1-\alpha$ prediction interval is $\bar{X} \pm$ $t_{n-1, \alpha / 2} S \sqrt{1+1 / n}$.

## Chapter 10

## Asymptotic Evaluations

10.1 First calculate some moments for this distribution.

$$
\mathrm{E} X=\theta / 3, \quad \mathrm{E} X^{2}=1 / 3, \quad \operatorname{Var} X=\frac{1}{3}-\frac{\theta^{2}}{9}
$$

So $3 \bar{X}_{n}$ is an unbiased estimator of $\theta$ with variance

$$
\operatorname{Var}\left(3 \bar{X}_{n}\right)=9(\operatorname{Var} X) / n=\left(3-\theta^{2}\right) / n \rightarrow 0 \text { as } n \rightarrow \infty
$$

So by Theorem 10.1.3, $3 \bar{X}_{n}$ is a consistent estimator of $\theta$.
10.3 a. The log likelihood is

$$
-\frac{n}{2} \log (2 \pi \theta)-\frac{1}{2} \sum\left(x_{i}-\theta\right) / \theta
$$

Differentiate and set equal to zero, and a little algebra will show that the MLE is the root of $\theta^{2}+\theta-W=0$. The roots of this equation are $(-1 \pm \sqrt{1+4 W}) / 2$, and the MLE is the root with the plus sign, as it has to be nonnegative.
b. The second derivative of the log likelihood is $\left(-2 \sum x_{i}^{2}+n \theta\right) /\left(2 \theta^{3}\right)$, yielding an expected Fisher information of

$$
I(\theta)=-\mathrm{E}_{\theta} \frac{-2 \sum X_{i}^{2}+n \theta}{2 \theta^{3}}=\frac{2 n \theta+n}{2 \theta^{2}}
$$

and by Theorem 10.1.12 the variance of the MLE is $1 / I(\theta)$.
10.4 a. Write

$$
\frac{\sum X_{i} Y_{i}}{\sum X_{i}^{2}}=\frac{\sum X_{i}\left(X_{i}+\epsilon_{i}\right)}{\sum X_{i}^{2}}=1+\frac{\sum X_{i} \epsilon_{i}}{\sum X_{i}^{2}} .
$$

From normality and independence

$$
\mathrm{E} X_{i} \epsilon_{i}=0, \quad \operatorname{Var} X_{i} \epsilon_{i}=\sigma^{2}\left(\mu^{2}+\tau^{2}\right), \quad \mathrm{E} X_{i}^{2}=\mu^{2}+\tau^{2}, \quad \operatorname{Var} X_{i}^{2}=2 \tau^{2}\left(2 \mu^{2}+\tau^{2}\right)
$$

and $\operatorname{Cov}\left(X_{i}, X_{i} \epsilon_{i}\right)=0$. Applying the formulas of Example 5.5.27, the asymptotic mean and variance are

$$
\mathrm{E}\left(\frac{\sum X_{i} Y_{i}}{\sum X_{i}^{2}}\right) \approx 1 \text { and } \operatorname{Var}\left(\frac{\sum X_{i} Y_{i}}{\sum X_{i}^{2}}\right) \approx \frac{n \sigma^{2}\left(\mu^{2}+\tau^{2}\right)}{\left[n\left(\mu^{2}+\tau^{2}\right)\right]^{2}}=\frac{\sigma^{2}}{n\left(\mu^{2}+\tau^{2}\right)}
$$

b.

$$
\frac{\sum Y_{i}}{\sum X_{i}}=\beta+\frac{\sum \epsilon_{i}}{\sum X_{i}}
$$

with approximate mean $\beta$ and variance $\sigma^{2} /\left(n \mu^{2}\right)$.
c.

$$
\frac{1}{n} \sum \frac{Y_{i}}{X_{i}}=\beta+\frac{1}{n} \sum \frac{\epsilon_{i}}{X_{i}}
$$

with approximate mean $\beta$ and variance $\sigma^{2} /\left(n \mu^{2}\right)$.
10.5 a. The integral of $E T_{n}^{2}$ is unbounded near zero. We have

$$
\mathrm{E} T_{n}^{2}>\sqrt{\frac{n}{2 \pi \sigma^{2}}} \int_{0}^{1} \frac{1}{x^{2}} e^{-(x-\mu)^{2} / 2 \sigma^{2}} d x>\sqrt{\frac{n}{2 \pi \sigma^{2}}} K \int_{0}^{1} \frac{1}{x^{2}} d x=\infty
$$

where $K=\max _{0 \leq x \leq 1} e^{-(x-\mu)^{2} / 2 \sigma^{2}}$
b. If we delete the interval $(-\delta, \delta)$, then the integrand is bounded, that is, over the range of integration $1 / x^{2}<1 / \delta^{2}$.
c. Assume $\mu>0$. A similar argument works for $\mu<0$. Then

$$
P(-\delta<X<\delta)=P[\sqrt{n}(-\delta-\mu)<\sqrt{n}(X-\mu)<\sqrt{n}(\delta-\mu)]<P[Z<\sqrt{n}(\delta-\mu)]
$$

where $Z \sim \mathrm{n}(0,1)$. For $\delta<\mu$, the probability goes to 0 as $n \rightarrow \infty$.
10.7 We need to assume that $\tau(\theta)$ is differentiable at $\theta=\theta_{0}$, the true value of the parameter. Then we apply Theorem 5.5.24 to Theorem 10.1.12.
10.9 We will do a more general problem that includes $a$ ) and $b$ ) as special cases. Suppose we want to estimate $\lambda^{t} e^{-\lambda} / t!=P(X=t)$. Let

$$
T=T\left(X_{1}, \ldots, X_{n}\right)= \begin{cases}1 & \text { if } X_{1}=t \\ 0 & \text { if } X_{1} \neq t\end{cases}
$$

Then $\mathrm{E} T=P(T=1)=P\left(X_{1}=t\right)$, so $T$ is an unbiased estimator. Since $\sum X_{i}$ is a complete sufficient statistic for $\lambda, \mathrm{E}\left(T \mid \sum X_{i}\right)$ is UMVUE. The UMVUE is 0 for $y=\sum X_{i}<t$, and for $y \geq t$,

$$
\begin{aligned}
\mathrm{E}(T \mid y) & =P\left(X_{1}=t \mid \sum X_{i}=y\right) \\
& =\frac{P\left(X_{1}=t, \sum X_{i}=y\right)}{P\left(\sum X_{i}=y\right)} \\
& =\frac{P\left(X_{1}=t\right) P\left(\sum_{i=2}^{n} X_{i}=y-t\right)}{P\left(\sum X_{i}=y\right)} \\
& =\frac{\left\{\lambda^{t} e^{-\lambda} / t!\right\}\left\{[(n-1) \lambda]^{y-t} e^{-(n-1) \lambda} /(y-t)!\right\}}{(n \lambda)^{y} e^{-n \lambda} / y!} \\
& =\binom{y}{t} \frac{(n-1)^{y-t}}{n^{y}} .
\end{aligned}
$$

a. The best unbiased estimator of $e^{-\lambda}$ is $((n-1) / n)^{y}$.
b. The best unbiased estimator of $\lambda e^{-\lambda}$ is $(y / n)[(n-1) / n]^{y-1}$
c. Use the fact that for constants $a$ and $b$,

$$
\frac{d}{d \lambda} \lambda^{a} b^{\lambda}=b^{\lambda} \lambda^{a-1}(a+\lambda \log b)
$$

to calculate the asymptotic variances of the UMVUEs. We have for $t=0$,

$$
\operatorname{ARE}\left(\left(\frac{n-1}{n}\right)^{n \hat{\lambda}}, e^{-\lambda}\right)=\left[\frac{e^{-\lambda}}{\left(\frac{n-1}{n}\right)^{n \lambda} \log \left(\frac{n-1}{n}\right)^{n}}\right]^{2},
$$

and for $t=1$

$$
\operatorname{ARE}\left(\frac{n}{n-1} \hat{\lambda}\left(\frac{n-1}{n}\right)^{n \hat{\lambda}}, \hat{\lambda} e^{-\lambda}\right)=\left[\frac{(\lambda-1) e^{-\lambda}}{\frac{n}{n-1}\left(\frac{n-1}{n}\right)^{n \lambda}\left[1+\log \left(\frac{n-1}{n}\right)^{n}\right]}\right]^{2}
$$

Since $[(n-1) / n]^{n} \rightarrow e^{-1}$ as $n \rightarrow \infty$, both of these AREs are equal to 1 in the limit.
d. For these data, $n=15, \sum X_{i}=y=104$ and the MLE of $\lambda$ is $\hat{\lambda}=\bar{X}=6.9333$. The estimates are

$$
\begin{array}{ccc} 
& \text { MLE } & \text { UMVUE } \\
P(X=0) & .000975 & .000765 \\
P(X=1) & .006758 & .005684
\end{array}
$$

10.11 a. It is easiest to use the Mathematica code in Example A.0.7. The second derivative of the log likelihood is

$$
\frac{\partial^{2}}{\partial \mu^{2}} \log \left(\frac{1}{\Gamma[\mu / \beta] \beta^{\mu / \beta}} x^{-1+\mu / \beta} e^{-x / \beta}\right)=\frac{1}{\beta^{2}} \psi^{\prime}(\mu / \beta),
$$

where $\psi(z)=\Gamma^{\prime}(z) / \Gamma(z)$ is the digamma function.
b. Estimation of $\beta$ does not affect the calculation.
c. For $\mu=\alpha \beta$ known, the MOM estimate of $\beta$ is $\bar{x} / \alpha$. The MLE comes from differentiating the log likelihood

$$
\frac{d}{d \beta}\left(-\alpha n \log \beta-\sum_{i} x_{i} / \beta\right) \stackrel{\text { set }}{=} 0 \Rightarrow \beta=\bar{x} / \alpha
$$

d. The MOM estimate of $\beta$ comes from solving

$$
\frac{1}{n} \sum_{i} x_{i}=\mu \text { and } \frac{1}{n} \sum_{i} x_{i}^{2}=\mu^{2}+\mu \beta
$$

which yields $\tilde{\beta}=\hat{\sigma}^{2} / \bar{x}$. The approximate variance is quite a pain to calculate. Start from

$$
\mathrm{E} \bar{X}=\mu, \quad \operatorname{Var} \bar{X}=\frac{1}{n} \mu \beta, \quad \mathrm{E} \hat{\sigma}^{2} \approx \mu \beta, \quad \operatorname{Var} \hat{\sigma}^{2} \approx \frac{2}{n} \mu \beta^{3}
$$

where we used Exercise $5.8(b)$ for the variance of $\hat{\sigma}^{2}$. Now using Example 5.5.27 and (and assuming the covariance is zero), we have $\operatorname{Var} \tilde{\beta} \approx \frac{3 \beta^{3}}{n \mu}$. The ARE is then

$$
\operatorname{ARE}(\hat{\beta}, \tilde{\beta})=\left[3 \beta^{3} / \mu\right]\left[\mathrm{E}\left(-\frac{d^{2}}{d \beta^{2}} l(\mu, \beta \mid \mathbf{X})\right]\right.
$$

Here is a small table of AREs. There are some entries that are less than one - this is due to using an approximation for the MOM variance.

|  | $\mu$ |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| $\beta$ | 1 | 3 | 6 | 10 |
| 1 | 1.878 | 0.547 | 0.262 | 0.154 |
| 2 | 4.238 | 1.179 | 0.547 | 0.317 |
| 3 | 6.816 | 1.878 | 0.853 | 0.488 |
| 4 | 9.509 | 2.629 | 1.179 | 0.667 |
| 5 | 12.27 | 3.419 | 1.521 | 0.853 |
| 6 | 15.075 | 4.238 | 1.878 | 1.046 |
| 7 | 17.913 | 5.08 | 2.248 | 1.246 |
| 8 | 20.774 | 5.941 | 2.629 | 1.451 |
| 9 | 23.653 | 6.816 | 3.02 | 1.662 |
| 10 | 26.546 | 7.704 | 3.419 | 1.878 |

10.13 Here are the 35 distinct samples from $\{2,4,9,12\}$ and their weights.

| $\{12,12,12,12\}, 1 / 256$ | $\{9,12,12,12\}, 1 / 64$ | $\{9,9,12,12\}, 3 / 128$ |
| :--- | :--- | :--- |
| $\{9,9,9,12\}, 1 / 64$ | $\{9,9,9,9\}, 1 / 256$ | $\{4,12,12,12\}, 1 / 64$ |
| $\{4,9,12,12\}, 3 / 64$ | $\{4,9,9,12\}, 3 / 64$ | $\{4,9,9,9\}, 1 / 64$ |
| $\{4,4,12,12\}, 3 / 128$ | $\{4,4,9,12\}, 3 / 64$ | $\{4,4,9,9\}, 3 / 128$ |
| $\{4,4,4,12\}, 1 / 64$ | $\{4,4,4,9\}, 1 / 64$ | $\{4,4,4,4\}, 1 / 256$ |
| $\{2,12,12,12\}, 1 / 64$ | $\{2,9,12,12\}, 3 / 64$ | $\{2,9,9,12\}, 3 / 64$ |
| $\{2,9,9,9\}, 1 / 64$ | $\{2,4,12,12\}, 3 / 64$ | $\{2,4,9,12\}, 3 / 32$ |
| $\{2,4,9,9\}, 3 / 64$ | $\{2,4,4,12\}, 3 / 64$ | $\{2,4,4,9\}, 3 / 64$ |
| $\{2,4,4,4\}, 1 / 64$ | $\{2,2,12,12\}, 3 / 128$ | $\{2,2,9,12\}, 3 / 64$ |
| $\{2,2,9,9\}, 3 / 128$ | $\{2,2,4,12\}, 3 / 64$ | $\{2,2,4,9\}, 3 / 64$ |
| $\{2,2,4,4\}, 3 / 128$ | $\{2,2,2,12\}, 1 / 64$ | $\{2,2,2,9\}, 1 / 64$ |
| $\{2,2,2,4\}, 1 / 64$ | $\{2,2,2,2\}, 1 / 256$ |  |

The verifications of parts $(a)-(d)$ can be done with this table, or the table of means in Example A.0.1 can be used. For part (e),verifying the bootstrap identities can involve much painful algebra, but it can be made easier if we understand what the bootstrap sample space (the space of all $n^{n}$ bootstrap samples) looks like. Given a sample $x_{1}, x_{2}, \ldots, x_{n}$, the bootstrap sample space can be thought of as a data array with $n^{n}$ rows (one for each bootstrap sample) and $n$ columns, so each row of the data array is one bootstrap sample. For example, if the sample size is $n=3$, the bootstrap sample space is

| $x_{1}$ | $x_{1}$ | $x_{1}$ |
| :--- | :--- | :--- |
| $x_{1}$ | $x_{1}$ | $x_{2}$ |
| $x_{1}$ | $x_{1}$ | $x_{3}$ |
| $x_{1}$ | $x_{2}$ | $x_{1}$ |
| $x_{1}$ | $x_{2}$ | $x_{2}$ |
| $x_{1}$ | $x_{2}$ | $x_{3}$ |
| $x_{1}$ | $x_{3}$ | $x_{1}$ |
| $x_{1}$ | $x_{3}$ | $x_{2}$ |
| $x_{1}$ | $x_{3}$ | $x_{3}$ |
| $x_{2}$ | $x_{1}$ | $x_{1}$ |
| $x_{2}$ | $x_{1}$ | $x_{2}$ |
| $x_{2}$ | $x_{1}$ | $x_{3}$ |
| $x_{2}$ | $x_{2}$ | $x_{1}$ |
| $x_{2}$ | $x_{2}$ | $x_{2}$ |
| $x_{2}$ | $x_{2}$ | $x_{3}$ |
| $x_{2}$ | $x_{3}$ | $x_{1}$ |
| $x_{2}$ | $x_{3}$ | $x_{2}$ |
| $x_{2}$ | $x_{3}$ | $x_{3}$ |
| $x_{3}$ | $x_{1}$ | $x_{1}$ |
| $x_{3}$ | $x_{1}$ | $x_{2}$ |
| $x_{3}$ | $x_{1}$ | $x_{3}$ |
| $x_{3}$ | $x_{2}$ | $x_{1}$ |
| $x_{3}$ | $x_{2}$ | $x_{2}$ |
| $x_{3}$ | $x_{2}$ | $x_{3}$ |
| $x_{3}$ | $x_{3}$ | $x_{1}$ |
| $x_{3}$ | $x_{3}$ | $x_{2}$ |
| $x_{3}$ | $x_{3}$ | $x_{3}$ |
| $x_{1}$ | $e_{1}$ |  |

Note the pattern. The first column is $9 x_{1} \mathrm{~s}$ followed by $9 x_{2}$ s followed by $9 x_{3} \mathrm{~s}$, the second column is $3 x_{1} \mathrm{~s}$ followed by $3 x_{2} \mathrm{~s}$ followed by $3 x_{3} \mathrm{~s}$, then repeated, etc. In general, for the entire bootstrap sample,

- The first column is $n^{n-1} x_{1}$ s followed by $n^{n-1} x_{2} \mathrm{~S}$ followed by, ..., followed by $n^{n-1} x_{n} \mathrm{~S}$
- The second column is $n^{n-2} x_{1}$ s followed by $n^{n-2} x_{2}$ s followed by, ..., followed by $n^{n-2}$ $x_{n} \mathrm{~s}$, repeated $n$ times
- The third column is $n^{n-3} x_{1}$ s followed by $n^{n-3} x_{2}$ s followed by, ..., followed by $n^{n-3}$ $x_{n} \mathrm{~s}$, repeated $n^{2}$ times
- The $n^{\text {th }}$ column is $1 x_{1}$ followed by $1 x_{2}$ followed by, $\ldots$, followed by $1 x_{n}$, repeated $n^{n-1}$ times
So now it is easy to see that each column in the data array has mean $\bar{x}$, hence the entire bootstrap data set has mean $\bar{x}$. Appealing to the $3^{3} \times 3$ data array, we can write the numerator of the variance of the bootstrap means as

$$
\begin{aligned}
& \sum_{i=1}^{3} \sum_{j=1}^{3} \sum_{k=1}^{3}\left[\frac{1}{3}\left(x_{i}+x_{j}+x_{k}\right)-\bar{x}\right]^{2} \\
& \quad=\frac{1}{3^{2}} \sum_{i=1}^{3} \sum_{j=1}^{3} \sum_{k=1}^{3}\left[\left(x_{i}-\bar{x}\right)+\left(x_{j}-\bar{x}\right)+\left(x_{k}-\bar{x}\right)\right]^{2} \\
& \quad=\frac{1}{3^{2}} \sum_{i=1}^{3} \sum_{j=1}^{3} \sum_{k=1}^{3}\left[\left(x_{i}-\bar{x}\right)^{2}+\left(x_{j}-\bar{x}\right)^{2}+\left(x_{k}-\bar{x}\right)^{2}\right]
\end{aligned}
$$

because all of the cross terms are zero (since they are the sum of deviations from the mean). Summing up and collecting terms shows that

$$
\frac{1}{3^{2}} \sum_{i=1}^{3} \sum_{j=1}^{3} \sum_{k=1}^{3}\left[\left(x_{i}-\bar{x}\right)^{2}+\left(x_{j}-\bar{x}\right)^{2}+\left(x_{k}-\bar{x}\right)^{2}\right]=3 \sum_{i=1}^{3}\left(x_{i}-\bar{x}\right)^{2}
$$

and thus the average of the variance of the bootstrap means is

$$
\frac{3 \sum_{i=1}^{3}\left(x_{i}-\bar{x}\right)^{2}}{3^{3}}
$$

which is the usual estimate of the variance of $\bar{X}$ if we divide by $n$ instead of $n-1$. The general result should now be clear. The variance of the bootstrap means is

$$
\begin{aligned}
& \sum_{i_{1}=1}^{n} \sum_{i_{2}=1}^{n} \cdots \sum_{i_{n}=1}^{n}\left[\frac{1}{n}\left(x_{i_{1}}+x_{i_{2}}+\cdots+x_{i_{n}}\right)-\bar{x}\right]^{2} \\
& \quad=\frac{1}{n^{2}} \sum_{i_{1}=1}^{n} \sum_{i_{2}=1}^{n} \cdots \sum_{i_{n}=1}^{n}\left[\left(x_{i_{1}}-\bar{x}\right)^{2}+\left(x_{i_{2}}-\bar{x}\right)^{2}+\cdots+\left(x_{i_{n}}-\bar{x}\right)^{2}\right]
\end{aligned}
$$

since all of the cross terms are zero. Summing and collecting terms shows that the sum is $n^{n-2} \sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2}$, and the variance of the bootstrap means is $n^{n-2} \sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2} / n^{n}=$ $\sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2} / n^{2}$.
10.15 a. As $B \rightarrow \infty \operatorname{Var}_{B}^{*}(\hat{\theta})=\operatorname{Var}^{*}(\hat{\theta})$.
b. Each $\operatorname{Var}_{B_{i}}^{*}(\hat{\theta})$ is a sample variance, and they are independent so the LLN applies and

$$
\frac{1}{m} \sum_{i=1}^{m} \operatorname{Var}_{B_{i}}^{*}(\hat{\theta}) \xrightarrow{m \rightarrow \infty} \operatorname{EVar}_{B}^{*}(\hat{\theta})=\operatorname{Var}^{*}(\hat{\theta})
$$

where the last equality follows from Theorem 5.2.6(c).
10.17 a. The correlation is .7781
b. Here is R code ( R is available free at http://cran.r-project.org/) to bootstrap the data, calculate the standard deviation, and produce the histogram:

```
cor(law)
n <- 15
theta <- function(x,law){ cor(law[x,1],law[x,2]) }
results <- bootstrap(1:n,1000,theta,law,func=sd)
results[2]
hist(results[[1]])
```

The data "law" is in two columns of length 15, "results[2]" contains the standard deviation. The vector "results[[1]]" is the bootstrap sample. The output is

```
        V1 V2
V1 1.0000000 0.7781716
V2 0.7781716 1.0000000
$func.thetastar
[1] 0.1322881
```

showing a correlation of . 7781 and a bootstrap standard deviation of .1323.
c. The R code for the parametric bootstrap is

```
mx<-600.6;my<-3.09
sdx<-sqrt(1791.83);sdy<-sqrt(.059)
rho<-.7782;b<-rho*sdx/sdy;sdxy<-sqrt(1-rho^2)*sdx
rhodata<-rho
for (j in 1:1000) {
y<-rnorm(15,mean=my,sd=sdy)
x<-rnorm(15,mean=mx+b*(y-my),sd=sdxy)
rhodata<-c(rhodata, cor (x,y))
}
sd(rhodata)
hist(rhodata)
```

where we generate the bivariate normal by first generating the marginal then the condidional, as R does not have a bivariate normal generator. The bootstrap standard deviation is 0.1159 , smaller than the nonparametric estimate. The histogram looks similar to the nonparametric bootstrap histogram, displaying a skewness left.
d. The Delta Method approximation is

$$
r \sim \mathrm{n}\left(\rho,\left(1-\rho^{2}\right)^{2} / n\right)
$$

and the "plug-in" estimate of standard error is $\sqrt{\left(1-.7782^{2}\right)^{2} / 15}=.1018$, the smallest so far. Also, the approximate pdf of $r$ will be normal, hence symmetric.
e. By the change of variables

$$
t=\frac{1}{2} \log \left(\frac{1+r}{1-r}\right), \quad d t=\frac{1}{1-r^{2}}
$$

the density of $r$ is

$$
\frac{1}{\sqrt{2 \pi}\left(1-r^{2}\right)} \exp \left(-\frac{n}{2}\left[\frac{1}{2} \log \left(\frac{1+r}{1-r}\right)-\frac{1}{2} \log \left(\frac{1+\rho}{1-\rho}\right)\right]^{2}\right), \quad-1 \leq r \leq 1
$$

More formally, we could start with the random variable $T$, normal with mean $\frac{1}{2} \log \left(\frac{1+\rho}{1-\rho}\right)$ and variance $1 / n$, and make the transformation to $R=\frac{e^{2 T}+1}{e^{2 T}-1}$ and get the same answer.
10.19 a. The variance of $\bar{X}$ is

$$
\begin{aligned}
\operatorname{Var} \bar{X}=\mathrm{E}(\bar{X}-\mu)^{2} & =\mathrm{E}\left(\frac{1}{n} \sum_{i} X_{i}-\mu\right)^{2} \\
& =\frac{1}{n^{2}} \mathrm{E}\left(\sum_{i}\left(X_{i}-\mu\right)^{2}+2 \sum_{i>j}\left(X_{i}-\mu\right)\left(X_{j}-\mu\right)\right) \\
& =\frac{1}{n^{2}}\left(n \sigma^{2}+2 \frac{n(n-1)}{2} \rho \sigma^{2}\right) \\
& =\frac{\sigma^{2}}{n}+\frac{n-1}{n} \rho \sigma^{2}
\end{aligned}
$$

b. In this case we have

$$
\mathrm{E}\left[\sum_{i>j}\left(X_{i}-\mu\right)\left(X_{j}-\mu\right)\right]=\sigma^{2} \sum_{i=2}^{n} \sum_{j=1}^{i-1} \rho^{i-j}
$$

In the double sum $\rho$ appears $n-1$ times, $\rho^{2}$ appears $n-2$ times, etc.. so

$$
\sum_{i=2}^{n} \sum_{j=1}^{i-1} \rho^{i-j}=\sum_{i=1}^{n-1}(n-i) \rho^{i}=\frac{\rho}{1-\rho}\left(n-\frac{1-\rho^{n}}{1-\rho}\right)
$$

where the series can be summed using (1.5.4), the partial sum of the geometric series, or using Mathematica.
c. The mean and variance of $X_{i}$ are

$$
\mathrm{E} X_{i}=\mathrm{E}\left[\mathrm{E}\left(X_{i} \mid X_{i-1}\right)\right]=\mathrm{E} \rho X_{i-1}=\cdots=\rho^{i-1} \mathrm{E} X_{1}
$$

and

$$
\operatorname{Var} X_{i}=\operatorname{VarE}\left(X_{i} \mid X_{i-1}\right)+\mathrm{E} \operatorname{Var}\left(X_{i} \mid X_{i-1}\right)=\rho^{2} \sigma^{2}+1=\sigma^{2}
$$

for $\sigma^{2}=1 /\left(1-\rho^{2}\right)$. Also, by iterating the expectation

$$
\mathrm{E} X_{1} X_{i}=\mathrm{E}\left[\mathrm{E}\left(X_{1} X_{i} \mid X_{i-1}\right)\right]=\mathrm{E}\left[\mathrm{E}\left(X_{1} \mid X_{i-1}\right) \mathrm{E}\left(X_{i} \mid X_{i-1}\right)\right]=\rho \mathrm{E}\left[X_{1} X_{i-1}\right]
$$

where we used the facts that $X_{1}$ and $X_{i}$ are independent conditional on $X_{i-1}$. Continuing with the argument we get that $\mathrm{E} X_{1} X_{i}=\rho^{i-1} \mathrm{E} X_{1}^{2}$. Thus,

$$
\operatorname{Corr}\left(X_{1}, X_{i}\right)=\frac{\rho^{i-1} \mathrm{E} X_{1}^{2}-\rho^{i-1}\left(\mathrm{E} X_{1}\right)^{2}}{\sqrt{\operatorname{Var} X_{1} \operatorname{Var} X_{i}}}=\frac{\rho^{i-1} \sigma^{2}}{\sqrt{\sigma^{2} \sigma^{2}}}=\rho^{i-1}
$$

10.21 a. If any $x_{i} \rightarrow \infty, s^{2} \rightarrow \infty$, so it has breakdown value 0 . To see this, suppose that $x_{1} \rightarrow \infty$. Write

$$
s^{2}=\frac{1}{n-1} \sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2}=\frac{1}{n-1}\left(\left[\left(1-\frac{1}{n}\right) x_{1}-\bar{x}_{-1}\right]^{2}+\sum_{i=2}^{n}\left(x_{i}-\bar{x}\right)^{2}\right)
$$

where $\bar{x}_{-1}=\left(x_{2}+\ldots+x_{n}\right) / n$. It is easy to see that as $x_{1} \rightarrow \infty$, each term in the sum $\rightarrow \infty$.
b. If less than $50 \%$ of the sample $\rightarrow \infty$, the median remains the same, and the median of $\left|x_{i}-M\right|$ remains the same. If more than $50 \%$ of the sample $\rightarrow \infty, M \rightarrow \infty$ and so does the MAD.
10.23 a. The ARE is $[2 \sigma f(\mu)]^{2}$. We have

| Distribution | Parameters | variance | $f(\mu)$ | ARE |
| :--- | :--- | :--- | :--- | :--- |
| normal | $\mu=0, \sigma=1$ | 1 | .3989 | .64 |
| logistic | $\mu=0, \beta=1$ | $\pi^{2} / 3$ | .25 | .82 |
| double exp. | $\mu=0, \sigma=1$ | 2 | .5 | 2 |

b. If $X_{1}, X_{2}, \ldots, X_{n}$ are iid $f_{X}$ with $\mathrm{E} X_{1}=\mu$ and $\operatorname{Var} X_{1}=\sigma^{2}$, the ARE is $\sigma^{2}\left[2 * f_{X}(\mu)\right]^{2}$. If we transform to $Y_{i}=\left(X_{i}-\mu\right) / \sigma$, the pdf of $Y_{i}$ is $f_{Y}(y)=\sigma f_{X}(\sigma y+\mu)$ with ARE $\left[2 * f_{Y}(0)\right]^{2}=\sigma^{2}\left[2 * f_{X}(\mu)\right]^{2}$
c. The median is more efficient for smaller $\nu$, the distributions with heavier tails.

| $\nu$ | $\operatorname{Var} X$ | $f(0)$ | ARE |
| :---: | :---: | :---: | :--- |
| 3 | 3 | .367 | 1.62 |
| 5 | $5 / 3$ | .379 | .960 |
| 10 | $5 / 4$ | .389 | .757 |
| 25 | $25 / 23$ | .395 | .678 |
| 50 | $25 / 24$ | .397 | .657 |
| $\infty$ | 1 | .399 | .637 |

d. Again the heavier tails favor the median.

| $\delta$ | $\sigma$ | ARE |
| :---: | :---: | :--- |
| .01 | 2 | .649 |
| .1 | 2 | .747 |
| .5 | 2 | .895 |
| .01 | 5 | .777 |
| .1 | 5 | 1.83 |
| .5 | 5 | 2.98 |

10.25 By transforming $y=x-\theta$,

$$
\int_{-\infty}^{\infty} \psi(x-\theta) f(x-\theta) d x=\int_{-\infty}^{\infty} \psi(y) f(y) d y
$$

Since $\psi$ is an odd function, $\psi(y)=-\psi(-y)$, and

$$
\begin{aligned}
\int_{-\infty}^{\infty} \psi(y) f(y) d y & =\int_{-\infty}^{0} \psi(y) f(y) d y+\int_{0}^{\infty} \psi(y) f(y) d y \\
& =\int_{-\infty}^{0}-\psi(-y) f(y) d y+\int_{0}^{\infty} \psi(y) f(y) d y \\
& =-\int_{0}^{\infty} \psi(y) f(y) d y+\int_{0}^{\infty} \psi(y) f(y) d y=0
\end{aligned}
$$

where in the last line we made the transformation $y \rightarrow-y$ and used the fact the $f$ is symmetric, so $f(y)=f(-y)$. From the discussion preceding Example 10.2.6, $\hat{\theta}_{M}$ is asymptotically normal with mean equal to the true $\theta$.
10.27 a.

$$
\lim _{\delta \rightarrow 0} \frac{1}{\delta}[(1-\delta) \mu+\delta x-\mu]=\lim _{\delta \rightarrow 0} \frac{\delta(x-\mu)}{\delta}=x-\mu
$$

b.

$$
P(X \leq a)=P(X \leq a \mid X \sim F)(1-\delta)+P(x \leq a \mid X=x) \delta=(1-\delta) F(a)+\delta I(x \leq a)
$$

and

$$
\begin{aligned}
(1-\delta) F(a) & =\frac{1}{2} \quad \Rightarrow \quad a=F^{-1}\left(\frac{1}{2(1-\delta)}\right) \\
(1-\delta) F(a)+\delta & =\frac{1}{2} \quad \Rightarrow \quad a=F^{-1}\left(\frac{\frac{1}{2}-\delta}{2(1-\delta)}\right)
\end{aligned}
$$

c. The limit is

$$
\lim _{\delta \rightarrow 0} \frac{a_{\delta}-a_{0}}{\delta}=\left.a_{\delta}^{\prime}\right|_{\delta=0}
$$

by the definition of derivative. Since $F\left(a_{\delta}\right)=\frac{1}{2(1-\delta)}$,

$$
\frac{d}{d \delta} F\left(a_{\delta}\right)=\frac{d}{d \delta} \frac{1}{2(1-\delta)}
$$

or

$$
f\left(a_{\delta}\right) a_{\delta}^{\prime}=\frac{1}{2(1-\delta)^{2}} \Rightarrow a_{\delta}^{\prime}=\frac{1}{2(1-\delta)^{2} f\left(a_{\delta}\right)}
$$

Since $a_{0}=m$, the result follows. The other limit can be calculated in a similar manner.
10.29 a . Substituting $c l^{\prime}$ for $\psi$ makes the ARE equal to 1.
b. For each distribution is the case that the given $\psi$ function is equal to $c l^{\prime}$, hence the resulting M-estimator is asymptotically efficient by (10.2.9).
10.31 a. By the CLT,

$$
\sqrt{n_{1}} \frac{\hat{p_{1}}-p_{1}}{\sqrt{p_{1}\left(1-p_{1}\right)}} \rightarrow \mathrm{n}(0,1) \quad \text { and } \quad \sqrt{n_{2}} \frac{\hat{p_{2}}-p_{2}}{\sqrt{p_{2}\left(1-p_{2}\right)}} \rightarrow \mathrm{n}(0,1)
$$

so if $\hat{p}_{1}$ and $\hat{p}_{2}$ are independent, under $H_{0}: p_{1}=p_{2}=p$,

$$
\frac{\hat{p}_{1}-\hat{p}_{2}}{\sqrt{\left(\frac{1}{n_{1}}+\frac{1}{n_{2}}\right) \hat{p}(1-\hat{p})}} \rightarrow \mathrm{n}(0,1)
$$

where we use Slutsky's Theorem and the fact that $\hat{p}=\left(S_{1}+S_{2}\right) /\left(n_{1}+n_{2}\right)$ is the MLE of p under $H_{0}$ and converges to $p$ in probability. Therefore, $T \rightarrow \chi_{1}^{2}$.
b. Substitute $\hat{p}_{i}$ s for $S_{i}$ and $F_{i}$ s to get

$$
\begin{aligned}
T^{*}= & \frac{n_{1}^{2}\left(\hat{p}_{1}-\hat{p}\right)^{2}}{n_{1} \hat{p}}+\frac{n_{2}^{2}\left(\hat{p}_{2}-\hat{p}\right)^{2}}{n_{2} \hat{p}} \\
& \quad+\frac{n_{1}^{2}\left[\left(1-\hat{p}_{1}\right)-(1-\hat{p})\right]^{2}}{n_{1}(1-\hat{p})}+\frac{n_{2}^{2}\left[\left(1-\hat{p}_{2}\right)-(1-\hat{p})\right]^{2}}{n_{2} \hat{p}} \\
= & \frac{n_{1}\left(\hat{p}_{1}-\hat{p}\right)^{2}}{\hat{p}(1-\hat{p})}+\frac{n_{2}\left(\hat{p}_{2}-\hat{p}\right)^{2}}{\hat{p}(1-\hat{p})}
\end{aligned}
$$

Write $\hat{p}=\left(n_{1} \hat{p}_{1}+n_{2} \hat{p}_{2}\right) /\left(n_{1}+n_{2}\right)$. Substitute this into the numerator, and some algebra will get

$$
n_{1}\left(\hat{p}_{1}-\hat{p}\right)^{2}+n_{2}\left(\hat{p}_{2}-\hat{p}\right)^{2}=\frac{\left(\hat{p}_{1}-\hat{p}_{2}\right)^{2}}{\frac{1}{n_{1}}+\frac{1}{n_{2}}}
$$

so $T^{*}=T$.
c. Under $H_{0}$,

$$
\frac{\hat{p}_{1}-\hat{p}_{2}}{\sqrt{\left(\frac{1}{n_{1}}+\frac{1}{n_{2}}\right) p(1-p)}} \rightarrow \mathrm{n}(0,1)
$$

and both $\hat{p}_{1}$ and $\hat{p}_{2}$ are consistent, so $\hat{p}_{1}\left(1-\hat{p}_{1}\right) \rightarrow p(1-p)$ and $\hat{p}_{2}\left(1-\hat{p}_{2}\right) \rightarrow p(1-p)$ in probability. Therefore, by Slutsky's Theorem,

$$
\frac{\hat{p}_{1}-\hat{p}_{2}}{\sqrt{\frac{\hat{p}_{1}\left(1-\hat{p}_{1}\right)}{n_{1}}+\frac{\hat{p}_{2}\left(1-\hat{p}_{2}\right)}{n_{2}}}} \rightarrow \mathrm{n}(0,1)
$$

and $\left(T^{* *}\right)^{2} \rightarrow \chi_{1}^{2}$. It is easy to see that $T^{* *} \neq T$ in general.
d. The estimator $\left(1 / n_{1}+1 / n_{2}\right) \hat{p}(1-\hat{p})$ is the MLE of $\operatorname{Var}\left(\hat{p}_{1}-\hat{p}_{2}\right)$ under $H_{0}$, while the estimator $\hat{p}_{1}\left(1-\hat{p}_{1}\right) / n_{1}+\hat{p}_{2}\left(1-\hat{p}_{2}\right) / n_{1}$ is the MLE of $\operatorname{Var}\left(\hat{p}_{1}-\hat{p}_{2}\right)$ under $H_{1}$. One might argue that in hypothesis testing, the first one should be used, since under $H_{0}$, it provides a better estimator of variance. If interest is in finding the confidence interval, however, we are making inference under both $H_{0}$ and $H_{1}$, and the second one is preferred.
e. We have $\hat{p}_{1}=34 / 40, \hat{p}_{2}=19 / 35, \hat{p}=(34+19) /(40+35)=53 / 75$, and $T=8.495$. Since $\chi_{1, .05}^{2}=3.84$, we can reject $H_{0}$ at $\alpha=.05$.
10.32 a. First calculate the MLEs under $p_{1}=p_{2}=p$. We have

$$
L(p \mid x)=p^{x_{1}} p^{x_{2}} p^{x_{3}} \cdots p_{n-1}^{x_{n-1}}\left(1-2 p-\sum_{i=3}^{n-1} p_{i}\right)^{m-x_{1}-x_{2}-\cdots-x_{n-1}}
$$

Taking logs and differentiating yield the following equations for the MLEs:

$$
\begin{gathered}
\frac{\partial \log L}{\partial p}=\frac{x_{1}+x_{2}}{p}-\frac{2\left(m-\sum_{i=1}^{n-1} x_{i}\right)}{1-2 p-\sum_{i=3}^{n-1} p_{i}}=0 \\
\frac{\partial \log L}{\partial p_{i}}=\frac{x_{i}}{p_{i}}-\frac{x_{n}}{1-2 p-\sum_{i=3}^{n-1} p_{i}}=0, \quad i=3, \ldots, n-1
\end{gathered}
$$

with solutions $\hat{p}=\frac{x_{1}+x_{2}}{2 m}, \hat{p}_{i}=\frac{x_{i}}{m}, i=3, \ldots, n-1$, and $\hat{p}_{n}=\left(m-\sum_{i=1}^{n-1} x_{i}\right) / m$. Except for the first and second cells, we have expected $=$ observed, since both are equal to $x_{i}$. For the first two terms, expected $=m \hat{p}=\left(x_{1}+x_{2}\right) / 2$ and we get

$$
\sum \frac{(\text { observed }- \text { expected })^{2}}{\text { expected }}=\frac{\left(x_{1}-\frac{x_{1}+x_{2}}{2}\right)^{2}}{\frac{x_{1}+x_{2}}{2}}+\frac{\left(x_{2}-\frac{x_{1}+x_{2}}{2}\right)^{2}}{\frac{x_{1}+x_{2}}{2}}=\frac{\left(x_{1}-x_{2}\right)^{2}}{x_{1}+x_{2}}
$$

b. Now the hypothesis is about conditional probabilities is given by $H_{0}: \mathrm{P}$ (change-initial agree $)=\mathrm{P}($ change -initial disagree $)$ or, in terms of the parameters $H_{0}: \frac{p_{1}}{p_{1}+p_{3}}=\frac{p_{2}}{p_{2}+p_{4}}$. This is the same as $p_{1} p_{4}=p_{2} p_{3}$, which is not the same as $p_{1}=p_{2}$.
10.33 Theorem 10.1.12 and Slutsky's Theorem imply that

$$
\frac{\hat{\theta}-\theta}{\sqrt{\frac{1}{n} I_{n}(\hat{\theta})}} \rightarrow \mathrm{n}(0,1)
$$

and the result follows.
10.35 a. Since $\sigma / \sqrt{n}$ is the estimated standard deviation of $\bar{X}$ in this case, the statistic is a Wald statistic
b. The MLE of $\sigma^{2}$ is $\hat{\sigma}_{\mu}^{2}=\sum_{i}\left(x_{i}-\mu\right)^{2} / n$. The information number is

$$
-\left.\frac{d^{2}}{d\left(\sigma^{2}\right)^{2}}\left(-\frac{n}{2} \log \sigma^{2}-\frac{1}{2} \frac{\hat{\sigma}_{\mu}^{2}}{\sigma^{2}}\right)\right|_{\sigma^{2}=\hat{\sigma}_{\mu}^{2}}=\frac{n}{2 \hat{\sigma}_{\mu}^{2}}
$$

Using the Delta method, the variance of $\hat{\sigma}_{\mu}=\sqrt{\hat{\sigma}_{\mu}^{2}}$ is $\hat{\sigma}_{\mu}^{2} / 8 n$, and a Wald statistic is

$$
\frac{\hat{\sigma}_{\mu}-\sigma_{0}}{\sqrt{\sigma_{\mu}^{2} / 8 n}}
$$

10.37 a. The log likelihood is

$$
\log L=-\frac{n}{2} \log \sigma^{2}-\frac{1}{2} \sum_{i}\left(x_{i}-\mu\right)^{2} / \sigma^{2}
$$

with

$$
\begin{aligned}
\frac{d}{d \mu} & =\frac{1}{\sigma^{2}} \sum_{i}\left(x_{i}-\mu\right)=\frac{n}{\sigma^{2}}(\bar{x}-\mu) \\
\frac{d^{2}}{d \mu^{2}} & =-\frac{n}{\sigma^{2}}
\end{aligned}
$$

so the test statistic for the score test is

$$
\frac{\frac{n}{\sigma^{2}}(\bar{x}-\mu)}{\sqrt{\sigma^{2} / n}}=\sqrt{n} \frac{\bar{x}-\mu}{\sigma}
$$

b. We test the equivalent hypothesis $H_{0}: \sigma^{2}=\sigma_{0}^{2}$. The likelihood is the same as Exercise $10.35(b)$, with first derivative

$$
-\frac{d}{d \sigma^{2}}=\frac{n\left(\hat{\sigma}_{\mu}^{2}-\sigma^{2}\right)}{2 \sigma^{4}}
$$

and expected information number

$$
\mathrm{E}\left(\frac{n\left(2 \hat{\sigma}_{\mu}^{2}-\sigma^{2}\right)}{2 \sigma^{6}}\right)=\frac{n\left(2 \sigma^{2}-\sigma^{2}\right)}{2 \sigma^{6}}=\frac{n}{2 \sigma^{4}} .
$$

The score test statistic is

$$
\sqrt{\frac{n}{2}} \frac{\hat{\sigma}_{\mu}^{2}-\sigma_{0}^{2}}{\sigma_{0}^{2}}
$$

10.39 We summarize the results for $(a)-(c)$ in the following table. We assume that the underlying distribution is normal, and use that for all score calculations. The actual data is generated from normal, logistic, and double exponential. The sample size is 15 , we use 1000 simulations and draw 20 bootstrap samples. Here $\theta_{0}=0$, and the power is tabulated for a nominal $\alpha=.1$ test.

| Underlying <br> pdf |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Lest | $\theta_{0}$ | $\theta_{0}+.25 \sigma$ | $\theta_{0}+.5 \sigma$ | $\theta_{0}+.75 \sigma$ | $\theta_{0}+1 \sigma$ | $\theta_{0}+2 \sigma$ |  |
|  | Naive | 0.101 | 0.366 | 0.774 | 0.957 | 0.993 | 1. |
|  | Boot | 0.097 | 0.364 | 0.749 | 0.932 | 0.986 | 1. |
|  | Median | 0.065 | 0.245 | 0.706 | 0.962 | 0.995 | 1. |
|  |  |  |  |  |  |  |  |
|  | Naive | 0.137 | 0.341 | 0.683 | 0.896 | 0.97 | 1. |

    {j, 1, nsim}]], {i, 1, ntheta}]]
```

10.41 a . The log likelihood is

$$
\log L=n r \log p+n \bar{x} \log (1-p)
$$

with

$$
\frac{d}{d p} \log L=\frac{n r}{p}-\frac{n \bar{x}}{1-p} \quad \text { and } \quad \frac{d^{2}}{d p^{2}} \log L=-\frac{n r}{p^{2}}-\frac{n \bar{x}}{(1-p)^{2}},
$$

expected information $\frac{n r}{p^{2}(1-p)}$ and (Wilks) score test statistic

$$
\sqrt{n} \frac{\left(\frac{r}{p}-\frac{n \bar{x}}{1-p}\right)}{\sqrt{\frac{r}{p^{2}(1-p)}}}=\sqrt{\frac{n}{r}}\left(\frac{(1-p) r+p \bar{x}}{\sqrt{1-p}}\right) .
$$

Since this is approximately $n(0,1)$, a $1-\alpha$ confidence set is

$$
\left\{p:\left|\sqrt{\frac{n}{r}}\left(\frac{(1-p) r-p \bar{x}}{\sqrt{1-p}}\right)\right| \leq z_{\alpha / 2}\right\} .
$$

b. The mean is $\mu=r(1-p) / p$, and a little algebra will verify that the variance, $r(1-p) / p^{2}$ can be written $r(1-p) / p^{2}=\mu+\mu^{2} / r$. Thus

$$
\sqrt{\frac{n}{r}}\left(\frac{(1-p) r-p \bar{x}}{\sqrt{1-p}}\right)=\sqrt{n} \frac{\mu-\bar{x}}{\sqrt{\mu+\mu^{2} / r}} .
$$

The confidence interval is found by setting this equal to $z_{\alpha / 2}$, squaring both sides, and solving the quadratic for $\mu$. The endpoints of the interval are

$$
\frac{r\left(8 \bar{x}+z_{\alpha / 2}^{2}\right) \pm \sqrt{r z_{\alpha / 2}^{2}} \sqrt{16 r \bar{x}+16 \bar{x}^{2}+r z_{\alpha / 2}^{2}}}{8 r-2 z_{\alpha / 2}^{2}}
$$

For the continuity correction, replace $\bar{x}$ with $\bar{x}+1 /(2 n)$ when solving for the upper endpoint, and with $\bar{x}-1 /(2 n)$ when solving for the lower endpoint.
c. We table the endpoints for $\alpha=.1$ and a range of values of $r$. Note that $r=\infty$ is the Poisson, and smaller values of $r$ give a wider tail to the negative binomial distribution.

| $r$ | lower bound | upper bound |
| :---: | :--- | :--- |
| 1 | 22.1796 | 364.42 |
| 5 | 36.2315 | 107.99 |
| 10 | 38.4565 | 95.28 |
| 50 | 40.6807 | 85.71 |
| 100 | 41.0015 | 84.53 |
| 1000 | 41.3008 | 83.46 |
| $\infty$ | 41.3348 | 83.34 |

10.43 a. Since

$$
P\left(\sum_{i} X_{i}=0\right)=(1-p)^{n}=\alpha / 2 \Rightarrow p=1-\alpha^{1 / n}
$$

and

$$
P\left(\sum_{i} X_{i}=n\right)=p^{n}=\alpha / 2 \Rightarrow p=\alpha^{1 / n}
$$

these endpoints are exact, and are the shortest possible.
b. Since $p \in[0,1]$, any value outside has zero probability, so truncating the interval shortens it at no cost.
10.45 The continuity corrected roots are

$$
\frac{2 \hat{p}+z_{\alpha / 2}^{2} / n \pm \frac{1}{n} \pm \sqrt{\frac{z_{\alpha / 2}^{2}}{n^{3}}[ \pm 2 n(1-2 \hat{p})-1]+\left(2 \hat{p}+z_{\alpha / 2}^{2} / n\right)^{2}-4 \hat{p}^{2}\left(1+z_{\alpha / 2}^{2} / n\right)}}{2\left(1+z_{\alpha / 2}^{2} / n\right)}
$$

where we use the upper sign for the upper root and the lower sign for the lower root. Note that the only differences between the continuity-corrected intervals and the ordinary score intervals are the terms with $\pm$ in front. But it is still difficult to analytically compare lengths with the non-corrected interval - we will do a numerical comparison. For $n=10$ and $\alpha=.1$ we have the following table of length ratios, with the continuity-corrected length in the denominator

| $n$ | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Ratio | 0.79 | 0.82 | 0.84 | 0.85 | 0.86 | 0.86 | 0.86 | 0.85 | 0.84 | 0.82 | 0.79 |

The coverage probabilities are

| $p$ | 0 | .1 | .2 | .3 | .4 | .5 | .6 | .7 | .8 | .9 | 1 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| score | .99 | .93 | .97 | .92 | .90 | .89 | .90 | .92 | .97 | .93 | .99 |
| cc | .99 | .99 | .97 | .92 | .98 | .98 | .98 | .92 | .97 | .99 | .99 |

Mathematica code to do the calculations is:

```
Needs["Statistics'Master`"]
Clear [p, x]
pbino[p_, x_] = PDF[BinomialDistribution[n, p], x];
cut = 1.645^2;
n = 10;
```

The quadratic score interval with and without continuity correction

```
slowcc[\mp@subsup{x}{_}{\prime}] := p /. FindRoot[(x/n - 1/(2*n) - p)^2 ==
    cut*(p*((1 - p))/n, {p, .001}]
supcc[\mp@subsup{x}{_}{}] := p /. FindRoot[(x/n + 1/(2*n) - p)^2 ==
    cut*(p*((1 - p)/n, {p, .999}]
slow[x_] := p /. FindRoot[(x/n - p))^2 ==
    cut*(p*(1 - p))/n, {p, .001}]
sup[\mp@subsup{x}{_}{\prime}]:= p/. FindRoot [(x/n - p ^) 2 ==
    cut*(p*(1 - p)/n, {p, .999}]
scoreintcc=Partition[Flatten[{{0,sup[0]},Table[{slowcc[i],supcc[i]},
    {i,1,n-1}],{slowcc[n],1}},2],2];
scoreint=Partition[Flatten[{{0, sup[0]},Table[{slow[i],sup[i]},
    {i,1,n-1}],{slowcc[n],1}},2],2];
```

## Length Comparison

Table[(sup[i] - slow[i])/(supcc[i] - slowcc[i]), \{i, 0, n\}]
Now we'll calculate coverage probabilities

```
scoreindcc[p_, x_]:=If[scoreintcc[[x+1]][[1]]<=p<=scoreintcc[[x+1]][[2]], 1,0]
scorecovcc[p_] :=scorecovcc[p]=Sum[pbino[p,x]*scoreindcc[p,x],{x,0,n}]
scoreind[p_, x_]:=If [scoreint[[x+1]][[1]]<=p<=scoreint[[x+1]][[2]],1,0]
scorecov[p_]:=scorecov[p]=Sum[pbino[p,x]*scoreind[p,x],{x,0,n}]
{scorecovcc[.0001],Table[scorecovcc[i/10],{i,1,9}],scorecovcc[.9999]}//N
{scorecov[.0001],Table[scorecov[i/10],{i,1,9}],scorecov[.9999]}//N
```

10.47 a. Since $2 p Y \sim \chi_{n r}^{2}$ (approximately)

$$
P\left(\chi_{n r, 1-\alpha / 2}^{2} \leq 2 p Y \leq \chi_{n r, \alpha / 2}^{2}\right)=1-\alpha
$$

and rearrangment gives the interval.
b. The interval is of the form $P(a / 2 Y \leq p \leq b / 2 Y)$, so the length is proportional to $b-a$. This must be minimized subject to the constraint $\int_{a}^{b} f(y) d y=1-\alpha$, where $f(y)$ is the pdf of a $\chi_{n r}^{2}$. Treating $b$ as a function of $a$, differentiating gives

$$
b^{\prime}-1=0 \quad \text { and } \quad f(b) b^{\prime}-f(a)=0
$$

which implies that we need $f(b)=f(a)$.

## Chapter 11

## Analysis of Variance and Regression

11.1 a. The first order Taylor's series approximation is

$$
\operatorname{Var}[g(Y)] \approx\left[g^{\prime}(\theta)\right]^{2} \cdot \operatorname{Var} Y=\left[g^{\prime}(\theta)\right]^{2} \cdot v(\theta)
$$

b. If we choose $g(y)=g^{*}(y)=\int_{a}^{y} \frac{1}{\sqrt{v(x)}} d x$, then

$$
\frac{d g^{*}(\theta)}{d \theta}=\frac{d}{d \theta} \int_{a}^{\theta} \frac{1}{\sqrt{v(x)}} d x=\frac{1}{\sqrt{v(\theta)}}
$$

by the Fundamental Theorem of Calculus. Then, for any $\theta$,

$$
\operatorname{Var}\left[g^{*}(Y)\right] \approx\left(\frac{1}{\sqrt{v(\theta)}}\right)^{2} v(\theta)=1
$$

11.2 a. $v(\lambda)=\lambda, g^{*}(y)=\sqrt{y}, \frac{d g^{*}(\lambda)}{d \lambda}=\frac{1}{2 \sqrt{\lambda}}, \operatorname{Var} g^{*}(Y) \approx\left(\frac{d g^{*}(\lambda)}{d \lambda}\right)^{2} \cdot v(\lambda)=1 / 4$, independent of $\lambda$.
b. To use the Taylor's series approximation, we need to express everything in terms of $\theta=$ $\mathrm{E} Y=n p$. Then $v(\theta)=\theta(1-\theta / n)$ and

$$
\left(\frac{d g^{*}(\theta)}{d \theta}\right)^{2}=\left(\frac{1}{\sqrt{1-\frac{\theta}{n}}} \cdot \frac{1}{2 \sqrt{\frac{\theta}{n}}} \cdot \frac{1}{n}\right)^{2}=\frac{1}{4 n \theta(1-\theta / n)}
$$

Therefore

$$
\operatorname{Var}\left[g^{*}(Y)\right] \approx\left(\frac{d g^{*}(\theta)}{d \theta}\right)^{2} v(\theta)=\frac{1}{4 n}
$$

independent of $\theta$, that is, independent of $p$.
c. $v(\theta)=K \theta^{2}, \frac{d g^{*}(\theta)}{d \theta}=\frac{1}{\theta}$ and $\operatorname{Var}\left[g^{*}(Y)\right] \approx\left(\frac{1}{\theta}\right)^{2} \cdot K \theta^{2}=K$, independent of $\theta$.
11.3 a. $g_{\lambda}^{*}(y)$ is clearly continuous with the possible exception of $\lambda=0$. For that value use
l'Hôpital's rule to get

$$
\lim _{\lambda \rightarrow 0} \frac{y^{\lambda}-1}{\lambda}=\lim _{\lambda \rightarrow 0} \frac{(\log y) y^{\lambda}}{1}=\log y
$$

b. From Exercise 11.1, we want to find $v(\lambda)$ that satisfies

$$
\frac{y^{\lambda}-1}{\lambda}=\int_{a}^{y} \frac{1}{\sqrt{v(x)}} d x .
$$

Taking derivatives

$$
\frac{d}{d y}\left(\frac{y^{\lambda}-1}{\lambda}\right)=y^{\lambda-1}=\frac{d}{d y} \int_{a}^{y} \frac{1}{\sqrt{v(x)}} d x=\frac{1}{\sqrt{v(y)}}
$$

Thus $v(y)=y^{-2(\lambda-1)}$. From Exercise 11.1,

$$
\operatorname{Var}\left(\frac{y^{\lambda}-1}{\lambda}\right) \approx\left(\frac{d}{d y} \frac{\theta^{\lambda}-1}{\lambda}\right)^{2} v(\theta)=\theta^{2(\lambda-1)} \theta^{-2(\lambda-1)}=1
$$

Note: If $\lambda=1 / 2, v(\theta)=\theta$, which agrees with Exercise 11.2(a). If $\lambda=1$ then $v(\theta)=\theta^{2}$, which agrees with Exercise 11.2(c).
11.5 For the model

$$
Y_{i j}=\mu+\tau_{i}+\varepsilon_{i j}, \quad i=1, \ldots, k, \quad j=1, \ldots, n_{i}
$$

take $k=2$. The two parameter configurations

$$
\begin{aligned}
\left(\mu, \tau_{1}, \tau_{2}\right) & =(10,5,2) \\
\left(\mu, \tau_{1}, \tau_{2}\right) & =(7,8,5)
\end{aligned}
$$

have the same values for $\mu+\tau_{1}$ and $\mu+\tau_{2}$, so they give the same distributions for $Y_{1}$ and $Y_{2}$.
11.6 a. Under the ANOVA assumptions $Y_{i j}=\theta_{i}+\epsilon_{i j}$, where $\epsilon_{i j} \sim$ independent $\mathrm{n}\left(0, \sigma^{2}\right)$, so $Y_{i j} \sim$ independent $\mathrm{n}\left(\theta_{i}, \sigma^{2}\right)$. Therefore the sample pdf is

$$
\begin{aligned}
\prod_{i=1}^{k} \prod_{j=1}^{n_{i}}\left(2 \pi \sigma^{2}\right)^{-1 / 2} e^{-\frac{\left(y_{i j}-\theta_{i}\right)^{2}}{2 \sigma^{2}}}= & \left(2 \pi \sigma^{2}\right)^{-\Sigma n_{i} / 2} \exp \left\{-\frac{1}{2 \sigma^{2}} \sum_{i=1}^{k} \sum_{j=1}^{n_{i}}\left(y_{i j}-\theta_{i}\right)^{2}\right\} \\
= & \left(2 \pi \sigma^{2}\right)^{-\Sigma n_{i} / 2} \exp \left\{-\frac{1}{2 \sigma^{2}} \sum_{i=1}^{k} n_{i} \theta_{i}^{2}\right\} \\
& \times \exp \left\{-\frac{1}{2 \sigma^{2}} \sum_{i} \sum_{j} y_{i j}^{2}+\frac{2}{2 \sigma^{2}} \sum_{i=1}^{k} \theta_{i} n_{i} \bar{Y}_{i \cdot}\right\}
\end{aligned}
$$

Therefore, by the Factorization Theorem,

$$
\left(\bar{Y}_{1}, \bar{Y}_{2}, \ldots, \bar{Y}_{k}, \sum_{i} \sum_{j} Y_{i j}^{2}\right)
$$

is jointly sufficient for $\left(\theta_{1}, \ldots, \theta_{k}, \sigma^{2}\right)$. Since $\left(\bar{Y}_{1} ., \ldots, \bar{Y}_{k}, S_{p}^{2}\right)$ is a 1-to-1 function of this vector, $\left(\bar{Y}_{1 .}, \ldots, \bar{Y}_{k}, S_{p}^{2}\right)$ is also jointly sufficient.
b. We can write

$$
\begin{aligned}
& \left(2 \pi \sigma^{2}\right)^{-\Sigma n_{i} / 2} \exp \left\{-\frac{1}{2 \sigma^{2}} \sum_{i=1}^{k} \sum_{j=1}^{n_{i}}\left(y_{i j}-\theta_{i}\right)^{2}\right\} \\
& \quad=\left(2 \pi \sigma^{2}\right)^{-\Sigma n_{i} / 2} \exp \left\{-\frac{1}{2 \sigma^{2}} \sum_{i=1}^{k} \sum_{j=1}^{n_{i}}\left(\left[y_{i j}-\bar{y}_{i} \cdot\right]+\left[\bar{y}_{i} .-\theta_{i}\right]\right)^{2}\right\} \\
& \quad=\left(2 \pi \sigma^{2}\right)^{-\Sigma n_{i} / 2} \exp \left\{-\frac{1}{2 \sigma^{2}} \sum_{i=1}^{k} \sum_{j=1}^{n_{i}}\left[y_{i j}-\bar{y}_{i} \cdot\right]^{2}\right\} \exp \left\{-\frac{1}{2 \sigma^{2}} \sum_{i=1}^{k} n_{i}\left[\bar{y}_{i} .-\theta_{i}\right]^{2}\right\}
\end{aligned}
$$

so, by the Factorization Theorem, $\bar{Y}_{i \cdot}, i=1, \ldots, n$, is independent of $Y_{i j}-\bar{Y}_{i}, j=1, \ldots, n_{i}$, so $S_{p}^{2}$ is independent of each $\bar{Y}_{i}$.
c. Just identify $n_{i} \bar{Y}_{i}$. with $X_{i}$ and redefine $\theta_{i}$ as $n_{i} \theta_{i}$.
11.7 Let $U_{i}=\bar{Y}_{i} .-\theta_{i}$. Then

$$
\sum_{i=1}^{k} n_{i}\left[\left(\bar{Y}_{i .}-\overline{\bar{Y}}\right)-\left(\theta_{i}-\bar{\theta}\right)\right]^{2}=\sum_{i=1}^{k} n_{i}\left(U_{i}-\bar{U}\right)^{2}
$$

The $U_{i}$ are clearly $\mathrm{n}\left(0, \sigma^{2} / n_{i}\right)$. For $K=2$ we have

$$
\begin{aligned}
S_{2}^{2} & =n_{1}\left(U_{1}-\bar{U}\right)^{2}+n_{2}\left(U_{2}-\bar{U}\right)^{2} \\
& =n_{1}\left(U_{1}-\frac{n_{1} \bar{U}_{1}+n_{2} \bar{U}_{2}}{n_{1}+n_{2}}\right)^{2}+n_{2}\left(U_{2}-\frac{n_{1} \bar{U}_{1}+n_{2} \bar{U}_{2}}{n_{1}+n_{2}}\right)^{2} \\
& =\left(U_{1}-U_{2}\right)^{2}\left[n_{1}\left(\frac{n_{2}}{n_{1}+n_{2}}\right)^{2}+n_{2}\left(\frac{n_{1}}{n_{1}+n_{2}}\right)^{2}\right] \\
& =\frac{\left(U_{1}-U_{2}\right)^{2}}{\frac{1}{n_{1}}+\frac{1}{n_{2}}} .
\end{aligned}
$$

Since $U_{1}-U_{2} \sim \mathrm{n}\left(0, \sigma^{2}\left(1 / n_{1}+1 / n_{2}\right)\right), S_{2}^{2} / \sigma^{2} \sim \chi_{1}^{2}$. Let $\bar{U}_{k}$ be the weighted mean of $k U_{i} \mathrm{~s}$, and note that

$$
\bar{U}_{k+1}=\bar{U}_{k}+\frac{n_{k+1}}{N_{k+1}}\left(U_{k+1}-\bar{U}_{k}\right)
$$

where $N_{k}=\sum_{j=1}^{k} n_{j}$. Then

$$
\begin{aligned}
S_{k+1}^{2} & =\sum_{i=1}^{k+1} n_{i}\left(U_{i}-\bar{U}_{k+1}\right)^{2}=\sum_{i=1}^{k+1} n_{i}\left[\left(U_{i}-\bar{U}_{k}\right)-\frac{n_{k+1}}{N_{k+1}}\left(U_{k+1}-\bar{U}_{k}\right)\right]^{2} \\
& =S_{k}^{2}+\frac{n_{k+1} N_{k}}{N_{k+1}}\left(U_{k+1}-\bar{U}_{k}\right)^{2}
\end{aligned}
$$

where we have expanded the square, noted that the cross-term (summed up to $k$ ) is zero, and did a boat-load of algebra. Now since

$$
U_{k+1}-\bar{U}_{k} \sim \mathrm{n}\left(0, \sigma^{2}\left(1 / n_{k+1}+1 / N_{k}\right)\right)=\mathrm{n}\left(0, \sigma^{2}\left(N_{k+1} / n_{k+1} N_{k}\right)\right)
$$

independent of $S_{k}^{2}$, the rest of the argument is the same as in the proof of Theorem 5.3.1(c).
11.8 Under the oneway ANOVA assumptions, $Y_{i j} \sim$ independent $\mathrm{n}\left(\theta_{i}, \sigma^{2}\right)$. Therefore

$$
\begin{aligned}
\bar{Y}_{i .} & \sim \mathrm{n}\left(\theta_{i}, \sigma^{2} / n_{i}\right) \quad\left(Y_{i j} \text { 's are independent with common } \sigma^{2} .\right) \\
a_{i} \bar{Y}_{i .} . & \sim \mathrm{n}\left(a_{i} \theta_{i}, a_{i}^{2} \sigma^{2} / n_{i}\right) \\
\sum_{i=1}^{k} a_{i} \bar{Y}_{i .} . & \sim \mathrm{n}\left(\sum a_{i} \theta_{i}, \sigma^{2} \sum_{i=1}^{k} a_{i}^{2} / n_{i}\right) .
\end{aligned}
$$

All these distributions follow from Corollary 4.6.10.
11.9 a. From Exercise 11.8,

$$
T=\sum a_{i} \bar{Y}_{i} \sim \mathrm{n}\left(\sum a_{i} \theta_{i}, \sigma^{2} \sum a_{i}^{2}\right)
$$

and under $H_{0}, \mathrm{E} T=\delta$. Thus, under $H_{0}$,

$$
\frac{\sum a_{i} \bar{Y}_{i}-\delta}{\sqrt{S_{p}^{2} \sum a_{i}^{2}}} \sim t_{N-k}
$$

where $N=\sum n_{i}$. Therefore, the test is to reject $H_{0}$ if

$$
\frac{\left|\sum a_{i} \bar{Y}_{i}-\delta\right|}{\sqrt{S_{p}^{2} \sum a_{i}^{2} / n_{i}}}>t_{N-k, \frac{\alpha}{2}} .
$$

b. Similarly for $H_{0}: \sum a_{i} \theta_{i} \leq \delta$ vs. $H_{1}: \sum a_{i} \theta_{i}>\delta$, we reject $H_{0}$ if

$$
\frac{\sum a_{i} \bar{Y}_{i}-\delta}{\sqrt{S_{p}^{2} \sum a_{i}^{2} / n_{i}}}>t_{N-k, \alpha}
$$

11.10 a. Let $H_{0}^{i}, i=1, \ldots, 4$ denote the null hypothesis using contrast $a_{i}$, of the form

$$
H_{0}^{i}: \sum_{j} a_{i j} \theta_{j} \geq 0
$$

If $H_{0}^{1}$ is rejected, it indicates that the average of $\theta_{2}, \theta_{3}, \theta_{4}$, and $\theta_{5}$ is bigger than $\theta_{1}$ which is the control mean. If all $H_{0}^{i}$ 's are rejected, it indicates that $\theta_{5}>\theta_{i}$ for $i=1,2,3,4$. To see this, suppose $H_{0}^{4}$ and $H_{0}^{5}$ are rejected. This means $\theta_{5}>\frac{\theta_{5}+\theta_{4}}{2}>\theta_{3}$; the first inequality is implied by the rejection of $H_{0}^{5}$ and the second inequality is the rejection of $H_{0}^{4}$. A similar argument implies $\theta_{5}>\theta_{2}$ and $\theta_{5}>\theta_{1}$. But, for example, it does not mean that $\theta_{4}>\theta_{3}$ or $\theta_{3}>\theta_{2}$. It also indicates that

$$
\frac{1}{2}\left(\theta_{5}+\theta_{4}\right)>\theta_{3}, \quad \frac{1}{3}\left(\theta_{5}+\theta_{4}+\theta_{3}\right)>\theta_{2}, \quad \frac{1}{4}\left(\theta_{5}+\theta_{4}+\theta_{3}+\theta_{2}\right)>\theta_{1}
$$

b. In part a) all of the contrasts are orthogonal. For example,

$$
\sum_{i=1}^{5} a_{2 i} a_{3 i}=\left(0,1,-\frac{1}{3},-\frac{1}{3},-\frac{1}{3}\right)\left(\begin{array}{c}
0 \\
0 \\
1 \\
\frac{1}{2} \\
\frac{1}{2}
\end{array}\right)=-\frac{1}{3}+\frac{1}{6}+\frac{1}{6}=0
$$

and this holds for all pairs of contrasts. Now, from Lemma 5.4.2,

$$
\operatorname{Cov}\left(\sum_{i} a_{j i} \bar{Y}_{i \cdot}, \sum_{i} a_{j^{\prime} i} \bar{Y}_{i} .\right)=\frac{\sigma^{2}}{n} \sum_{i} a_{j i} a_{j^{\prime} i}
$$

which is zero because the contrasts are orthogonal. Note that the equal number of observations per treatment is important, since if $n_{i} \neq n_{i^{\prime}}$ for some $i, i^{\prime}$, then

$$
\operatorname{Cov}\left(\sum_{i=1}^{k} a_{j i} \bar{Y}_{i}, \sum_{i=1}^{k} a_{j^{\prime} i} \bar{Y}_{i}\right)=\sum_{i=1}^{k} a_{j i} a_{j^{\prime} i} \frac{\sigma^{2}}{n_{i}}=\sigma^{2} \sum_{i=1}^{k} \frac{a_{j i} a_{j^{\prime} i}}{n_{i}} \neq 0
$$

c. This is not a set of orthogonal contrasts because, for example, $a_{1} \times a_{2}=-1$. However, each contrast can be interpreted meaningfully in the context of the experiment. For example, $a_{1}$ tests the effect of potassium alone, while $a_{5}$ looks at the effect of adding zinc to potassium.
11.11 This is a direct consequence of Lemma 5.3.3.
11.12 a . This is a special case of (11.2.6) and (11.2.7).
b. From Exercise 5.8(a) We know that

$$
s^{2}=\frac{1}{k-1} \sum_{i=1}^{k}\left(\bar{y}_{i .}-\overline{\bar{y}}\right)^{2}=\frac{1}{2 k(k-1)} \sum_{i, i^{\prime}}\left(\bar{y}_{i} .-\bar{y}_{i^{\prime}} .\right)^{2} .
$$

Then

$$
\begin{aligned}
\frac{1}{k(k-1)} \sum_{i, i^{\prime}} t_{i i^{\prime}}^{2} & =\frac{1}{2 k(k-1)} \sum_{i, i^{\prime}} \frac{\left(\bar{y}_{i \cdot}-\bar{y}_{i^{\prime} \cdot}\right)^{2}}{s_{p}^{2} / n}=\sum_{i=1}^{k} \frac{\left(\bar{y}_{i} \cdot-\overline{\bar{y}}\right)^{2}}{(k-1) s_{p}^{2} / n} \\
& =\frac{\sum_{i} n\left(\bar{y}_{i} \cdot-\overline{\bar{y}}\right)^{2} /(k-1)}{s_{p}^{2}}
\end{aligned}
$$

which is distributed as $F_{k-1, N-k}$ under $H_{0}: \theta_{1}=\cdots=\theta_{k}$. Note that

$$
\sum_{i, i^{\prime}} t_{i i^{\prime}}^{2}=\sum_{i=1}^{k} \sum_{i^{\prime}=1}^{k} t_{i i^{\prime}}^{2}
$$

therefore $t_{i i^{\prime}}^{2}$ and $t_{i^{\prime} i}^{2}$ are both included, which is why the divisor is $k(k-1)$, not $\frac{k(k-1)}{2}=\binom{k}{2}$. Also, to use the result of Example 5.9(a), we treated each mean $\bar{Y}_{i}$. as an observation, with overall mean $\overline{\bar{Y}}$. This is true for equal sample sizes.
11.13 a.

$$
L(\theta \mid y)=\left(\frac{1}{2 \pi \sigma^{2}}\right)^{N k / 2} e^{-\frac{1}{2} \sum_{i=1}^{k} \sum_{j=1}^{n_{i}}\left(y_{i j}-\theta_{i}\right)^{2} / \sigma^{2}}
$$

Note that

$$
\begin{aligned}
\sum_{i=1}^{k} \sum_{j=1}^{n_{i}}\left(y_{i j}-\theta_{i}\right)^{2} & =\sum_{i=1}^{k} \sum_{j=1}^{n_{i}}\left(y_{i j}-\bar{y}_{i .}\right)^{2}+\sum_{i=1}^{k} n_{i}\left(\bar{y}_{i} .-\theta_{i}\right)^{2} \\
& =S S W+\sum_{i=1}^{k} n_{i}\left(\bar{y}_{i} .-\theta_{i}\right)^{2}
\end{aligned}
$$

and the LRT statistic is

$$
\lambda=\left(\hat{\tau}^{2} / \hat{\tau}_{0}^{2}\right)^{N k / 2}
$$

where

$$
\hat{\tau}^{2}=S S W \quad \text { and } \quad \hat{\tau}_{0}^{2}=S S W+\sum_{i} n_{i}\left(\bar{y}_{i .}-\bar{y}_{. .}\right)^{2}=S S W+S S B
$$

Thus $\lambda<k$ if and only if $S S B / S S W$ is large, which is equivalent to the $F$ test.
b. The error probabilities of the test are a function of the $\theta_{i}$ s only through $\eta=\sum \theta_{i}^{2}$. The distribution of $F$ is that of a ratio of chi squared random variables, with the numerator being noncentral (dependent on $\eta$ ). Thus the Type II error is given by

$$
P(F>k \mid \eta)=P\left(\frac{\chi_{k-1}^{2}(\eta) /(k-1)}{\chi_{N-k}^{2} /(N-k)}>k\right) \geq P\left(\frac{\chi_{k-1}^{2}(0) /(k-1)}{\chi_{N-k}^{2} /(N-k)}>k\right)=\alpha
$$

where the inequality follows from the fact that the noncentral chi squared is stochastically increasing in the noncentrality parameter.
11.14 Let $X_{i} \sim \mathrm{n}\left(\theta_{i}, \sigma^{2}\right)$. Then from Exercise 11.11

$$
\begin{gathered}
\operatorname{Cov}\left(\sum_{i} \frac{a_{i}}{\sqrt{c_{i}}} X_{i}, \sum_{i} \sqrt{c_{i}} v_{i} X_{i}\right)=\sigma^{2} \sum a_{i} v_{i} \\
\operatorname{Var}\left(\sum_{i} \frac{a_{i}}{\sqrt{c_{i}}} X_{i}\right)=\sigma^{2} \sum \frac{a_{i}^{2}}{c_{i}}, \quad \operatorname{Var}\left(\sum_{i} \sqrt{c_{i}} v_{i} X_{i}\right)=\sigma^{2} \sum c_{i} v_{i}^{2}
\end{gathered}
$$

and the Cauchy-Schwarz inequality gives

$$
\left(\sum a_{i} v_{i}\right) /\left(\sum a_{i}^{2} / c_{i}\right) \leq \sum c_{i} v_{i}^{2}
$$

If $a_{i}=c_{i} v_{i}$ this is an equality, hence the LHS is maximized. The simultaneous statement is equivalent to

$$
\frac{\left(\sum_{i=1}^{k} a_{i}\left(\bar{y}_{i}-\theta_{i}\right)\right)^{2}}{\left(s_{p}^{2} \sum_{i=1}^{k} a_{i}^{2} / n\right)} \leq M \text { for all } a_{1}, \ldots, a_{k}
$$

and the LHS is maximized by $a_{i}=n_{i}\left(\bar{y}_{i} .-\theta_{i}\right)$. This produces the $F$ statistic.
11.15 a. Since $t_{\nu}^{2}=F_{1, \nu}$, it follows from Exercise 5.19(b) that for $k \geq 2$

$$
P\left[(k-1) F_{k-1, \nu} \geq a\right] \geq P\left(t_{\nu}^{2} \geq a\right)
$$

So if $a=t_{\nu, \alpha / 2}^{2}$, the $F$ probability is greater than $\alpha$, and thus the $\alpha$-level cutoff for the $F$ must be greater than $t_{\nu, \alpha / 2}^{2}$.
b. The only difference in the intervals is the cutoff point, so the Scheffé intervals are wider.
c. Both sets of intervals have nominal level $1-\alpha$, but since the Scheffé intervals are wider, tests based on them have a smaller rejection region. In fact, the rejection region is contained in the $t$ rejection region. So the $t$ is more powerful.
11.16 a. If $\theta_{i}=\theta_{j}$ for all $i, j$, then $\theta_{i}-\theta_{j}=0$ for all $i, j$, and the converse is also true.
b. $H_{0}: \boldsymbol{\theta} \in \cap_{i j} \Theta_{i j}$ and $H_{1}: \boldsymbol{\theta} \in \cup_{i j}\left(\Theta_{i j}\right)^{c}$.
11.17 a. If all of the means are equal, the Scheffé test will only reject $\alpha$ of the time, so the $t$ tests will be done only $\alpha$ of the time. The experimentwise error rate is preserved.
b. This follows from the fact that the $t$ tests use a smaller cutoff point, so there can be rejection using the $t$ test but no rejection using Scheffé. Since Scheffé has experimentwise level $\alpha$, the $t$ test has experimentwise error greater than $\alpha$.
c. The pooled standard deviation is 2.358 , and the means and $t$ statistics are

| Mean |  |  |  | $t$ statistic |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Low | Medium | High |  | Med-Low | High-Med | High-Low |
| 3.51. | 9.27 | 24.93 |  | 3.86 | 10.49 | 14.36 |

The $t$ statistics all have 12 degrees of freedom and, for example, $t_{12, .01}=2.68$, so all of the tests reject and we conclude that the means are all significantly different.
11.18 a.

$$
\begin{array}{rlr}
P(Y>a \mid Y>b) & =P(Y>a, Y>b) / P(Y>b) & \\
& =P(Y>a) / P(Y>b) & (a>b) \\
& >P(Y>a) . & (P(Y>b)<1)
\end{array}
$$

b. If $a$ is a cutoff point then we would declare significance if $Y>a$. But if we only check if $Y$ is significant because we see a big $Y(Y>b)$, the proper significance level is $P(Y>a \mid Y>b)$, which will show less significance than $P(Y>a)$.
11.19 a. The marginal distributions of the $Y_{i}$ are somewhat straightforward to derive. As $X_{i+1} \sim$ $\operatorname{gamma}\left(\lambda_{i+1}, 1\right)$ and, independently, $\sum_{j=1}^{i} X_{j} \sim \operatorname{gamma}\left(\sum_{j=1}^{i} \lambda_{j}, 1\right)$ (Example 4.6.8), we only need to derive the distribution of the ratio of two independent gammas. Let $X \sim$ $\operatorname{gamma}\left(\lambda_{1}, 1\right)$ and $\mathrm{Y} \sim \operatorname{gamma}\left(\lambda_{2}, 1\right)$. Make the transformation

$$
u=x / y, \quad v=y \quad \Rightarrow \quad x=u v, \quad y=v
$$

with Jacobian $v$. The density of $(U, V)$ is

$$
f(u, v)=\frac{1}{\Gamma\left(\lambda_{1}\right) \Gamma\left(\lambda_{2}\right)}(u v)^{\lambda_{1}-1} v^{\lambda_{2}-1} v e^{-u v} e^{-v}=\frac{u^{\lambda_{1}-1}}{\Gamma\left(\lambda_{1}\right) \Gamma\left(\lambda_{2}\right)} v^{\lambda_{1}+\lambda_{2}-1} e^{-v(1+u)}
$$

To get the density of $U$, integrate with respect to $v$. Note that we have the kernel of a $\operatorname{gamma}\left(\lambda_{1}+\lambda_{2}, 1 /(1+u)\right)$, which yields

$$
f(u)=\frac{\Gamma\left(\lambda_{1}+\lambda_{2}\right)}{\Gamma\left(\lambda_{1}\right) \Gamma\left(\lambda_{2}\right)} \frac{u^{\lambda_{1}-1}}{(1+u)^{\lambda_{1}+\lambda_{2}-1}} .
$$

The joint distribution is a nightmare. We have to make a multivariate change of variable. This is made a bit more palatable if we do it in two steps. First transform

$$
W_{1}=X_{1}, \quad W_{2}=X_{1}+X_{2}, \quad W_{3}=X_{1}+X_{2}+X_{3}, \quad \ldots, \quad W_{n}=X_{1}+X_{2}+\cdots+X_{n}
$$

with

$$
X_{1}=W_{1}, \quad X_{2}=W_{2}-W_{1}, \quad X_{3}=W_{3}-W_{2}, \quad \ldots \quad X_{n}=W_{n}-W_{n-1}
$$

and Jacobian 1 . The joint density of the $W_{i}$ is

$$
f\left(w_{1}, w_{2}, \ldots, w_{n}\right)=\prod_{i=1}^{n} \frac{1}{\Gamma\left(\lambda_{i}\right)}\left(w_{i}-w_{i-1}\right)^{\lambda_{i}-1} e^{-w_{n}}, \quad w_{1} \leq w_{2} \leq \cdots \leq w_{n}
$$

where we set $w_{0}=0$ and note that the exponent telescopes. Next note that

$$
y_{1}=\frac{w_{2}-w_{1}}{w_{1}}, \quad y_{2}=\frac{w_{3}-w_{2}}{w_{2}}, \quad \ldots \quad y_{n-1}=\frac{w_{n}-w_{n-1}}{w_{n-1}}, \quad y_{n}=w_{n}
$$

with

$$
w_{i}=\frac{y_{n}}{\prod_{j=i}^{n-1}\left(1+y_{j}\right)}, \quad i=1, \ldots, n-1, \quad w_{n}=y_{n}
$$

Since each $w_{i}$ only involves $y_{j}$ with $j \geq i$, the Jacobian matrix is triangular and the determinant is the product of the diagonal elements. We have

$$
\frac{d w_{i}}{d y_{i}}=-\frac{y_{n}}{\left(1+y_{i}\right) \prod_{j=i}^{n-1}\left(1+y_{j}\right)}, \quad i=1, \ldots, n-1, \quad \frac{d w_{n}}{d y_{n}}=1
$$

and

$$
\begin{aligned}
f\left(y_{1}, y_{2}, \ldots, y_{n}\right)= & \frac{1}{\Gamma\left(\lambda_{1}\right)}\left(\frac{y_{n}}{\prod_{j=1}^{n-1}\left(1+y_{j}\right)}\right)^{\lambda_{1}-1} \\
& \times \prod_{i=2}^{n-1} \frac{1}{\Gamma\left(\lambda_{i}\right)}\left(\frac{y_{n}}{\prod_{j=i}^{n-1}\left(1+y_{j}\right)}-\frac{y_{n}}{\prod_{j=i-1}^{n-1}\left(1+y_{j}\right)}\right)^{\lambda_{i}-1} e^{-y_{n}} \\
& \times \prod_{i=1}^{n-1} \frac{y_{n}}{\left(1+y_{i}\right) \prod_{j=i}^{n-1}\left(1+y_{j}\right)} .
\end{aligned}
$$

Factor out the terms with $y_{n}$ and do some algebra on the middle term to get

$$
\begin{aligned}
f\left(y_{1}, y_{2}, \ldots, y_{n}\right)= & y_{n}^{\Sigma_{i} \lambda_{i}-1} e^{-y_{n}} \frac{1}{\Gamma\left(\lambda_{1}\right)}\left(\frac{1}{\prod_{j=1}^{n-1}\left(1+y_{j}\right)}\right)^{\lambda_{1}-1} \\
& \times \prod_{i=2}^{n-1} \frac{1}{\Gamma\left(\lambda_{i}\right)}\left(\frac{y_{i-1}}{1+y_{i-1}} \frac{1}{\prod_{j=i}^{n-1}\left(1+y_{j}\right)}\right)^{\lambda_{i}-1} \\
& \times \prod_{i=1}^{n-1} \frac{1}{\left(1+y_{i}\right) \prod_{j=i}^{n-1}\left(1+y_{j}\right)}
\end{aligned}
$$

We see that $Y_{n}$ is independent of the other $Y_{i}$ (and has a gamma distribution), but there does not seem to be any other obvious conclusion to draw from this density.
b. The $Y_{i}$ are related to the $F$ distribution in the ANOVA. For example, as long as the sum of the $\lambda_{i}$ are integers,

$$
Y_{i}=\frac{X_{i+1}}{\sum_{j=1}^{i} X_{j}}=\frac{2 X_{i+1}}{2 \sum_{j=1}^{i} X_{j}}=\frac{\chi_{\lambda_{i+1}}^{2}}{\chi_{\sum_{j=1}^{i} \lambda_{j}}^{2}} \sim F_{\lambda_{i+1}, \sum_{j=1}^{i} \lambda_{j}}
$$

Note that the $F$ density makes sense even if the $\lambda_{i}$ are not integers.
11.21 a.

$$
\begin{aligned}
\text { Grand mean } \bar{y} . . & =\frac{188.54}{15}=12.57 \\
\text { Total sum of squares } & =\sum_{i=1}^{3} \sum_{j=1}^{5}\left(y_{i j}-\bar{y}_{. .}\right)^{2}=1295.01 . \\
\text { Within SS } & =\sum_{1}^{3} \sum_{1}^{5}\left(y_{i j}-\bar{y}_{i .}\right)^{2} \\
& =\sum_{1}^{5}\left(y_{1 j}-3.508\right)^{2}+\sum_{1}^{5}\left(y_{2 j}-9.274\right)^{2}+\sum_{1}^{5}\left(y_{3 j}-24.926\right)^{2} \\
& =1.089+2.189+63.459=66.74 \\
& =5\left(\sum_{1}^{3}\left(y_{i j}-\bar{y}_{i} .\right)^{2}\right) \\
& =5(82.120+10.864+152.671)=245.65 \cdot 5=1228.25 .
\end{aligned}
$$

ANOVA table:

| Source | df | SS | MS | F |
| :--- | ---: | ---: | ---: | ---: |
| Treatment | 2 | 1228.25 | 614.125 | 110.42 |
| Within | 12 | 66.74 | 5.562 |  |
| Total | 14 | 1294.99 |  |  |

Note that the total SS here is different from above - round off error is to blame. Also, $F_{2,12}=110.42$ is highly significant.
b. Completing the proof of (11.2.4), we have

$$
\sum_{i=1}^{k} \sum_{j=1}^{n_{i}}\left(y_{i j}-\overline{\bar{y}}\right)^{2}=\sum_{i=1}^{k} \sum_{j=1}^{n_{i}}\left(\left(y_{i j}-\bar{y}_{i .}\right)+\left(\bar{y}_{i}-\overline{\bar{y}}\right)\right)^{2}
$$

$$
\begin{aligned}
= & \sum_{i=1}^{k} \sum_{j=1}^{n_{i}}\left(y_{i j}-\bar{y}_{i .}\right)^{2}+\sum_{i=1}^{k} \sum_{j=1}^{n_{i}}\left(\bar{y}_{i} .-\overline{\bar{y}}\right)^{2} \\
& +\sum_{i=1}^{k} \sum_{j=1}^{n_{i}}\left(y_{i j}-\bar{y}_{i .} .\right)\left(\bar{y}_{i .}-\overline{\bar{y}}\right),
\end{aligned}
$$

where the cross term (the sum over $j$ ) is zero, so the sum of squares is partitioned as

$$
\sum_{i=1}^{k} \sum_{j=1}^{n_{i}}\left(y_{i j}-\bar{y}_{i .}\right)^{2}+\sum_{i=1}^{k} n_{i}\left(\bar{y}_{i}-\overline{\bar{y}}\right)^{2}
$$

c. From a), the $F$ statistic for the ANOVA is 110.42 . The individual two-sample $t$ 's, using $s_{p}^{2}=\frac{1}{15-3}(66.74)=5.5617$, are

$$
\begin{aligned}
& t_{12}^{2}=\frac{(3.508-9.274)^{2}}{(5.5617)(2 / 5)}=\frac{33.247}{2.2247}=14.945, \\
& t_{13}^{2}=\frac{(3.508-24.926)^{2}}{2.2247}=206.201, \\
& t_{23}^{2}=\frac{(9.274-24.926)^{2}}{2.2247}=110.122
\end{aligned}
$$

and

$$
\frac{2(14.945)+2(206.201)+(110.122)}{6}=110.42=F .
$$

11.23 a.

$$
\begin{aligned}
\mathrm{E} Y_{i j} & =\mathrm{E}\left(\mu+\tau_{i}+b_{j}+\epsilon_{i j}\right)=\mu+\tau_{i}+\mathrm{E} b_{j}+\mathrm{E} \epsilon_{i j}=\mu+\tau_{i} \\
\operatorname{Var} Y_{i j} & =\operatorname{Var}_{j}+\operatorname{Var}_{i j}=\sigma_{B}^{2}+\sigma^{2},
\end{aligned}
$$

by independence of $b_{j}$ and $\epsilon_{i j}$.
b.

$$
\operatorname{Var}\left(\sum_{i=1}^{n} a_{i} \bar{Y}_{i .}\right)=\sum_{i=1}^{n} a_{i}^{2} \operatorname{Var} \bar{Y}_{i} .+2 \sum_{i>i^{\prime}} \operatorname{Cov}\left(a_{i} Y_{i .}, a_{i^{\prime}} Y_{i^{\prime} .}\right)
$$

The first term is

$$
\sum_{i=1}^{n} a_{i}^{2} \operatorname{Var} \bar{Y}_{i}=\sum_{i=1}^{n} a_{i}^{2} \operatorname{Var}\left(\frac{1}{r} \sum_{j=1}^{r} \mu+\tau_{i}+b_{j}+\epsilon_{i j}\right)=\frac{1}{r^{2}} \sum_{i=1}^{n} a_{i}^{2}\left(r \sigma_{B}^{2}+r \sigma^{2}\right)
$$

from part (a). For the covariance

$$
\mathrm{E} \bar{Y}_{i}=\mu+\tau_{i}
$$

and

$$
\begin{aligned}
\mathrm{E}\left(\bar{Y}_{i} \cdot \bar{Y}_{i^{\prime} .}\right) & =\mathrm{E}\left(\left[\mu+\tau_{i}+\frac{1}{r} \sum_{j}\left(b_{j}+\epsilon_{i j}\right)\right]\left[\mu+\tau_{i^{\prime}}+\frac{1}{r} \sum_{j}\left(b_{j}+\epsilon_{i^{\prime} j}\right)\right]\right) \\
& =\left(\mu+\tau_{i}\right)\left(\mu+\tau_{i^{\prime}}\right)+\frac{1}{r^{2}} \mathrm{E}\left(\left[\sum_{j}\left(b_{j}+\epsilon_{i j}\right)\right]\left[\sum_{j}\left(b_{j}+\epsilon_{i^{\prime} j}\right)\right]\right)
\end{aligned}
$$

since the cross terms have expectation zero. Next, expanding the product in the second term again gives all zero cross terms, and we have

$$
\mathrm{E}\left(\bar{Y}_{i} . \bar{Y}_{i^{\prime} \cdot}\right)=\left(\mu+\tau_{i}\right)\left(\mu+\tau_{i^{\prime}}\right)+\frac{1}{r^{2}}\left(r \sigma_{B}^{2}\right),
$$

and

$$
\operatorname{Cov}\left(\bar{Y}_{i \cdot}, \bar{Y}_{i^{\prime} .}\right)=\sigma_{B}^{2} / r
$$

Finally, this gives

$$
\begin{aligned}
\operatorname{Var}\left(\sum_{i=1}^{n} a_{i} \bar{Y}_{i} .\right) & =\frac{1}{r^{2}} \sum_{i=1}^{n} a_{i}^{2}\left(r \sigma_{B}^{2}+r \sigma^{2}\right)+2 \sum_{i>i^{\prime}} a_{i} a_{i^{\prime}} \sigma_{B}^{2} / r \\
& =\frac{1}{r}\left[\sum_{i=1}^{n} a_{i}^{2} \sigma^{2}+\sigma_{B}^{2}\left(\sum_{i=1}^{n} a_{i}\right)^{2}\right] \\
& =\frac{1}{r} \sigma^{2} \sum_{i=1}^{n} a_{i}^{2} \\
& =\frac{1}{r}\left(\sigma^{2}+\sigma_{B}^{2}\right)(1-\rho) \sum_{i=1}^{n} a_{i}^{2}
\end{aligned}
$$

where, in the third equality we used the fact that $\sum_{i} a_{i}=0$.
11.25 Differentiation yields
a. $\frac{\partial}{\partial c} R S S=2 \sum\left[y_{i}-\left(c+d x_{i}\right)\right](-1) \stackrel{\text { set }}{=} 0 \Rightarrow n c+d \sum x_{i}=\sum y_{i}$
$\frac{\partial}{\partial d} R S S=2 \sum\left[y_{i}-\left(c_{i}+d x_{i}\right)\right]\left(-x_{i}\right) \stackrel{\text { set }}{=} 0 \Rightarrow c \sum x_{i}+d \sum x_{i}^{2}=\sum x_{i} y_{i}$.
b. Note that $n c+d \sum x_{i}=\sum y_{i} \Rightarrow c=\bar{y}-d \bar{x}$. Then

$$
(\bar{y}-d \bar{x}) \sum x_{i}+d \sum x_{i}^{2}=\sum x_{i} y_{i} \quad \text { and } \quad d\left(\sum x_{i}^{2}-n \bar{x}^{2}\right)=\sum x_{i} y_{i}-\sum x_{i} \bar{y}
$$

which simplifies to $d=\sum x_{i}\left(y_{i}-\bar{y}\right) / \sum\left(x_{i}-\bar{x}\right)^{2}$. Thus $c$ and $d$ are the least squares estimates.
c. The second derivatives are

$$
\frac{\partial^{2}}{\partial c^{2}} \mathrm{RSS}=n, \quad \frac{\partial^{2}}{\partial c \partial d} \mathrm{RSS}=\sum x_{i}, \quad \frac{\partial^{2}}{\partial d^{2}} \mathrm{RSS}=\sum x_{i}^{2}
$$

Thus the Jacobian of the second-order partials is

$$
\left|\begin{array}{cc}
n & \sum x_{i} \\
\sum x_{i} & \sum x_{i}^{2}
\end{array}\right|=n \sum x_{i}^{2}-\left(\sum x_{i}\right)^{2}=n \sum\left(x_{i}-\bar{x}\right)^{2}>0 .
$$

11.27 For the linear estimator $\sum_{i} a_{i} Y_{i}$ to be unbiased for $\alpha$ we have

$$
\mathrm{E}\left(\sum_{i} a_{i} Y_{i}\right)=\sum_{i} a_{i}\left(\alpha+\beta x_{i}\right)=\alpha \Rightarrow \sum_{i} a_{i}=1 \text { and } \sum_{i} a_{i} x_{i}=0
$$

Since $\operatorname{Var} \sum_{i} a_{i} Y_{i}=\sigma^{2} \sum_{i} a_{i}^{2}$, we need to solve:

$$
\operatorname{minimize} \sum_{i} a_{i}^{2} \text { subject to } \sum_{i} a_{i}=1 \text { and } \sum_{i} a_{i} x_{i}=0
$$

A solution can be found with Lagrange multipliers, but verifying that it is a minimum is excruciating. So instead we note that

$$
\sum_{i} a_{i}=1 \Rightarrow a_{i}=\frac{1}{n}+k\left(b_{i}-\bar{b}\right)
$$

for some constants $k, b_{1}, b_{2}, \ldots, b_{n}$, and

$$
\sum_{i} a_{i} x_{i}=0 \Rightarrow k=\frac{-\bar{x}}{\sum_{i}\left(b_{i}-\bar{b}\right)\left(x_{i}-\bar{x}\right)} \text { and } a_{i}=\frac{1}{n}-\frac{\bar{x}\left(b_{i}-\bar{b}\right)}{\sum_{i}\left(b_{i}-\bar{b}\right)\left(x_{i}-\bar{x}\right)} .
$$

Now

$$
\sum_{i} a_{i}^{2}=\sum_{i}\left[\frac{1}{n}-\frac{\bar{x}\left(b_{i}-\bar{b}\right)}{\sum_{i}\left(b_{i}-\bar{b}\right)\left(x_{i}-\bar{x}\right)}\right]^{2}=\frac{1}{n}+\frac{\bar{x}^{2} \sum_{i}\left(b_{i}-\bar{b}\right)^{2}}{\left[\sum_{i}\left(b_{i}-\bar{b}\right)\left(x_{i}-\bar{x}\right)\right]^{2}}
$$

since the cross term is zero. So we need to minimize the last term. From Cauchy-Schwarz we know that

$$
\frac{\sum_{i}\left(b_{i}-\bar{b}\right)^{2}}{\left[\sum_{i}\left(b_{i}-\bar{b}\right)\left(x_{i}-\bar{x}\right)\right]^{2}} \geq \frac{1}{\left.\sum_{i}\left(x_{i}-\bar{x}\right)\right]^{2}}
$$

and the minimum is attained at $b_{i}=x_{i}$. Substituting back we get that the minimizing $a_{i}$ is $\frac{1}{n}-\frac{\bar{x}\left(x_{i}-\bar{x}\right)}{\sum_{i}\left(x_{i}-\bar{x}\right)^{2}}$, which results in $\sum_{i} a_{i} Y_{i}=\bar{Y}-\hat{\beta} \bar{x}$, the least squares estimator.
11.28 To calculate

$$
\max _{\sigma^{2}} L\left(\sigma^{2} \mid y, \hat{\alpha} \hat{\beta}\right)=\max _{\sigma^{2}}\left(\frac{1}{2 \pi \sigma^{2}}\right)^{n / 2} e^{-\frac{1}{2} \Sigma_{i}\left[y_{i}-\left(\hat{\alpha}+\hat{\beta} x_{i}\right)\right]^{2} / \sigma^{2}}
$$

take logs and differentiate with respect to $\sigma^{2}$ to get

$$
\frac{d}{d \sigma^{2}} \log L\left(\sigma^{2} \mid y, \hat{\alpha}, \hat{\beta}\right)=-\frac{n}{2 \sigma^{2}}+\frac{1}{2} \frac{\sum_{i}\left[y_{i}-\left(\hat{\alpha}+\hat{\beta} x_{i}\right)\right]^{2}}{\left(\sigma^{2}\right)^{2}}
$$

Set this equal to zero and solve for $\sigma^{2}$. The solution is $\hat{\sigma}^{2}$.
11.29 a.

$$
\mathrm{E} \hat{\epsilon}_{i}=\mathrm{E}\left(Y_{i}-\hat{\alpha}-\hat{\beta} x_{i}\right)=\left(\alpha+\beta x_{i}\right)-\alpha-\beta x_{i}=0
$$

b.

$$
\begin{aligned}
\operatorname{Var} \hat{\epsilon}_{i} & =\mathrm{E}\left[Y_{i}-\hat{\alpha}-\hat{\beta} x_{i}\right]^{2} \\
& =\mathrm{E}\left[\left(Y_{i}-\alpha-\beta x_{i}\right)-(\hat{\alpha}-\alpha)-x_{i}(\hat{\beta}-\beta)\right]^{2} \\
& =\operatorname{Var} Y_{i}+\operatorname{Var} \hat{\alpha}+x_{i}^{2} \operatorname{Var} \hat{\beta}-2 \operatorname{Cov}\left(Y_{i}, \hat{\alpha}\right)-2 x_{i} \operatorname{Cov}\left(Y_{i}, \hat{\beta}\right)+2 x_{i} \operatorname{Cov}(\hat{\alpha}, \hat{\beta}) .
\end{aligned}
$$

11.30 a. Straightforward algebra shows

$$
\begin{aligned}
\hat{\alpha} & =\bar{y}-\hat{\beta} \bar{x} \\
& =\sum \frac{1}{n} y_{i}-\frac{\bar{x} \sum\left(x_{i}-\bar{x}\right) y_{i}}{\sum\left(x_{i}-\bar{x}\right)^{2}} \\
& =\sum\left[\frac{1}{n}-\frac{\bar{x}\left(x_{i}-\bar{x}\right)}{\sum\left(x_{i}-\bar{x}\right)^{2}}\right] y_{i} .
\end{aligned}
$$

b. Note that for $c_{i}=\frac{1}{n}-\frac{\bar{x}\left(x_{i}-\bar{x}\right)}{\sum\left(x_{i}-\bar{x}\right)^{2}}, \sum c_{i}=1$ and $\sum c_{i} x_{i}=0$. Then

$$
\begin{aligned}
\mathrm{E} \hat{\alpha} & =\mathrm{E} \sum c_{i} Y_{i}=\sum c_{i}\left(\alpha+\beta x_{i}=\alpha,\right. \\
\operatorname{Var} \hat{\alpha} & =\sum c_{i}^{2} \operatorname{Var} Y_{i}=\sigma^{2} \sum c_{i}^{2},
\end{aligned}
$$

and

$$
\begin{aligned}
\sum c_{i}^{2} & =\sum\left[\frac{1}{n}-\frac{\bar{x}\left(x_{i}-\bar{x}\right)}{\sum\left(x_{i}-\bar{x}\right)^{2}}\right]^{2}=\sum \frac{1}{n^{2}}+\frac{\sum \bar{x}^{2}\left(x_{i}-\bar{x}\right)^{2}}{\left(\sum\left(x_{i}-\bar{x}\right)^{2}\right)^{2}} \quad(\text { cross term }=0) \\
& =\frac{1}{n}+\frac{\bar{x}^{2}}{\sum\left(x_{i}-\bar{x}\right)^{2}}=\frac{\sum x_{i}^{2}}{n S_{x x}}
\end{aligned}
$$

c. Write $\hat{\beta}=\sum d_{i} y_{i}$, where

$$
d_{i}=\frac{x_{i}-\bar{x}}{\sum\left(x_{i}-\bar{x}\right)^{2}}
$$

From Exercise 11.11,

$$
\begin{aligned}
\operatorname{Cov}(\hat{\alpha}, \hat{\beta}) & =\operatorname{Cov}\left(\sum c_{i} Y_{i}, \sum d_{i} Y_{i}\right)=\sigma^{2} \sum c_{i} d_{i} \\
& =\sigma^{2} \sum\left[\frac{1}{n}-\frac{\bar{x}\left(x_{i}-\bar{x}\right)}{\sum\left(x_{i}-\bar{x}\right)^{2}}\right] \frac{\left(x_{i}-\bar{x}\right)}{\sum\left(x_{i}-\bar{x}\right)^{2}}=\frac{-\sigma^{2} \bar{x}}{\sum\left(x_{i}-\bar{x}\right)^{2}}
\end{aligned}
$$

11.31 The fact that

$$
\hat{\epsilon}_{i}=\sum_{i}\left[\delta_{i j}-\left(c_{j}+d_{j} x_{i}\right)\right] Y_{j}
$$

follows directly from (11.3.27) and the definition of $c_{j}$ and $d_{j}$. Since $\hat{\alpha}=\sum_{i} c_{i} Y_{i}$, from Lemma 11.3.2

$$
\begin{aligned}
\operatorname{Cov}\left(\hat{\epsilon}_{i}, \hat{\alpha}\right) & =\sigma^{2} \sum_{j} c_{j}\left[\delta_{i j}-\left(c_{j}+d_{j} x_{i}\right)\right] \\
& =\sigma^{2}\left[c_{i}-\sum_{j} c_{j}\left(c_{j}+d_{j} x_{i}\right)\right] \\
& =\sigma^{2}\left[c_{i}-\sum_{j} c_{j}^{2}-x_{i} \sum_{j} c_{j} d_{j}\right] .
\end{aligned}
$$

Substituting for $c_{j}$ and $d_{j}$ gives

$$
\begin{aligned}
c_{i} & =\frac{1}{n}-\frac{\left(x_{i}-\bar{x}\right) \bar{x}}{S_{x x}} \\
\sum_{j} c_{j}^{2} & =\frac{1}{n}+\frac{\bar{x}^{2}}{S_{x x}} \\
x_{i} \sum_{j} c_{j} d_{j} & =-\frac{x_{i} \bar{x}}{S_{x x}}
\end{aligned}
$$

and substituting these values shows $\operatorname{Cov}\left(\hat{\epsilon}_{i}, \hat{\alpha}\right)=0$. Similarly, for $\hat{\beta}$,

$$
\operatorname{Cov}\left(\hat{\epsilon}_{i}, \hat{\beta}\right)=\sigma^{2}\left[d_{i}-\sum_{j} c_{j} d_{j}-x_{i} \sum_{j} d_{j}^{2}\right]
$$

with

$$
\begin{aligned}
d_{i} & =\frac{\left(x_{i}-\bar{x}\right)}{S_{x x}} \\
\sum_{j} c_{j} d_{j} & =-\frac{\bar{x}}{S_{x x}} \\
x_{i} \sum_{j} d_{j}^{2} & =\frac{1}{S_{x x}},
\end{aligned}
$$

and substituting these values shows $\operatorname{Cov}\left(\hat{\epsilon}_{i}, \hat{\beta}\right)=0$.
11.32 Write the models as

$$
\begin{aligned}
3 y_{i} & =\alpha+\beta x_{i}+\epsilon_{i} \\
y_{i} & =\alpha^{\prime}+\beta^{\prime}\left(x_{i}-\bar{x}\right)+\epsilon_{i} \\
& =\alpha^{\prime}+\beta^{\prime} z_{i}+\epsilon_{i}
\end{aligned}
$$

a. Since $\bar{z}=0$,

$$
\hat{\beta}=\frac{\sum\left(x_{i}-\bar{x}\right)\left(y_{i}-\bar{y}\right)}{\sum\left(x_{i}-\bar{x}\right)^{2}}=\frac{\sum z_{i}\left(y_{i}-\bar{y}\right)}{\sum z_{i}^{2}}=\hat{\beta}^{\prime}
$$

b.

$$
\begin{aligned}
\hat{\alpha} & =\bar{y}-\hat{\beta} \bar{x} \\
\hat{\alpha}^{\prime} & =\bar{y}-\hat{\beta}^{\prime} \bar{z}=\bar{y}
\end{aligned}
$$

since $\bar{z}=0$.

$$
\hat{\alpha}^{\prime} \sim \mathrm{n}\left(\alpha+\beta \bar{z}, \sigma^{2} / n\right)=\mathrm{n}\left(\alpha, \sigma^{2} / n\right)
$$

c. Write

$$
\hat{\alpha}^{\prime}=\sum \frac{1}{n} y_{i} \hat{\beta}^{\prime}=\sum\left(\frac{z_{i}}{\sum z_{i}^{2}}\right) y_{i} .
$$

Then

$$
\operatorname{Cov}(\hat{\alpha}, \hat{\beta})=-\sigma^{2} \sum \frac{1}{n}\left(\frac{z_{i}}{\sum z_{i}^{2}}\right)=0
$$

since $\sum z_{i}=0$.
11.33 a. From (11.23.25), $\beta=\rho\left(\sigma_{Y} / \sigma_{X}\right)$, so $\beta=0$ if and only if $\rho=0$ (since we assume that the variances are positive).
b. Start from the display following (11.3.35). We have

$$
\begin{aligned}
\frac{\hat{\beta}^{2}}{S^{2} / S_{x x}} & =\frac{S_{x y}^{2} / S_{x x}}{R S S /(n-2)} \\
& =(n-2) \frac{S_{x y}^{2}}{\left(S_{y y}-S_{x y}^{2} / S_{x x}\right) S_{x x}} \\
& =(n-2) \frac{S_{x y}^{2}}{\left(S_{y y} S_{x x}-S_{x y}^{2}\right)}
\end{aligned}
$$

and dividing top and bottom by $S_{y y} S_{x x}$ finishes the proof.
c. From (11.3.33) if $\rho=0$ (equivalently $\beta=0$ ), then $\hat{\beta} /\left(S / \sqrt{S_{x x}}\right)=\sqrt{n-2} r / \sqrt{1-r^{2}}$ has a $t_{n-2}$ distribution.
11.34 a. ANOVA table for height data

| Source | df | SS | MS | F |
| :--- | ---: | ---: | ---: | ---: |
| Regression | 1 | 60.36 | 60.36 | 50.7 |
| Residual | 6 | 7.14 | 1.19 |  |
| Total | 7 | 67.50 |  |  |

The least squares line is $\hat{y}=35.18+.93 x$.
b. Since $y_{i}-\bar{y}=\left(y_{i}-\hat{y}_{i}\right)+\left(\hat{y}_{i}-\bar{y}\right)$, we just need to show that the cross term is zero.

$$
\begin{aligned}
\sum_{i=1}^{n}\left(y_{i}-\hat{y}_{i}\right)\left(\hat{y}_{i}-\bar{y}\right) & =\sum_{i=1}^{n}\left[y_{i}-\left(\hat{\alpha}+\hat{\beta} x_{i}\right)\right]\left[\left(\hat{\alpha}+\hat{\beta} x_{i}\right)-\bar{y}\right] \\
& =\sum_{i=1}^{n}\left[\left(\hat{y}_{i}-\bar{y}\right)-\hat{\beta}\left(x_{i}-\bar{x}\right)\right]\left[\hat{\beta}\left(x_{i}-\bar{x}\right)\right] \quad(\hat{\alpha}=\bar{y}-\hat{\beta} \bar{x}) \\
& =\hat{\beta} \sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)\left(y_{i}-\bar{y}\right)-\hat{\beta}^{2} \sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2}=0
\end{aligned}
$$

from the definition of $\hat{\beta}$.
c.

$$
\sum\left(\hat{y}_{i}-\bar{y}\right)^{2}=\hat{\beta}^{2} \sum\left(x_{i}-\bar{x}\right)^{2}=\frac{S_{x y}^{2}}{S_{x x}}
$$

11.35 a. For the least squares estimate:

$$
\frac{d}{d \theta} \sum_{i}\left(y_{i}-\theta x_{i}^{2}\right)^{2}=2 \sum_{i}\left(y_{i}-\theta x_{i}^{2}\right) x_{i}^{2}=0
$$

which implies

$$
\hat{\theta}=\frac{\sum_{i} y_{i} x_{i}^{2}}{\sum_{i} x_{i}^{4}} .
$$

b. The log likelihood is

$$
\log L=-\frac{n}{2} \log \left(2 \pi \sigma^{2}\right)-\frac{1}{2 \sigma^{2}} \sum_{i}\left(y_{i}-\theta x_{i}^{2}\right)^{2}
$$

and maximizing this is the same as the minimization in part (a).
c. The derivatives of the log likelihood are

$$
\begin{aligned}
\frac{d}{d \theta} \log L & =\frac{1}{\sigma^{2}} \sum_{i}\left(y_{i}-\theta x_{i}^{2}\right) x_{i}^{2} \\
\frac{d^{2}}{d \theta^{2}} \log L & =\frac{-1}{\sigma^{2}} \sum_{i} x_{i}^{4}
\end{aligned}
$$

so the CRLB is $\sigma^{2} / \sum_{i} x_{i}^{4}$. The variance of $\hat{\theta}$ is

$$
\operatorname{Var} \hat{\theta}=\operatorname{Var}\left(\frac{\sum_{i} y_{i} x_{i}^{2}}{\sum_{i} x_{i}^{4}}\right)=\sum_{i}\left(\frac{x_{i}^{2}}{\sum_{j} x_{j}^{4}}\right) \sigma^{2}=\sigma^{2} / \sum_{i} x_{i}^{4}
$$

so $\hat{\theta}$ is the best unbiased estimator.
11.36 a.

$$
\begin{aligned}
& \mathrm{E} \hat{\alpha}=\mathrm{E}(\bar{Y}-\hat{\beta} \bar{X})=\mathrm{E}[\mathrm{E}(\bar{Y}-\hat{\beta} \bar{X} \mid \bar{X})]=\mathrm{E}[\alpha+\beta \bar{X}-\beta \bar{X}]=\mathrm{E} \alpha=\alpha . \\
& \mathrm{E} \hat{\beta}=\mathrm{E}[\mathrm{E}(\hat{\beta} \mid \bar{X})]=\mathrm{E} \beta=\beta .
\end{aligned}
$$

b. Recall

$$
\begin{aligned}
\operatorname{Var} Y & =\operatorname{Var}[\mathrm{E}(Y \mid X)]+\mathrm{E}[\operatorname{Var}(Y \mid X)] \\
\operatorname{Cov}(Y, Z) & =\operatorname{Cov}[\mathrm{E}(Y \mid X), \mathrm{E}(Z \mid X)]+\mathrm{E}[\operatorname{Cov}(Y, Z \mid X)]
\end{aligned}
$$

Thus

$$
\begin{aligned}
\operatorname{Var} \hat{\alpha} & =\mathrm{E}[\operatorname{Var}(\hat{\alpha} \mid X)]=\sigma^{2} \mathrm{E}\left[\sum X_{i}^{2} / S_{X X}\right] \\
\operatorname{Var} \hat{\beta} & =\sigma^{2} \mathrm{E}\left[1 / S_{X X}\right] \\
\operatorname{Cov}(\hat{\alpha}, \hat{\beta}) & =\mathrm{E}[\operatorname{Cov}(\hat{\alpha}, \hat{\beta} \mid \hat{X})]=-\sigma^{2} \mathrm{E}\left[\bar{X} / S_{X X}\right] .
\end{aligned}
$$

11.37 This is almost the same problem as Exercise 11.35. The log likelihood is

$$
\log L=-\frac{n}{2} \log \left(2 \pi \sigma^{2}\right)-\frac{1}{2 \sigma^{2}} \sum_{i}\left(y_{i}-\beta x_{i}\right)^{2} .
$$

The MLE is $\sum_{i} x_{i} y_{i} / \sum_{i} x_{i}^{2}$, with mean $\beta$ and variance $\sigma^{2} / \sum_{i} x_{i}^{2}$, the CRLB.
11.38 a. The model is $y_{i}=\theta x_{i}+\epsilon_{i}$, so the least squares estimate of $\theta$ is $\sum x_{i} y_{i} / \sum x_{i}^{2}$ (regression through the origin).

$$
\begin{aligned}
\mathrm{E}\left(\frac{\sum x_{i} Y_{i}}{\sum x_{i}^{2}}\right) & =\frac{\sum x_{i}\left(x_{i} \theta\right)}{\sum x_{i}^{2}}=\theta \\
\operatorname{Var}\left(\frac{\sum x_{i} Y_{i}}{\sum x_{i}^{2}}\right) & =\frac{\sum x_{i}^{2}\left(x_{i} \theta\right)}{\left(\sum x_{i}^{2}\right)^{2}}=\theta \frac{\sum x_{i}^{3}}{\left(\sum x_{i}^{2}\right)^{2}}
\end{aligned}
$$

The estimator is unbiased.
b. The likelihood function is

$$
\begin{aligned}
L(\theta \mid \mathbf{x}) & =\prod_{i=1}^{n} \frac{e^{-\theta x_{i}}\left(\theta x_{i}\right)^{y_{i}}}{\left(y_{i}\right)!}=\frac{e^{-\theta \Sigma x_{i}} \prod\left(\theta x_{i}\right)^{y_{i}}}{\prod y_{i}!} \\
\frac{\partial}{\partial \theta} \log L & =\frac{\partial}{\partial \theta}\left[-\theta \sum x_{i}+\sum y_{i} \log \left(\theta x_{i}\right)-\log \prod y_{i}!\right] \\
& =-\sum x_{i}+\sum \frac{x_{i} y_{i}}{\theta x_{i}} \stackrel{\text { set }}{=} 0
\end{aligned}
$$

which implies

$$
\begin{aligned}
\hat{\theta} & =\frac{\sum y_{i}}{\sum x_{i}} \\
\mathrm{E} \hat{\theta}=\frac{\sum \theta x_{i}}{\sum x_{i}}=\theta \quad \text { and } \quad \operatorname{Var} \hat{\theta} & =\operatorname{Var}\left(\frac{\sum y_{i}}{\sum x_{i}}\right)=\frac{\sum \theta x_{i}}{\left(\sum x_{i}\right)^{2}}=\frac{\theta}{\sum x_{i}}
\end{aligned}
$$

c.

$$
\frac{\partial^{2}}{\partial \theta^{2}} \log L=\frac{\partial}{\partial \theta}\left[-\sum x_{i}+\frac{\sum y_{i}}{\theta}\right]=\frac{-\sum y_{i}}{\theta^{2}} \quad \text { and } \quad E-\frac{\partial^{2}}{\partial \theta^{2}} \log L=\frac{\sum x_{i}}{\theta}
$$

Thus, the CRLB is $\theta / \sum x_{i}$, and the MLE is the best unbiased estimator.
11.39 Let $A_{i}$ be the set

$$
A_{i}=\left\{\hat{\alpha}, \hat{\beta}:\left[\left(\hat{\alpha}+\hat{\beta} x_{0 i}\right)-\left(\alpha+\beta x_{0 i}\right)\right] /\left[S \sqrt{\frac{1}{n}+\frac{\left(x_{0 i}-\bar{x}\right)^{2}}{S_{x x}}}\right] \leq t_{n-2, \alpha / 2 m}\right\} .
$$

Then $P\left(\cap_{i=1}^{m} A_{i}\right)$ is the probability of simultaneous coverage, and using the Bonferroni Inequality (1.2.10) we have

$$
P\left(\cap_{i=1}^{m} A_{i}\right) \geq \sum_{i=1}^{m} P\left(A_{i}\right)-(m-1)=\sum_{i=1}^{m}\left(1-\frac{\alpha}{m}\right)-(m-1)=1-\alpha
$$

11.41 Assume that we have observed data $\left(y_{1}, x_{1}\right),\left(y_{2}, x_{2}\right), \ldots,\left(y_{n-1}, x_{n-1}\right)$ and we have $x_{n}$ but not $y_{n}$. Let $\phi\left(y_{i} \mid x_{i}\right)$ denote the density of $Y_{i}$, a $\mathrm{n}\left(a+b x_{i}, \sigma^{2}\right)$.
a. The expected complete-data log likelihood is

$$
\mathrm{E}\left(\sum_{i=1}^{n} \log \phi\left(Y_{i} \mid x_{i}\right)\right)=\sum_{i=1}^{n-1} \log \phi\left(y_{i} \mid x_{i}\right)+\mathrm{E} \log \phi\left(Y \mid x_{n}\right),
$$

where the expectation is respect to the distribution $\phi\left(y \mid x_{n}\right)$ with the current values of the parameter estimates. Thus we need to evaluate

$$
\mathrm{E} \log \phi\left(Y \mid x_{n}\right)=\mathrm{E}\left(-\frac{1}{2} \log \left(2 \pi \sigma_{1}^{2}\right)-\frac{1}{2 \sigma_{1}^{2}}\left(Y-\mu_{1}\right)^{2}\right)
$$

where $Y \sim \mathrm{n}\left(\mu_{0}, \sigma_{0}^{2}\right)$. We have

$$
\mathrm{E}\left(Y-\mu_{1}\right)^{2}=\mathrm{E}\left(\left[Y-\mu_{0}\right]+\left[\mu_{0}-\mu_{1}\right]\right)^{2}=\sigma_{0}^{2}+\left[\mu_{0}-\mu_{1}\right]^{2}
$$

since the cross term is zero. Putting this all together, the expected complete-data log likelihood is

$$
\begin{aligned}
& -\frac{n}{2} \log \left(2 \pi \sigma_{1}^{2}\right)-\frac{1}{2 \sigma_{1}^{2}} \sum_{i=1}^{n-1}\left[y_{i}-\left(a_{1}+b_{1} x_{i}\right)\right]^{2}-\frac{\sigma_{0}^{2}+\left[\left(a_{0}+b_{0} x_{n}\right)-\left(a_{1}+b_{1} x_{n}\right)\right]^{2}}{2 \sigma_{1}^{2}} \\
& \quad=-\frac{n}{2} \log \left(2 \pi \sigma_{1}^{2}\right)-\frac{1}{2 \sigma_{1}^{2}} \sum_{i=1}^{n}\left[y_{i}-\left(a_{1}+b_{1} x_{i}\right)\right]^{2}-\frac{\sigma_{0}^{2}}{2 \sigma_{1}^{2}}
\end{aligned}
$$

if we define $y_{n}=a_{0}+b_{0} x_{n}$.
b. For fixed $a_{0}$ and $b_{0}$, maximizing this likelihood gives the least squares estimates, while the maximum with respect to $\sigma_{1}^{2}$ is

$$
\hat{\sigma}_{1}^{2}=\frac{\sum_{i=1}^{n}\left[y_{i}-\left(a_{1}+b_{1} x_{i}\right)\right]^{2}+\sigma_{0}^{2}}{n}
$$

So the EM algorithm is the following: At iteration $t$, we have estimates $\hat{a}^{(t)}, \hat{b}^{(t)}$, and $\hat{\sigma}^{2(t)}$. We then set $y_{n}^{(t)}=\hat{a}^{(t)}+\hat{b}^{(t)} x_{n}$ (which is essentially the E-step) and then the M-step is to calculate $\hat{a}^{(t+1)}$ and $\hat{b}^{(t+1)}$ as the least squares estimators using $\left(y_{1}, x_{1}\right),\left(y_{2}, x_{2}\right), \ldots$ $\left(y_{n-1}, x_{n-1}\right),\left(y_{n}^{(t)}, x_{n}\right)$, and

$$
\hat{\sigma}_{1}^{2(t+1)}=\frac{\sum_{i=1}^{n}\left[y_{i}-\left(a^{(t+1)}+b^{(t+1)} x_{i}\right)\right]^{2}+\sigma_{0}^{2(t)}}{n} .
$$

c. The EM calculations are simple here. Since $y_{n}^{(t)}=\hat{a}^{(t)}+\hat{b}^{(t)} x_{n}$, the estimates of $a$ and $b$ must converge to the least squares estimates (since they minimize the sum of squares of the observed data, and the last term adds nothing. For $\hat{\sigma}^{2}$ we have (substituting the least squares estimates) the stationary point

$$
\hat{\sigma}^{2}=\frac{\sum_{i=1}^{n}\left[y_{i}-\left(\hat{a}+\hat{b} x_{i}\right)\right]^{2}+\hat{\sigma}^{2}}{n} \Rightarrow \hat{\sigma}^{2}=\sigma_{\mathrm{obs}}^{2}
$$

where $\sigma_{\text {obs }}^{2}$ is the MLE from the $n-1$ observed data points. So the MLE s are the same as those without the extra $x_{n}$.
d. Now we use the bivariate normal density (see Definition 4.5.10 and Exercise 4.45 ). Denote the density by $\phi(x, y)$. Then the expected complete-data log likelihood is

$$
\sum_{i=1}^{n-1} \log \phi\left(x_{i}, y_{i}\right)+\mathrm{E} \log \phi\left(X, y_{n}\right)
$$

where after iteration $t$ the missing data density is the conditional density of $X$ given $Y=y_{n}$,

$$
X \mid Y=y_{n} \sim \mathrm{n}\left(\mu_{X}^{(t)}+\rho^{(t)}\left(\sigma_{X}^{(t)} / \sigma_{Y}^{(t)}\right)\left(y_{n}-\mu_{Y}^{(t)}\right),\left(1-\rho^{2(t)}\right) \sigma_{X}^{2(t)}\right)
$$

Denoting the mean by $\mu_{0}$ and the variance by $\sigma_{0}^{2}$, the expected value of the last piece in the likelihood is

$$
\begin{aligned}
& \mathrm{E} \log \phi\left(X, y_{n}\right) \\
&=-\frac{1}{2} \log \left(2 \pi \sigma_{X}^{2} \sigma_{Y}^{2}\left(1-\rho^{2}\right)\right) \\
&-\frac{1}{2\left(1-\rho^{2}\right)}\left[\mathrm{E}\left(\frac{X-\mu_{X}}{\sigma_{X}}\right)^{2}-2 \rho \mathrm{E}\left(\frac{\left(X-\mu_{X}\right)\left(y_{n}-\mu_{Y}\right)}{\sigma_{X} \sigma_{Y}}\right)+\left(\frac{y_{n}-\mu_{Y}}{\sigma_{Y}}\right)^{2}\right] \\
&=-\frac{1}{2} \log \left(2 \pi \sigma_{X}^{2} \sigma_{Y}^{2}\left(1-\rho^{2}\right)\right) \\
&-\frac{1}{2\left(1-\rho^{2}\right)}\left[\frac{\sigma_{0}^{2}}{\sigma_{X}^{2}}+\left(\frac{\mu_{0}-\mu_{X}}{\sigma_{X}}\right)^{2}-2 \rho\left(\frac{\left(\mu_{0}-\mu_{X}\right)\left(y_{n}-\mu_{Y}\right)}{\sigma_{X} \sigma_{Y}}\right)+\left(\frac{y_{n}-\mu_{Y}}{\sigma_{Y}}\right)^{2}\right] .
\end{aligned}
$$

So the expected complete-data log likelihood is

$$
\sum_{i=1}^{n-1} \log \phi\left(x_{i}, y_{i}\right)+\log \phi\left(\mu_{0}, y_{n}\right)-\frac{\sigma_{0}^{2}}{2\left(1-\rho^{2}\right) \sigma_{X}^{2}}
$$

The EM algorithm is similar to the previous one. First note that the MLEs of $\mu_{Y}$ and $\sigma_{Y}^{2}$ are the usual ones, $\bar{y}$ and $\hat{\sigma}_{Y}^{2}$, and don't change with the iterations. We update the other estimates as follows. At iteration $t$, the E-step consists of replacing $x_{n}^{(t)}$ by

$$
x_{n}^{(t+1)}=\hat{\mu}_{X}^{(t)}+\rho^{(t)} \frac{\sigma_{X}^{(t)}}{\sigma_{Y}^{(t)}}\left(y_{n}-\bar{y}\right) .
$$

Then $\mu_{X}^{(t+1)}=\bar{x}$ and we can write the likelihood as

$$
-\frac{1}{2} \log \left(2 \pi \sigma_{X}^{2} \hat{\sigma}_{Y}^{2}\left(1-\rho^{2}\right)\right)-\frac{1}{2\left(1-\rho^{2}\right)}\left[\frac{S_{x x}+\sigma_{0}^{2}}{\sigma_{X}^{2}}-2 \rho \frac{S_{x y}}{\sigma_{X} \hat{\sigma}_{Y}}+\frac{S_{y y}}{\hat{\sigma}_{Y}^{2}}\right]
$$

which is the usual bivariate normal likelihood except that we replace $S_{x x}$ with $S_{x x}+\sigma_{0}^{2}$. So the MLEs are the usual ones, and the EM iterations are

$$
\begin{aligned}
x_{n}^{(t+1)} & =\hat{\mu}_{X}^{(t)}+\rho^{(t)} \frac{\sigma_{X}^{(t)}}{\sigma_{Y}^{(t)}}\left(y_{n}-\bar{y}\right) \\
\hat{\mu}_{X}^{(t+1)} & =\bar{x}^{(t)} \\
\hat{\sigma}_{X}^{2(t+1)} & =\frac{S_{x x}^{(t)}+\left(1-\hat{\rho}^{2(t)}\right) \hat{\sigma}_{X}^{2(t)}}{n} \\
\hat{\rho}^{(t+1)} & =\frac{S_{x y}^{(t)}}{\sqrt{\left(S_{x x}^{(t)}+\left(1-\hat{\rho}^{2(t)}\right) \hat{\sigma}_{X}^{2(t+1)}\right) S_{y y}}}
\end{aligned}
$$

Here is R code for the EM algorithm:

```
nsim<-20;
xdata0<-c(20,19.6,19.6,19.4,18.4,19,19,18.3,18.2,18.6,19.2,18.2,
18.7,18.5,18,17.4,16.5,17.2,17.3,17.8,17.3,18.4,16.9)
ydata0<-(1,1.2,1.1,1.4,2.3,1.7,1.7,2.4,2.1,2.1,1.2,2.3,1.9,2.4,2.6,
2.9,4,3.3,3,3.4,2.9,1.9,3.9,4.2)
nx<-length(xdata0);
ny<-length(ydata0);
#initial values from mles on the observed data#
xmean<-18.24167;xvar<-0.9597797;ymean<-2.370833;yvar<- 0.8312327;
rho<- -0.9700159;
for (j in 1:nsim) {
#This is the augmented x (02) data#
xdata<-c(xdata0,xmean+rho*(4.2-ymean)/(sqrt(xvar*yvar)))
xmean<-mean(xdata);
Sxx<-(ny-1)*var(xdata)+(1-rho^2)*xvar
xvar<-Sxx/ny
rho<-cor(xdata,ydata0)*sqrt((ny-1)*var(xdata)/Sxx)
}
```

The algorithm converges very quickly. The MLEs are

$$
\hat{\mu}_{X}=18.24, \quad \hat{\mu}_{Y}=2.37, \quad \hat{\sigma}_{X}^{2}=.969, \quad \hat{\sigma}_{Y}^{2}=.831, \quad \hat{\rho}=-0.969
$$

## Chapter 12

## Regression Models

12.1 The point $\left(\hat{x}^{\prime}, \hat{y}^{\prime}\right)$ is the closest if it lies on the vertex of the right triangle with vertices $\left(x^{\prime}, y^{\prime}\right)$ and ( $x^{\prime}, a+b x^{\prime}$ ). By the Pythagorean theorem, we must have

$$
\left[\left(\hat{x}^{\prime}-x^{\prime}\right)^{2}+\left(\hat{y}^{\prime}-\left(a+b x^{\prime}\right)\right)^{2}\right]+\left[\left(\hat{x}^{\prime}-x^{\prime}\right)^{2}+\left(\hat{y}^{\prime}-y^{\prime}\right)^{2}\right]=\left(x^{\prime}-x^{\prime}\right)^{2}+\left(y^{\prime}-\left(a+b x^{\prime}\right)\right)^{2} .
$$

Substituting the values of $\hat{x}^{\prime}$ and $\hat{y}^{\prime}$ from (12.2.7) we obtain for the LHS above

$$
\begin{array}{r}
{\left[\left(\frac{b\left(y^{\prime}-b x^{\prime}-a\right)}{1+b^{2}}\right)^{2}+\left(\frac{b^{2}\left(y^{\prime}-b x^{\prime}-a\right)}{1+b^{2}}\right)^{2}\right]+\left[\left(\frac{b\left(y^{\prime}-b x^{\prime}-a\right)}{1+b^{2}}\right)^{2}+\left(\frac{\left.y^{\prime}-b x-a\right)}{1+b^{2}}\right)^{2}\right]} \\
=\left(y^{\prime}-\left(a+b x^{\prime}\right)\right)^{2}\left[\frac{b^{2}+b^{4}+b^{2}+1}{\left(1+b^{2}\right)^{2}}\right]=\left(y^{\prime}-\left(a+b x^{\prime}\right)\right)^{2}
\end{array}
$$

12.3 a. Differentiation yields $\partial f / \partial \xi_{i}=-2\left(x_{i}-\xi_{i}\right)-2 \lambda \beta\left[y_{i}-\left(\alpha+\beta \xi_{i}\right)\right] \stackrel{\text { set }}{=} 0 \Rightarrow \xi_{i}\left(1+\lambda \beta^{2}\right)=$ $x_{i}-\lambda \beta\left(y_{i}-\alpha\right)$, which is the required solution. Also, $\partial^{2} f / \partial \xi^{2}=2\left(1+\lambda \beta^{2}\right)>0$, so this is a minimum.
b. Parts i), ii), and iii) are immediate. For iv) just note that $D$ is Euclidean distance between $\left(x_{1}, \sqrt{\lambda} y_{1}\right)$ and $\left(x_{2}, \sqrt{\lambda} y_{2}\right)$, hence satisfies the triangle inequality.
12.5 Differentiate $\log L$, for $L$ in (12.2.17), to get

$$
\frac{\partial}{\partial \sigma_{\delta}^{2}} \log L=\frac{-n}{\sigma_{\delta}^{2}}+\frac{1}{2\left(\sigma_{\delta}^{2}\right)^{2}} \frac{\lambda}{1+\hat{\beta}^{2}} \sum_{i=1}^{n}\left[y_{i}-\left(\hat{\alpha}+\hat{\beta} x_{i}\right)\right]^{2} .
$$

Set this equal to zero and solve for $\sigma_{\delta}^{2}$. The answer is (12.2.18).
12.7 a. Suppressing the subscript $i$ and the minus sign, the exponent is

$$
\frac{(x-\xi)^{2}}{\sigma_{\delta}^{2}}+\frac{[y-(\alpha+\beta \xi)]^{2}}{\sigma_{\epsilon}^{2}}=\left(\frac{\sigma_{\epsilon}^{2}+\beta^{2} \sigma_{\delta}^{2}}{\sigma_{\epsilon}^{2} \sigma_{\delta}^{2}}\right)(\xi-k)^{2}+\frac{[y-(\alpha+\beta x)]^{2}}{\sigma_{\epsilon}^{2}+\beta^{2} \sigma_{\delta}^{2}}
$$

where $k=\frac{\sigma_{\epsilon}^{2} x+\sigma_{\delta}^{2} \beta(y-\alpha)}{\sigma_{\epsilon}^{2}+\beta^{2} \sigma_{\delta}^{2}}$. Thus, integrating with respect to $\xi$ eliminates the first term.
b. The resulting function must be the joint pdf of $X$ and $Y$. The double integral is infinite, however.
12.9 a. From the last two equations in (12.2.19),

$$
\hat{\sigma}_{\delta}^{2}=\frac{1}{n} S_{x x}-\hat{\sigma}_{\xi}^{2}=\frac{1}{n} S_{x x}-\frac{1}{n} \frac{S_{x y}}{\hat{\beta}},
$$

which is positive only if $S_{x x}>S_{x y} / \hat{\beta}$. Similarly,

$$
\hat{\sigma}_{\epsilon}^{2}=\frac{1}{n} S_{y y}-\hat{\beta}^{2} \hat{\sigma}_{\xi}^{2}=\frac{1}{n} S_{y y}-\hat{\beta}^{2} \frac{1}{n} \frac{S_{x y}}{\hat{\beta}}
$$

which is positive only if $S_{y y}>\hat{\beta} S_{x y}$.
b. We have from part a), $\hat{\sigma}_{\delta}^{2}>0 \Rightarrow S_{x x}>S_{x y} / \hat{\beta}$ and $\hat{\sigma}_{\epsilon}^{2}>0 \Rightarrow S_{y y}>\hat{\beta} S_{x y}$. Furthermore, $\hat{\sigma}_{\xi}^{2}>0$ implies that $S_{x y}$ and $\hat{\beta}$ have the same sign. Thus $S_{x x}>\left|S_{x y}\right| /|\hat{\beta}|$ and $S_{y y}>|\hat{\beta}|\left|S_{x y}\right|$. Combining yields

$$
\frac{\left|S_{x y}\right|}{S_{x x}}<|\hat{\beta}|<\frac{S_{y y}}{\left|S_{x y}\right|}
$$

12.11 a.

$$
\begin{aligned}
& \operatorname{Cov}(a Y+b X, c Y+d X) \\
&= \mathrm{E}(a Y+b X)(c Y+d X)-\mathrm{E}(a Y+b X) E(c Y+d X) \\
&= \mathrm{E}\left(a c Y^{2}+(b c+a d) X Y+b d X^{2}\right)-\mathrm{E}(a Y+b X) E(c Y+d X) \\
&= a c \operatorname{Var} Y+a c(\mathrm{E} Y)^{2}+(b c+a d) \operatorname{Cov}(X, Y) \\
&+(b c+a d) \mathrm{E} X \mathrm{E} Y+b d \operatorname{Var} X+b d(\mathrm{E} X)^{2}-\mathrm{E}(a Y+b X) \mathrm{E}(c Y+d X) \\
&= a c \operatorname{Var} Y+(b c+a d) \operatorname{Cov}(X, Y)+b d \operatorname{Var} X
\end{aligned}
$$

b. Identify $a=\beta \lambda, b=1, c=1, d=-\beta$, and using (12.3.19)

$$
\begin{aligned}
\operatorname{Cov}\left(\beta \lambda Y_{i}+X_{i}, Y_{i}-\beta X_{i}\right) & =\beta \lambda \operatorname{Var} Y+\left(1-\lambda \beta^{2}\right) \operatorname{Cov}(X, Y)-\beta \operatorname{Var} X \\
& =\beta \lambda\left(\sigma_{\epsilon}^{2}+\beta^{2} \sigma_{\xi}^{2}\right)+\left(1-\lambda \beta^{2}\right) \beta \sigma_{\xi}^{2}-\beta\left(\sigma_{\delta}^{2}+\sigma_{\xi}^{2}\right) \\
& =\beta \lambda \sigma_{\epsilon}^{2}-\beta \sigma_{\delta}^{2}=0
\end{aligned}
$$

if $\lambda \sigma_{\epsilon}^{2}=\sigma_{\delta}^{2}$. (Note that we did not need the normality assumption, just the moments.)
c. Let $W_{i}=\beta \lambda Y_{i}+X_{i}, V_{i}=Y_{i}+\beta X_{i}$. Exercise 11.33 shows that if $\operatorname{Cov}\left(W_{i}, V_{i}\right)=0$, then $\sqrt{n-2} r / \sqrt{1-r^{2}}$ has a $t_{n-2}$ distribution. Thus $\sqrt{n-2} r_{\lambda}(\beta) / \sqrt{1-r_{\lambda}^{2}(\beta)}$ has a $t_{n-2}$ distribution for all values of $\beta$, by part (b). Also

$$
P\left(\left\{\beta: \frac{(n-2) r_{\lambda(\beta)}^{2}}{1-r_{\lambda(\beta)}^{2}} \leq F_{1, n-2, \alpha}\right\}\right)=P\left(\left\{(X, Y): \frac{(n-2) r_{\lambda}^{2}(\beta)}{1-r_{\lambda}^{2}(\beta)} \leq F_{1, n-2, \alpha}\right\}\right)=1-\alpha
$$

12.13 a. Rewrite (12.2.22) to get

$$
\left\{\beta: \hat{\beta}-\frac{t \hat{\sigma}_{\beta}}{\sqrt{n-2}} \leq \beta \leq \hat{\beta}+\frac{t \hat{\sigma}_{\beta}}{\sqrt{n-2}}\right\}=\left\{\beta: \frac{(\hat{\beta}-\beta)^{2}}{\sigma_{\beta}^{2} /(n-2)} \leq F\right\}
$$

b. For $\hat{\beta}$ of (12.2.16), the numerator of $r_{\lambda}(\beta)$ in (12.2.22) can be written

$$
\beta \lambda S_{y y}+\left(1-\beta^{2} \lambda\right) S_{x y}-\beta S_{x y}=\beta^{2}\left(\lambda S_{x y}\right)+\beta\left(S_{x x}-\lambda S_{y y}\right)+S_{x y}=\lambda S_{x y}(\beta-\hat{\beta})\left(\beta+\frac{1}{\lambda \hat{\beta}}\right)
$$

Again from (12.2.22), we have

$$
\begin{aligned}
& \frac{r_{\lambda}^{2}(\beta)}{1-r_{\lambda}^{2}(\beta)} \\
& \quad=\frac{\left(\beta \lambda S_{y y}+\left(1-\beta^{2} \lambda\right) S_{x y}-\beta S_{x y}\right)^{2}}{\left(\beta^{2} \lambda^{2} S_{y y}+2 \beta \lambda S_{x y}+S_{x x}\right)\left(S_{y y}-2 \beta S_{x y}+\beta^{2} S_{x x}\right)-\left(\beta \lambda S_{y y}+\left(1-\beta^{2} \lambda\right) S_{x y}-\beta S_{x x}\right)^{2}},
\end{aligned}
$$

and a great deal of straightforward (but tedious) algebra will show that the denominator of this expression is equal to

$$
\left(1+\lambda \beta^{2}\right)^{2}\left(S_{y y} S_{x x}-S_{x y}^{2}\right)
$$

Thus

$$
\begin{aligned}
\frac{r_{\lambda}^{2}(\beta)}{1-r_{\lambda}^{2}(\beta)} & =y \frac{\lambda^{2} S_{x y}^{2}(\beta-\hat{\beta})^{2}\left(\beta+\frac{1}{\lambda \hat{\beta}}\right)^{2}}{\left(1-\lambda \beta^{2}\right)^{2}\left(S_{y y} S_{x}-S_{x y}^{2}\right)} \\
& =\frac{(\beta-\hat{\beta})^{2}}{\hat{\sigma}_{\beta}^{2}}\left(\frac{1+\lambda \beta \hat{\beta}}{1+\lambda \beta^{2}}\right)^{2} \frac{\left(1+\lambda \hat{\beta}^{2}\right)^{2} S_{x y}^{2}}{\hat{\beta}^{2}\left[\left(S_{x x}-\lambda S_{y y}\right)^{2}+4 \lambda S_{x y}^{2}\right]}
\end{aligned}
$$

after substituting $\hat{\sigma}_{\beta}^{2}$ from page 588 . Now using the fact that $\hat{\beta}$ and $-1 / \lambda \hat{\beta}$ are both roots of the same quadratic equation, we have

$$
\frac{\left(1+\lambda \hat{\beta}^{2}\right)^{2}}{\hat{\beta}^{2}}=\left(\frac{1}{\hat{\beta}}+\lambda \hat{\beta}\right)^{2}=\frac{\left(S_{x x}-\lambda S_{y y}\right)^{2}+4 \lambda S_{x y}^{2}}{S_{x y}^{2}}
$$

Thus the expression in square brackets is equal to 1 .
12.15 a.

$$
\pi(-\alpha / \beta)=\frac{e^{\alpha+\beta(-\alpha / \beta)}}{1+e^{\alpha+\beta(-\alpha / \beta)}}=\frac{e^{0}}{1+e^{0}}=\frac{1}{2}
$$

b.

$$
\pi((-\alpha / \beta)+c)=\frac{e^{\alpha+\beta((-\alpha / \beta)+c)}}{1+e^{\alpha+\beta((-\alpha / \beta)+c)}}=\frac{e^{\beta c}}{1+e^{\beta c}}
$$

and

$$
1-\pi((-\alpha / \beta)-c)=1-\frac{e^{-\beta c}}{1+e^{-\beta c}}=\frac{e^{\beta c}}{1+e^{\beta c}}
$$

c.

$$
\frac{d}{d x} \pi(x)=\beta \frac{e^{\alpha+\beta x}}{\left[1+e^{\alpha+\beta x}\right]^{2}}=\beta \pi(x)(1-\pi(x))
$$

d. Because

$$
\frac{\pi(x)}{1-\pi(x)}=e^{\alpha+\beta x}
$$

the result follows from direct substitution.
e. Follows directly from (d).
f. Follows directly from

$$
\frac{\partial}{\partial \alpha} F(\alpha+\beta x)=f(\alpha+\beta x) \text { and } \frac{\partial}{\partial \beta} F(\alpha+\beta x)=x f(\alpha+\beta x) .
$$

g. For $F(x)=e^{x} /\left(1+e^{x}\right), f(x)=F(x)(1-F(x))$ and the result follows. For $F(x)=\pi(x)$ of (12.3.2), from part (c) if follows that $\frac{f}{F(1-F)}=\beta$.
12.17 a. The likelihood equations and solution are the same as in Example 12.3.1 with the exception that here $\pi\left(x_{j}\right)=\Phi\left(\alpha+\beta x_{j}\right)$, where $\Phi$ is the cdf of a standard normal.
b. If the $0-1$ failure response in denoted "oring" and the temperature data is "temp", the following $R$ code will generate the logit and probit regression:

```
summary(glm(oring~temp, family=binomial(link=logit)))
summary(glm(oring~
```

For the logit model we have

|  | Estimate | Std. Error | z value | $\operatorname{Pr}(>\|z\|)$ |
| :---: | :---: | :---: | :---: | :---: |
| Intercept | 15.0429 | 7.3719 | 2.041 | 0.0413 |
| temp | -0.2322 | 0.1081 | -2.147 | 0.0318 |

and for the probit model we have

|  | Estimate | Std. Error | z value | $\operatorname{Pr}(>\|z\|)$ |
| :---: | :---: | :---: | :---: | :---: |
| Intercept | 8.77084 | 3.86222 | 2.271 | 0.0232 |
| temp | -0.13504 | 0.05632 | -2.398 | 0.0165 |

Although the coefficients are different, the fit is qualitatively the same, and the probability of failure at $31^{\circ}$, using the probit model, is .9999 .
12.19 a. Using the notation of Example 12.3.1, the likelihood (joint density) is

$$
\prod_{j=1}^{J}\left[\frac{e^{\alpha+\beta x_{j}}}{1+e^{\alpha+\beta x_{j}}}\right]^{y_{j}^{*}}\left[\frac{1}{1+e^{\alpha+\beta x_{j}}}\right]^{n_{j}-y_{j}^{*}}=\prod_{j=1}^{J}\left[\frac{1}{1+e^{\alpha+\beta x_{j}}}\right]^{n_{j}} e^{\alpha \sum_{j} y_{j}^{*}+\beta \sum_{j} x_{j} y_{j}^{*}}
$$

By the Factorization Theorem, $\sum_{j} y_{j}^{*}$ and $\sum_{j} x_{j} y_{j}^{*}$ are sufficient.
b. Straightforward substitution.
12.21 Since $\frac{d}{d \pi} \log (\pi /(1-\pi))=1 /(\pi(1-\pi))$,

$$
\operatorname{Var} \log \left(\frac{\hat{\pi}}{1-\hat{\pi}}\right) \approx\left(\frac{1}{\pi(1-\pi)}\right)^{2} \frac{\pi(1-\pi)}{n}=\frac{1}{n \pi(1-\pi)}
$$

12.23 a. If $\sum a_{i}=0$,

$$
\mathrm{E} \sum_{i} a_{i} Y_{i}=\sum_{i} a_{i}\left[\alpha+\beta \boldsymbol{x}_{i}+\mu(1-\delta)\right]=\beta \sum_{i} a_{i} x_{i}=\beta
$$

for $a_{i}=x_{i}-\bar{x}$.
b.

$$
\mathrm{E}(\bar{Y}-\beta \bar{x})=\frac{1}{n} \sum_{i}\left[\alpha+\beta x_{i}+\mu(1-\delta)\right]-\beta \bar{x}=\alpha+\mu(1-\delta),
$$

so the least squares estimate $a$ is unbiased in the model $Y_{i}=\alpha^{\prime}+\beta x_{i}+\epsilon_{i}$, where $\alpha^{\prime}=$ $\alpha+\mu(1-\delta)$.
12.25 a. The least absolute deviation line minimizes

$$
\left|y_{1}-\left(c+d x_{1}\right)\right|+\left|y_{2}-\left(c+d x_{1}\right)\right|+\left|y_{3}-\left(c+d x_{3}\right)\right| .
$$

Any line that lies between $\left(x_{1}, y_{1}\right)$ and $\left(x_{1}, y_{2}\right)$ has the same value for the sum of the first two terms, and this value is smaller than that of any line outside of $\left(x_{1}, y_{1}\right)$ and $\left(x_{2}, y_{2}\right)$. Of all the lines that lie inside, the ones that go through $\left(x_{3}, y_{3}\right)$ minimize the entire sum.
b. For the least squares line, $a=-53.88$ and $b=.53$. Any line with $b$ between $(17.9-14.4) / 9=$ .39 and $(17.9-11.9) / 9=.67$ and $a=17.9-136 b$ is a least absolute deviation line.
12.27 In the terminology of $M$-estimators (see the argument on pages $485-486$ ), $\hat{\beta}_{L}$ is consistent for the $\beta_{0}$ that satisfies $\mathrm{E}_{\beta_{0}} \sum_{i} \psi\left(Y_{i}-\beta_{0} x_{i}\right)=0$, so we must take the "true" $\beta$ to be this value. We then see that

$$
\sum_{i} \psi\left(Y_{i}-\hat{\beta}_{L} x_{i}\right) \rightarrow 0
$$

as long as the derivative term is bounded, which we assume is so.
12.29 The argument for the median is a special case of Example 12.4.3, where we take $x_{i}=1$ so $\sigma_{x}^{2}=1$. The asymptotic distribution is given in (12.4.5) which, for $\sigma_{x}^{2}=1$, agrees with Example 10.2.3.
12.31 The LAD estimates, from Example 12.4.2 are $\tilde{\alpha}=18.59$ and $\tilde{\beta}=-.89$. Here is Mathematica code to bootstrap the standard deviations. (Mathematica is probably not the best choice here, as it is somewhat slow. Also, the minimization seemed a bit delicate, and worked better when done iteratively.) Sad is the sum of the absolute deviations, which is minimized iteratively in bmin and amin. The residuals are bootstrapped by generating random indices $u$ from the discrete uniform distribution on the integers 1 to 23 .

1. First enter data and initialize
```
Needs["Statistics`Master`"]
Clear[a,b,r,u]
a0=18.59;b0=-.89;aboot=a0;bboot=b0;
y0={1,1.2,1.1,1.4,2.3,1.7,1.7,2.4,2.1,2.1,1.2,2.3.1.9,2.4,
    2.6,2.9,4,3.3,3,3.4,2.9,1.9,3.9};
x0={20,19.6,19.6,19.4,18.4,19,19,18.3,18.2,18.6,19.2,18.2,
    18.7,18.5,18,17.4,16.5,17.2,17.3,17.8,17.3,18.4,16.9};
model=a0+b0*x0;
r=y0-model;
u:=Random[DiscreteUniformDistribution[23]]
Sad[a_,b_]:=Mean[Abs[model+rstar-(a+b*x0)]]
bmin[a_]:=FindMinimum[Sad[a,b],{b,{.5,1.5}}]
amin:=FindMinimum[Sad[a,b/.bmin[a][[2]]],{a,{16,19}}]
```

2. Here is the actual bootstrap. The vectors aboot and bboot contain the bootstrapped values.
```
B=500;
Do[
    rstar=Table[r[[u]],{i,1,23}];
    astar=a/.amin[[2]];
    bstar=b/.bmin[astar][[2]];
    aboot=Flatten[{aboot,astar}];
    bboot=Flatten[{bboot,bstar}],
    {i,1,B}]
```

3. Summary Statistics

Mean [aboot]
StandardDeviation [aboot]
Mean [bboot]
StandardDeviation [bboot]
4. The results are Intercept: Mean 18.66, SD . 923 Slope: Mean -.893, SD . 050 .
